Distribution of this document is unlimited.
PREFACE

Slender re-entry vehicles at high altitude and high velocity possess a flow field which results from the interaction between the boundary layer formed near the surface and the shock wave originating from the leading edge or tip. This Memorandum studies the analytical conditions necessary for the solution of a set of simplified equations which describe the interaction flow field. Surface mass transfer, which occurs in the case of an ablating vehicle, is also considered. The results of this Memorandum will be useful in the interpretation of experimental data and the implementation of numerical analyses. The Memorandum is part of a continuing study for the Advanced Research Projects Agency in re-entry aerodynamics.

One of the authors, T. Y. Li, is a professor in the Department of Aeronautical and Astronautical Engineering, Ohio State University, Columbus, Ohio, and consultant to The RAND Corporation.
ABSTRACT

An analytical formulation of the problem of hypersonic viscous interaction on a very slender body of revolution with a thick boundary layer and mass transfer is attempted. Particular attention is directed to the establishment of the mathematical restrictions necessary to ensure the existence of similar solutions of the laminar boundary layer equations for this class of problems. Yasuhara's analysis is extended to include surface mass transfer and binary mixture effects, and it is shown that similar solutions are possible only for three-quarter-power-law bodies of revolution. With regard to the problem of hypersonic viscous interaction on a slender body of revolution with a thick boundary layer and surface mass transfer, it is shown that the criterion for the existence of similar solutions is that \( r^{3/4} \) must govern the body surface shape and the surface injection velocity.

I. INTRODUCTION

The purpose of this Memorandum is to present an analytical formulation of the problem of hypersonic viscous interaction on a very slender body of revolution with a thick boundary layer and surface mass transfer. Particular attention is directed to establishing the mathematical restrictions necessary to ensure the existence of similar solutions of the laminar boundary layer equations for this class of problems. The determination of similarity conditions is important because similar solutions are amenable to comparatively simple analysis and find diverse application through the use of the local similarity concept. Recently, Yasuhara demonstrated that similar solutions can be determined for a slender, three-quarter-power-law body of revolution when the boundary layer thickness is of the same order as the body radius. In this Memorandum we extend Yasuhara's analysis to include surface mass transfer and binary mixture effects, and show that in the extended case similar solutions are possible only for three-quarter-power-law bodies of revolution. It is further shown that these similar solutions are characterized by the restrictive condition that $r_e/r_w = \text{constant}$. This requirement for similar solutions is particularly pertinent in the regime where $r_e/r_w = 0(1)$ or $y_e/r_w = 0(1)$.

The equations which describe the boundary-layer growth on a body of revolution contain the transverse curvature expression $(r^2/r_w^2)$. For similar solutions to exist, this expression must be a function of the similarity variable $\eta$. Particular attention is directed to the regime where $r_w^2/r_e^2 \ll 1$ or $y_e/r_w \gg 1$. We derive a new system of equations that possesses the same analytical features as the equations studied previously by Stewartson, Glaeuert-Lighthill, and Mark. The possibility that this new system has similar solutions is then examined under appropriate boundary conditions, including the injection of gas at the body surface. The results indicate that similar solutions characterized by $prv$-similarity in the boundary layer can be obtained. Finally, with regard to the problem of hypersonic interaction

*See List of Symbols
on a very slender body of revolution with a thick boundary layer and surface mass transfer, it is shown that the criterion for the existence of similar solutions is that $r_w v_w \sim x^{1/2}$ must govern the body surface shape and the surface injection velocity.
II. CLASSIFICATION OF FLOW REGIMES

Viscous flow regimes may be usefully classified with respect to the ratio of the characteristic body radius to the thickness of the boundary layer. Three such regimes described below, may be distinguished for the purposes of our problem.

THE M REGIME

This regime comprises cases in which \( \frac{y_e}{r_w} = 0(\varepsilon) \) where \( \varepsilon \ll 1 \). Here, Mangler's transformation\(^{6}\) permits a reduction of axisymmetric flow boundary layer equations to two-dimensional boundary layer equations. Transverse curvature effects are, of course, unimportant in this regime.

THE P-E-Y REGIME

This regime comprises cases in which \( \frac{y_e}{r_w} = 0(1) \) or \( \frac{r_e}{r_w} = 0(1) \). The appropriate compressible boundary layer equations with mass transfer are considered by Yasuhara\(^2\) and Probstein and Elliott\(^7\) who show the importance of the effect of transverse curvature in this regime.

THE G-L REGIME

In this regime the boundary layer thickness is large compared with the radius of the body of revolution; that is, \( \frac{y_e}{r_w} \gg 1 \). Using the criterion stated above, we can characterize this regime by \( \left( \frac{y_e}{r_w} \right)^2 = 0(\varepsilon) \), where \( \varepsilon \ll 1 \). Stewartson\(^3\) and Glauert and Lighthill\(^4\) dealt with incompressible flow problems in this regime. Mark\(^5\) and Steiger and Bloom\(^8\) also considered certain classes of compressible boundary layer flows in this regime. Their results demonstrated the extreme importance of transverse curvature effects. The boundary layer equations for the G-L regime possess a basic structure which leads to a logarithmic velocity profile distribution near the body surface in the case of zero mass transfer.
III. BINARY BOUNDARY LAYER EQUATIONS AND BOUNDARY CONDITIONS

The no-slip condition must apply at the body surface. This requires the use of the boundary layer equations in the region adjacent to the body surface. A gas is injected normal to the surface such that a binary boundary layer flow results. The binary boundary layer equations for axisymmetric flow may be written:

\[
\frac{\partial}{\partial x} (\rho u) + \frac{\partial}{\partial y} (\rho v) = 0 \tag{1}
\]

\[
\rho u \frac{\partial u}{\partial x} + \rho v \frac{\partial u}{\partial y} = -\frac{\partial p}{\partial x} + \frac{1}{r} \frac{\partial}{\partial y} \left( \mu r \frac{\partial u}{\partial y} \right) \tag{2}
\]

\[
\frac{\partial p}{\partial y} = 0 \tag{3}
\]

\[
\rho u \frac{\partial H_i}{\partial x} + \rho v \frac{\partial H_i}{\partial y} = \frac{1}{r} \frac{\partial}{\partial y} \left[ r \frac{\mu}{Pr} \frac{\partial H_i}{\partial y} \right] + \frac{1}{r} \frac{\partial}{\partial y} \left[ r u \left( 1 - \frac{1}{Pr} \right) \frac{\partial u}{\partial y} \left( u^2 \right) \right] \tag{4}
\]

\[
+ \frac{1}{r} \frac{\partial}{\partial y} \left[ r u \left( 1 - \frac{1}{Le} \right) \sum_i C_{i} h_i \frac{\partial c_i}{\partial y} \right]
\]

\[
\rho u \frac{\partial C_i}{\partial x} + \rho v \frac{\partial C_i}{\partial y} = \frac{1}{r} \frac{\partial}{\partial y} \left( \rho D_{ij} \frac{\partial c_i}{\partial y} \right) \tag{5}
\]

