COPY NO. 100
The application of the dyadic Green's function technique to a number of electromagnetic problems involving a perfectly conducting half-plane sheet is discussed. A derivation of the dyadic Green's function is given by the method of Fourier and Hankel transforms. Several sets of curves have been presented to show the radiation patterns in the principal plane for different excitations. The radiation resistance of a quarter-wave monopole attached to the edge of a half-plane sheet, and that of a half-wave dipole placed parallel to the edge of the sheet are also evaluated.

</table>
Among the boundary-value problems involving a perfectly conducting half-plane sheet, the problem of diffraction of a plane polarized wave was treated long ago by Sommerfeld by applying the theory of multi-valued functions of a complex variable to the formulation of the problem. The same problem can also be formulated and solved by using the Hopf-Wiener integral equation technique. In this report, problems involving dipoles and apertures as exciting sources will be discussed. By applying the technique of dyadic Green's functions, the electromagnetic field due to electric and magnetic dipoles in the presence of a half-plane sheet and the related problems involving apertures can be formulated in a compact manner. For certain ranges of the parameters, corresponding to the far-zone region, the complex integral that represents the formal solution can be evaluated approximately by means of the saddle-point method of integration to yield some pertinent information regarding the radiation pattern in the principal plane. The radiation field can, of course, be obtained by applying the reciprocal theorem and making use of Sommerfeld's solution. The method adopted here, however, seems to be more direct. As a whole, the general formulation not only gives a better view of the relationship between various problems but also provides a foundation for further investigation in subjects not covered in this work, particularly the near-zone field.
II DYADIC GREEN'S FUNCTION PERTAINING TO A PERFECTLY CONDUCTING HALF-PLANE SHEET

It is well known in electromagnetic theory that for a harmonic varying field with a time dependence of the form $e^{-i\omega t}$, the electric and the magnetic vectors satisfy the following two equations:

$$\nabla \times \nabla \times \mathbf{E} - k^2 \mathbf{E} = i\omega \mathbf{J}$$  \hspace{1cm} (1)
$$\nabla \times \nabla \times \mathbf{H} - k^2 \mathbf{H} = \nabla \times \mathbf{J}$$  \hspace{1cm} (2)

where $\mathbf{J}$ denotes the electric current density function. In dealing with radiation from circulating currents it is convenient to introduce an equivalent magnetic current density function $\mathbf{J}_m$ defined by

$$\nabla \times \mathbf{J}_m = i\omega \mathbf{J}_m$$  \hspace{1cm} (3)

Equation (2) can then be written in a form similar to Eq. (1)

$$\nabla \times \nabla \times \mathbf{H} - k^2 \mathbf{H} = i\omega \mathbf{J}_m$$  \hspace{1cm} (4)

To integrate Eqs. (1) and (4) two dyadic Green's functions, denoted respectively by $\mathbf{G}_e$ and $\mathbf{G}_m$, are introduced. They both satisfy the equation

$$\nabla \times \nabla \times \mathbf{G} - k^2 \mathbf{G} = \mathbf{I} \delta(x - x') \delta(y - y') \delta(z - z')$$  \hspace{1cm} (5)*

where $\mathbf{I}$ denotes the unit dyadic or idem factor. The electric dyadic Green's function satisfies the boundary condition that at the surface of a perfectly conducting body

$$\mathbf{n} \times \mathbf{G}_e = \mathbf{G}$$  \hspace{1cm} (6)

* In regard to notations used in this paper, the bold face type is used for vectors; boldface type with a bar denotes a dyadic.
while the magnetic dyadic Green's function is characterized by

\[ n \times \nabla \times \mathbf{G}_m = 0. \]  (7)

Once the explicit expressions of \( \mathbf{G}_e \) and \( \mathbf{G}_m \) are known, the formal solution for the electromagnetic field due to a given source in the presence of a perfectly conducting body can be presented in the form of certain integrals. If the exciting source consists of current elements, the electric field is given by

\[ \mathbf{E} = \text{tomega} \iiint \mathbf{J} \times \mathbf{G}_e \, d\mathbf{u}' \]  (8)

If the source is made of apertures on the conducting body with a given electric field distribution, then

\[ \mathbf{E} = \iint_{\text{apertures}} (\mathbf{E}' \times \mathbf{n}') \cdot \nabla' \times \mathbf{G}_e \, dS' \]  (9)

For the case of circulating currents as exciting sources, the magnetic field is given by

\[ \mathbf{H} = \text{tomega} \iiint \mathbf{J} \times \mathbf{G}_m \, d\mathbf{u}' \]  (10)

The corresponding electric field is

\[ \mathbf{E} = -\iiint \nabla \times (\mathbf{J} \times \mathbf{G}_m) \, d\mathbf{u}' \]  (11)

Equations (8) - (11) constitute the basic formulae to be used in studying the radiation from current elements and apertures in the presence of a perfectly conducting body.

Let us now consider a perfectly conducting half-plane sheet as the diffracting body. The half-plane is defined by \( y = 0 \) and \( x > 0 \) in the Cartesian coordinate system (Fig. 1). The longitudinal axis of the half-plane is parallel to the \( z \)-axis. For convenience, the entire \( x-y \) plane corresponding to \( z = 0 \) will be designated as the principal plane. The method used here to derive the dyadic Green's functions pertaining to this structure follows very closely the one described by Morse and Feshbach in dealing with the interior boundary value problems of a circular cylinder. The main difference is that the spectrum of eigenvalues in the present
problem is continuous both in the $z$-coordinate and the $r$-coordinate, where $r$ is the cylindrical radial coordinate defined in the $x$-$y$ plane.

