Publication of this report does not constitute Air Force approval of the report's findings or conclusions. It is published only for the exchange and stimulation of ideas.

Arthur W. Banister, Col, USAF
Acting Director for Development
AF Satellite Control Facility
The Trajectory Analysis Program (TAP) is designed specifically for use on the CDC 6000 series machine as a computational tool to generate trajectories by different mathematical formulations and to compare the results. In particular, the reference trajectory is the result of numerical integration of the equations of motion in a Cowell formulation with time as the independent variable; whereas, the comparison trajectory selected is achieved by an analytic (Pines, Kyner, or Escobal) or a numerically integrated Encke (classical or modified) formulation. A comprehensive description is presented of the algorithms implemented in TAP with emphasis on characteristics such as logic flow, equations, numerical techniques, comparison differencing, and plotting. A basic usage guide is included with complete instructions for input data preparation and explanations of output tables.

rate parameter of the line of nodes of the nominal plane
latitude of the vehicle
longitude of the ascending node
argument of perigee or pericenter
SECTION I
INTRODUCTION

A. PURPOSE, SCOPE, AND LIMITATIONS

This document is intended to serve as a technical reference manual and basic usage guide for the Trajectory Analysis Program (TAP). Trajectory generation and comparison, as defined in Section II, are the result of the evaluation of a particular formulation for the equations of motion, which yields the position and velocity components of a vehicle at some desired time, and comparison of that solution with one obtained by another method. The mathematical formulations implemented in TAP consist both of numerical integration methods (Cowell and Encke) and analytic algorithms (Pines, Kyner, and Escobal).

A precision numerical integration scheme used in the Cowell and Encke formulations is described in Appendix A. A comprehensive description of all the methods used in TAP is presented with emphasis placed on key characteristics.

Sections III (Reference Systems and Equations), IV (Cowell and Encke Implementation), V (Program Structure and Logic Flow), and VI (Program Usage) are sufficiently detailed to meet the needs of users concerned with trajectory generation and comparison.

Only the class of elliptical geodetic orbits within a specific inertial reference system is considered; force models allow for the noncentral gravitational effects and a basic atmospheric drag effect. Particular emphasis is placed on the use of the Modified Encke formulation for trajectory computation. The algorithm for the Kyner II nominal trajectory is developed in Appendix B.

B. HISTORICAL BACKGROUND

In recent years, trajectory generation has been performed primarily by numerical integration of the equations of motion in the Cowell formulation by the TRACE Orbit Determination Program (Ref. 1) at Aerospace Corporation.
TAP was developed to analyze different computational methods for trajectory generation, and to provide a tool to establish solution accuracy by means of comparison. The program is written entirely in CDC 6000 series FORTRAN and its flexible design permits the addition of new formulations and accuracy tests of interest.

C. SUMMARY OF KEY FEATURES

By a collection of computational algorithms, TAP generates trajectories and associated quantities, which are then compared and illustrated. The key features of TAP can be identified by the following:

1. Methods of Trajectory Generation considered are the Cowell formulation for the reference solution; and the Encke, Pines, Kyner, or Escobal formulation for the comparison solution.

2. Event Detection During Generation consists of:
   - Ascending and descending nodes
   - Apsides
   - Specified print times
   - Crash radius
   - Integration step-size change

3. Comparison of Orbital Parameters, both directly and indirectly (in the form of differences and root-sum-square), are in three basic coordinate systems: Earth-Centered Inertial (ECI), Classical Elliptic, and Orbit-Plane.

4. Printer Plot of prespecified parameters versus time.

5. Integration Closure results.
SECTION II
TRAJECTORY GENERATION AND COMPARISON

A. THE BASIC PROBLEM

Fundamentally, trajectory generation is a numerical process for obtaining the position and velocity components of the vehicle state vector $S(r, \dot{r}, t)$ at some desired time $t$. A basic problem of trajectory generation is to choose a process that evaluates a given formulation for the state vector by means of a computational algorithm. In the Trajectory Analysis Program, several mathematical formulations of the equations of motion and associated computational algorithms are considered; both numerical integration methods (Cowell and Encke) and analytic algorithms (Pines, Kyner, and Escobal) are implemented.

Trajectory comparison of different processes or methods of trajectory generation is of particular interest. Typically, the state vector and related quantities resulting from one method are compared at some common time $t$ with those of another. Numerical properties are expressed in exact and difference form. To exhibit a comparison, TAP generates a precise numerical integration method as a reference trajectory, which is then differenced at times of interest with a trajectory generated by another method. In addition, a quick-look plotting feature graphically presents the behavior characteristics of specified quantities.

B. TRAJECTORY GENERATION TECHNIQUES

Solution of the equations of motion in TAP can be expressed in analytical form by an algorithm (Pines, Kyner, or Escobal), or it can be obtained in numerical form by special perturbation methods (Cowell or Encke).

In the case of the Cowell and Encke formulations for numerical integration of the equations of motion or deviation, a predictor/corrector (eighth-order differencing) Runge-Kutta/Gauss-Jackson technique is used (see Appendix A), with time as the independent variable.
Analytic methods available in TAP generate the Keplerian or non-Keplerian state vector at some specified time $t$ by the evaluation of closed-form expressions, as follows.

