FOR AERONAUTICS
WASHINGTON

CONFIDENTIAL
INVESTIGATION OF A THREE-BLADE PROPELLER IN COMBINATION
WITH TWO DIFFERENT SPINNERS AND AN NACA D-TYPE
COWL AT MACH NUMBERS UP TO 0.80

By George C. Kenyon and Robert M. Reynolds

SUMMARY

An investigation has been made to determine the aerodynamic characteristics of a three-blade propeller designed to operate ahead of a D-type cowl. The propeller (designated NACA 3.638-(675)(057)(0572) in combination with two different spinner shapes and an NACA 1-62.8-070 D-type cowl was investigated at Mach numbers up to 0.80. The characteristics of the isolated propeller-spinner combination operating at positive thrust, negative thrust, and at near static conditions were also determined. Included are results of air-stream surveys of the local velocities in the plane of the propeller. All tests were made with the model at an angle of attack of 0° and at a Reynolds number of 1,000,000 per foot, based on free-stream conditions.

The efficiency of the propeller in the presence of the cowl was higher at all Mach numbers than that of the isolated propeller-spinner combination. At design cruise conditions (\( M = 0.60, \beta = 53° \)), the efficiency of the propeller with the 1-series spinner and cowl was 80 percent, as compared with 72 percent for the isolated propeller-spinner combination. The onset of marked compressibility losses was delayed from a Mach number of 0.50 to a Mach number of 0.60 by the addition of the cowl.

The effects of inlet velocity ratio and spinner shape on the propeller characteristics were not large except at the higher Mach numbers (0.70 and 0.80).

INTRODUCTION

Considerable research has been conducted on propeller-spinner-cowling combinations suitable for use with large turbine engines (refs. 1 to 5). To augment this research, an investigation was conducted in the Ames

CONFIDENTIAL
12-foot pressure wind tunnel to determine the characteristics of a three-blade propeller and a D-type cowl with both an NACA 1-series spinner and a more nearly conical spinner. The pressure-recovery characteristics of these propeller-spinner-cowling combinations have been reported in reference 6. Reference 7 has presented some preliminary results for the propeller with the cowl and spinners.

Presented herein are results of force tests, obtained concurrently with the data presented in reference 6, for the propeller operating in the presence of the cowl with the two different spinners. Also presented are force-test results for the isolated propeller-spinner combination operating at positive thrust, negative thrust, and at near static conditions. The velocity distributions in the plane of the propeller are included.

The tests were conducted for a range of blade angles from -20° to 63° and at Mach numbers up to 0.80. All tests were made with the model at an angle of attack of 0° and at a Reynolds number of 1,000,000 per foot, based on free-stream conditions.

**NOTATION**

- $a$: speed of sound
- $b$: blade width
- $C_P$: power coefficient, $\frac{P}{\rho n^2 B^5}$
- $C_T$: thrust coefficient, $\frac{T}{\rho n^2 B^4}$
- $c_{ld}$: blade-section design lift coefficient
- $D$: propeller diameter
- $HP$: horsepower
- $h$: maximum thickness of blade section
- $J$: advance ratio, $\frac{V_o}{nD}$
- $M$: Mach number, $\frac{V}{a}$
- $M_t$: tip Mach number, $M \sqrt{1 + \left(\frac{\pi}{J}\right)^2}$
n  propeller rotational speed
P  power
R  propeller-tip radius
r  blade-section radius
S  propeller disc area
T  thrust

\(T_c\)  thrust coefficient, \(\frac{T}{\rho V^2 D^2}\)

U  local velocity in the plane of the propeller
V  air-stream velocity

\(V_o\)  equivalent free-air velocity

MODEL AND APPARATUS

This investigation was conducted in the Ames 12-foot pressure wind tunnel with the model mounted on the 1000-horsepower dynamometer (described in ref. 8). A photograph of the model is presented in figure 1 and a sketch of the general model arrangement is given in figure 2. The propeller used was a three-blade type designed by Hamilton Standard Division and...
it corresponded to the designation NACA 3.638-(675)(057)-0572. Blade-form curves for the propeller are shown in figure 3. Additional details of the model and its instrumentation as well as information on the full-scale design conditions can be found in reference 6.

Figure 4 is a photograph of the survey rake used to determine the velocity distribution in the plane of the propeller. The rake consisted of 24 static pressure tubes located at the radial stations listed in table I.