where

- \( \rho \) = specific heat at constant pressure of the \( i^{th} \) component
- \( C_i = \sum_{i} C_i C_i \)
- \( C_i = \) mass fraction of \( i^{th} \) component
- \( D_{ij} = \) binary diffusion coefficient
- \( H = \) total enthalpy = \( h + (i/2)u^2 \)
- \( h = \sum_{i} C_{i} h_i \)
\( h_i = \text{enthalpy of the } i^{th} \text{ component} \)
\( k = \text{thermal conductivity of the fluid} \)
\( \text{Le} = \text{Lewis number, } \rho \frac{D_{12} C_p}{k} \)
\( \text{Fr} = \text{Prandtl number, } \mu \frac{C_p}{k} \)
\( p = \text{fluid pressure} \)
\( r = r_0 + y \cos \alpha \)
\( r_w(x) \) defines the shape of the body surface
\( \text{Sc} = \text{Schmidt number, } \mu / \rho D_{12} \)
\( u, v = \text{flow velocities in the } x, y \text{ directions, respectively} \)
\( x, y = \text{coordinates, as shown in Fig. 1} \)
\( \mu = \text{viscosity coefficient of the fluid} \)
\( \rho = \text{fluid density} \)

Within the boundary layer we have, from Eq. (3),

\[
p_e(x) = \hat{R} \rho T
\]

where

\[
\hat{R} = \sum \frac{C_i R_i}{m_i} = \sum \frac{C_i R}{m_i}
\]

\( m_i = \text{molecular weight of } i^{th} \text{ gas} \)
\( R = \text{universal gas constant} \)
\( R_i = \text{component gas constant} \)
\( \hat{R} = \text{mixture gas constant} \)

The boundary conditions at the wall are characterized by the no-slip condition, constant wall temperature, the concentration of the injectant gas, and the Eckert condition, which specifies that the normal mass flow velocity of the main component \((i = 2)\) in the gas mixture vanishes at the body surface.
when \( y = 0; \quad u = 0 \) \hfill (8a)

\[
C_1 = C_{1w} = \text{constant} \hfill (8b)
\]

\[
h = H_w = \text{constant} \hfill (8c)
\]

\[

C_1 = 0 \hfill (9b)
\]

\[
H = H_e \hfill (9c)
\]

**TRANSFORMATION OF BINARY BOUNDARY LAYER EQUATIONS**

We shall introduce a coordinate transformation to transform, under certain prescribed conditions, the partial differential equations describing the axially symmetric laminar boundary layer into a set of nonlinear coupled ordinary differential equations. The transformation is quite general so that it can be applied to all the regimes described above. The boundary layer coordinates \((x,y)\) are transformed into the similarity coordinates \((s_k, \eta_k)\) as follows:

\[
s_k = \int_0^x C_\rho \frac{u}{e} e^\frac{r^2}{2s_k} \, dx \hfill (10)
\]

\[
\eta_k = \frac{\rho}{e} \frac{u}{e} \frac{e}{s_k} \int_0^y \frac{\rho}{e} \, r \, dy \hfill (11)
\]
where \( C \) = the Chapman-Rubesin constant

\( r_k \) = characteristic dimension

The transformation can be applied to the P-E-Y and the G-L regimes as follows:

In the P-E-Y regime, \( r_k = r_w \), thus

\[
s_k = s = \int_0^\infty C \rho e \mu u e r^2 dx
\]

(12)

\[
\eta_k = \eta = \frac{\rho u e \sqrt{2s}}{\rho e} \int_0^y \frac{\rho}{\rho e} r dy
\]

(13)

In the G-L regime, \( r_k = r_e \), thus

\[
s_k = s^* = \int_0^\infty C \rho e \mu u e r^2 dx
\]

(14)

\[
\eta_k = \eta^* = \frac{\rho u e \sqrt{2s}}{\rho e} \int_0^y \frac{\rho}{\rho e} r dy
\]

(15)

We shall discuss later these forms of the transformation and their significance. Their immediate application is to the boundary layer equations which can now be rewritten in the new variables \((s_k, \eta_k)\). The stream function \( \psi \) is defined by:

\[
\frac{\partial \psi}{\partial x} = -\rho v r
\]

(16)

\[
\frac{\partial \psi}{\partial y} = \rho u r
\]

(17)

We consider those flows where \( u, \bar{H}, \) and \( C \) are expressed as follows:

\[
\frac{u}{u_e} = K'(\eta_k, s_k)
\]

(18)
\[ \frac{H}{H_e} = G(\eta_k, s_k) \] (19)

\[ \frac{C_{1w}}{C_{1w}} = Z(\eta_k, s_k) \] (20)

where the prime denotes \( \frac{\partial}{\partial \eta_k} \). Equations (2), (4), and (5) may now be written:

\[
\left( \lambda \frac{r^2}{r_k^2} K'' \right)' + K K'' = \frac{2s_k}{u_e} \frac{d}{d s_k} \left( K' \frac{r^2}{r_k^2} - \frac{\rho}{\rho} \right)
\]

\[ + 2s_k \left[ \frac{\partial K'}{\partial s_k} - \frac{\partial K}{\partial s_k} K'' \right] \] (21)

\[
\left( \lambda \frac{r^2}{r_k^2} \frac{G}{Pr} \right)' + KG' = \frac{u_e^2}{H_e} \left[ \frac{r^2}{r_k^2} \left( \frac{1}{Pr} - 1 \right) K' K'' \right]
\]

\[ + 2s_k \left[ K' \frac{\partial G}{\partial s_k} - \frac{\partial K}{\partial s_k} G' \right] \] (22)

\[
+ \frac{C_{1w}}{H_e} \left[ \frac{r^2}{r_k^2} \frac{1}{Sc} \left( \frac{1}{Le} - 1 \right) \left( h_1 - h_2 \right) Z_{11} \right]'
\]

\[
\left( \lambda \frac{r^2}{r_k^2} \frac{1}{Sc} Z_{11} \right)' + KZ_{11}' = 2s_k \left[ \frac{\partial Z_{11}}{\partial s_k} K' - \frac{\partial K}{\partial s_k} Z_{11} \right] \] (23)

where

\[ \lambda = \frac{1}{C} \frac{\rho \mu}{\rho_i \mu_i} \] (24)
In the new coordinate system, the boundary conditions are expressed as follows:

When \( \eta_k = 0 \)

\[
K'(0) = 0 \quad (25)
\]
\[
Z_1(0) = 1 \quad (26a)
\]
\[
G(0) = \frac{H_w}{H_e} \quad (26b)
\]

\[
2s_k \frac{3K}{\beta s_k} (0) + K(0) = \left( \frac{\Lambda}{Sc} \right) \frac{c_{lw}}{1 - c_{lw}} Z_1(0) \left( \frac{r_w}{r_k} \right)^2 \quad (27)
\]

When \( \eta = \eta_{k_e} \)

\[
K'(\eta_{k_e}) = 1 \quad (28)
\]
\[
Z_1(\eta_{k_e}) = 0 \quad (29a)
\]
\[
G(\eta_{k_e}) = 1 \quad (29b)
\]
IV. SIMILAR SOLUTIONS OF THE HYPERSONIC, BINARY AXISYMMETRIC BOUNDARY LAYER

