Contract No. DAAG17-67-C-0199

Project Reference: 1T061102B52A
Series: ES-61

September 1970

Earth Sciences Laboratory
U. S. Army Natick Laboratories
Natick, Massachusetts 01760
FOREWORD

In 1969 the Earth Sciences Laboratory initiated Task 04 (Military Geography) of Project 1T061102B52A, Research in Military Aspects of Terrestrial Sciences, under which basic research in the earth sciences is conducted by the Army Materiel Command. One of the work items established under this task was a study of new methodologies in desert research, to determine how they might be used to further the mission of the Earth Sciences Laboratory. As a first step in this study, the Office of Arid Lands Studies, University of Arizona, was asked to compile a bibliography of references on remote sensing as applied to the study of desert environments and to evaluate the usefulness of the various items listed. That compilation is presented in the present report.

iii
A comprehensive review has been made of remote sensing publications relating to military geography of arid lands. These have been abstracted or annotated and arranged in tables relating devices and processes to geographic features including terrain, groundwater, surface materials, cultural features, flora, fauna, weather and climate, coastal zones, and general geography. The devices and processes include black and white, color, and infrared photography and devices utilizing longer wave lengths such as radar. Vehicles include conventional airplanes and spacecraft. Each reference is rated as especially useful, useful, or of little value.
Under a previous contract (DA-49-092-ARO-71), inventories of arid lands publications related to military geography were furnished to the Earth Sciences Laboratory, U. S. Army Natick Laboratories. Most of the material had to do with ground observations, and almost no attention was given to the rapidly developing fields for obtaining information through remotely situated devices. The present contract included a review of literature under the general heading of methodologies and techniques for the identification and evaluation of features related to military geography. It soon became apparent that the principal devices and methodologies are those utilizing the electromagnetic spectrum, and that the devices may be supported by various aerial platforms such as airplanes and orbiting spacecraft. Hence our reviews are largely concentrated on remote sensing.

Our effort has been centered on a search to determine the nature and extent of information together with an evaluation of the various publications as they may relate to the use of remotely situated devices for military geography in arid regions. Two general categories have been covered: (1) literature related to the basic science and art, and (2) literature of specific application in arid environments. Under the first category the object was to obtain an evaluation of various devices and processes, and under the second to provide references relating specifically to arid environments.

An abstract or annotation was prepared for each of the appropriate publications and these make up the bulk of this report. In addition, tables were prepared to provide a cross reference between devices and geographic features.

A large number of references were checked and those believed to be of value to military geography in arid regions were annotated and classified. Many were eliminated because they did not tie in with arid lands or were of little reference value. Those retained were given a rating as to their value based on the opinion of the present author. Although this subjective rating may be biased, it is hoped that it may save the reader considerable time by the elimination of articles of little or limited value. It should be stressed that the rating is based on the usefulness for readers seeking knowledge of remote sensing, and hence may be considered elementary to scientists with a great deal of knowledge and experience in this field.

In approaching the problems of military geography in arid environments, we first established what we considered the important items to be covered and then searched for appropriate reference material.
In the previous contract (An Inventory of Geographical Research on Desert Environments, DA49-092-ARO-71)* specifications were listed for coverage as follows:

Emphasis will be placed upon those aspects which have military significance because of their bearing on movement, communications, visibility, concealment, cover, fields of fire, deterioration, durability, storage, construction, food supply, water supply, fuel, disease or other military considerations. These are:

1. Physical features including:
   a. Surface configuration - landform types.
   b. Drainage features - perennial and intermittent streams, bodies of standing water, irrigation canals and ditches.
   c. Groundwater - aquifers, water tables, springs, wells.
   d. Surface materials - soils and other unconsolidated materials, rocks.
2. Flora and Fauna - distribution and characteristics of flora and fauna.
3. Weather and Climate.

For purposes of the present literature review these were grouped into nine categories as follows:

1. Terrain (TERR) - including surface configuration and drainage
2. Groundwater (GRW)
3. Surface Materials (SOILS)
4. Cultural Features (CUL) - physical works of man
5. Flora (FL)
6. Fauna (FA)
7. Weather and Climate (W & C)
8. Coastal Zones (CO)
9. General Geography (GG)

Surface configuration and drainage features were combined under the heading of "terrain" because of the large overlap of these two features in the literature. The other categories are essentially those listed in the inventory except that the heading "general geography" has been added to cover situations where several different features were discussed in the same article. In some cases where the emphasis warranted it, specific features were marked in addition to general geography.

Devices and processes have been developed to obtain significant amounts of information on various aspects of the environment, but so far these have not been integrated into a comprehensive methodology for obtaining all desired information on the environment at a specific time and place. Existing devices will probably undergo additional developments before comprehensive methodology is possible. Basically, there is a sufficient variety of devices available to furnish most of the information needed, but the techniques of using these devices to best advantage and their integration to provide for most efficient use are at an early development stage.

According to Golwell 1966b, the five most important imaging devices are: (1) the converted aerial camera, (2) the panoramic camera, (3) the multispectral camera, (4) the optical mechanical scanner, and (5) the side-looking airborne radar device (SLAR). The term process as used here relates to the recording on film or other sensitized material of information obtained through the use of aerial cameras or other sensing devices operated at some distance from the geographic area that is being investigated. In the literature review developed we found it convenient to list literature under a combination of devices and processes:

1. Black-and-white aerial photography (b)
2. Black-and-white infrared aerial photography (BIA)
3. Color aerial photography (C)
4. Color infrared aerial photography (CIR)
5. Infrared emissions (IR)
6. Multispectral and multiple sensing (M)
7. Side-looking airborne radar (and other types of radar (S)
8. Space photography (SP)
9. Other, including general discussion and basic references (O)

The references are listed in tables 1 through 9 covering the nine geographical features. Each table includes the author's name in the first column on the left and the date of publication in the next column. Together these two items provide easy reference to the reviewed articles included in this report.

Column 3, "Use," shows our evaluation of these references as they apply to military geography of desert environments. The references were coded as follows:

1. Especially useful
2. Useful
3. Of little value

The remaining columns are checked to show the principal devices and processes discussed in the publication reviewed.
It is only that a device is checked in the tables gives some indication of its remote sensing value for that feature, but this general tendency may not be relied upon as more than an indication, since the various devices and processes are not in the same stage of development. For example, the large number of black-and-white photographs in the tables might appear to show that this approach is superior to others, but it must be remembered that black-and-white aerial photography has been in practice for a much longer period than the other techniques. Also, even though satisfactory results are obtained with black-and-white aerial photography, more recently developed devices and processes may be superior in bringing out information impossible to obtain without the newer technique; hence the newer technique offers more promise and may eventually be used more. Methods such as radar sensing, for instance, have recently received a great amount of attention, and the literature shows that they can provide information that cannot be obtained readily, if at all, by orthodox aerial photography. This is especially true for terrain features. The larger number of entries under M (multi-band or multiple sensors) shows that the use of more than one approach is desirable. An examination of the literature strongly supports this thesis.

It is not the purpose of this report to summarize the extensive literature on remote sensing as applied to arid lands military security, but a few examples may serve to show how various devices and processes can be used to get information.

Aerial photography using black-and-white has been, over the years, the basic technique for landscape studies. Development in the remote sensing tool has led to a very sophisticated and comprehensive delineation of landscapes including all the principal natural and cultural features. Soil surveys, accurate topographic maps can directly from aerial photographs, and timber surveys in which the kind and amount of timber can be determined with little ground check, are examples of the things that can be done with basic black-and-white photography.

The identification of individual plant species under desert conditions poses many difficulties. Where species have a range related to edaphic conditions, they may be identified through interpretation of topographic and soil conditions. Thus areas dominated by an artemisia (Artemisia) and salt bush (Atriplex) can be delineated on the basis of soils, so color photography and color infrared photography can be repeated at different seasons. Also, because of the different transpiration characteristics of plants, thermal infrared images may prove valuable, especially where both daytime and nighttime photography is possible.
Near-infrared black-and-white photography is particularly useful to show the boundaries of water, as these relatively long wavelengths do not penetrate water and hence shorelines are distinctly demonstrated. On the other hand, color films without filters are sensitive in short wavelengths and can depict underwater conditions at considerable depths.

Side-looking aerial radar (SLAR) may be of limited value for continental deserts, but because of its ability to penetrate fogs it should be of great value in coastal deserts such as the Atacama and the Namib. It is of limited value in areas of large topographic range, according to Colwell (1966), but because of the sharp shadow effects it is of great value in depicting minor topographic differences. SLAR also has the advantage that shadows are the same at all times of the day, whereas aerial photographs taken at midday on the desert are noticeably lacking in detail.

Trafficability appears to be one of the most difficult features to evaluate. The general trafficability conditions in regions of low rainfall and hence generally dry soils may remain fairly constant for long periods, but during and following rains, they may vary greatly. Sandy soils may actually improve in trafficability whereas soils with a high clay content may become a serious handicap to the movement of men and equipment. A playa in dry weather may serve as a landing field for light aircraft, but following rains, and depending upon pH and salt content of the surface, the playa may have entirely different and often unsatisfactory characteristics. Washes that may be traversed easily when dry sometimes become torrential watercourses following rains, and as such they may be hazards or impediments to men and equipment.