**TESTS AND REDUCTION OF DATA**

Thrust, torque, and rotational speed were measured (as described in refs. 2 and 8) for the propeller-spinner-cowl combinations and the isolated propeller-spinner combination (1-series spinner) for a range of blade angles from $33^\circ$ to $63^\circ$ at Mach numbers from 0.20 to 0.80. Data for the isolated propeller-spinner combination were obtained at negative thrust conditions at the same Mach numbers and blade angles and, in addition, data were obtained for this combination at a Mach number of 0.15 for blade angles from $-20^\circ$ to $25^\circ$. The characteristics of the isolated propeller-spinner combination were also measured at near static conditions for a blade-angle range from $10^\circ$ to $25^\circ$.

Surveys of the air-stream velocity in the plane of the propeller were made at Mach numbers from 0.15 to 0.80. With the cowl installed, the effect of inlet velocity ratio on the local velocity in the propeller plane was also determined.

The Mach number used in this report was the average Mach number over the disc area as determined by velocity surveys reported in reference 8. For the tests made with the cowl installed, this Mach number (and the corresponding dynamic pressure) was corrected for blockage of the cowl by the method of reference 9. In no case did this correction exceed 1 percent.

The air-stream velocity (and, consequently, propeller advance ratio and efficiency) was corrected for the wind-tunnel-wall constraint on the propeller slipstream by the method of reference 10. Figure 5 presents a comparison of this correction with that determined experimentally by the method of reference 11 from measurements of wall pressures. The data included herein are for advance ratios at which the thrust-coefficient parameter $T_c/(1 - M^2)$ was greater than -0.5.

Analysis of the accuracy of the separate measurements of thrust, torque, and air-stream velocity, as in reference 8, indicates that errors in the propeller efficiencies reported herein are probably less than 2 percent.
RESULTS

The distribution of velocity across the propeller disc is listed in table I. These data are plotted in figure 6 for a few typical Mach numbers and inlet velocity ratios.

The characteristics of the propeller operating in the presence of the cowl are presented in figures 7 and 8 and the characteristics of the isolated propeller-spinner combination for conditions of positive thrust are presented in figure 9. The variation of maximum propeller efficiency with Mach number is summarized in figure 10 and the effect of inlet velocity ratio on the propeller characteristics is shown in figure 11.

The negative-thrust characteristics of the propeller-spinner combination are presented in figures 12 through 15 and the characteristics of the propeller-spinner combination at near static conditions are shown in figure 16 and are summarized in figure 17.

DISCUSSION

Propeller Characteristics at Positive Thrust

As in reference 2, the characteristics of the propeller operating in the presence of the cowl are presented as apparent values (figs. 7 and 8) since the determination of the propulsive thrust of the propeller was precluded by the fact that it was impractical, with the dynamometer arrangement used in the present investigation, to measure the increase in drag of the cowl and dynamometer parts within the influence of the propeller slipstream. The addition of the cowl behind the propeller resulted in reduced velocities throughout the propeller flow field, as evidenced by a comparison of figures 6(a) and 6(b) with figure 6(c). As a consequence of these reduced velocities (and in accord with the discussion of ref. 12), the thrust and power for the propeller operating ahead of the cowl were greater than that for the isolated propeller-spinner combination (at the same advance ratio), as can be seen from a comparison of figures 7 and 8 with figure 9.

Maximum efficiency.- As shown in figure 10, the efficiency of the propeller in the presence of the cowl was higher at all Mach numbers than that of the isolated propeller-spinner combination. At design cruise conditions ($M = 0.60$, $\beta = 53^\circ$), the efficiency of the propeller with the 1-series spinner and cowl was 80 percent, as compared with 72 percent for the isolated propeller-spinner combination. It may be noted here that the higher efficiencies for the propeller with the cowl were due not only to interference effects but partly to the fact that, in the presence of
the cowl, the propeller was operating more nearly in the flow field for which it was designed.

