FOREWORD

The work reported herein was done at the request of the Air Force Office of Scientific Research (AFOSR), Air Force Systems Command (AFSC), for Aerospace Research Associates, West Covina, California, under Program Element 6144501F, Project 9781.

The results of tests presented were obtained by ARO, Inc. (a subsidiary of Sverdrup & Parcel and Associates, Inc.), contract operator of the Arnold Engineering Development Center (AEDC), AFSC, Arnold Air Force Station, Tennessee, under Contract F40600-69-C-0001. The test program was conducted from August 20 through 28, 1968, under ARO Project No. VT0864, and the manuscript was submitted for publication on October 16, 1968.

Information in this report is embargoed under the Department of State International Traffic in Arms Regulations. This report may be released to foreign governments by departments or agencies of the U. S. Government subject to approval of the Air Force Office of Scientific Research (SREM), or higher authority within the Department of the Air Force. Private individuals or firms require a Department of State export license.

This technical report has been reviewed and is approved.

ABSTRACT

Tests were conducted in the 40-in. supersonic wind tunnel of the von Kármán Gas Dynamics Facility on a 70-deg-sweep delta wing. A gap between the leading edge and main body was varied from a sealed condition to a nominal 0.030-in. opening for three leading edges of various camber. The aerodynamic characteristics of these configurations were obtained at Mach numbers 1.5, 2.0, and 3.0 at angles of attack from -12 to 12 deg and Reynolds numbers, based on the 10-in. model root chord, from $1.3 \times 10^6$ to $6.0 \times 10^6$. Results are presented showing the variation in lift/drag for various combinations of gap width and leading-edge camber.

SECTION I
INTRODUCTION

Static force tests were conducted in the 40-in. supersonic tunnel (Gas Dynamic Wind Tunnel, Supersonic (A)) of the von Kármán Gas Dynamics Facility (VKF) to investigate the effects of gap width and leading-edge camber on the lift and drag of a delta wing model. The three leading-edge configurations, cambered 0, 7, and 11 deg, were tested with nominal gap widths of 0, 0.010, 0.020, and 0.030 in.

Data were obtained at nominal Mach numbers of 1.5, 2.0, and 3.0 at Reynolds numbers, based on wing root chord, of 1.3 x 10^6 to 6.0 x 10^6. The angle of attack was varied from -12 to 12 deg.

SECTION II
APPARATUS

2.1 WIND TUNNEL

Tunnel A is a continuous, closed-circuit, variable density wind tunnel with an automatically driven flexible plate-type nozzle and a 40- by 40-in. test section. The tunnel can be operated at Mach numbers from 1.5 to 6 at maximum stagnation pressures from 29 to 200 psia, respectively, and stagnation temperatures up to 750°R (M∞ = 6). Minimum operating pressures range from about one-tenth to one-twentieth of the maximum pressures. A description of the tunnel and airflow calibration information may be found in Ref. 1.

2.2 MODEL

The model was a 70-deg-sweep delta wing with a 10-deg included thickness angle (angle between upper and lower surfaces in a longitudinal cross section) and a 10.00-in. centerline chord length. Photographs of the model basic configuration (zero camber leading edge, gap sealed), installed in Tunnel A and of the model with the three leading edges are presented in Figs. 1a and b (Appendix I), respectively. The three leading edges were cambered 0-, 7-, and 11-deg in a plane parallel to the free-stream flow (see Fig. 2). The gap between the main body and the leading edge, w, was measured normal to the centerbody-leading edge junction as shown in Fig. 2.
It should be noted that the gap was not uniform (maximum deviation from nominal value was ±0.010 in.) along the leading edge. An epoxy was used to seal the gap for the sealed gap configurations. Also, the leading edge was thicker than the centerbody at their junction, and a discontinuity (0.006 to 0.025 in.) existed in the model surface contour. A summary of the configurations tested is given in Table I (Appendix II).