Photography from satellites has brought a new dimension to the use of remotely situated devices; although it loses in identification of details, it gains in broader perspective. Physiographic provinces can be seen in their entirety, and the relation of one landscape feature to another is more clearly shown than on smaller-scale photos. The amount of detail that can be recognized with the aid of "ground-truth" control and supplementary information obtained by low-level flights is surprising.

The following acronyms occur throughout the Bibliography following. Some of them refer to the abstracting tools that were helpful in the location of these citations (where fuller abstracts may be found if the user wishes to consult them), others to agencies responsible for research in this field, and still others to devices or techniques used in remote sensing. Any not found here are fully explained in citations using these abbreviations or in the accompanying abstracts.

AN ANNOTATED BIBLIOGRAPHY AND EVALUATION
OF REMOTE SENSING PUBLICATIONS RELATING TO
MILITARY GEOGRAPHY OF ARID LANDS
1. *Alexander, R. H.*
   *A general summary.*

2. *--- ---*
   *NASA-sponsored study of the geographic potential of observations and experiments which might be carried out from the remote vantage of earth-orbiting spacecraft. Early emphasis was on problems of systematizing and managing the flow of geographic information resulting from such a program.*

3. *--- ---*
   *A general discussion with no specific information on remote sensing.*

4. *Alexander, R. H./L. W. Bowden/D. F. Marble/E. G. Moore*
   *A discussion of the potential of remote sensing to provide information to help solve urban problems.*

5. *Allied Research Associates, Concord, Massachusetts*
   *This catalog, published by NASA, pictorially documents the data from the High Resolution Infrared Radiometer experiment carried out on Nimbus II; it may be used in conjunction with the Nimbus II data catalog. The montages, arranged in chronological order in a world format, represent nighttime high resolution infrared data.*

*The particular format of the following citations has been determined by the computer program developed at the University of Arizona for automated retrieval of the world desert reference information bank in the Office of Arid Lands Studies. The use of asterisks herein indicates to the computer a new element in each citation, and has no meaning whatsoever to the user of this bibliography, nor should it affect his use of the information in this form.*
data obtained for each day (IT). Daytime data for June 24, 1966, are included for comparison purposes. A transparent overlay for general orientation with the latitude and longitude of the data is included. Nimbus II user's guide is referred to for background information and a description of the experiment.

6. *Allied Research Associates, Concord, Massachusetts
   *Entirely photos. This pictorial data catalog contains photostatic copies for data orbits 503-4 through 984-4.

7. *American Society of Photogrammetry

8. *--- ---
   1966 *Selected papers on remote sensing of environment. Reprinted by the *American Society of Photogrammetry in cooperation with University of Michigan, Institute of Science, Willow Run Laboratories, Falls Church, Virginia. 291 p.
   *A collection of papers largely from Symposia on Remote Sensing of Environment held at the University of Michigan, 1962-1964. The papers with important relevance to geography have been reviewed separately and entered in the present bibliography under the author's name.

9. *--- ---

10. *American Society of Photogrammetry, Photointerpretation Committee, Subcommittee VII
    *Oriented toward outer space bodies.

11. *Anscheutz, G./Stallard, A. H.

-28-
The use of photogrammetry for site studies including landform, geology, hydrology and drainage, land use, and other factors are considered.

12. *Anson, A.*
   1966   *Color photo comparison. A photo interpretation test with panchromatic, color and Ektachrome IR establishes the superiority of the latter two for mapping drainage, vegetation, soils and culture. *Photogrammetric Engineering 32:286-297.*

Panchromatic, color and Ektachrome IR photography of the same area were compared under essentially identical conditions. The study includes the identification and interpretation of drainage, vegetation, soils and map features such as roads, railroads and buildings. As a control, the same features were identified on the ground. On the basis of the limited study, Ektachrome IR photography proved to be superior to color and to panchromatic photography for mapping vegetation and drainage. Color photography was found to be superior to panchromatic and Ektachrome IR for mapping soils and culture.

13. *———*

Several controlled tests are described - in the Coastal Plain, Bennettsville, South Carolina, and in the western desert near Phoenix, Arizona. Other work in color photography and some results are summarized. A highly skilled soils engineer performing interpretation on the Phoenix photography reached a valid conclusion as to the type of soils in the desert area when he was halfway through the study of the 1:40,000 color airphotos along with infrared. Technical questions regarding the falloff in color density with the use of wide angle lenses are answered.

14. *———*

A report of progress in the development of aerial color photography. Ektachrome IR was superior for mapping drainage and moist soils; color photographs best for discriminating soils; and Ektachrome IR for types of vegetations. Describes an Arizona test, but little on results.

15. *Artsybachev, E. S.*

This useful report presents the study of the spectral reflectivity of some landscape elements (primarily vegetation and soils) which are ground water indicators and describes the use of these data.
for the hydrogeological interpretation of aerial photographs. The areas studied were desert (Turkmenia) and semi-desert (Caspian lowland). Similar studies were made in the forest zone of the northwestern regions of the USSR.

16. *Avery, T. E.*
*A how to do it manual with examples outside of arid zone, but the guide is nevertheless useful for general arid photo interpretation.*

17. ***---***
*A useful publication.*

18. ***---***
*A general review of developments in remote sensing in relation to forestry.*

19. *Badgley, P. C./Childs, L./Vest, W. L.*
*A very good summary of remote sensing devices that can be used by space satellites. The sensing abilities for various agricultural, geographic, geologic, hydrologic and oceanographic features are discussed in the text, summarized in graphic figures and illustrated with comparisons of the imagery of various sensing devices.*

20. *Badgley, P. C./Fischer, W. A./Lyon, R. J. P.*
*A discussion of plans of NASA for examining new and refined exploration tools from orbiting spacecraft. Areas selected for tests include Pisgah and Mono Craters areas and Willcox Playa, the last with various rocks emplaced at various depths. All common sensors are used.*

21. *Badgley, P. C./Vest, W. L.*
*Resources which can be studied include mineral districts, soils, crops, timber, water, housing, transportation networks and human resources. Advantages are rapidity and continuity of observations,*
greater freedom from weather disturbances, synoptic views for regional syntheses, reduced costs and better quality of data of several types. Paper includes some charts showing the application of common sensors to various resource surveys.

22. **Barrett, E. G.**
   *1967*  «Viewing weather from space.» Frederick A. Praeger, N. Y.
   *MGA 19.6-7.*
   «Draws attention to the potentialities of weather satellites in meteorology and climatology and their usefulness in geographical research. The volume contains a survey of the first six years of satellite meteorology, from April 1960 to February 1966, the findings of which provide a solution to the mysteries of hurricane formation and the intertropical convergence zone.

23. **Barringer, A. R.**
   «Audio and radio frequency pulse systems have a definite place in the sensing of terrain characteristics. It appears that magnetic, pulse electromagnetic, VHF radar, normal radar, infrared and gamma ray spectrometry equipment can be compatible.

24. **Bawden, M. G.**

25. **Becasio, A. D./Simons, J. H.**
   *1965*  «Regional geologic interpretation from side-looking airborne radar (SLAR).» *Photogrammetric Engineering 31(3): 507.*

26. **Becking, R. W.**
   *1959*  «Forestry applications of aerial color photography.» *Photogrammetric Engineering 25: 559-565.*
   «Aerial color photography offers greater possibilities to forestry than the conventional black-and-white photography. The represent-
tation of a wide range of colors distinct in hue, value and chroma and the excellent reproduction of the subdued hues are of utmost importance in the distinction between tree species, understory vegetation and soil types. The color negative process offers excellent possibilities for additional color correction in the positive transparency in order to produce the optimum color contrast wanted for special purposes of photo interpretation. The fine grain of the color transparency, coupled with its range of colors, will allow it to serve a greater multiplicity of photogrammetric and photo interpretive purposes than can possibly be served by any one type of black-and-white photography. The demand is growing for more accurate and speedier methods of obtaining mensurational and silvicultural details of large tracts of forest land and color photography will be increasingly used.

28. Belcher, D. J.
   *A good concise discussion of the use of black and white aerial photography for obtaining information on soil conditions. Discussion covers analysis to provide evidence of (1) soil texture, (2) soil moisture and ground water conditions, (3) type of rock and depth below surface, and (4) vegetative cover. These observations can be connected to military uses.

29. Belcher, D. J. et al.
   *This series, originally "restricted", provides the means of training a large number of people of mixed background in the field of photo-intelligence. Contents: (1) general analysis, (2) sedimentary rocks, (3) igneous/metamorphic rocks, (4) waterlaid materials, (5) glacial materials and (6) windlaid materials.

30. Belasky, R. K.
   *Detection patterns are discussed for rainfall in showers or thunderstorms and for snow. Probabilities of snow detection are much the lowest. Area of radar surveillance and probabilities of detection of thunderstorms, rain, rain showers and snow or snow showers are illustrated.

31. Berkowitz, R. S., editor.
   *The purpose of this book is to provide an intensive exposition of the techniques used for radar system design, analysis and evaluation. The book is divided into six sections: the first
three are mainly introductory and theoretical in nature; the last three present specific techniques. There are thirteen contributors in addition to the editor. A list of references is included with each chapter.

32. Bertram, S.  
   1965  *The universal automatic map compilation equipment.  
   *Photogrammetric Engineering 31(2):244-260.  
   *The universal automatic map compilation equipment is being developed to produce accurate orthophotos and altitude charts automatically in a map production environment.