Like all other cylindrical problems the elementary vector wave functions that are needed to construct $G$ are of two kinds defined as follows:

\[ M = \nabla \times (\psi z) \quad (12) \]
\[ N = k_e^{-1} \nabla \times M = k_e^{-1} \nabla \times \nabla \times (\psi z) \quad (13) \]

where $\psi$ denotes an eigen function satisfying the scalar wave equation

\[ \nabla^2 \psi + k_e^2 \psi = 0 \quad (14) \]

The wave number $k_e$ is, at this point, completely arbitrary. The appropriate scalar eigen functions that will satisfy the boundary conditions on a half-plane sheet are

\[ \psi_{o(\pi/2)}(\lambda_e r) = e^{i k_e \phi} J_{\frac{n+1}{2}}(\lambda_e r) \sin \left( \frac{n\phi}{2} \right) \quad (15) \]

with

\[ \lambda_e^2 = k_e^2 - \gamma^2, \quad n = 0, 1, \ldots \]

In Eq. (15), $J_{\frac{n+1}{2}}(\lambda_e r)$ denotes the Bessel Function of order $n/2$, and $(r, \phi, z)$ are the circular cylindrical coordinates. The corresponding vector wave functions are then given by

\[ M_{o(\pi/2)}(\lambda_e r) = e^{i k_e \phi} \left[ \frac{\gamma r}{2} J_{\frac{n+1}{2}}(\lambda_e r) \cos \left( \frac{n\phi}{2} \right) \right. \]
\[ + \left. \frac{\lambda_e^2}{k_e} J_{\frac{n+1}{2}}(\lambda_e r) \sin \left( \frac{n\phi}{2} \right) \sin \left( \frac{n\phi}{2} \right) \right] \quad (16a) \]

\[ \frac{\gamma r}{2} J_{\frac{n+1}{2}}(\lambda_e r) \sin \left( \frac{n\phi}{2} \right) - \lambda_e J_{\frac{n+1}{2}}(\lambda_e r) \cos \left( \frac{n\phi}{2} \right) \phi \]
\[ N_{o(\pi/2)}(\lambda_e r) = e^{i k_e \phi} \left[ \frac{\gamma r}{2} J_{\frac{n+1}{2}}(\lambda_e r) \cos \left( \frac{n\phi}{2} \right) \right. \]
\[ + \left. \frac{\lambda_e^2}{k_e} J_{\frac{n+1}{2}}(\lambda_e r) \sin \left( \frac{n\phi}{2} \right) \sin \left( \frac{n\phi}{2} \right) \right] \quad (16b) \]

\[ \frac{\gamma r}{2} J_{\frac{n+1}{2}}(\lambda_e r) \sin \left( \frac{n\phi}{2} \right) - \lambda_e J_{\frac{n+1}{2}}(\lambda_e r) \cos \left( \frac{n\phi}{2} \right) \phi \]
\[ N_{o(\pi/2)}(\lambda_e r) = e^{i k_e \phi} \left[ \frac{\gamma r}{2} J_{\frac{n+1}{2}}(\lambda_e r) \cos \left( \frac{n\phi}{2} \right) \right. \]
\[ + \left. \frac{\lambda_e^2}{k_e} J_{\frac{n+1}{2}}(\lambda_e r) \sin \left( \frac{n\phi}{2} \right) \sin \left( \frac{n\phi}{2} \right) \right] \quad (17a) \]
Since the derivations of $G^*$ and $G$ are very similar, only the former will be considered in detail. To express $G^*$ in terms of these vector wave functions, one needs only the $M_\nu$ and $N_\nu$ functions because they are the only functions that would satisfy the boundary condition stated by Eq. (6). In order to solve Eq. (5), using the method of orthogonal functions, the orthogonal property of the two sets of vector wave functions must first be established.

Consider two arbitrary sets of eigenvalues denoted, respectively, by $(n/2, \lambda_\nu, \hbar)$ and $(n'/2, \lambda'_\nu, \hbar')$. It can easily be shown that

$$
\begin{align*}
\int_0^{2\pi} \mathbf{e}_{e(n/2)\lambda_\nu} \cdot \mathbf{e}_{e(n'/2)\lambda'_\nu} d\phi &= 0, \\
\int_0^{2\pi} \mathbf{e}_{o(n/2)\lambda_\nu} \cdot \mathbf{e}_{o(n'/2)\lambda'_\nu} d\phi &= 0, \\
\int_0^{2\pi} \mathbf{e}_{o(n/2)\lambda_\nu} \cdot \mathbf{e}_{e(n'/2)\lambda'_\nu} d\phi &= 0.
\end{align*}
$$

By applying the formula of Hankel that

$$
\int_0^\infty \mathbf{e}_{e(n/2)\lambda_\nu} \int_0^\infty r dr J_\mu(\lambda_\nu r) J_\mu(\lambda_\nu r) f(\lambda_\nu) = f(\lambda'_\nu)
$$

one finds that for $n = n'$

$$
\int_0^\infty \mathbf{e}_{e(n/2)\lambda_\nu} \int_0^\infty r dr d\phi \left\{ \mathbf{e}_{e(n/2)\lambda_\nu} \cdot \mathbf{e}_{e(n/2)\lambda'_\nu} \right\} = (1 + \delta_{n'}) n\lambda_\nu^2
$$

while

$$
\int_0^\infty \mathbf{e}_{o(n/2)\lambda_\nu} \int_0^\infty r dr d\phi \mathbf{e}_{o(n/2)\lambda_\nu} \cdot \mathbf{e}_{e(n'/2)\lambda'_\nu} = 0.
$$