By neglecting terms of order \(1/M^2\) in a hypersonic boundary layer, we obtain the following expressions from Eqs. (18) and (19).

\[
\left(K' - \frac{\rho e}{\rho} \right) \frac{2s_k}{u_e} \frac{du_e}{ds_k} = \frac{\gamma_e - 1}{2Y_e} \beta F_1(\eta'_k, s_k) (G - K'^2) \tag{30}
\]

\[
\frac{u_e^2}{H_e} = 2 \tag{31}
\]

\[
C_{1w} \frac{h_1 - h_2}{H_e} = F_2(\eta'_k, s_k) (G - K'^2) \tag{32}
\]

where

\[
\beta = 2 \frac{d \ln p_e}{d \ln s_k} \tag{33}
\]

\[
F_1(\eta'_k, s_k) = \frac{1 + C_{1w} \left( \frac{m_2}{m_1} - 1 \right) Z_1(\eta'_k, s_k)}{1 + C_{1w} \left( \frac{j_1}{j_2 + 2} \frac{m_2}{m_1} - 1 \right) Z_1(\eta'_k, s_k)} \tag{34}
\]

\[
F_2(\eta'_k, s_k) = \frac{C_{1w} \left( \frac{j_1 + 2}{j_2 + 2} \frac{m_2}{m_1} - 1 \right)}{1 + C_{1w} \left( \frac{j_1}{j_2 + 2} \frac{m_2}{m_1} - 1 \right) Z_1(\eta'_k, s_k)} \tag{35}
\]

The following relationships were used in the derivation of Eqs. (34) and (35):
\begin{align*}
\frac{\bar{R}}{R_e} &= \frac{\Sigma C_R I_1}{(\Sigma C_R I_1)_e} = 1 + \left(\frac{R_1}{R_2} - 1\right) C_{1w} z_1(\eta, s_k) \quad (36) \\
C_{p_1} &= \frac{J_1 + 2}{2} R_1 \quad (37)
\end{align*}

The \( j \) is defined as the effective number of degrees of freedom of the \( i \)th component. In this study, \( j = 5 \) for diatomic gases and \( j = 3 \) for monatomic gases. Substitution of Eqs. (30) to (35) into Eqs. (21) to (23) gives:

\begin{align*}
\left(\frac{\lambda \frac{x^2}{r_k^2} K'}{K} + K K'\right)' &= \frac{\gamma_e - 1}{2\gamma_e} \beta \Phi_1(\eta, s_k, G - K'^2) \\
+ 2s_k \left[ \frac{\partial K'}{\partial s_k} K' - \frac{\partial K}{\partial s_k} K'' \right] \\
\left(\frac{1}{Fr} \frac{\lambda \frac{x^2}{r_k^2} G'}{K} + K G'\right)' &= 2 \left[ \frac{\lambda \frac{x^2}{r_k^2} (\frac{1}{Fr} - 1) K K' \right]' \\
+ 2s_k \left[ K' \frac{\partial G}{\partial s_k} - \frac{\partial K}{\partial s_k} G' \right] \\
+ \left[ \frac{\lambda \frac{x^2}{r_k^2} \frac{1}{Sc} (\frac{1}{Le} - 1) F_2(\eta, s_k, G - K'^2) z_1' \right]' \\
\left(\frac{\lambda \frac{x^2}{r_k^2} \frac{1}{Sc} z_1'}{K} + K z_1' \right)' &= 2s_k \left[ \frac{\partial z_1}{\partial s_k} K' - \frac{\partial K}{\partial s_k} z_1' \right] \quad (39)
\end{align*}

For the problem of hypersonic viscous flow past a very slender body of revolution with injection of coolant gas at the surface, these equations
can be treated under the boundary conditions given in Eqs. (25) to (29).

If similar solutions are to be obtained, the following conditions must be satisfied:

(a) \[ K = K(\eta_k) \]

\[ G = G(\eta_k) \]

\[ z_1 = z_1(\eta_k) \]

Hence, Eqs. (38) to (40) become:

\[ \left( \lambda \frac{r^2}{r_k^2} K'' \right)' + KK'' = \frac{\gamma_e - 1}{2\gamma_e} \beta F_1(\eta_k)(G - K'^2) \] (38a)

\[ \left( \frac{1}{Pr} \lambda \frac{r^2}{r_k^2} G' \right)' + KG' = 2\left( \lambda \frac{r^2}{r_k^2} \left( \frac{1}{Pr} - 1 \right) KK' \right) \]

\[ + \left[ \lambda \frac{r^2}{r_k^2} \frac{1}{Sc} \left( \frac{1}{Le} - 1 \right) F_2(\eta_k)(G - K'^2 z_1') \right] \] (39a)

\[ \left( \lambda \frac{r^2}{r_k^2} \frac{1}{Sc} z_1' \right)' + Kz_1' = 0 \] (40a)

These equations are to be solved under the boundary conditions given in Eqs. (25) to (29), whence Eq. (27) becomes

\[ K(0) = \left( \frac{\lambda}{Sc} \right) \frac{C_{lw}}{1 - C_{lw}} z_1'(0) \left( \frac{r_w}{r_k} \right)^2 \] (27a)
(b) \[ \lambda = \lambda(\eta_k) \quad (41) \]

\[ Sc = Sc(\eta_k) \quad (42) \]

\[ Pr = Pr(\eta_k) \quad (43) \]

(c) The transverse curvature parameter \( r^2/r_k^2 \) must be a function of \( \eta_k \); that is,

\[ \frac{r^2}{r_k^2} = f(\eta_k) \quad (44) \]

(d) The pressure gradient parameter, as defined in Eq. (33), must be constant:

\[ \beta = 2 \frac{d \ln p_w}{d \ln s_k} \quad (45) \]

(e) The surface boundary conditions are defined such that \( C_{1w}, H_w/H_e, \) and \( (r_w/r_k)^2 \) are constants.

**THE ANALYTIC CHARACTERISTICS OF THE G-L EQUATIONS**

Glauert and Lighthill(4) studied the problem of the incompressible axisymmetric boundary layer of a long cylinder. Their primary purpose was to examine a very thick boundary layer on a slender body; that is, where \( r_e/r_w \gg 1 \). In our notation, their equation for the boundary layer flow is

\[ [\eta^* K^n]' + \frac{1}{2} KK'' = 0 \quad (46) \]

Suppression of the pressure gradient term in Eq. (38a) and taking \( \lambda = 1 \) gives
For incompressible flow, it will be shown later that \((r/r_e)^2 = \eta^*/\eta_e^*\). Hence, Eq. (47) can be written

\[
\left[ \frac{r}{r_e} \right]^2 K'' + KK'' = 0 \quad (48)
\]

The similarity between Eqs. (46) and (48) demonstrates that the system of equations presented here is entirely consistent with the Glaauert and Lighthill equation.