33. Bird, J. B./Morrison, A.  
   1964  *Space photography and its geographical applications.  
   *A review of space photography from 1946 to December 1963. Problems and uses of rocket and satellite photography are discussed. A summary table is included giving photographic data and regions photographed. The bibliography of 65 references is classified into a general category, rocket photography (other than Project Mercury), Mercury photography and Tiros photography.

34. Bird, J. B./Morrison, A./Chown, M. C.  
   1964  *World atlas of photography from Tiros satellites I to IV.  
   *The major part of this report is a selection of over 400 photographs taken by Tiros satellites I-IV, including other land areas of the world between 55°N and 55°S. They are identified as clearly as the data permit by distinctive and commonly recognized landmarks. A variety of surface features can be distinguished on the best of the Tiros photographic land areas, when they are not obscured by clouds.

35. Elythe, R./Kurath, E.  
   1967  *Infrared and water vapor.  
   *Portion of the study included an irrigated desert region in California. An infrared thermal mapper flown in daytime showed possibilities for indications of plant health, variations of water supply or adequacy of irrigation.

36. Bomback, E. S.  
   1964  *Encyclopedia of color photography.  
   *The coverage is very thorough for an encyclopedia approach to the many aspects of color photography. Recommended as a reference handbook. Covers all aspects of color photography. Useful for basic information.

-33-
37. Hornback, E. S.
Comprehensive coverage for use of Kodachrome, Kodacolor and Ekta- 
chrome films. Illustrated entirely in color, eleven chapters.

38. Borchert, J. J.
1968 Remote sensors and geographical science. Professional 
A general discussion of little specific value.

39. Bowden, L. W.
1968 Southern California regional resources studies. In 
Earth Resources Aircraft Program Status Review, IR 
Geology, Geography and Sensor Studies. Presented at 
the NASA Manned Spacecraft Center, Houston, Texas, 
A very useful summary of results obtained by various sensing 
devices in southern California, with excellent illustrations. 
Important conclusions: aero Ektachrome IR 8443 is the single 
most useful sensor package for land use, geomorphology, urban 
analysis, vegetation mapping, agricultural inventory and eco-
ological studies. SLAR, multiband photography, thermal IR imagery, 
telescopic systems and imaging passive microwave devices are 
useful as secondary sensors.

40. Brandenberger, A. J.
1967 What can photos tell us about the size of a thing as 
it really is? International Science and Technology 
(69):56-66.
Popular discussion of photo-triangulation.

41. Suttner, K. J. K./Kern, C. D.
1963 Infrared emissivity of the Sahara from Tiros data. 
Science 142:671-672.
A theoretical discussion of infrared emissivity.

42. Cain, S. A.
1966 Current and future needs for remote sensor data in 
ecology. In Symposium on Remote Sensing of Environ-
ment, 4th, 1966, Proceedings p. 3-6. University of 
Michigan, Institute of Science and Technology, Ann 
Arbor. Also available as AD-638 919.
A statement of problems faced by the Bureau of Commercial 
Fisheries, Bureau of Sport Fisheries and Wildlife and the Na-
tional Park Service.

43. Cantrell, J. L.
1964 Infrared geology. Photogrammetric Engineering 30(6): 
916-941.
Infrared imagery can indicate even slight differences in soil and soil moisture capable of influencing vegetative growth; surface materials (sandstone or limestone) can be distinguished. The method is especially good for studying surface water conditions. Some examples on edge or arid zone.

44. *Carnegie, C. A.
   1967 *The use of high altitude, color and spectrozonal imagery for the inventory of wildlife resources. v. 1 (of 3).
   University of California, Berkeley, Timber Resources Forestry Remote Sensing Laboratory, for NASA.

   Article includes a table showing relation of various sensors, and ground resolutions in relation to identification of range features and conditions. These relationships are also brought out in color illustrations. Orbital sensing is chiefly valuable for synoptic view. Low altitude sensing is essential for detailed studies. Color films, Ektachrome and Ektachrome IR are best for single lens sensors. 3-band color additive films are excellent.

   Various remote sensing devices, including photographic systems, optical mechanical scanners and thermal infrared scanners obtained remote sensing data at different seasons and scales. Portions of the electromagnetic spectrum in which remote sensing was accomplished ranged from the ultraviolet, through the visible and near infrared to the thermal infrared. Analysis of the data showed that the season when imagery is obtained is critical in determining the amount of useful information obtainable from remote sensing imagery. For the most part high image resolution is desirable, although broad vegetation and soil typing can be accomplished using lower resolution imagery. The level of detail required is partially determined by the intensity of management that is to be practiced.

   University of Michigan, Institute of Science and Technology, Ann Arbor. Also available as AD-676 327.
Various sensors are described and their usefulness for identifying range characteristics are discussed. Infrared and multispectral imagery offers great possibilities, but interpretation is complicated.

This article considers kinds of information that can be obtained by using thermal infrared and radar imagery in conjunction with conventional aerial photography. Each type of imagery is analyzed in terms of inventory of vegetation classes, timber types (height, age and density), species composition, terrain features, watershed boundaries and human activity.

The stability and the forms of vertical wind erosion noted on aerial photographs are evidence of the remarkable stability of the local atmospheric oscillatory state. It is suggested that these erosion forms could provide information about the climatic evolution during the Quaternary.
54. Cochran, G. R.
   In Australia color infrared does not show up insect and disease conditions better than color film. Leaves with heavy cuticle have greater reflectance than mesic types.

55. Colwell, R. N.
   Simultaneous aerial photographs of wildland areas on infrared and panchromatic aerial negative films are compared and discussed. In general, since subject and atmospheric conditions vary so widely, exposures on both types of films furnish a more adequate basis for the interpretation. Two films for infrared aerial photography and their uses (including suitable filters) are briefly discussed: (1) Kodak Infrared Aerographic Film, a black-and-white negative material, and (2) Kodak Ektachrome Aero Film (Camouflage Detection), a reversal tripack color film.

56. --- ---
   The applications of the techniques used are described. For example, multiband spectral reconnaissance may be used to distinguish between different terrestrial surfaces and types of terrain; for observing celestial phenomena and events related to them; for studying crop diseases; and for recording the underwater features of coastal areas, etc. Techniques mentioned include diffraction analysis, fluorescent microscopy, autoradiography and integration of several color photographic images.

57. --- ---
   #1965a The extraction of data from aerial photography by human and mechanical means. *Photogrammetria* 20:211-228.
   Machinery can be devised for all photo-image characteristics (size, shape, shadow, tone, texture, pattern and location) but identification of objects and judging of significance are better solved by human photo interpreters.

58. --- ---
   #1965b Spectrometric considerations involved in making rural land use studies with aerial photography. *Photogrammetria* 20:15-33.
   Although not concerned with arid lands, the paper gives some practical suggestions for film-filter combinations to bring out various landscape features.
The stated purpose of this article is to (1) highlight the ways in which applied optics prints aerial photography of suitable image quality to be obtained and (2) summarize the kinds of highly useful information relative to the Earth's surface that can be obtained from such imagery. Applications are briefly and broadly discussed for cartography, geology, soil science, forestry, range management, wildlife management, agriculture, hydrology and engineering.

A comprehensive discussion of multispectral remote sensing, beginning with a brief historical account. An analysis follows each of the major factors governing the ability to obtain information through multispectral remote sensing. The paper concludes with several examples to illustrate the uses and limitations of multispectral imagery. It is concluded that multispectral remote sensing is a potentially valuable means of solving inventory requirements.

If an accurate evaluation of land is to be made, an accurate inventory of its resources must first be obtained. (Photography of the land surface, when taken from aircraft and spacecraft, and used in conjunction with small amounts of direct on-the-ground observation, usually provides the best means of making such an inventory. To be of maximum usefulness, however, this photography must have been taken to proper specifications in terms of photographic film, filter, scale resolution, time of day and season of year.) In some instances more than one kind of photography is needed in order to make an adequate
inventory of the land's many resources as quickly and economically as possible. Aerial or space photography, suitably annotated and supported with only a limited amount of tabular and textual data, commonly provides the best means for presenting such an integrated picture to the land evaluator.

63. *Colwell, R. N.*
   A review of devices now available for remote sensing of natural resources. Techniques range through the spectrum from the very short wavelengths to the comparatively long wavelengths at which radar operates. Information is given on remote sensing equipment. Those which show the most promise for the inventory of natural resources are the conventional aerial camera, the panoramic camera, the multiband camera, the optical-mechanical scanner, side-looking airborne radar and the gamma-ray spectrometer. Following description of the sensing equipment and analytical techniques, consideration is given to some of the ways in which remote sensing can contribute to the management of natural resources. The prospect is that techniques will evolve into a highly automatic operation, in which an unmanned satellite orbiting the Earth will carry multiband sensing equipment together with a computer.

64. **Photographic studies and applications of the NASA Earth Resources Survey Program. In Earth Resources Aircraft Program Status Review, II: Agriculture, Forestry and Sensor Studies. Presented at the NASA Manned Spacecraft Center, Houston, Texas, September 16-18, 1968, p. 28/1-28/35. Tables.**
   A rather general introductory-type discussion, but including tables covering the feasibility of identifying natural resource features based on studies in California and Arizona. The various aspects are well illustrated.

65. *Colwell, R. N., ed.*
   An outline of a general brief extension course on remote sensing, with some papers (including Colwell's introduction) in their entirety, others in outline form with illustrations.