In Eq. (20) $\mathbf{e}_{o(n/2)\lambda_\nu}(-i\hbar)$ denotes the function $\mathbf{e}_{o(n/2)\lambda_\nu}$ with the sign of $i\hbar$ reversed. It may be remarked here that the normalization regarding these vector wave functions for the case in which the $n$'s are even integers has been discussed by Stratton. The orthogonal relationship between $\mathbf{e}_{o(n/2)\lambda_\nu}$ and $\mathbf{e}_{e(n'/2)\lambda'_\nu}$, however, was not correctly established. The two functions are, in general, not orthogonal with respect to $\phi$, although they
are orthogonal in the entire domain of \( r, \lambda, \) and \( \phi \). To derive the explicit expression for \( G \), let us first expand the right side of Eq. (5) in terms of \( M_{e(n/2)} \lambda_c(\theta h) \) and \( N_{e(n/2)} \lambda_c(\theta h) \) as follows:

\[
\mathbb{I} \delta(x - x') \delta(y - y') \delta(z - z') =
\]

\[
\int_0^\infty \lambda_c \, d\lambda_c \int_0^\infty dh \sum_{n=0}^\infty \left[ A_n(-ih) \, M_{e(n/2)} \lambda_c(\theta h) + B_n(-ih) \, N_{e(n/2)} \lambda_c(\theta h) \right]
\]

(22)

where \( A_n \) and \( B_n \) are two unknown functions to be determined. The double integration contained in Eq. (22) indicates that the eigenvalues are continuous both in the \( r \) and the \( z \) coordinates. Taking the scalar product of Eq. (22) with \( M_{e(n'/2)} \lambda_c'(\theta h') \) and \( N_{e(n'/2)} \lambda_c'(\theta h') \), respectively, and then integrating with respect to \( dv \) over all space, one obtains

\[
M_{e(n'/2)} \lambda_c'(\theta h') = \int_0^\infty r dr \int_0^\infty dz \int_0^{2\pi} d\phi \int_0^\infty \lambda_c d\lambda_c \int_0^\infty dh \sum_{n=0}^\infty \left[ A_n(-ih) \, M_{e(n/2)} \lambda_c(\theta h) + B_n(-ih) \, N_{e(n/2)} \lambda_c(\theta h) \right].
\]

(23)

The prime functions at the left side of Eq. (23) are defined in the prime coordinates \( (r', \phi', z') \). The multiple integral contained in Eq. (23) can be simplified by making use of the orthogonal relations described by Eqs. (18) - (21), and the Fourier integral theorem

\[
\int_0^\infty dz \int_0^\infty dh \left[ e^{i(A \cdot h')} \tilde{f}(h) \right] = 2\pi f(h')
\]

(24)

to obtain

\[
M_{e(n'/2)} \lambda_c'(\theta h') = 2\pi^2 (1 + \delta_0) \lambda_c^2 A_n'(\theta h')
\]

(25)

\[
N_{e(n'/2)} \lambda_c'(\theta h') = 2\pi^2 (1 + \delta_0) \lambda_c^2 B_n'(\theta h')
\]

(26)
hence, 

\[ \delta(x - x') \delta(y - y') \delta(z - z') = \int_0^\infty d\lambda_c \int_0^\infty dh \cdot \sum_{n=0}^2 2 - \delta_0 \left[ M'_{e(n/2)}(\lambda_c)(-th) M_{e(n/2)}(\lambda_c)(th) + N'_{o(n/2)}(\lambda_c)(-th) N_{o(n/2)}(\lambda_c)(th) \right] . \]  

(27)

To determine \( G_e \) one writes

\[ G_e = \int_0^\infty d\lambda_c \int_0^\infty dh \sum_{n=0}^2 C_n \left[ M'_{e(n/2)}(\lambda_c)(-th) M_{e(n/2)}(\lambda_c)(th) + N'_{o(n/2)}(\lambda_c)(-th) N_{o(n/2)}(\lambda_c)(th) \right] , \]  

(28)

where \( C_n \) is an unknown function of \( \lambda_c \) and \( h \). The unknown function can be determined by substituting Eqs. (27) and (28) into Eq. (5) to obtain

\[ C_n = \frac{2 - \delta_0}{4\pi \lambda_c(h^2 + \lambda_c^2 - k^2)} . \]  

(29)

and hence,

\[ G_e = \int_0^\infty d\lambda_c \int_0^\infty dh \sum_{n=0}^2 \frac{(2 - \delta_0)}{4\pi \lambda_c(h^2 + \lambda_c^2 - k^2)} \cdot \left[ M'_{e(n/2)}(\lambda_c)(-th) M_{e(n/2)}(\lambda_c)(th) + N'_{o(n/2)}(\lambda_c)(-th) N_{o(n/2)}(\lambda_c)(th) \right] . \]  

(30)