**SIMILARITY CONDITIONS FOR THE NORMAL VELOCITY**

In seeking similar solutions for problems relating to mass transfer in the boundary layer, it is essential to ensure that the normal velocity at the surface, which governs the axial rate of mass transfer, is a function of the similarity variable only. This can be shown by first combining Eqs. (11) and (17):

\[
u = u_e \frac{1}{\sqrt{2s_k}} \frac{\partial \psi}{\partial \eta_k} \quad (49)
\]

Combining Eqs. (18) and (49) gives, in the case of similar solutions,

\[
\psi = \sqrt{2s_k} K(\eta_k) \quad (50)
\]

From Eq. (16), one obtains

\[
-\rho v y = \sqrt{2s_k} \frac{\partial \eta_k}{\partial \xi} K' + K \frac{\partial}{\partial \xi} \left( \sqrt{2s_k} \right) \quad (51)
\]
Now

\[ \frac{\partial \eta_k}{\partial x} = - \frac{\partial \eta_k}{\partial y} \frac{\partial y}{\partial z_k} \frac{\partial z_k}{\partial x} \]  

(52)

Inversion of Eq. (11) gives

\[ y = \frac{2s_k}{\rho u e_k} \int_0^{\eta_k} \frac{\rho e_k}{\rho r} \, d\eta \]  

(53)

which by differentiation, yields

\[ \frac{\partial y}{\partial s_k} = \frac{1}{\rho u e_k} \frac{1}{\sqrt{2s_k}} \left\{ 1 - \frac{2s_k}{\rho u e_k} \frac{\partial}{\partial s_k} (\rho u e_k) \right\} \int_0^{\eta_k} \frac{\rho e_k}{\rho r} \, d\eta \]  

(54)

Combining Eqs. (52) and (54) yields

\[ \frac{\partial \eta_k}{\partial x} = - \frac{1}{2s_k} \frac{\partial s_k}{\partial x} \left\{ 1 - \frac{2s_k}{\rho u e_k} \frac{\partial}{\partial s_k} (\rho u e_k) \right\} \frac{\rho r}{\rho e_k} \int_0^{\eta_k} \frac{\rho e_k}{\rho r} \, d\eta \]  

(55)

This result is substituted into Eq. (51) to yield

\[ \frac{\rho v r}{\sqrt{2s_k}} \frac{\partial s_k}{\partial x} = K + \left[ \frac{2s_k}{\rho u e_k} \frac{\partial (\rho u e r)}{\partial s_k} \right] - \frac{1}{2} \int_0^{\eta_k} \frac{\rho e_k}{\rho r} \, d\eta \int_0^{\eta_k} \frac{\rho e_k}{\rho r} \, d\eta \]  

(56)

From Eqs. (30) and (33), we obtain, respectively

\[ \frac{2s_k}{\rho u e_k} \frac{\partial e e}{\partial s_k} = - \frac{\beta}{\gamma k^2} \]  

(57)
\[
\frac{\rho e}{\nu} = \frac{\gamma e - 1}{2} \frac{2s_k}{e e_k} (0 - K'^2) + K'^2 \quad (58)
\]

Hence, Eq. (56) can be written

\[
- \frac{\rho v r}{1 \frac{\partial s_k}{\partial x}} = K - \left\{ 1 - \frac{2s_k}{\rho e_k e_k} \left( \frac{\partial}{\partial x} - \frac{1}{2} \frac{2s_k}{e e_k} \right) \right\} \frac{r}{r_k} F_3 \left( \eta_k, \frac{r_k}{r} \right) K' \quad (59)
\]

where

\[
F_3 \left( \eta_k, \frac{r_k}{r} \right) = \frac{\int_0^{\eta k} \left[ K'^2 + \frac{\gamma e - 1}{2} \frac{2s_k}{e e_k} (0 - K'^2) \right] \frac{r_k}{r} d\eta}{K'^2 + \frac{\gamma e - 1}{2} \frac{2s_k}{e e_k} (0 - K'^2)} \quad (60)
\]

In hypersonic boundary layer, the terms of \( O(1/M_e^2) \) are neglected, and Eqs. (59) and (60) reduce to

\[
- \frac{\rho v r}{1 \frac{\partial s_k}{\partial x}} = K - \left\{ 1 - \frac{2s_k}{\rho e_k e_k} \left( \frac{\partial}{\partial x} - \frac{1}{2} \frac{2s_k}{e e_k} \right) \right\} \frac{r}{r_k} F_4 \left( \eta_k, \frac{r_k}{r} \right) K' \quad (61)
\]

where

\[
F_4 \left( \eta_k, \frac{r_k}{r} \right) = \frac{\int_0^{\eta k} F_1 (0 - K'^2) \frac{r_k}{r} d\eta}{F_1 (0 - K'^2)} \quad (62)
\]

It should be pointed out that the right-hand side of Eq. (61) is a function of \( \eta_k \) only, provided that

(a) \[ \frac{r}{r_k} = f(\eta_k) \quad (63) \]
and

\( \frac{2s_k}{\rho u r_k} \frac{\partial}{\partial s_k} (\rho u r_k) = \text{const.} \) \quad (64)

Now condition (b) can be written as follows:

\[
\frac{2s_k}{\rho u r_k} \frac{\partial}{\partial s_k} (\rho u r_k) = -\frac{\beta}{\gamma M^2 e} \left\{ 1 + \frac{2s_k}{\rho e} \frac{\partial r_k}{\partial s_k} + \frac{2r_k}{\rho e} \frac{\partial s_k}{\partial u e} \right\}
\]

where

\[
\frac{2s_k}{\rho u r_k} = \frac{2s_k du e}{\rho e dt_k}
\]

as defined in Eq. (57). In the hypersonic adiabatic free stream, the total enthalpy is constant so that \( dh_e + u_e du_e = 0 \). Indeed, in the hypersonic boundary layer, \( \delta \approx \delta^* \) so that very little mass flows into the boundary layer. Hence, the specific entropy is constant along the edge of the boundary layer and it follows that

\[
\frac{1}{\rho e} dp_e + u_e du_e = 0 \quad (66)
\]

which leads to

\[
\frac{u_e}{\rho e} \frac{\partial p_e}{\partial u e} + M^2 e = 0 \quad (67)
\]

and
We therefore have

\[
\frac{1}{\rho_e} \frac{\partial \rho_e}{\partial s_k} - \frac{1}{u_e} \frac{\partial u_e}{\partial s_k} = -M_e^2
\]

(68)

This shows that

\[
\frac{2s_k}{\rho u_e r_k} \frac{3}{\partial s_k} (\rho u_e r_k) = -\frac{8}{\gamma M_e^2} (1 - M_e^2) + \frac{2s_k}{r_k} \frac{\partial r_k}{\partial s_k}
\]

(69)

is sufficient for condition (b); this is a geometrical constraint on the problem.

**BOUNDARY LAYER EFFECTS ON THE MATCHING CONDITIONS BETWEEN INVISCID AND VISCOUS FLOW REGIONS**

The axis of symmetry of the body lies along the direction of the undisturbed free stream. At the body surface, a particular rate of mass transfer due to coolant gas injection is specified. The disturbed flow region surrounding the body is separated from the undisturbed flow by the leading-edge shock wave. The region between the shock wave and the body surface can be divided into an inviscid flow region and a viscous boundary layer region. We shall match the normal velocity and the pressure on the common boundary of these inviscid and viscous flow regions.