66. *Colwell, R. N./Olson, D. L.*
A simplified discussion of the use of thermal infrared imagery for obtaining information from military and civilian standpoints. Examples include some semi-arid conditions.

67. Cooper, C. F.
*A summary of general state of knowledge. Important properties potentially measurable by remote sensing techniques include leaf area, volume, weight and chlorophyll content of vegetation; water content of soils and vegetation; depth and density of snow. Multi-band sensors are essential.

68. Corriher, H. A./Byron, B. O.
*1120 references for the time period 1957-1964. Includes an author index.

*A review of flights and hardware up to Apollo. Excellent photos of arid regions show possibilities of satellite photography where cloud cover is low. Arid regions offer greatest possibilities for studies of landscape features.

70. Coulson, C. L.
*Basic information on reflectance of soils and vegetation including desert soils and sand. Gives evidence of the possibility of using reflectance to distinguish landscape features.

71. Crandall, C. J.
*Studies have been completed showing the feasibility of mapping from radar photographs.

72. Current, I. B.
*Sensitometry is useful for the practical determination of film speed and setting correct exposure, control of processing conditions,
adjustment of color balance and control of printing.

73. Curtis, L. F.  
*Soil classification in use in 1962 will have to be changed for best results from aerial surveys.*

74. Davis, A./Vieses, W.  
*Too far removed from operational activities and hence of little direct value in military geography.*

75. Davis, C. K./Neal, J. T.  
*A good brief discussion of desert landforms and their characteristic appearance on aerial photographs. Landforms include (1) river floodplains through flowing streams, (2) structural plains, (3) playas, (4) desert flat, (5) alluvial fans and bajadas, (6) pediments, (7) desert domes, (8) desert mountains, (9) dunes and (10) drainage. All are illustrated - information discernible from standard black-and-white photograph at scales of 1:10,000 and 1:40,000 is discussed.*

76. Davis, J. M.  
*This handbook describes ways in which air photos can be used to obtain information of value to planners and others interested in terrain and culture features. It also provides information on the availability of air photos in the U. S. and how to obtain them.*

77. DeLancie, R./Steen, W. W./Pippen, R. B.  
The use of dichotomous and selective keys, if well organized, gives approximately the same results for aerial photography, and are independent of the experience of the observer.
The most unique contribution of radar will be at a maximum in remote and poorly mapped areas of the world where regional rather than a detailed picture is desired, and where climatic conditions are all adverse to ground and aerial photographic investigation.

The value of low-resolution radar imagery for regional geologic studies lies in its lack of detail which allows the geologist to establish regional relationships. Example is in the Arkansas Ozarks.

Radar has its greatest potential in regional studies where terrain or climatic conditions are adverse to either ground or aerial photographic investigations.

Remote sensing of Pisgah Crater area in California shows the value of simultaneously produced like- and cross-polarized imagery, providing the geologist with information not attainable from only like-polarized radar imagery.

This catalog lists and describes 317 sets of aerial photographs (9- by 9-inch contact prints) available for purchase from the U. S. Geological Survey. Most sets are of vertical photographs and provide stereoscopic coverage. The features shown are listed in an index. Information given for each set includes location, scale and date of photography, a brief description of the features illustrated and reference to a geologic report and topographic map of the area.
83. Dietz, R. S.  
*1977*  
"Under proper conditions photos may penetrate 10 to 40 feet in coastal water and 60 to 100 feet in oceanic water. Submerged features show up well from the air. Film sensitive to short wave lengths should be used.

84. Dill, H. W.  
*1967*  
"This bulletin was prepared for NASA as part of an overall study to appraise potential benefits from obtaining land-use and other agricultural data from Earth-orbiting satellites. Arid areas included are Australia, Chile, India, Kenya, Mexico, Morocco, Peru, South Africa, Sudan, UAR, and US.

85. Dmitrenko, V. P./et al.  
*1967*  
"Methodik aerovizual'nykh agrometeorologicheskikh nablyudenii (Methods of visual agrometeorological observations from the air). "Nauchno-Issledovatel'skii gidrometeorologicheskii Institut, Trudy 68:74-86.  
"Description of principal crops and of stages of their development and a method of evaluating conditions of plants by color, density and spotiness.

86. Doverspike, G. E./Flya, P. M./Heller, R. C.  
*1975*  
"Color density alone does not seem to offer a solution to differentiate land use. Microdensitometer can be helpful but more research is needed. Results of comprehensive color photo studies outside of arid region are reported.

87. Draeger, W. C.  
*1968*  
"Test site out of arid region, but some of the results have applicability to arid areas. Emphasis is on multispectral black and white photography for color-enhanced imagery by projecting black and white negatives of several spectral bands through filters of various colors on a translucent viewing screen. The composite color image thus formed is photographed in color from behind the screen and reproduced in color print form.

88. Drayson, S. R.  
*1969*  
"Investigation of atmospheric absorption for remote
The report discusses the need for an understanding of atmospheric absorption processes in the interpretation of remote radiance measurements. Specifically included are absorption by the 15 micrometers in carbon dioxide bands, the 14 micrometers in ozone band and the oxygen A-band.

Studies with ground-based unit demonstrate that a definite relation exists between the radiometric brightness, temperature and moisture content of soils. This relationship can be used for qualitative estimates of the bearing strength of cohesive soils.

Horsefly Mountain, Oregon, is part of study on the use of radar image combination and enhancement techniques for the discrimination of terrain characteristics using multiple polarization radar images.

Operational and technical aspects of earth resources satellite projects are discussed. Attention is concentrated on problems of orbital sensing of electromagnetic earth radiance in the visual, infrared and microwave regions. A list of organizations engaged in relevant branches of science and technology together with bibliographic references are appended.
93. Enzmann, R. D., ed.  

94. Esten, R. D.  
Developments in automatic instruments are discussed and illustrated.

95. Estes, J. E.  
The applications of infrared imagery are discussed including geological features, hydrographic features and vegetation. Illustrations include arid areas.

96.  
This article briefly discusses in simple language infrared imagery as a tool to aid geographers and others to obtain information on climatology, hydrology, physiography, vegetation resource development, urban and rural land use. A good article to provide a general view of the subject for the nontechnical reader.

97. Feder, A. M.  
A good discussion of the capabilities of radar, including the following seven: (1) composition and conditions below visual rock and soil surface of terrain can be read. (2) Vegetation can be penetrated and subsurface information obtained. (3) Terrain - surface materials can be determined down to small gravel-size and finer materials can be inferred. (4) Moisture content of terrain can be determined when temperature data are available. (5) Temperature can be determined when moisture content is known. (6) Metallic content of surface and near surface materials can be determined. (7) The properties of a snow cover can be read, or the terrain beneath the snow.
98. *Feder, A. K.
*A review of programs with little specific application.

99. *Fiorio, C.
*a basic discussion of an engineering model for correction of geometric distortion involving two data collecting flights and special processing techniques.

100. *Fischer, W. A.
*The U.S. Geological Survey is conducting continuing investigations of the geologic uses of color aerial photography, including study of color photographs of Torrance Station SE quadrangle, located approximately 100 miles southeast of Albuquerque, New Mexico. Some geologic features are recognizable locally on conventional black-and-white photographs but cannot be traced with assurance. These same features show more continuity on black-and-white prints made from the Aero Ektachrome film, and evidence much more continuity and clarity on full color photographs. New developments in films, lenses, and color measurement devices make the future applications of color aerial photography to geologic study even more promising than they are now.

101. *--- ---
*a example showing possibilities of geological interpretations of radar imagery.

102. *--- ---
*Color aerial photography has many geologic applications, particularly in the study of: 1) areas having relatively heavy tree cover in which ground detail is illuminated by the scattered blue light not normally recorded on black-and-white photographs; 2) areas underlain by different colored rocks that would generally photograph with similar gray tones; 3) underwater features, because of the penetration of water by blue light and resultant illumination of features at depths...
as great as 80 feet; 4) surficial features, such as gravels of slightly different colors and ages; and 5) other areas where color differences or shadow illumination is important.

103. *Fischer, W. A. 

104. *--- *Satellite detection of natural resources. *Advances in the Astronautical Sciences 21:399-409. *AIAA 1(7)H202906 67A. International Aerospace Abstracts 19(30)A67 356 55. *Analyzes of Gemini and Nimbus photographs have demonstrated that some features known to be associated with mineral deposits are visible from orbital altitudes. The benefits resulting from programs of orbital observation include: 1) significant improvement in the precision of natural resource inventories by increasing the knowledge of the size of sedimentary basins and the thickness of strata and the character of the structures within them; and 2) fundamental advances in knowledge of the Earth's crust, its shape, mass distribution, and magnetic qualities.

105. *--- *EROS, viewing the Earth from space. *GeoScience News 1(3):16-19. ANAG 68-00352. *From the Gemini and Mercury program came images of the Earth that can aid in regional classification of landforms and recognition of large subtle anomalies. They show that dynamic phenomena are observable from space, and that small scale images have value in resource planning. A photomosaic map was compiled of a third of a million square miles in Peru, Bolivia, and Chile, and the features shown are discussed. An observation satellite in orbit will allow study of the effects of earthquakes and volcanoes.