The integration with respect to \( \lambda_c \) can be simplified by making use of the identity that

\[ \int_0^\infty \frac{J_{\frac{1}{2}}(\lambda_c r')}{\lambda_c^2 - \lambda_c^2} d\lambda_c = \frac{\pi}{2\Gamma(\lambda)} f(\lambda) \begin{cases} J_{\frac{1}{2}}(\lambda r') H_{\frac{1}{2}}^{(1)}(\lambda r'), r > r' \\ J_{\frac{1}{2}}(\lambda r) H_{\frac{1}{2}}^{(1)}(\lambda r'), r < r' \end{cases} \]  

(31)

It is assumed that \( \lambda \) is the only pole of the integrand. The final expression of \( G_e \) is therefore given by
\[ \mathbf{G}_e = \frac{i}{\sqrt{\sigma}} \int_0^\infty dh \sum_{\lambda=0}^{\infty} \frac{\lambda^2}{2} \mathbf{M}_{e(n/2)\lambda} (-i\hbar) \mathbf{M}_{e(n/2)\lambda} (i\hbar) + \mathbf{N}_{e(n/2)\lambda} (-i\hbar) \mathbf{N}_{e(n/2)\lambda} (i\hbar), \quad r > r' \] 

\[ \mathbf{M}_{e(n/2)\lambda} (-i\hbar) \mathbf{M}_{e(n/2)\lambda} (i\hbar) + \mathbf{N}_{e(n/2)\lambda} (-i\hbar) \mathbf{N}_{e(n/2)\lambda} (i\hbar), \quad r < r' \] 

where 

\[ \lambda^2 = k^2 - \hbar^2. \]

The superscripts (1) and (3) are the conventional notations for the two kinds of vector wave functions with different cylindrical functions. Thus,

\[ \mathbf{M}_{e(n/2)\lambda} (i\hbar) = \mathbf{\nabla} \times \left[ e^{i\hbar z} J_{\lambda}(\lambda r) \cos \left( \frac{np}{2} \right) Z \right] \]

\[ \mathbf{M}_{e(n/2)\lambda} (i\hbar) = \mathbf{\nabla} \times \left[ e^{i\hbar z} H_{\lambda}(\lambda r) \cos \left( \frac{np}{2} \right) Z \right] \]

and similarly for the \(\mathbf{N}\)-functions.

In regard to the magnetic dyadic Green's function the deviation is practically the same. The only difference is that the vector functions \(\mathbf{M}_o\) and \(\mathbf{N}_o\) are now used to construct \(\mathbf{G}_o\) so that the boundary condition stated by Eq. (7) is satisfied. The final expression for \(\mathbf{G}_o\) is therefore similar to that of \(\mathbf{G}_e\) except that \(\mathbf{M}_o\) and \(\mathbf{N}_o\) in \(\mathbf{G}_e\) are replaced by \(\mathbf{M}_o\) and \(\mathbf{N}_o\) for \(\mathbf{G}_o\). Because of the mutual relationship that

\[ \mathbf{\nabla} \times \mathbf{M}_{o(n/2)\lambda} = k \mathbf{N}_{o(n/2)\lambda} \]

\[ \mathbf{\nabla} \times \mathbf{N}_{o(n/2)\lambda} = k \mathbf{M}_{o(n/2)\lambda} \]

it is obvious that

\[ \mathbf{\nabla} \times \mathbf{\nabla}' \times \mathbf{G}_e = k^2 \mathbf{G}_e \]

and

\[ \mathbf{\nabla} \times \mathbf{\nabla}' \times \mathbf{G}_o = k^2 \mathbf{G}_o \]

With slight modifications the method described here can be used to derive the dyadic Green's functions pertaining to other cylindrical structures.
III APPLICATION FOR THE DYADIC GREEN'S FUNCTIONS TO RADIATION FROM DIPOLES AND APERTURES IN THE PRESENCE OF A HALF-PLANE SHEET

Once the expressions for $G_e$ and $G_m$ are known the discussion of the radiation from given current elements or apertures with given field distribution reduces to that of evaluating some complex integrals. In general, integrals of the type contained in Eqs. (8)-(11) are difficult to evaluate. However, for certain restricted ranges of the parameters, corresponding to the far-zone region, most of the integrals can be evaluated in a closed form. Depending upon the nature of the exciting sources, the problems can most conveniently be divided into three groups:

Radiation from Electric Dipoles
Radiation from Magnetic Dipoles
Radiation from Slots Cut in the Half-Plane Sheet

A. RADIATION FROM ELECTRIC DIPOLES

1. LONGITUDINAL ELECTRIC DIPOLE

Let us first consider an electric dipole with moment $p_z$ oriented along the direction of the longitudinal axis of the half-plane sheet. The dipole is placed at $(a, \varphi_0, 0)$. The electric current density function can be written as

$$J_e = -i\omega p_z \delta(r - a) \delta(\varphi - \varphi_0) \delta(z - 0) \hat{z}. \quad (39)$$

Substituting Eqs. (32a) and (39) into Eq. (8), one finds that the longitudinal component of the electric field is given by

$$E_z = \frac{ip_z}{4\pi e} \int_0^\infty \lambda^2 e^{iK\lambda} \sum_{n=1}^\infty \sin \left(\frac{n\varphi_0}{2}\right) \sin \left(\frac{n\varphi}{2}\right) J_n(\lambda a) \frac{H_n^{(1)}(\lambda r)}{\lambda} \, dh. \quad (40)$$