Stewartson(11) and Oguchi(12) have obtained similar solutions of the hypersonic inviscid flow region using the small-perturbation theory. These results can be summarized in the following equations for the normal velocity and pressure in the flow field:
where $A$, $N$, and $\theta_0$ are constants. These values $\nu$ and $p_e$ will be matched with the corresponding viscous flow solution at the edge of the boundary layer. These matching conditions will determine $n$ and $e$ in Eqs. (71) and (72).

The value of $\nu / u_e$ can be obtained from the boundary layer analysis by evaluating Eq. (56) at $y = \delta$. This result has also been obtained by the authors using a direct integration of the continuity equation, and gives, for hypersonic boundary layers,

$$
\frac{\nu_e}{u_e} = \frac{\rho_v \nu \nu \nu}{\rho \nu \nu \nu \nu} + \frac{d \delta^*}{dx}
$$

(73)
v. SIMILAR SOLUTIONS IN THE P-E-Y REGIME

We note that in the P-E-Y regime, \( r_k = r_w \) and \( (r_k, \eta_k) \) become \( (s, \eta) \), as defined in Eqs. (12) and (13). The conditions for similar solutions in this regime are:

(a) \( \lambda = \lambda(\eta) \)  

\( \text{Sc} = \text{Sc}(\eta) \)  

\( \text{Pr} = \text{Pr}(\eta) \)  

(b) The transverse curvature parameter \( r^2 / r_w^2 \) must be a function of \( \eta \):

\[
\frac{r^2}{r_w^2} = f_1(\eta) \tag{75}
\]

(c) The pressure gradient parameter as defined in Eq. (33) must be constant:

\[
\beta = 2 \frac{d \ln p_e}{d \ln s} \tag{76}
\]

(d) The surface boundary conditions are defined such that \( c_{1w} \) and \( H_w / H_e \) are constant. This requires uniform distribution of the wall temperature and the concentration of the injectant gas.

(e) The boundary layer effects given in Eq. (73) must be included in the matching condition.

The above condition (c) implies that

\[
s^{\beta/2} = A' p_e \tag{77}
\]

where \( A' \) is a dimensional constant. From Eq. (12), one obtains
In the hypersonic flow regime, \( u_e = u_\infty \). In Eq. (78), \( \lambda \) can be treated as a constant evaluated at some reference temperature and composition, \( \lambda = \lambda_m \). To the same approximation, then,

\[
\frac{\mu}{RT} = \left( \frac{\mu}{RT_m} \right) = \text{const.} \tag{79}
\]

and hence

\[
s = B \int_0^\infty p e^{\frac{r^2}{\beta}} dx \tag{80}
\]

where

\[
B = \left( \frac{\mu}{RT_m} \right) u_\infty = \text{const.} \tag{81}
\]

Combining Eqs. (77) and (80) yields

\[
\frac{\int_0^\infty p e^{\frac{r^2}{\beta}} dx}{p_e^{2/\beta}} = \left( \frac{A^*}{B} \right)^{2/\beta} = \text{const.} \tag{82}
\]

Consider now condition (b), which requires that \( r^2/r_w^2 \) be a function of \( \theta \) only. From geometry

\[
\left( \frac{r}{r_w} \right)^2 = 1 + \frac{2 \cos \alpha}{r_w^2} \int_0^\theta r dy \tag{83}
\]

or
Equations (58), (80), and (84) together give

\[
\left(\frac{r}{r_w}\right)^2 = 1 + \frac{(2 \cos \alpha) \sqrt{s}}{\rho u e r_w^2} \int_0^{\eta} \rho \, d\eta
\]

(84)

where terms of \(0(1/M_\infty^2)\) have been neglected, \(\cos \alpha = 1\), and \(a^*\) is defined as

\[
a^* = \left[ \int_0^x \frac{\rho e^{r_w^2}}{r_w^2} \frac{dx}{dx} \right]^{1/2}
\]

(86)

Now \(a^*\) must be a constant in order that \(r^2/r_w^2\) be a function of \(\eta\) only.

Consider finally the matching condition. From Eqs. (71) and (73), we have

\[
nc \theta (\frac{x}{L})^{n-1} = \left( \frac{\rho \, e u \, r_w \, d\alpha^*}{\rho \, u \, e \, r} + \frac{dr_w}{dx} \right) + \frac{dr_w}{dx}
\]

(87)

\[\text{(Effective body)} \quad \text{(viscous effects)} \quad \text{(local inviscid)} \quad \text{(on body surface)} \quad \text{(body angle)}\]

In matching the viscous and inviscid solutions, we have included the boundary layer effects. Since

\[
r_e = r_w + \delta \cos \alpha
\]

(88)

\[
r_e = r_w + \delta^*
\]

(89)
Equation (87) may be written

\[ n e \theta \left( \frac{x}{L} \right)^{-1} = \frac{\rho}{\rho e} e \frac{v r}{e} + \frac{dr}{dx} \]  

(90)

Since, by Eq. (51),

\[ \frac{\rho v r}{\rho e e e} = - \frac{u K(0)}{\gamma M^2 e} \frac{1}{p e e} \frac{\partial}{\partial x} \left( \sqrt{2s} \right) \]  

(91)

we may write

\[ \frac{\rho v r}{\rho e e e} = - \sqrt{\frac{2 \rho \mu}{\rho e e}} \frac{M^2}{e} \sqrt{p} \frac{K(0)}{a} \frac{1}{p e e} \sqrt{\frac{B}{e}} \]  

(92)

where \( B_e = (\mu u / R T) e \). The final expression for the matching condition is therefore

\[ n e \theta \left( \frac{x}{L} \right)^{-1} = - \sqrt{\frac{2 \rho \mu}{\rho e e}} \frac{M^2}{e} \sqrt{p} \frac{K(0)}{a} \frac{1}{p e e} \sqrt{\frac{B}{e}} + \frac{dr}{dx} \]  

(93)

Similar solutions in the P E-Y regime must satisfy the conditions given in Eqs. (82), (86), and (93). Equation (72) can be rewritten

\[ p_e = \frac{dx^{2(n-1)}}{2} \]  

(94)

\[ d = (2) ^ n \frac{n^2}{n^2} \gamma e \left( \frac{\gamma e - 1}{\gamma e + 1} \right) \frac{1}{\theta o} \left( A N^N \right) L^{2(1-n)} M^2 e^2 p_e \]  

(95)
Let

\[ r_w = bx^m \]  

(96)

where \( b \) is a dimensional constant. From Eqs. (82), (86), and (93), one obtains

\[ 1 + \frac{2m + 1}{2(n - 1)} = \frac{2}{\beta} \]  

(97)

\[ n + m = \frac{3}{2} \]  

(98)

\[ n = m \]  

(99)

These equations yield \( n = m = 3/4, \beta = -1/2 \). Equations (38a), (39a), and (40a) may now be written

\[ \left( \frac{r_w^2}{\lambda'} \right)' + \left( \frac{r_w^2}{\lambda''} \right)' + \frac{2}{\Pr} \left( \frac{r_w^2}{r_w} \right)' + \frac{1}{K'2} \left( \frac{r_w^2}{r_w} \right)' = 0 \]  