The onset of marked compressibility losses was delayed (also as a consequence of the interference effects) from a Mach number of 0.50 to a Mach number of 0.60 by the addition of the cowl (fig. 10). The large losses in efficiency at Mach numbers from 0.60 to 0.80 were due not only to the effects of compressibility but also to the fact that at blade angles of 58.5° and 63° the inner portions of the blades were probably operating at negative thrust, since the local blade angles for this portion of the blade were greater than 90° (up to 98° for β = 63°). Operation of the propeller at lower blade angles at these Mach numbers (requiring higher rotational speeds) might have resulted in higher efficiencies but was not permissible because of structural limitations of the model propeller.

Effect of inlet velocity ratio. - Although the air-stream surveys (tables I(a) and I(b), and figs. 6(a) and 6(b)) show that decreasing inlet velocity ratio resulted in reduced local velocities at the propeller plane, the changes were small in comparison with the reduction in velocity occasioned by the addition of the cowl to the spinner (fig. 6(a) compared with fig. 6(c)). Consequently, as shown in figures 7, 8, and 11, the effect of inlet velocity ratio on the propeller characteristics was not large except at the higher Mach numbers (0.70 and 0.80), where small changes in local velocity resulted in relatively large changes in the propeller characteristics due to the effects of compressibility.

Effect of spinner shape. - Although the data of figures 6(a) and 6(b) indicate only small differences in the local velocity distributions for the two spinners with the propeller removed, figure 11 shows that higher thrust and power coefficients were obtained with the propeller and modified conical spinner. However, as shown in figure 10, the differences in maximum efficiency were generally of the order of the stated accuracy of the results.

Propeller Characteristics at Negative Thrust

The data presented in figure 14(a) indicate that at any constant value of advance ratio, relatively constant negative-thrust coefficients were attained at blade angles from -50° to -20°. However, as shown in figure 15(a), the power coefficients corresponding to this range of blade angles increased rapidly, indicating that use of a more negative blade angle resulted in additional power absorption rather than an increase in negative thrust. For the range of blade angles and Mach numbers covered in the present investigation, there was practically no effect of compressibility on the negative-thrust and torque characteristics of the propeller at Mach numbers up to 0.60 (see figs. 14 and 15).
Propeller Characteristics at Near Static Conditions

The thrust and torque characteristics presented in figures 16(a) and 16(b) were obtained at near static conditions, as shown by the variation of velocity with \( nD \) in figure 16(c). The abrupt decrease in thrust coefficient and increase in power coefficient at values of \( nD \) below 60 are believed to be due to the effects of Reynolds number. At these low values of \( nD \), the blade sections were operating at Reynolds numbers less than about 500,000.

The experimental data shown in figure 16 were used to compute the static thrust per horsepower and were then plotted as a function of power disc loading for constant values of \( nD \). The envelope of these curves is presented in figure 17. The theoretical curve shown in figure 17 was computed by the method of reference 13. The variation of static thrust per horsepower with disc loading was adequately predicted by the theory, but the experimental values were only approximately 67 percent of the theoretical ideal values. However, the theory neglects rotational losses and blade drag which presumably accounts for the discrepancy between experiment and theory.

CONCLUDING REMARKS

The following remarks may be made regarding the results of the subject investigation.

The efficiency of the propeller with the two different spinners and the cowl was higher at all Mach numbers than that of the isolated propeller-spinner combination. At design cruise conditions \((M = 0.60, \beta = 53^\circ)\), the efficiency of the propeller with the 1-series spinner and cowl was 80 percent, as compared with 72 percent for the isolated propeller-spinner combination.

The onset of marked compressibility losses was delayed from a Mach number of 0.50 to a Mach number of 0.60 by the addition of the cowl.

The effects of inlet velocity ratio and spinner shape on the propeller characteristics were not large except at the higher Mach numbers (0.70 and 0.80).

There was practically no effect of compressibility on the characteristics of the propeller-spinner combination operating at negative thrust at Mach numbers through 0.60.
The propeller static thrust varied with power disc loading as predicted by actuator disc theory, but the experimental static thrust was only 67 percent of the theoretical ideal thrust.

ABSTRACT

This report presents the aerodynamic characteristics of a three-blade propeller (designated NACA 3.638-(675)(057)-0572) at Mach numbers up to 0.80. Tests were made at positive thrust for the propeller with a 1-series spinner and a modified conical spinner operating in the presence of an NACA 1-series D-type cowl. Tests were also conducted for the isolated propeller-spinner combination operating at positive thrust, negative thrust, and at near static conditions. Included are the results of airstream surveys of the local velocities in the plane of the propeller.