2.3 INSTRUMENTATION

Model force measurements were made with a six-component, moment-type, strain-gage balance supplied and calibrated by VKF. Before the tests, loading in a single plane, that is, normal force or axial force only, and combined static loadings, that is, normal and axial force together, were applied to the balance which simulated the range of model loadings anticipated for the test. The range of uncertainties listed below corresponds to the difference between the applied loads and the values calculated with the balance equations used in the final data reduction. The minimum uncertainties are for loadings on the particular component only (i.e., no combined loading effects), and the maximum uncertainties are for combined loading conditions.

</tr>
<tr>
<td>Axial force, lb</td>
<td>50</td>
<td>3 to 15</td>
<td>±0.04 to ±0.05</td>
</tr>
</tbody>
</table>

Model base pressures were measured with 15-psid transducers which were calibrated for ranges of 1, 5, and 15 psia and are considered accurate to within 0.3 percent of full scale of the range being used for measurement. The tunnel sector angle of attack is considered accurate to within ±0.1 deg, and the centerline flow uniformity is within ±0.5 percent in Mach number.

SECTION III
RESULTS AND DISCUSSION

Lift and drag coefficients and the lift-to-drag ratio of the basic configuration are compared with computed theoretical values in Fig. 3. The lift coefficients are compared with conical flow theory (Ref. 2) and conical flow theory including vortex lift (Ref. 3) in Fig. 3a. The vortex lift theory applies only in the case of subsonic leading edges which for this model occurred at Mach numbers 1.5 and 2.0. Conical flow theory predicts the initial slope of the lift curve at all Mach numbers. Inclusion of
vortex lift indicates the trend of the nonlinearity of the lift curve in the subsonic leading edge case but tends to overestimate the magnitude for this configuration.

The drag coefficients are compared in Fig. 3b with calculated values which are the sum of zero angle-of-attack pressure drag (Ref. 2), zero angle-of-attack laminar (Ref. 4) or turbulent (Ref. 5) skin-friction drag, and induced drag (product of $C_L$ and the angle of attack in radians, where $C_L$ is computed from Ref. 2). The experimental values generally fall between the laminar and turbulent curves, indicating that boundary-layer transition occurred on the model at this Reynolds number.

Experimental and estimated lift-to-drag ratios are compared in Fig. 3c. Lift was calculated from conical flow theory (see Fig. 3a), and the drag values are for laminar or turbulent boundary layers (see Fig. 3b). It is considered simply fortuitous that the experimental data at $M_\infty = 1.5$ agree so well with the laminar $L/D$ curve since these data should be closer to the turbulent curve than the data at the higher Mach numbers. As can be readily observed, the theoretical maximum $L/D$ is very sensitive to the condition of the model boundary layer.

Leading-edge camber effects on lift, drag, and lift-to-drag ratios are presented in Fig. 4. The lift (Fig. 4a) and drag (Fig. 4b) decreased with increasing camber in such a manner that the lift-to-drag ratio (Fig. 4c) tended to increase with camber at or above $\alpha$ at $(L/D)_{\text{max}}$.

The change in the maximum lift-to-drag ratio with camber is summarized in Fig. 5. Maximum lift-to-drag ratio increased between 0- and 7-deg camber when the leading edges were subsonic ($M_\infty = 1.5$ and 2.0), then decreased between 7 and 11 deg. The supersonic leading-edge case ($M_\infty = 3.0$) produced a reduction in $(L/D)_{\text{max}}$ with increasing camber. The angle of attack at which the lift-to-drag ratio was a maximum increased with increasing camber angle.

A small decrease in lift and increase in drag were observed for increasing gap width, producing the reduction in the lift-to-drag ratios presented in Fig. 6. Variations in the lift-to-drag ratios as a function of $\alpha$ for two gap widths and a summary of the lift-to-drag ratio versus gap width illustrate this reduction with gap width in Figs. 6a and b, respectively. The angle of attack for maximum lift-to-drag ratio did not vary appreciably with the change in gap width.