106. *Fischer, W.A./Ray, R.G. *1957 *Geology from the air. *Science 126:725-735. *Methods and equipment available for aerial surveying and photography are discussed. High-altitude (30,000 feet) photography has been developed so that areas of 50 to 100 square miles in extent can be covered. All details detected on aerial photographs can be measured, the accuracy of measurement being dependent upon the scale of photography selected. Study of stream patterns shown on the photographs reveal underlying structures. Color aerial photographs also often reveal features not visible on black-and-white pictures of the same terrain.

---

Butcher paper, surveyor stakes, lath strips, plastic letter number codes, paper plates, and drop-panel markers were tested and found useful for photography at 1:600 to 1:2,400.

A discussion of the state of the art as applied to agriculture. Includes information on the feasibility of various sensing activities for various agricultural features and conditions.

Kodak Ektachrome Infrared Aero Film, Type A, is discussed as a remote sensor for applications as diverse as aerial reconnaissance and the detection of disease and pests in agricultural crops. Descriptions are given of the film and scene characteristics, along with methods of keeping, exposing, and processing to produce photographs with the highest information content.

Designed to give scientists, research managers, administrators, engineers, information specialists, librarians, students, and the informed public up-to-date and comprehensive coverage of all significant sources of information, published and unpublished, of domestic and foreign origin on space science and technology. This is an excellent source book covering specialized information centers and services, references, and all phases of technology.

A discussion of methods of obtaining radiation imagery.

A good summary of historical development of aerial photography.

124. Grabau, W. E.
A general methodological statement of what is necessary for terrain analysis for military geographic intelligence. A diagram showing the flow of information through an ideal terrain evaluation system is provided.
125. Hackman, R. J.

Radar imagery has some advantages over conventional aerial photography: 1) it shows a view of a larger area than a single aerial photo; 2) surface areas covered by clouds can be recorded; 3) it shows greater topographic detail because of shadow enhancement; 4) it is not restricted on the direction of flight by control of elevation; 5) it depicts some geologic faults not visible on aerial photos; 6) it provides some rock signatures; and 7) it makes some Quaternary alluvial deposits more discernible than on aerial photos; however, it does not differentiate between surficial windblown sand and sandstone.

126. Hammond, R.

Contains chapters on the scope, techniques, and instruments for air survey, as well as on the cameras and plotting equipment and aircraft. Based on black and white photography.

A series of experiments designed to investigate critical problem areas in the presentation of multisensor intelligence imagery, was described. This paper presents here. The group of sensors considered includes a panoramic camera, an image-forming side looking radar system, and an image-forming infrared sensing system. The individual problems were studied in the context of the complete multisensor intelligence collecting and evaluation system.

128. Hawkins, J. K./Kunsey, C. J.

An optical system combined with the use of photographic film in a multiple stage nonlinear decision process is described. The image resolution attainable with photography is largely retained, while the complex logical decisions possible with electronics are readily performed.

129. Hemphill, W. R.

The advantage of small scale 1:50,000 or smaller for some geologic features is pointed out. The main feature is the larger area covered permitting greater continuity of observation.

164. *Latham, J. P./Witmer, R. E.*  
*1967  Comparative waveform analysis of multisensor imagery.  

An introduction to a research methodology for quantitative comparative analysis of multisensor imagery and to relate transmitted signals containing geographic information to the actually occurring geographic pattern.

165. *Lauer, D. T.*  

A systematic analysis was made of the factors affecting image tone or color, image detail, and stereoscopic parallax in order to improve the quality of remote sensing imagery. The optimum combination of factors was determined for identifying the major tree species and timber types in selected parts of the world, using imagery taken from earth orbit.

166. *----*-  

Primary objective of research was to analyze factors governing the interpretability of tree species on high-altitude small-scale imagery. Photographic results of various film and filter combinations are shown.

167. *Lesstma, R. A.*  
University of Michigan, Institute of Science and Technology, Ann Arbor. Also available as AD-638 919.

Manned orbiting satellites equipped with multisensor systems will offer an opportunity to measure and sense the total land, ice and water surfaces of the earth. The information can be organized under a topical geographic methodology to include: atmosphere, biosphere, hydrosphere, lithosphere, and culturesphere.

168. *----*-  
*1967  A methodology for military geographic analysis.  

This is a methodological report that describes a matrix system adaptable for either manual or machine use in making a military
geographic analysis. This is presented as a direction for further research.

169. Weighty, R. D.  
   Also available as AD-676 327.  
   *An excellent review of radar and its potential for investigations of terrain. The article covers: radar uses, radar systems, radar theory and empirical measurements, qualitative analysis of radar imagery and miscellaneous radar techniques. There is a bibliography of 26 titles.

170. Leonardo, E. S.  
   *A discussion of the problems of interpreting radar imagery. An understanding of the differences between photographic and radar images is essential for interpreting radar photographs, especially for smaller objects.

171. Lepley, L. K.  
   *On a yearly average 85 percent of the world's coastal water is sufficiently clear for the use of an airborne laser fathometer for mapping sea floor topography from shore out to at least 20 meters depth. 35 percent is clear enough for mapping by color photogrammetry to at least 20 meters depth and laser sounding to 40 meters. 44 references.

172. Levine, D., ed.  
   *This is the bible for radargrammetry, covering everything from theory to specific techniques and devices. A bibliography of 64 references is included.

173. Lewis, G. K.  
   *Analogous area keys are based on studies of known areas thought to be similar to inaccessible areas.
175. *Llaverias, R. K.

This preliminary bibliography was prepared to acquaint hydrologists with the basic literature involved in this field. Some of the references concern specific hydrological topics or specific remote sensing methods. Other references on vegetation mapping and geology were included so that the reader can find information on the selection, processing, and use of remote sensing data in these cognate fields. A number of meteorological references were included because in many remote sensing applications, especially from earth orbital satellites, atmospheric effects must be taken into account in interpreting the views of the earth.

176. *Lowe, D. S.

The title is somewhat misleading as most of the discussion has to do with the operation of multispectral scanners.

177. *--- ---

This technical paper summarizes the technological development of scanners, shows the relationship between scanner performance and component specifications, and discusses some modification for converting the conventional scanner into quantitative research tool.

*1965 *Space photography, a review. *Photogrammetric Engineering 31(1):76-86.

A review of the history, present status and capabilities of space photography. Advantages are wider perspective, potential worldwide coverage, greater speed, and rapid repetition coverage. Applications are in geologic and topographic mapping, oceanography and other fields. A chart of space flights from V-2 to Mercury 9 is included. Illustrations include arid lands.

179. *Lueker, D. R.

An important handbook for everyone interested in aerial photography.

Aimed at the moon - of little direct value.

Field geology can be performed by using spectral signatures from rocks and soils in the 8 to 13 micron wavelength region. Developments of equipment are discussed as well as applications to terrestrial and lunar problems.

Study conducted in British Columbia. Results indicate that same techniques could be used in arid regions, but the cost might be excessive.

This paper presents research in which the investigators studied similarities and contrasts between panchromatic aerial photography and radar imagery from the Cane Springs area, Arizona, for which precise surface geologic data are available. Lithologic and structural information is available on the radar imagery which is not as apparent on the air photography; however, the converse is also true. Interpretations also reveal the fundamental advantage of multisensor reconnaissance.

A series of 39 overlapping photographs of the southwestern United States and adjacent areas of Mexico was obtained as part of an ex-
periment of the Gemini 11 mission. A 1:1,000,000-scale, black and white, semi-controlled mosaic was constructed covering about 150,000 square miles extending along the 32d parallel of north latitude from the Pacific Ocean to the 100th meridian in west-central Texas, and averages about 150 miles in width. Many of the individual rectified photographs can be enlarged to a scale of 1:250,000 with little or no loss of resolution; such enlargements will be of great value to earth resources studies. If the angle of tilt is more than 35 degrees, some detail in the background of the photograph is lost.

185. MacKallor, J. A.  
*A photomosaic of western Peru from Gemini photography.  
A 1:1,000,000-scale mosaic, prepared from photographs taken during the Gemini IX mission, shows the area from the Sechura desert in northern Peru to northern Chile and from the Pacific Ocean to the headwaters of the Amazon. A wide variety of geological features as well as landslides, roads, snowfields, irrigated lands, jungle agricultural sites, archeological sites, and smoke (brush burning) have been identified on the mosaic.

186. Malila, W. A.  
The use of multispectral techniques can produce increased image contrasts. They also have possibilities: automatic recognition of objects through processing and computational techniques.

187. Martin, A. F.  
Chapter headings: include: modern infrared spectrometers, interferometric spectrometers, miscellaneous instruments, and accessories.

188. Matalucci, R. V./Abel-Hady, M.  
*Infrared aerial surveys in environmental engineering.  
An illustrated review is given of the basic principles related to the nature of IR radiation and the problems associated with its atmospheric attenuation. Some of the differences between IR photography and imagery are analyzed, and illustrations are used to demonstrate techniques for locating thermal water pollution by IR sensing. Stream valleys and subsurface drainage patterns are distinctly shown by IR imagery, which can also be used for locating buried conduits and utility systems.
189. *McAnerney, J. M.*

*1966*  

Imagery from high-resolution side-looking radar is a useful tool in the remote sensing of environment; although resolution and definition are not as good as that obtained with visual aerial photography, it has the advantage over the latter in that the image is equally good in daylight and darkness, and can be obtained under all weather conditions except heavy rain clouds. Trained observers can describe physiography, geology, soil and cultural features on the basis of side-looking radar imagery alone.