(100)

The boundary conditions for this set are:
\[ \eta = 0; \quad K'(0) = 0 \quad (103a) \]

\[ Z_1(0) = 1 \quad (103b) \]

\[ G(0) = \frac{H^w}{H^e} \quad (103c) \]

\[ K(0) = \frac{1}{Sc} \cdot \frac{C_{1w}}{C_{2w}} \cdot Z_1'(0) \quad (103d) \]

\[ \eta = \eta_e; \quad K'((\eta_e)) = 1 \quad (104a) \]

\[ Z_1((\eta_e)) = 0 \quad (104b) \]

\[ G((\eta_e)) = 1 \quad (104c) \]

The geometrical constraint for similarity given by Eq. (70) will now be examined for this regime. Equation (80) reduces to

\[ \frac{1}{s} \frac{\partial s}{\partial x} = \frac{P_{e,w}^2}{\int_0^x p_e r_w^2 \, dx} \quad (105) \]

By Eqs. (94) and (96), we obtain

\[ \frac{1}{r_w} \frac{\partial r_w}{\partial x} = \frac{s}{r_w} \frac{\partial r_w}{\partial s} = \frac{m}{2(n - 1) + 2m + 1} = \text{const.} \quad (106) \]

Thus the condition of similarity is satisfied. The foregoing arguments show that similar solutions exist for the case of a slender body of revolution in hypersonic flow with surface mass transfer. The shape of the body must be
For zero mass transfer, the result confirms the conclusions reached by Yasuhara. (2)
VI. SIMILAR SOLUTIONS IN THE G-L REGIME

In the G-L regime, \( r_k = r_e \) and \((s_k, \eta_k)\) is transformed into \((s^*, \eta^*)\), as shown in Eqs. (14) and (15). The conditions for similarity in this regime are:

(a) \[
\lambda = \lambda(\eta^*) \quad (108a)
\]

\[
Sc = Sc(\eta^*) \quad (108b)
\]

\[
Pr = Pr(\eta^*) \quad (108c)
\]

(b) The transverse curvature parameter \( r_k^2 / r_e^2 \) must be a function of \( \eta^* \):

\[
\frac{r_k^2}{r_e^2} = \varepsilon_2(\eta^*) \quad (109)
\]

(c) The pressure gradient parameter as defined in Eq. (33) must be constant:

\[
\beta = 2 \frac{d \ln p_s}{d \ln s^*} \quad (110)
\]

(d) The viscous term given in Eq. (73) must be included in the matching condition:

\[
\frac{v_e}{u_e} = \frac{\rho w w w}{\rho w u w} \quad (73)
\]

(e) The surface boundary conditions are defined such that \( C_{lw} \) and \( H_w / H_e \) are constant.

(f) The boundary condition [Eq. (27a)] relating to the mass transfer at the surface must be compatible with the requirements for a similar solution.
\[ K(0) = \left( \frac{3}{5c} \right) \frac{C_{lw}}{1 - C_{lw}} Z'_1(0) \left( \frac{w}{r_e} \right)^2 \]  

(111)

Condition (c) implies that

\[ (s^*)^{3/2} = A_1^* p_e \]  

(112)

where \( A_1^* \) is a dimensional constant. Equations (14), (81), and (112) give

\[ \int_0^x p_e r_e^2 \, dx \left( \frac{2}{2^\beta} \right) = \frac{(A_1^*)^{2/\beta}}{B} = \text{const.} \]  

(113)

which is similar to Eq. (82) for the P-E-Y regime.

Condition (b) requires that the transverse curvature parameter \( r^2/r_e^2 \) must be a function of \( \eta^* \). Since this study concerns a slender body of revolution, an approximation is made by assuming that the x-axis and the axis of symmetry are coincident; that is, \( \cos \alpha = 1 \).

Equation (15) then yields

\[ \sqrt{2s^*} \frac{\rho e}{\rho} \frac{d\eta^*}{d \eta} = r \, dy = r \, dr \]  

(114)

It follows that

\[ r^2 = 2\sqrt{2s^*} \frac{1}{\rho e u_e} \int_0^{\eta^*} \frac{\rho e}{\rho} \, d\eta^* \]  

(114a)

\[ r_e^2 = 2\sqrt{2s^*} \frac{1}{\rho e u_e} \int_0^{\eta^*} \frac{\rho e}{\rho} \, d\eta^* \]  

(114b)
where $\eta_e^*$ denotes the boundary layer thickness in the $\eta^*$ variable.

These equations show that, in the G-L regime,

$$
\left( \frac{r}{r_e} \right)^2 = \frac{\int_0^{\eta_e^*} \eta_e^* \rho_e \, d\eta_e^*}{\int_0^{\eta_e^*} \rho_e \, d\eta_e^*} 
\tag{115}
$$

Combining Eqs. (58) and (115) gives

$$
\left( \frac{r}{r_e} \right)^2 = \frac{\int_0^{\eta_e^*} F_1(C - \kappa' r_e^2) \, d\eta_e^*}{\int_0^{\eta_e^*} F_1(G - \kappa' r_e^2) \, d\eta_e^*} 
\tag{116}
$$

where terms of $O(1/M_e^2)$ are neglected. Equation (116) shows that

$$
\left( \frac{r}{r_e} \right)^2 \text{ is a function of } \eta_e^* \text{ within the present approximation. Indeed,}
$$

$$
r/r_e = y/\delta, \text{ so that } r/r_e \text{ is a proper similarity variable in the physical coordinate of the boundary layer.}
$$

For this regime, the matching condition in Eq. (87) is

$$
\eta_0 \left( \frac{\chi}{\eta_e} \right)^{-1} = -\sqrt{\frac{u_B \rho_e}{2 \rho \mu_B}} \sqrt{\frac{\rho_e}{\rho}} \frac{M_e^2}{\kappa} \frac{K(0)}{p_e} + \frac{d}{dx} \left[ \frac{p_e}{r_e} \right] \tag{117}
$$

where

$$
a_1^* = \left[ \int_0^x \frac{p_e r_e^2 \, dx}{r_e^2} \right]^{1/2} \quad = \text{constant} \tag{118}
$$
Therefore, similar solutions in the G-l regime must satisfy the conditions in Eqs. (113), (117), and (118). Next we assume that

\[ r_e = cx^m \quad (119) \]

\[ p_e = cx^{2(n-1)} \quad (120) \]

and determine that \( m = n = 3/4, \beta = -1/2 \). The boundary layer equations may be rewritten as:

\[
\left( \frac{\lambda \frac{r^2}{r_e} K'}{r_e} \right)' + KK'' = \frac{\gamma e - 1}{4\gamma e} F_1(K' - G) \]

\( (121) \)

\[
\left( \frac{\lambda \frac{r^2}{r_e} G'}{r_e} \right)' + KG' = 2\left[ \frac{\lambda \frac{r^2}{r_e} (\frac{1}{Pr} - 1) KK''}{r_e} \right]'
\]

\[
+ \left[ \frac{\lambda \frac{r^2}{r_e} (1 - 1)}{Sc} F_2(G - K' - 2)Z_1 \right]' \]