For large values of $\lambda R$, where $R$, $\theta$, and $\phi$ are the spherical coordinates of the point of observation, the complex integral continued in Eq. (40)
can be evaluated approximately by means of the saddle-point method of integration, with the result

\[ \mathcal{E}_t = \frac{\omega^2 \mu_0}{2\pi} \frac{e^{ikR}}{R} \sin^2 \theta \sum_{n=1}^{\infty} (-1)^{n-1} \sin \left( \frac{n\phi}{2} \right) \sin \left( \frac{n\phi_0}{2} \right) J_{n/2} \left( k\alpha \sin \theta \right). \tag{41} \]

Because of the reciprocal relationship between the properties of transmitting and receiving antennas it can be inferred from Sommerfeld's diffraction theory that one should be able to transform the series in Eq. (41) into certain Fresnel integrals which represent the original form of Sommerfeld's solution. The transformation can be done either by applying an expansion theorem due to Hargreaves in connection with the half-order Bessel functions or by using an alternative method described by Morse and Feshbach. It has been shown by these authors that if one writes

\[ S(\rho, \phi) = \frac{1}{2} \sum_{n=0}^{\infty} (2 - \delta_{n0}) \cos \left( \frac{n\phi}{2} \right) J_{n/2} \left( \rho \right) \tag{42} \]

the integral representation of the series is given by

\[ S(\rho, \phi) = (n)^{1/2} e^{-i(\rho \cos \phi + \frac{\pi}{4})} \int_{-\infty}^{\infty} e^{i\xi^2} ds \tag{43} \]

The integral contained in Eq. (43) can be transformed into the standard Fresnel integrals defined as follows:

\[ C(x) = \int_{0}^{x} \cos t \frac{dt}{(2nt)^{1/4}} , \quad S(x) = \int_{0}^{x} \sin t \frac{dt}{(2nt)^{1/4}} \tag{44} \]

Adequate tabulations are available for these two functions. For numerical computation the following formula for \( S(\rho, \phi) \) is therefore more desirable

\[ S(\rho, \phi) = 2^{1/4} e^{-i\rho \cos \phi + \frac{\pi}{4}} \left\{ \frac{1}{2} (1 + i) \pm [C(x) + iS(x)] \right\} \tag{45} \]

\[ x = k\alpha(1 + \cos \phi) \]
where the sign is fixed according to the range of $\varphi$

\[
\begin{cases}
0 < \varphi < \pi \\
\pi < \varphi < 2\pi
\end{cases}
\]

Regarding $S(p,^>)$ as an "elementary" function, one can reduce Eq. (41) into the following form

\[
E_z = \frac{2}{\omega \mu_0} \frac{\epsilon^{ikR}}{4\pi R} \sin^2 \theta \left[ S(ka \sin \theta, \varphi - \varphi_0) - S(ka \sin \theta, \varphi + \varphi_0) \right] .
\]

In the principal plane, corresponding to $\theta = 90^\circ$, the radiation pattern of the $z$-component of the electric field due to a longitudinal electric dipole in the presence of the half-plane sheet is therefore simply given by

\[
F(E_z) = S(ka, \varphi - \varphi_0) - S(ka, \varphi + \varphi_0) .
\]

It is, of course, possible to obtain the same information regarding the radiation pattern from Sommerfeld's solution by applying the reciprocal theorem. Equation (47) also contains the essential result obtained by Harrington, concerning the radiation pattern of a line source in the presence of a half-plane sheet. In fact the complex integral obtained by Harrington based upon the solution of the Hopf-Wiener integral equation can readily be reduced into Fresnel integrals.

For other orientations of the dipole, the derivation of the essential formulae concerning the radiation pattern in the principal plane is practically the same. The final results are summarized below.

2. **Horizontal Electric Dipole (In the Direction of X-Axis)**

\[
F(E_x) = \sin \varphi \left[ S(ka, \varphi - \varphi_0) - S(ka, \varphi + \varphi_0) \right] + \left( \frac{2}{nk\alpha} \right)^{\frac{1}{2}} e^{i(\kappa x + \frac{\pi}{4})} \sin \left( \frac{\varphi_0}{2} \right) \cos \left( \frac{\varphi}{2} \right)
\]
3. **Vertical Electric Dipole (In the Direction of y-Axis)**

\[
P(E_\phi) = \cos \phi \left[ S(ka, \phi - \phi_0) + S(ka, \phi + \phi_0) \right] \\
+ \left( \frac{2}{nka} \right)^{\frac{1}{3}} e^{i(ka+\frac{\pi}{4})} \cos \left( \frac{\phi_0}{2} \right) \cos \left( \frac{\phi}{2} \right)
\]  

The patterns based upon Eqs. (47), (48), and (49), after being properly normalized, are plotted in Figs. 2, 3, and 4 for several different values of \(ka\) and \(\phi_0\).

**B. Radiation from Magnetic Dipoles**

1. **Longitudinal Magnetic Dipole (In the Direction of z-Axis)**

\[
P(E_\phi) = S(ka, \phi - \phi_0) + S(ka, \phi + \phi_0)
\]  

2. **Horizontal Magnetic Dipole (In the Direction of x-Axis)**

\[
P(E_x) = \sin \phi \left[ S(ka, \phi - \phi_0) + S(ka, \phi + \phi_0) \right] \\
+ \left( \frac{2}{nka} \right)^{\frac{1}{3}} e^{i(ka+\frac{\pi}{4})} \cos \left( \frac{\phi_0}{2} \right) \sin \left( \frac{\phi}{2} \right)
\]