190. *McCoy, R. M.*

*1968*  

Radar imagery offers several advantages: (1) side-looking imaging radars obtain greater ground cover than vertical mapping cameras carried at the same altitude; (2) radar systems present more geomorphic detail relative to their scale; (3) there is a consistent relationship between the quantitative data derived from radar and the data from large-scale topographic maps (1:24,000). The use of spacecraft makes possible topographic information from areas inaccessible to other mapping methods.

191. *McDaniel, J. F.*

*1959*  
*Aerial color-film in military photo interpretation.*  
*Photogrammetric Engineering 25*:529-533.

In recent years, color-film has been and is being used in sharply increased quantities for non-military purposes. This paper is essentially a review of the factors associated with the use of color-film by the armed forces. It also describes developments which may affect its role in future intelligence-reconnaissance operations.

192. *McLerran, J. H.*

*1967*  

Includes one example from Yuma, Arizona, but is mostly concerned with Yellowstone Park and cold regions.

193. *--- ---*

*1968*  

The author concludes that there must be considerably more study of the factors that influence the radiation properties of terrain fea-
tures before infrared sensing can be used for surveys.

194. Muller, G. Y./Nefetov, K. E.  

The report gives a geographical description of the natural landscapes existing in Turkmenia and the individual landscape elements in that Soviet Republic: topography, climate, hydrography, soils, and culture features. Particular attention in this article is given to the relationship between ground water and relief, vegetation and soils, and a description of what features serve as indicators of ground water and how these indicators appear on aerial photographs. Mountains, sandy areas, and techniques are discussed among other geomorphological features.

195. Mendez, R.  

Statistical analyses were made using observations of backscattered radiation recorded by Channel 3 (0.2 to 6.0 microns) of the Tiros 7 radiometer, as it passed over the Sahara Desert. Three orbits were selected for this study. In order that the results be consistent the areas involved were classified and labeled according to the terrain. A composite map of the area was then constructed from Gemini II pictures and Nimbus I A70 3 pictures. Both closed mode scanning and alternating mode scanning have been used in order to obtain reflectance values from the ground at different angles of view.

196. Merifield, P. M./Cronin, J./Foshee, L. L./Gamracci, S. J./Neal, J. T.  

A general review of satellite imagery as related to atmospheric and Earth sciences. Gemini and Apollo photographs have furnished information on sea surface roughness, areas of potential upwelling and oceanic current systems. Regional geologic structures and geomorphologic features are also recorded in orbital photographs. Infrared satellite imagery provides meteorological and hydrological data and is potentially useful for locating fresh water springs along coastal areas, sources of geothermal power and volcanic activity.

197. Merifield, P. M./Ramsalkamp, J.  
Tiros pictures have some possibilities of showing physiographic and geologic features in arid regions, but their use is limited.

*Includes 13 papers of which about half have some relation to handling of remote sensing data.

199. *Mintzer, O. W.  
*A review of photo interpretation for engineering purposes, followed by a discussion of potential value of multispectral, radar and infrared imagery. Bibliography has 28 references.

200. *Moeller, F.  
*Extraterrestrial radiation balance during a two week period from July 2-15, 1966, was plotted from measurements, obtained by NASA, of reflected solar radiation in the range of 0.2-4 microns and the long wave thermal radiation transmitted by Nimbus 2, launched into a polar orbit. Desert areas exhibited high albedos.

201. *Molineux, C. E.  
*A general discussion of limited value to arid lands problems.

*Surface effects of moisture content, vegetation conditions, subsidence, deposition of dust can be detected. Multi-band photography can detect more subtle changes than single sensors.

This system including camera and data reduction equipment was designed especially for detecting manifestations of underground nuclear test activity. The use of this system can also provide much information to enhance the photointerpretation of vegetation, soil and geologic conditions. The airborne system consists of a nine-lens multiband camera, associated color reference cameras, a dual spectrometer system, cartographic camera, and skylight recording camera, flown in a C-130 aircraft.

Orthophoto maps have planimetric accuracy combined with the imagery of the photo-mosaic. The method of preparation and uses are discussed.

205. *Moore, E. G., Willar, B. S.  
A good example of the use of multiband photography for geography. Examples include identification of housing characteristics and four different road surfaces. Includes a discussion of automated data retrieval from a set of multiband photographs.

206. *Moore, R. K.  
A basic discussion of radar scatterometry. Various systems are described and the range-angle system is outlined in detail. So far, land applications are speculative.

207.  
This report is concerned first with the scatterometer and then with imaging radar. Enough measurements have been made to show that scatterometry can be a useful tool for land geoscience. Evidence is at hand to show that radar will be useful in discriminating both cultivated and natural vegetation. The values of multifrequency and polychromatic imagery are predicted.

208. *Moore, R. K./Simonett, D. S.  
Potential application of radar in agricultural surveys, in mapping natural vegetation and in forest surveys.

209. Morain, S. A./Simonett, D. S.  
*Radar imagery, combined with interpretation techniques, may serve as a reliable tool for intermediate scale mapping of already recognized vegetation zones in the semi-arid part of the United States and thus may be of significant value for ecologists, botanists and range managers interested in knowing actual distribution of grassland, shrub land and grazing density of stands.

210. ---  
*K-band imagery of Horsefly Mountain, Oregon shows the possibilities of discrimination patterns of vegetation. Techniques for improving ability to discriminate include: use of tri-color image combinations; the generation of probability; density functions to quantify variations in gray-scale level between types; and the employment of a space sensor to help distinguish between vegetation types, although examples only extend into semiarid conditions, the techniques should apply to arid environments.

211. Morgan, J. O.  
*Theory and processes. In summary it is stated that remote sensing techniques are available which permit the measurements of radiation fluctuations corresponding to temperature fluctuations of 0.01°C, and that resolution is equal to mediocre aerial photography.

212. Morrison, A./Bird, J. B.  
*The principal advantages of space photography are the wide geographical coverage and provisions for repeat coverage. Space photography can assist in mapping geology, landforms, vegetation, generalized land use, forest fire burns and temporary lakes and streams.
213. *Morrison, A./Chown, K. C.*
*Sequence of high oblique color photographs taken by the automatic camera in the MA-4 spacecraft over the western Sahara in 1961. The larger geological and landform patterns of the area as well as vegetation boundaries on the southern edge of the Sahara can be mapped from the photographs. One photograph illustrated the potentiality of space photography for small-scale land-use mapping. Observations and calculations show that the smallest ground features that can be seen stereoscopically on these photos are of the order of 1000 feet high.*

214. *Morrison, A. F.*
*The soil classification map was compiled from a mosaic of rectified black-and-white reproductions of space photographs from the Gemini IV and V missions. Unrectified color prints were used to determine soils colors as portrayed by the photographs, and their distribution; rectified black-and-white prints were used to plot detailed information on topographic base maps at the same scale. This information was then transferred to the small scale mosaic.*

*Spectrophotometry as applied to agricultural and desert vegetation is discussed. Through the use of pictorial and thermal infrared sensing, it is possible to determine relative subsurface salinity and moisture conditions affecting crop production.*

216. *National Academy of Sciences/National Research Council*
The report contains estimates of the value satellite reporting systems might have to the agriculture and forest industry, United States and world-wide. The intangible effects on increasing the efficiency of farming and forestry through new satellite technology are potentially significant. Remote sensing is now technically feasible for: (1) inventory and productivity evaluation of the world’s food, fiber, and other natural resources; (2) assessment of environmental conditions and of man-environment interactions.

The findings and recommendations of a technical study group on the applications of space technology to hydrologic problems are presented. Four hydrologic objectives are identified: basic studies of the hydrologic cycle and large scale hydrologic systems; snow and ice mapping; surveys of coastal hydrologic features and large inland lakes, and real-time communications of ground based hydrologic data. The benefits to be derived from a collection of more and better hydrologic data and improved weather forecasting are evaluated and a cost estimate on a hydrology satellite system is also included.

Major types of playa surfaces can be recognized on the basis of the amount of light reflection. Geomorphic features that can be observed include sheet wash stains, giant contraction polygons, giant contraction stripes, salt pressure polygons, phreatophytes, hot and cold springs, and surface drainage forms.

*Playas are useful as emergency aircraft landing sites and as indicators of the hydrologic environment. A factor that has limited their use is the inability to intermittently monitor surface changes that occur as result of rain. Reflectance changes that indicate soil moisture or compositional variations (which in turn affect trafficability) have been observed on Gemini color photographs and Nimbus AVCS (Advanced Vidicon Camera System) imagery. The best data currently available is the Gemini color photography. The use of infrared and false-color films provide advantages in discriminating moisture as well as improving low-visibility conditions.

1968. A comparison of microdensitometry and TV waveform analysis as expressions of observed landscape patterns on radar.
Florida Atlantic University, Boca Raton, Department of Geography, Report TR-6. 15 p. NONR Contract 4761(00).
Also available as AD-672 561.

Identification of landscape regions with radar is largely dependent upon recognition of variations in texture patterns on the radar image. Comparison of microdensitometer traces with television waveform reveals that, for similar resolution systems, essentially the same tonal information can be obtained from either system. The advantages of lower cost, faster speed, and the ability to simultaneously see the location of the scan line being analyzed favor the use of waveform analysis.
228. Ockert, D. L.  
1960  Satellite photography with strip and frame cameras.  
The advantages and disadvantages of strip and frame cameras are discussed. Although both have good and bad points, the author thinks the frame camera will be most useful.