\( (122) \)

\[
\left( \frac{\lambda \frac{r^2}{r_e} Z_1'}{r_e} \right)' + \kappa_1' = 0 \]

\( (123) \)

The boundary conditions are

\[
\eta^* = 0 \quad K'(0) = 0 \quad (124a) \]

\[
Z_1(0) = 1 \quad (124b) \]

\[
G(0) = \frac{H}{h_e} \quad (124c) \]

\[
K(0) = (\frac{\lambda}{Sc}) \frac{C_1}{C_2} Z_1(0) \left( \frac{r_e}{r} \right)^2 \quad (124d) \]
and
\[ \eta^* = \eta_e^* \quad K'(\eta_e^*) = 1 \quad (125a) \]
\[ Z_1(\eta_e^*) = 0 \quad (125b) \]
\[ G(\eta_e^*) = 1 \quad (125c) \]

Condition (f) requires that
\[ \left( \frac{r_w}{r_e} \right)^2 = \text{const.} \quad (126) \]

Treatment of the geometrical constraint given by \( L_4 \), (70) gives the same result for the G-L regime that was shown previously in Eq. (106). In the G-L regime, therefore, "exact" similar solutions are obtainable only for the case where \( r_w \sim x^{3/4} \). For very slender bodies, the condition \( (r_w/r_e)^2 = 0 \) should be considered. This suggests an inconsistency, since \( K(0) \approx 0 \) for finite \( Z'_1(0) \). To alleviate this difficulty the present authors, in Ref. 18, adopt the following condition:

\[ K(0) = \frac{C_{1w}}{C_{2w}} D \quad (127) \]

where \( D \) is a finite and negative constant. When this alternative condition can be accepted, it replaces Eq. (124d) thus making then possible "approximate" similar solutions of the G-L regime. Within this approximation, it may be observed that

\[ r_e \sim s \sim x^{3/4} \quad (128) \]

\[ p_e \sim x^{-1/2} \quad (129) \]
in the hypersonic viscous interaction solutions of the G-L regime. This approximate result is completely analogous to the strong interaction solution on a hypersonic flat plate with surface mass transfer.\textsuperscript{(14)} Pressure data on a solid cone in the strong interaction region have been analyzed by Yasuhara,\textsuperscript{(15)} and these data are in general agreement with the present prediction. This agreement may be fortuitous, however, as the hypersonic viscous interaction problem for a slender impermeable cone yields rigorously only a nonsimilar solution.
VII. MATCHING THE INVISCID AND VISCOUS FLOW SOLUTIONS

Consideration of the above solutions and those of Mirels\(^{(17)}\) for viscous and inviscid regions show that similar solutions exist both in the inviscid and viscous flow regions. It remains now to match these solutions to obtain the proper behavior in the strong interaction region.

Equations (83) and (85) yield

\[
\left( \frac{r_e}{r_k} \right)^2 = \left( \frac{r_w}{r_k} \right)^2 + \frac{\gamma_e - 1}{\gamma_e} \frac{u_e \sqrt{2} \rho e}{A_k} \cos \alpha
\]

(130)

where

\[
I_k = \int_0^{\eta_k} F_1(G - K'^2) \, d\eta_k
\]

(131)

and

\[
a_k = \left[ \int_0^{\infty} \frac{p e_k r_k^2}{p e_k^2} \, dx \right]^{-1/2}
\]

(132)

In the P-E-Y regime, \( \eta_k = \eta \), \( a_k = a^* \), \( r_k = r_w \). In the G-L regime, \( \eta_k = \eta^* \), \( a_k = a_1^* \), \( (r_w/r_e)^2 \to 0 \), \( r_k = r_e \). It can be shown that

\[
a^* = \frac{1}{b/2d}
\]

(133)

\[
a_1^* = \frac{1}{c/2d}
\]

(134)

\( b, c, \) and \( d \) being the same as defined in Eqs. (96), (110), and (94), respectively.
In the P-E-Y regime, Eq. (130) becomes \((\cos \alpha = 1)\)

\[
c = b \left(1 + \frac{e^2}{\gamma_e} \frac{1}{\sqrt{d}} \frac{B}{\Gamma(b)} \right)^{1/2}
\]  
\(\text{(135)}\)

where

\[
I = \int_0^\eta e F(G-K'') d\eta
\]  
\(\text{(136)}\)

In the G-L regime, the analogous result is:

\[
c = \frac{\gamma_e - 1}{\gamma_e} \frac{e^2}{\sqrt{d}} \frac{B}{\Gamma(b)} I^*
\]  
\(\text{(137)}\)

where

\[
I^* = \int_0^\eta e F(G-K'') d\eta^*
\]  
\(\text{(138)}\)

If

\[
\frac{\gamma_e - 1}{\gamma_e} \frac{e^2}{\Gamma(b) \sqrt{d}} B I \gg 1
\]  
\(\text{(139)}\)

then Eq. (135) becomes approximately

\[
c = \frac{\gamma_e - 1}{\gamma_e} \frac{e^2}{\sqrt{d}} \frac{B}{\Gamma(b)} \left(\frac{a^{*}}{a}\right)
\]  
\(\text{(140)}\)

which is formally identical to Eq. (137). Thus Eq. (139) provides a numerical estimate of the size of the body to which the G-L regime approximation applies; that is,
It also shows that the G-L regime may be treated in a manner similar
to the general scheme of the P-E-Y regime. Therefore, only the P-E-Y
regime will be examined in this section. Equation (135) may be written
as

\[
\frac{r_2^2}{r_w^2} = \left(\frac{c}{b}\right)^2 = 1 + \Omega
\]  

(142)

where

\[
\Omega = \sqrt{\frac{B}{B_e}} (\gamma - 1) \frac{1}{2^{1/3}} \left(\frac{\nu}{\nu_e}\right)^{\frac{1}{3}} \left(\frac{\nu + 1}{\nu_e + 1}\right)^{\frac{1}{3}} \frac{\nu_e}{\nu_e - 1} \sqrt{\bar{\beta}_0} \left(\frac{\gamma}{N}\right)^{\frac{1}{2}} \frac{1}{\mu_e} \left(\frac{1}{b\xi}\right)^{\frac{1}{4}}
\]  

(143)

and

\[
\chi = \frac{A_{\infty}}{\sqrt{R_{e,\infty}}} \quad R_{e,\infty} = \frac{\rho u L}{\mu_{e,\infty}}
\]  

(144)

where \(\chi\) is the hypersonic viscous interaction parameter. In the present problem, \(b/L^{1/4}\) is nondimensional. In terms of this representation, Eq. (139) becomes \(\Omega >> 1\), which would be the condition for the
G-L regime approximation. Values of \(A\) and \(\theta_0\) to be used in Eq. (143)
are given in the Appendix. From Eq. (92), one obtains

\[
\frac{\rho_w \nu_w r_w}{\rho_e \nu_e r_e} = -\frac{\Omega}{\sqrt{1 + \Omega}} \frac{K(0)}{l} \frac{b}{M_e} \left(\frac{1}{\chi}\right)^{1/4}
\]  

(145)

It can be further shown that
Define

\[ \epsilon_{\text{inv}} = \frac{b}{L^{1/4} \theta_0} \]  

(147)

then

\[ \frac{\epsilon}{\epsilon_{\text{inv}}} = \sqrt{1 + \frac{\Omega}{1 + \Omega} \left(1 - \frac{4}{3} \frac{\Omega}{1 + \Omega} \frac{K(0) \, 1}{M_e^2}\right)} \]  

(148)

For very slender bodies of revolution, \( M_e = 0(M_\infty) \); thus, neglecting \( 0(1/M_e^2) \) terms,

\[ \frac{\epsilon}{\epsilon_{\text{inv}}} = \sqrt{1 + \frac{\Omega}{1 + \Omega}} \]  

(149)

provided \( K(0)/I = 0(1) \). Equation (149) applies when the effect of the \( \rho w \omega r/\rho u r \) term is negligible and is of \( 0(1/M_e^2) \).