3. **Vertical Magnetic Dipole (In the Direction of y-Axis)**

\[
P(E_y) = \cos \phi \left[ S(ka, \phi - \phi_0) - S(ka, \phi + \phi_0) \right] \\
- \left( \frac{2}{nka} \right)^{\frac{1}{3}} e^{i(ka+\frac{\pi}{4})} \sin \left( \frac{\phi_0}{2} \right) \sin \left( \frac{\phi}{2} \right)
\]

As shown in the following section, when a longitudinal magnetic dipole or a horizontal magnetic dipole is placed at the half-plane sheet, the pattern is the same as that of a small longitudinal slot or a small horizontal slot cut in the sheet.
C. RADIATION FROM APERTURES

The electromagnetic field due to apertures with given electric field distribution can be evaluated by applying Eq. (9). The aperture can be excited either "one-sided" or "two-sided." In practice, the one-sided excitation corresponds to the aperture radiation from a waveguide terminated by a half-plane sheet. If the opening on the sheet is fed by a two-wire transmission line or a coaxial transmission line the excitation would be two-sided. Much useful information regarding the radiation field due to apertures can be gathered by considering the radiation from narrow slots.

1. LONGITUDINAL SLOT

The field distribution for a narrow longitudinal slot can be written as

\[ E = f(z) \delta(r - a) \hat{r} \]  \hspace{1cm} (53)

where \( f(z) \) is a given function of \( z \) depending upon the assumed field distribution along the slot. For a one-sided excitation the far-zone field in the principal plane, obtained by substituting Eqs. (32a) and (53) into Eq. (9) and applying the saddle-point method of integration, is

\[ F_1(E_\phi) = S(ka, \varphi) \]  \hspace{1cm} (54)

The pattern is the same as that of a longitudinal magnetic dipole when the latter is placed at the surface of the half-plane sheet corresponding to \( \varphi_0 = 0 \) and at a distance \( r = a \) from the edge. The corresponding formula for a two-sided excitation is

\[ F_2(E_\phi) = S(ka, \varphi) - S(ka, 2\pi - \varphi) \]

\[ = \pm (2)^{1/2} e^{-i(ka \cos \varphi + \pi)} \left[ C(x) + iS(x) \right] , \]

\[ x = ka(1 + \cos \varphi) \]  \hspace{1cm} (55)

2. HORIZONTAL SLOT

The radiation field due to a horizontal slot is somewhat more difficult to evaluate. Assuming that the field distribution in the slot is of the form
where \( f(r) \) is a given function of \( r \), then the far-zone field in the principal plane due to a one-sided slot is, in general, given by

\[
E_z = \frac{e^{ikR}}{4\pi R} \sum_{n=1} \frac{n(-i)^n}{2} \sin \left( \frac{n\varphi}{2} \right) \frac{f(r')J_n(ka)}{r'} dr'.
\]  

(57)

The integral contained in Eq. (57) cannot be evaluated in closed form unless the function \( f(r') \) is a delta function so that the analysis applies to the problem of a very short slot or one of another class of functions discussed in a later section. As present, let us consider the special case of a short slot. Replacing \( f(r') \) in Eq. (57) by \( \delta(r'-a) \), where \( a \) is the radial distance measured from the edge of the half-plane sheet to the small opening, one obtains

\[
E_z = \frac{e^{ikR}}{4\pi a R} \sum_{n=1} \frac{n(-i)^n}{2} J_n(ka) \sin \left( \frac{n\varphi}{2} \right).
\]

(58)

The radiation pattern of a one-sided small horizontal slot in the principal plane is therefore given by

\[
P_1(E_z) = \frac{1}{ika} \frac{\partial}{\partial \varphi} S(ka, \varphi)
\]

\[
= \sin \varphi S(ka, \varphi) + \frac{e^{i\left(\frac{ka}{2}\right)}}{(2\pi \alpha)^{1/2}} \sin \left( \frac{\varphi}{2} \right).
\]

(59)

The pattern is, of course, the same as that of a horizontal magnetic dipole placed at the surface of the sheet obtained by putting \( \varphi_0 = 0 \) in Eq. (51). The corresponding formula for a two-sided small horizontal slot is
\[ P_2(E_f) = |\sin \varphi| e^{-i \kappa \cos \phi} \left[ C(x) + i S(x) \right] z = k \alpha (1 + \cos \phi) \]

\[ + \frac{ie^{ikx}}{(nk\alpha)^{\frac{1}{2}}} \sin \left( \frac{x}{2} \right) \]  

(60)

Patterns based upon Eqs. (54), (55), and (60) are plotted in Figs. 5-8 for several different values of \( \kappa \alpha \).
Since extensive tables of the Fresnel Integrals are available, it is possible to compute the radiation patterns corresponding to various excitations for practically any value of $ka$. If the value of $ka$ is large, the pattern exhibits certain distinct properties. A typical pattern for a one-sided longitudinal slot placed a distance corresponding to $ka = 30$ from the edge of the sheet is shown in Fig. 9. The locations of the maxima and the minima of such a pattern can be ascertained in a relatively simple manner. In the case of a one-sided longitudinal slot, the extreme values of the pattern are determined by the condition

$$
\frac{\partial |S(ka, \varphi)|}{\partial \varphi} = 0
$$

(61)