229. Olson, C. E., Jr.  
1960  Elements of photographic interpretation common to several sensors.  
Nine basic elements for interpretation are outlined and illustrated. They are: shape, size, tone, shadow, pattern, texture, site, association and resolution.

1967  Accuracy of land-use interpretation from infrared imagery in the 4.5 to 5.5 micron band.  
Study in Michigan brought out differences in agricultural land use. Best results in mid-day and early afternoon.

232. Olson, C. E., Jr./Good, R. E.  
1962  Seasonal changes in light reflectance from forest vegetation.  
Study in Illinois, with 3. E. recording spectrophotometer showed greater light reflectance from hardwoods. Difference between hardwood species was measurable, but difference between pine species was very small.

233. Olson, C. E., Jr./Ward, J. M.  
1968  Remote sensing changes in morphology and physiology of trees under stress.  
Greenhouse studies with tree seedlings exposed to varying concentrations of NaCl and CaCl₂ indicate that oak species tested are more resistant to salt injury than aspen, tulip poplar, maple, or willow; and that salt tolerances of these species decreases in the order listed. No consistent differences in foliar reflectance or moisture tension between salt-treated and control plants are observed until leaf mortality occurred. Drought conditions in sugar maple seedlings were accompanied by increasing foliar reflectance of the stressed plants at all wavelengths from 0.5 to 2.5 micrometers.

-73-
Previsual detection of drought or salt-stress was not achieved using color or infrared-color photography in the laboratory. Girdled oaks were successfully detected in daytime imagery obtained from altitudes up to 14,000 feet above mean terrain. Detection was unsuccessful from any altitude at night.

23h. Neill, H. T.
*Too general to be of much value.

23k. Ory, T. P.
*Advantages of line-scanning are discussed. Can be used with spectral range from ultraviolet to the far infrared. Terrain features stand out from backgrounds.*
Advantages of satellite surveying include a continuous and regularly repeatable broad synoptic view of total earth cover over a long period, and low cost per unit of data collected. Sensors operating different bands of the electromagnetic spectrum can cover a wide range of natural features including geologic, geographic, agricultural, and oceanographic. The equipment carried by satellites, handling of data, and administrative problems are discussed. Earth resource satellite programs in the U. S., the United Kingdom, and Europe are reviewed.

A discussion of theory, process and systems as related to remote sensing. Some basic concepts.

Developments in remote sensing applicable to airborne engineering surveys of soils and rocks. Materials Research and Standards 8(2):22-30.

Uses of various airborne sensors in engineering surveys of soils and rocks are discussed. The sensors include cameras, infrared and passive microwave mappers, radar, spectrometers, laser, radiofrequency, and induction devices. Applications include identifying and delimiting soil and rock units and locating information about surface and subsurface conditions that would affect ease of excavation, slope stability, and suitability for subgrade, foundation, or fill materials.

Experiments have demonstrated our ability to study and
assess natural resources from remote-sensed data.

Examples discussed are mapping, geographical research, hydrology, such as salt-water intrusion and pollution, mineral and fuel discoveries, and engineering geology. Some examples are given of the use of infrared imagery in Nevada, Yellowstone Park, and Scranton, Pa., where underground coal beds are turning. A similar location has located faults in a mining area in Nevada. Although this data can help with conservation of public lands and forests, and in oceanography, it is too general to be of much use for specific arid lands problems.

*A basic text on military geography.

2h2. *Peterson, R.M./Cochrane, G.R./Morain, S.A./Simonett, D.S.*

*The Horsefly Mountain region is a complex of upland pine and fir forests and of near-flat, stony basins supporting grass or sage. The diverse plant communities occur with a wide range of sharply to diffusely-defined boundaries and with a wide range of densities within communities. The region thus lends itself well to the testing of image-combining devices now being used in vegetation studies. The IDECS system, which is an Image Discrimination, Enhancement, Combination, and Sampling device used, produces color images by combining data from up to six black-and-white multi-sensor images.

2h3. *Petrov, K.P.*

*A very useful discussion of black-and-white aerial photography covering work in the deserts of East Central Asia, in comparison with the deserts in West Central Asia. The methods of Soviet scientists to utilize aerial photography in the geographic studies on the desert territories of the Soviet Union are projected for East Central Asia. The various desert types are discussed in relation to their appearance on aerial photographs.

-76-
Highly reflective terrestrial features seen in TV photographs from weather satellites have the same apparent brightness as many cloud features. In order to properly identify such features one must learn to recognize their shape, appearance, and general characteristics. The 3 atlases of the U.S. and contiguous areas of Canada and Mexico have been compiled by the Applications Group of the National Environmental Satellite Center, ESSA, primarily for use as a guide in training meteorological personnel to recognize features which might otherwise be interpreted as clouds.

A progress report with little in the way of usable results. The objectives of the study were: (1) to determine potentialities and limitations of mapping and interpreting characteristics of native vegetation areas from space photography. (2) to compare vegetation maps from this photography with other available vegetation-resource maps and (3) identify problems and limitations in the practical use of space photography in earth resources applications. The area covered was that from Gemini, Apollo photographs in southwestern U.S.

Space photographs taken during Gemini IV overflight of southern Arizona are being studied to assess the appropriateness of this system of remote sensing for inventorying native vegetation and related resources. Close examination and experience in relating images to their vegetation and soil subjects indicate that a meaningful inventory of these resources can be accomplished through the use of space photographs. An inventory can be obtained through strict adherence to specific mapping concepts and ecological principles as they apply to several steps in the flow chart.

Brightness temperature analyses were made from nighttime Nimbus high resolution infrared data in the 3.5 - 4.2 micron region. Data for the northeast Sahara Desert and the Nile delta regions, obtained during September 1968, were selected. The brightness temperatures detect: (1) the widespread humidity in the upper soil horizons, and (2) the heat storage capacity in various rock formations such as sands and alluvial deposits.

Efforts were undertaken to find a better geological tool utilizing the nighttime infrared radiations emitted by the ground, and thereby obtain a better knowledge of the agricultural possibilities of arid and sub-arid lands. From this preliminary study certain predominant features emerged and were used as a basis for the interpretation of data.

Nighttime infrared imagery of the area between Lordsburg and Silver City, New Mexico, indicates numerous applications for studies of geology and hydrology of desert regions. Tertiary volcanic rocks consisting of flows and welded tuffs show good tonal contrasts within themselves. Precambrian granites and gneisses appear mottled. Water courses appear as dark streaks, cold water springs as dark patches, and water standing in ponds and reservoirs is bright in contrast to the darker (cooler) surrounding materials.

This document reports investigation of progress in the unclassified areas in the technology of remote sensing of environment. It includes a synopsis of progress in the field as reported at the Fourth Symposium on Remote Sensing of Environment, a discussion of the existence and availability of unclassified imagery, and a summary of related activities. It includes an extensive bibliography.

A general discussion bringing out the value of aerial photography in the early sixties. The many advances since then reduce the value of the article materially.

*1969*  
Some guidelines for remote sensing in hydrology.  

A discussion of remote sensing in the field of hydrology is given to guide the hydrologist to a better understanding of how he may collect, synthesize, and interpret remote sensing data. The techniques discussed include color aerial photography, infrared aerial photography, infrared imagery, and photogrammetry. Data reduction methods and equipment are briefly outlined.

263. Robinove, C. J./Skibitzke, H. E.
*1967*  
An airborne multispectral television system.  

Airborne multispectral television images in visible and near-infrared regions of the spectrum have lower spatial resolution than aerial photographs, but have the advantage of instant reproduction and are especially useful for vast coverage of dynamic events such as floods.

264. Romanova, M. A.
*1968*  

An investigation was made to determine if the spectral luminance of sands in Karakum desert could be registered by remote sensing apparatus, and it was shown that the spectral luminance of the sands does indeed reflect the origin of the deposits. Desert sands are suited to this method because their diffuse reflection of light gives similar luminance values over a range of angles of illumination.

265. Rose, C. W./Thomas, D. A.
*1958*  

The problems involved in measuring land surface temperature from remote radiometric measurements, made in the 8-13 micrometre atmospheric "window" are discussed. Two possible applications of using land surface temperature in land evaluation are examined: 1) the assessment of the extent and density of vegetation over large areas and 2) the relative assessment of water storage in bare soil.
266. House, J. W., Jr./Haite, W. P./Walters, R. L.

Radar in the fields of scatterometry, altimetry, imagery, and penetration is described. Scatterometry, dealing with the scattering coefficients of terrain targets, is discussed. The effect of surface texture or roughness on the magnitude of the scattering coefficient is discussed. Several radar images are examined which contain information applicable to geology, agriculture, and sea-ice studies. Vegetation penetration is described as the best use for the penetrating capability of radar. Applications of radar altimetry for determining sea slope, height of tides and storm surges, orbit calculations, and in glaciology are evaluated.

267. Rubin, L.

The advent of weather satellites has made possible the realistic examination of large scale atmospheric phenomena essential to a more thorough understanding of man's environment. The purpose of this report is to provide a key to the operational data processing of the LRIR (low resolution infrared) data. Hardware and technique are discussed relevant to the data recovery problem, and appropriate references are furnished for detailed study.