The expression for \( \Omega \) in Eq. (143) contains \( \epsilon \); thus,

\[ \Omega = \frac{L}{(M_e \epsilon)(M_e \epsilon_{\text{inv}})} \]  

(150)

where

\[ L = \sqrt{\frac{B_{\text{e}}}{B_e}} (\gamma_e - 1) \frac{1}{2^{1/3}} \left(\frac{4}{3}\right) \left(\gamma_e + 1\right)^{1/2} \left(\frac{\gamma_e + 1}{\gamma_e - 1}\right) \frac{\gamma_e/2}{\gamma_e/2} \frac{1}{\gamma_e/2} \left(A N N\right) \]  

(151)

These expressions can be introduced into Eq. (149) to yield
Thus $\varepsilon$ can be determined and the hypersonic viscous interaction problem is solved. To compute the induced pressure due to viscous interaction, we define

$$d_{\text{inv}} = \frac{d}{1 + \Omega}$$

(153)

$$p_{\text{inv}} = d_{\text{inv}} \gamma^{-1/2}$$

(154)

The surface pressure on the body of revolution in an inviscid hypersonic flow is $p_{\text{inv}}$. The induced pressure rise is due to viscous interaction

$$\Delta p = p_e - p_{\text{inv}} = (d - d_{\text{inv}}) \gamma^{-1/2} = \Omega p_{\text{inv}}$$

(155)

Therefore

$$\frac{\Delta p}{p_\infty} = 2^{1/3} \frac{3}{4} \frac{\gamma_e/2}{\gamma_e - 1} (\gamma_e - 1) \sqrt{\frac{\gamma_e}{\gamma_e + 1}}$$

$$\left\{ \varepsilon_{3/2} \left( \frac{A^N}{N} \right) \left[ \frac{1}{B_e} \right] \frac{M_\infty^3}{1 + \frac{1}{\gamma_e - 1} \sqrt{\frac{\gamma_e}{\gamma_e + 1}}} \right\}$$

(156)
VIII. CONCLUSIONS

We have obtained a similar solution for the case of a hypersonic laminar boundary layer on an axisymmetric body. The strong interaction between the boundary layer and the shock wave has been considered, and the analysis includes mass transfer from the surface. In the viscous flow regime, the boundary layer equations were transformed to a set of ordinary differential equations employing appropriate similarity variables. The inviscid region was treated using the well-known similarity transformation for the small-disturbance equations. These solutions were matched at the interface between the two regions, requiring that the pressure and normal velocity be continuous. The matching procedure yielded an analytical expression for the surface pressure and a similarity law for the normal velocity at the wall.

We have derived a set of analytic expressions that gives the relationship among the induced pressure at the wall, normal injection velocity at the wall, and other important wall variables, in terms of the parameters that describe the strong interaction flow.

A transformation appropriate to both the P-E-Y regime and the G-L regime has been derived from Eqs. (10) and (11). This transformation leads to the general set of equations, which can then be applied to the appropriate regime.

Within the restrictions indicated in the present study, similar solutions have been obtained for the case of a thick boundary layer on a very slender body of revolution. However, when the boundary layer thickness and the characteristic body dimension are of the same order of magnitude, it was shown, in agreement with Yashuara's earlier conclusions, that rigorous similarity is possible only for three-quarter-power bodies.

For an axisymmetric body, the similarity condition for the normal velocity at the wall follows a \((\rho vr)\) law rather than the well-known \((\rho v)\) law in the two-dimensional case.

The restrictive nature of the similar solutions is adequately illustrated in the present study. In physical problems of interest, it may be necessary to deal with more complicated situations than those
allowed by similar solutions. We have seen in Section VI that in hypersonic viscous interaction problems, similar solution may be applicable only in the outer viscous flow region and may not be applicable in the inner viscous flow region (cf. Eq. (124d)). In such cases, we strictly must obtain nonsimilar solutions of Eqs. (38) to (40), under the boundary conditions in Eqs. (25) to (29). The scheme of calculations used in Refs. 19 and 20 may be adopted for this purpose. In the present Memorandum, the surface condition in Eq. (127) is adopted to obtain "approximate" similar solutions of the G-L regime. Alternatively, for the G-L regime, the viscous flow region may be dealt with by a composite layer approach in order that all the physical boundary conditions are rigorously satisfied. Stewartson (16) has recently treated the hypersonic slender cone problems by this composite viscous layer representation.
Appendix
VALUES OF A AND \( \theta_0 \)

The similarity solutions for inviscid hypersonic flow over slender power-law bodies have been computed by Mirels. \(^{17}\). In terms of Mirel's data for axisymmetric three-quarter-power law bodies, we have

\[
\begin{align*}
\gamma_e & \quad \eta_b & \quad F(\eta_b) \\
1.4 & \quad .875 & \quad .696 \\
1.67 & \quad .819 & \quad .634
\end{align*}
\]

These values of \( \eta_b \) and \( F(\eta_b) \) are related to \( \theta_0 \) and \( A \) by the following formulas:

\[
\theta_0 = \eta_b
\]

\[
F(\eta_b) = \frac{1}{\gamma_e + 1} 2^{n-1} \left( \frac{\gamma_e - 1}{\gamma_e + 1} \right) \frac{1}{\theta_0} \left( \frac{1}{A} \right)^N N
\]

where

\[
N = \frac{v_e}{n - 1 + n\gamma_e} > 0
\]

\[
n = \frac{3}{4}
\]

    Axisymmetric Hypersonic Boundary Layers," AIAA Journal, October

An analytical formulation of the problem of hypersonic viscous interaction on a very slender body of revolution with a thick boundary layer and mass transfer. Particular attention is directed to the establishment of the mathematical restrictions necessary to ensure the existence of similar solutions of the laminar boundary-layer equations for this class of problems. Yasuhara's analysis is extended to include surface mass transfer and binary mixture effects. It is shown that when the boundary-layer thickness is of the same order of magnitude as the characteristic body dimension, rigorous similarity is possible only for three-quarter-power-law bodies. This is in agreement with Yasuhara's earlier conclusions. Similar solutions to the boundary-layer growth equations exist when the transverse curvature expression is a function of the similarity variable. The criterion for the existence of similar solutions for the problem of hypersonic viscous interaction is that there must be a definite relationship between body surface shape and surface injection velocity.