Using the explicit expression of $S(ka, \varphi)$ given by Eq. (45), one obtains

$$
\frac{1}{2} + \frac{C(x)}{S(x)} = - \tan x
$$

(62)

where

$$
x = ka(1 + \cos \varphi)
$$

The graphical solution for the roots of Eq. (62) is shown in Fig. 10. Denoting these roots by $x_m$, one can see from Fig. 10 that the approximate solutions for the roots are given by

$$
x_m = (4m - 1) \frac{n}{4}
$$

or

$$
\cos \varphi_m = (4m - 1) \frac{n}{4ka} - 1, \quad m = 1, 2, \cdots
$$

(63)
Equation (63) determines the locations of the maxima when m's are odd integers. Interlaced between the maxima are the minima corresponding to even integers of m. Since the magnitude of $S(\kappa \alpha, \phi_1)$ and that of $S(\kappa \alpha, \pi)$ are independent of $\kappa \alpha$, their ratio

$$\frac{S(\kappa \alpha, \phi_1)}{S(\kappa \alpha, \pi)} = 0.426 \quad (64)$$

is therefore also independent of $\kappa \alpha$. It is a measure of the rapidity of the decay of the field from the peak value to the value observed at the boundary between the shadow region and the illuminated region. Similar discussions can be carried out for the fields set up by the other types of antennas considered above.
V RADIATION RESISTANCE OF ANTENNAS NEAR HALF-PLANE SHEETS, AND RADIATION CONDUCTANCE OF THE COMPLEMENTARY SLOTS

In this section we will discuss the radiation resistance of a quarter-wave monopole attached to the edge of a half plane sheet, and that of a half-wave dipole placed in front of the sheet with its axis parallel to the edge of the sheet as shown in Fig. 11 (a) and (b). The complementary problems of a quarter-wave slot normal to the edge of the sheet, and a half-wave slot cut in the sheet parallel to the edge, are shown in Fig. 11 (c) and (d). Since the Babinet-Booker relationship regarding the radiation resistance of the dipole and the radiation conductance of the complementary slot applies, namely

\[
\frac{R_d}{G} = \frac{\eta^2}{4}
\]

where \( \eta = 120\pi \) ohms,

it is therefore sufficient for our purpose to present only the detailed analysis for the cases involving the monopole and the dipole.

A. QUARTER-WAVE MONOPOLE ATTACHED TO THE EDGE OF A HALF-PLANE SHEET

To evaluate the radiation resistance of the monopole for this case, the method of Poynting-energy theorem will be applied. For a base driven monopole it will be assumed that the current distribution is sinusoidal. The current density function to be used in Eq. (8) can therefore be written in the form

\[
J_x = I_0 \cos \theta r \frac{\delta(z - 0) \delta(\phi - \pi)}{r} \hat{r}.
\]

Using the expression of \( G_z \) given by Eq. (32a), and applying the method of saddle-point integration, one can obtain the explicit expression for the far-zone electric field. Expressed in spherical coordinates, it is
\[ E = E_\theta \hat{\vartheta} + E_\phi \hat{\varphi} \]  

(67)

\[ E_\theta = -\frac{\eta I_0 e^{ikR}}{2nR} \sum_{n=1,3\ldots} (i)_{n/2}^{-1} \sin \left( \frac{np}{2} \right) \cos \theta \frac{K_{\eta/2}(\varphi)}{2} \]  

(67a)

\[ E_\phi = -\frac{\eta I_0 e^{ikR}}{2nR} \sum_{n=1,3\ldots} (i)_{n/2}^{-1} \cos \left( \frac{np}{2} \right) \frac{1}{\sin \theta} \frac{(n)}{(2)} I_{\eta/2}(\varphi) \]  

(67b)

where

\[ K_{\eta/2}(\varphi) = k \int_0^{\Delta} J_{\eta/2} (kr \sin \vartheta) \cos kr \, dr \]  

(68)

\[ I_{\eta/2}(\varphi) = \int_0^{\Delta} J_{\eta/2} (kr \sin \vartheta) \cos kr \frac{dr}{r} \]  

(69)

The functions \( K_{\eta/2}(\varphi) \) and \( I_{\eta/2}(\varphi) \) defined in Eqs. (68) and (69) can be evaluated in terms of the Fresnel integrals. They are tabulated in the Appendix for \( n = 1 \) and 3. Using Eqs. (67a) and (67b), one finds that the radiation resistance of the quarter-wave monopole defined with respect to the base current \( I_0 \) is given by

\[ R_* = \frac{2}{\eta I_0^2} \frac{1}{2} \int_0^{2\pi} \int_0^{\pi} \left( E_\theta^2 + E_\phi^2 \right) R^2 \sin \theta \, d\theta \, d\varphi \]

\[ = \frac{\eta}{2\pi} \sum_{n=1,3\ldots} \left[ \left( \frac{n}{2} \right)^2 \frac{1}{2} \frac{I_{\eta/2}^2(\varphi)}{\sin \theta} \frac{d\theta}{\sin \theta} + \left( \frac{\pi}{2} \right)^2 \frac{k^2(\varphi)}{2} \cos^2 \theta \sin \theta \, d\theta \right] \]  

(70)

The integrals contained in Eq. (70) can only be evaluated numerically.

The integrands \( \left( \frac{n}{2} \right)^2 \frac{I_{\eta/2}^2(\varphi)}{\sin \theta} \) and \( \frac{k^2(\varphi)}{2} \cos^2 \theta \sin \theta \) are plotted in
Fig. 12 for \( n = 1 \) and 3. The contributions to \( R \) by terms with \( n = 5 \) and higher are negligible. The sum of the four leading terms gives a value of \( R \) equal to 86.3 ohms. It is interesting to observe that the value is greater than the free-space radiation resistance of a half-wave dipole, namely 73.13 ohms. For a quarter-wave monopole driven against a ground plane, the radiation resistance is, of course, only 36.56 ohms. The input impedance of a monopole driven against a large, but finite, half-plane sheet has been measured experimentally. The result is plotted in Fig. 13. The antenna is a quarter-wavelength long at a frequency of 700 Mc. The input resistance of the antenna at this frequency is around 92 ohms. It confirms the calculated value of \( R \) within the experimental error.