268. Rydström, H. O.

From study of the radar imagery of earth features and application of radar imaging principles to their analysis, it is concluded that high resolution side-looking radar in the existing state of the art can be useful in local geologic interpretation. The intensity of radar return energy, as modified by the factors of radar illumination, surface roughness, and the geometry of objects, is discussed. The principles involved are described and applied to analyses of local geology in the southwestern United States. Local geologic interpretations of radar imagery are applicable to military terrain intelligence, natural resources exploration, and planetary exploration.

-83-
The intensity of radar return energy, which is dependent on the manner of radar illumination, surface roughness, and geometry of the object, is discussed as applicable to the interpretation of local geology. The principles of radar interpretation of local geology and the use of radar principles in conjunction with knowledge of geomorphic principles to obtain a maximum of information are discussed. These are illustrated with radar images and photographs of areas in the southwestern U. S. Applications of radar imagery to military terrain intelligence, natural resources exploration, and planetary exploration are examined.

   Objects submerged in water can be measured from vertical aerial photos. In clear water depths to 90 feet, contours
   have been traced to a depth of 60 feet. Depth of water observed needs to be multiplied by a factor of 1.1 to 1.5.

319. Theurer, C.
   1959  Color and infrared experimental photography for coastal mapping. *Photogrammetric Engineering
         25(1):555-569.
   Color, infrared and panchromatic aerial photography of shoal areas have been obtained for comparative studies for
   applications to coastal mapping. One application of color photography is to determine relative depths; not isolating
   shallow areas which may require a dense hydrographic study. Special devices and techniques are discussed, including the
   problem of obtaining aerial photographs at a specific stage of the tide, and the possible adaptation of stereoscopic
   instruments.

-941-
Examples of the ways in which high-altitude color transparencies, taken from Gemini flight, can be used in geological interpretation are given. The broad range of red colors, so typical of desert landscapes, is clearly evident. Colors of soils, especially on the pediments and bajadas, are very distinct. Limestones, with few exceptions, do not breed red soils; most of the red comes from volcanic rock soil. Landforms are especially clear in such high-altitude photos. Other structural features are pointed out also.

A rather general discussion based on black-and-white aerial photography. It is pointed out that the characteristics of soil cover are closely related with all components of the landscape, reflecting the specifics of the geologic and geomorphologic structure of the territory, hydrological conditions, migration of chemical compounds, composition of vegetative cover, etc. Examples of interpretation of aerial photographs are given.

Part 1 (p.13-286) includes fairly long reviews of research on the application of aerial photographic interpretation to the investigation of natural resources. These are very informative and the more appropriate areas are cited separately by author. This part of the book could well serve as an introduction to aerial surveys and their applications to the inventory of natural resources as a basis for land use. The emphasis is on standard aerial survey procedures. Extensive bibliographies are appended. Part 2 (p. 289-370) includes shorter reports on various aerial surveys and their application to a variety of land use problems. Part 3 (p. 373-530) includes very brief reports on various aspects of aerial photography and its applications. Part 4 (p. 533-570) is a report on a panel discussion of survey principles.
A complete manual of value not only to the soil surveyor but also to anyone using soil survey maps. Soil surveys have been based on aerial photos since 1930. Unfortunately examples are mostly from humid areas.

32h. *U. S. Department of the Army
*The purpose of this handbook is to provide military image interpreters with current reference material basic to all types of image interpretation. It provides detailed information on various kinds of imagery and their application to interpretation. The value and limitation of various sensors is included together with detailed information on equipment and processes. It is a text of major importance for all technicians seriously interested in remote sensing.

#1967 #Earth photographs from Gemini III, IV, and V.
#Special Publication SP-129. 266 p.
*Gemini IV and V carried Synoptic Terrain Photography and Synoptic Weather Photograph experiments. Gemini IV photographed areas of east Africa, the Arabian Peninsula, Mexico and the southwestern U.S.: Gemini V, selected land and near-shore areas of oceanographic interest. The 2nd photographs include 39 near-vertical views of the Pacific coast of Mexico to central Texas which show such details as contact between Quaternary alluvium and bedrock, fault zones, tectonic provinces in Sonora and sediment distribution in the Colorado River delta, deposition patterns, and some North African sand dunes.

326. *VanLopik, J. R.
*A discussion of what sensors should provide.

327. **
*Topics discussed under infrared imagery are: atmospheric effects, basic physics, infrared sensing systems, and applications. Under the last, the geothermal gradient, internal heat and its conductivity, soil mapping by radiometric temperatures and reflectance levels, and surveys for hydrographic purposes are examined.
328. VanLopik, J.R./Yarbrough, L.A.

   *1969

   "The collection of articles covers a wide range of problems: the use of aerial methods in the tundra, taiga, stepps, and sandy deserts; the possibilities of aerial methods for the study of regional characteristics of landscapes; and the applications of aerial photography for large-scale mapping.

331. Vinogradov, B.V.
   *1958

   "In this area of abundant springs, lenses of underground water occur under depressions. The distribution of vegetation and soils in the 3 main vegetation types occurring in depressions: Sedge-reed, Sedge-willow and meadows are described. The close dependence of soil distribution and vegetation on hydrogeological conditions is stressed.

332. --- ---
   *1966
This excellent report is a complete survey of the application of aerial photography to the analysis of vegetation in arid zones. Techniques for photographing, identifying, analyzing, and interpreting vegetation at all photographic scales from 1:3,000 and larger to 1:50,000 and smaller are discussed. The technique which receives primary emphasis for the photographic interpretation of vegetation over wide areas is the selection of key sites, the preparation of aerial photographic interpretation standards and the extrapolation of these standards from the key sites over the entire area. Almost 400 different plants are mentioned by name, and important ecological plant societies, terrain features, and soils are discussed. Areas covered are primarily within the bounds of the Soviet Union, with some references to Africa and the Near East.

   1966  "The practical application of aerial photography
   for ecological surveys in the savannah regions
   A brief but useful discussion of the use of aerial photo-
   graphy, including when and how to make photos, material to
   use, and interpretation of photos.

3h5. *Williams, F.,C.*
   1950  "Objectives and methods of density measurement
   in sensitometry of color films." *Optical Society
   Density measurements used in the sensitometry of color films
   can be divided into two broad classes: Integral densito-
   metry, which provides a description of the multilayer image
   as a whole in terms of its absorptions; and analytical den-
   sitometry, which gives a description of the image in terms
   of its components by determining their individual density
   values. Terms and units are defined for each class and
   subclass. The field of usefulness and methods of measure-
   ment are briefly discussed.
Satellites can be used in geodetic research in 2 ways. In one the position of the satellite can be determined accurately from 2 tracking stations and the exact position of other tracking stations determined. In the other the height of the satellite can be compared with its expected height, assuming that the Earth were a sphere, and gravitational anomalies can be plotted.

One of the drawbacks of infrared imagery for mapping and areal interpretation has been the "strip" format of the imagery. Through careful planning and execution of infrared surveys, it is possible to assemble uncontrolled infrared imagery mosaics that provide broad areal coverage, resulting in better interpretation and mapping capability.

Results largely negative.

Subject matter outside arid zone, but same principles may apply. Basically space photography provides synoptic overviews of large regions superior to conventional aerial mosaics.

Monthly and seasonal global charts of long wave radiation and albedo are presented for the periods Feb.-June 1962 (Tiros 4) and July 1963-May 1964 (Tiros 7).

In order to assess the value of additive color photography for photo-reconnaissance, the colorvision system was analyzed in terms of its inherent capability for projecting black-and-white, full-color, and color-separation records. Full-color permits increased target detection but shows no apparent increase in detail resolved on simulated panchromatic records.

Orbital remote sensing can provide synoptic environmental data for geoscientists. Color space photographs obtained incident to the Gemini Program provide tools for analyzing sedimentary environments and processes. The principal advantages of orbital geoscience data collection include frequency of coverage leading to environmental analysis within the full spectrum of seasonal contrasts, and opportunities for environmental syntheses by synoptic observations. Gemini space photography is an available source of semi-quantitative data concerning changing environmental phenomena and mechanisms of sediment distribution. It also enables the survey and inventory of global sedimentary landforms.

Thermal infrared (8 to 13 micron) imagery was obtained in the Caliente and Temblor Ranges and Carrizo Plain, southern California, in predawn and post-sunrise hours. Field observations: measurements of moisture and specific gravity of the regolith, and radiation temperatures; and comparison with geologic maps and aerial photographs lead to the following conclusions: (1) The specific gravities of surficial materials (usually not bedrock) influence tonal densities in the pre-dawn imagery. (2) Geologic interpretation of tonal density patterns is complicated by topographic, atmospheric,
and vegetative effects on pre-dawn radiation. (3) Geo-
logic features such as outcrop patterns and some faults
are recognizable in the infrared imagery as well as in
aerial photographs. (4) Local radiative anomalies, pre-
viously suggested to be caused by the occurrence of ground
water at shallow depths may be caused by night-time entrap-
ment of cold air in poorly drained, topographically low
areas.

A comprehensive review has been made of remote sensing publications relating to military geography of arid lands. These have been abstracted or annotated and arranged in tables relating devices and processes to geographic features including terrain, groundwater, surface materials, cultural features, flora, fauna, weather and climate, coastal zones, and general geography. The devices and processes include black and white, color, and infrared photography and devices utilizing longer wave lengths such as radar. Vehicles include conventional airplanes and spacecraft. Each reference is rated as especially useful, useful, or of little value.