B. HALF-WAVE DIPOLE PLACED PARALLEL TO THE EDGE OF A HALF-PLANE SHEET

As in the previous case, it is assumed that the current distribution on the dipole is sinusoidal. The current density function to be used in Eq. (8) is

\[
J_r = I_0 \cos k_z \frac{\delta(r - d) \delta(\phi - n)}{r}
\]  

(71)

The far-zone field in this case has only one component, i.e., \( E_\theta \). Following the same procedure as before, one obtains

\[
E_\theta = \frac{-\eta I_0 e^{ikR}}{nr} \frac{\cos \left(\frac{n}{2} \cos \theta\right)}{\sin \theta} \sum_{n=1,3} (1)^n J_{n/2} (kd \sin \theta) \sin \left(\frac{np}{2}\right).
\]  

(72)

The radiation resistance of the dipole can be evaluated according to the following formula

\[
R_d = \frac{2}{\eta I_0^2} \int_0^{2\pi} \int_0^{\pi/2} E_{\theta}^2 R^2 \sin \theta \, d\theta \, d\phi
\]

\[
= \frac{2\eta}{n} \sum \int_0^{\pi/2} \cos \left(\frac{n}{2} \cos \theta\right) J_{n/2}^2 (kd \sin \theta) \, d\theta.
\]  

(73)
The integrals contained in Eq. (73) may be evaluated numerically with the aid of an adequate table of half-order Bessel functions. The result is plotted in Fig. 14. For comparison, the radiation resistance of a horizontal half-wave dipole placed above a ground plane is also plotted in the same figure. The two curves are seen to intersect at those points when \( d \) is a multiple of a quarter wavelength. It is believed that the identity of the two equations for radiation resistance could be demonstrated at these points without difficulty, but such a demonstration has not been carried out. Physically, however, it is difficult to explain why the two configurations yield the same radiation resistance, since the field distribution of the two structures are entirely different.

Our discussion on the radiation resistance of a half-wave dipole in the presence of a half-plane sheet supplements the earlier work by Kraus 11 on the radiation resistance of a dipole placed in a corner reflector. A half-plane sheet is structurally a limiting case of corner reflector when the angle of the reflector approaches 360 deg. Using the dyadic Green's function pertaining to a perfectly conducting wedge, one can, indeed, treat the same types of problems as have been discussed here for a half-plane sheet.

As a conclusion of this report we shall consider the problem of the radiation resistance of a half-wave dipole placed in front of a perfectly conducting wedge when the distance between the dipole and the edge of the wedge is small compared to a wavelength. By an analysis similar to that leading to Eq. (73), the general formula for the radiation resistance of the dipole in this case may be shown to be

\[
R_d = \frac{4\eta}{2\pi \varphi_0} \sum_{n=1,3} \int_{\theta_0}^{\pi/2} \frac{\cos^2(\frac{n}{2} \cos \theta)}{\sin \theta} J_{\mu_n}^2 (kd \sin \theta) \, d\theta
\]  

(74)

where

\[
\varphi_0 = \text{angle of the wedge}
\]

\[
\mu_n = \frac{n\pi}{2\pi - \varphi_0}, \quad n = 1, 3 \ldots
\]

Because of the lack of adequate tables of Bessel Functions of arbitrary fractional order, the integrals in Eq. (74) cannot easily be evaluated.
In the case

\[ \left( \frac{kd}{2} \right)^2 \ll \frac{\Gamma(\mu_1 + 2)}{\Gamma(\mu_1 + 1)} \]

the significant part in Eq. (74) is contributed by the leading term of

\[ J_{\mu_1}(kd \sin \theta) \]

which is given by

\[ J_{\mu_1}(kd \sin \theta) = \frac{1}{\gamma(\mu_1 + 1)} \left( \frac{1}{2} kd \sin \theta \right)^{\mu_1} . \quad (75) \]

The radiation resistance of the dipole under this condition can be computed from the following formula:

\[ R_d = \alpha (kd)^{2 \mu_1} \quad (76) \]

where

\[ \alpha = \frac{480 \mu_1}{2^{2 \mu_1 - 2} (\mu_1 + 1)} \int_0^{\pi} \cos \left( \frac{\pi}{2} \cos \theta \right) (\sin \theta)^{2 \mu_1 - 1} d\theta \]

The index \(2\mu_1\) and the constant \(\alpha\) are plotted in Fig. 15, as a function of the wedge angle \(\varphi_0\). When \(2\pi - \varphi_0 = \frac{\pi}{m}\) with \(m = 1, 2, \ldots\) the wedge becomes a regular corner reflector such that the method of images can be applied to determine the radiation field, and hence the radiation resistance, of the dipole as discussed by Kraus.
ACKNOWLEDGEMENT

The author is indebted to Dr. John T. Bolljahn for many valuable discussions in the course of this study. Mr. Ivan J. Stampalia has kindly supplied the experimental data mentioned in this report. The assistance of Mrs. E A. Clarke with numerical calculations is gratefully acknowledged.