<table>
<thead>
<tr>
<th>Method</th>
<th>Closed-Form Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pines</td>
<td>$F$ &amp; $G$ functions (Keplerian only)</td>
</tr>
<tr>
<td>Kyner I</td>
<td>Classical elements</td>
</tr>
<tr>
<td>Kyner II</td>
<td>$F$ &amp; $G$ functions</td>
</tr>
<tr>
<td>Escobal</td>
<td>Classical elements</td>
</tr>
</tbody>
</table>

In addition, Hermitian interpolation techniques (fifth- and third-degree polynomial schemes) are utilized to obtain trajectory quantities at special events (such as nodes, apsides, and crash radius), and specified print times.

C. TRAJECTORY COMPARISON TECHNIQUES

The state vectors and related quantities at time $t$ are obtained from different methods and compared in the form of differences ($\Delta \equiv$ reference minus comparison). Differences are given in three coordinate systems — Earth-Centered Inertial (ECI), Classical Elliptic, and Orbit-Plane — within which the maximum separation between the two state vectors at time $t$ is expressed as the root-sum-square (rss).

The Cowell formulation has been chosen to generate the reference trajectory in TAP, thereby defining the integration step times as comparison times. The comparison trajectory can be specified as the result of

- Encke formulation - Classical (Keplerian nominal) or Modified (non-Keplerian nominal)
- Analytic algorithm - Pines, Kyner I, Kyner II, or Escobal nominals.

That is, both the reference and the comparison trajectories are generated simultaneously for any trajectory generation case. In particular, the following combinations of methods are available.
Another useful trajectory comparison technique is contrasting integration closure errors obtained from two different methods. Integration closure error is the magnitude of the difference vector between the initial position vector \( \mathbf{r}_0 \) and the resulting position vector \( \mathbf{r}(t = \text{epoch}) \) after integrating forward to some terminal time and then backward to epoch. Thus

\[
\Delta_{\text{CLOSURE}} = |\mathbf{r}_0 - \mathbf{r}(t = \text{epoch})|.
\]
SECTION III
REFERENCE SYSTEMS AND EQUATIONS

The symbols used throughout this report follow, after which the basic reference systems and equations used in TAP are defined and discussed.

A. SYMBOLS (NOTATION)
   
   . time differentiation and vector dot product operation
   . time differentiation
   _ a vector; for example, \( \mathbf{r} \) is the vehicle position vector
   ( ) relates to a functional relationship, such as \( S(\mathbf{r}, \dot{\mathbf{r}}) \) the vehicle state vector, which is a function of \( \mathbf{r} \) and \( \dot{\mathbf{r}} \), or \( S(a, e, i, \Omega, \omega, M) \), the state vector expressed in terms of elliptical elements.
   Also, used to denote row vectors; for example, \( \mathbf{r} = (x, y, z) \)
   \( \Delta \) increment or difference
   \( \times \) vector cross product operation
   \( \| \) absolute value, or vector magnitude operation; for example, \( r = \| \mathbf{r} \| \)
   \( \nabla \) vector gradient operator
   \{ \} a matrix, or a set of elements
   \( I[ ] \) the integer operator of a scalar
   [ ] a matrix; for example,

   \[ \mathbf{r} = [x, y, z] \text{ (row vector), or } \mathbf{r} = \begin{bmatrix} x \\ y \\ z \end{bmatrix} \text{ (column vector)} \]

   \[
   I = \begin{bmatrix}
   1 & 0 & 0 \\
   0 & 1 & 0 \\
   0 & 0 & 1
   \end{bmatrix}
   \]

   \( I \) 3 x 3 identity matrix

   \( A = [A] 6 \times 6 \) matrix or array of trajectory quantities.

-7-
Superscripts

- \( c \) computed or simulated value
- \( i \) particular index relative to a set or vector
- \( T \) matrix transpose symbol
- \( * \) particular value of a predetermined constant

Subscripts

- \( C \) comparison solution or value
- \( e \) the earth
- \( g \) the Greenwich meridian
- \( i, j, k, l \) particular index denoting members of a set or components of a vector. In general, \( i, j, k, l = 1, 2, \ldots \)
- \( n \) nominal value
- \( a \) a transformation that is a function of \( a \)
- \( \gamma \) differentiation of a vector with respect to the parameter \( \gamma \)
- \( \phi \) a transformation that is a function of \( \phi \)
- \( o \) initial value or reference point

B. REFERENCE SYSTEMS

Trajectory generation and comparison involve coordinate transformations and require selection of the proper reference systems for evaluation and analysis. Several such systems are used in TAP. Basic to all is the earth-centered inertial (ECI) system, which has as its fundamental plane the true equator at epoch; its principal axis is the mean equinox at midnight of the date of epoch. This reference system does not take into account precession and nutation effects.

1. EARTH-CENTERED INERTIAL SYSTEM (ECI)

Inertial position, velocity, and acceleration vectors are oriented in the reference system illustrated in Figure 1.

The position and velocity components of a vehicle's state vector within this reference system may also be expressed in terms of the classical elliptic and orbit-plane systems.
radius vector \( (x, y, z) \)

velocity vector \( (\dot{x}, \dot{y}, \dot{z}) \)

direction of the vernal equinox \( T \) in the equator plane

position component in the \( x \) direction

velocity component in the \( x \) direction (relative to \( O \))

right-hand axis to \( X \) and \( Z \)

position component in the \( y \) direction

velocity component in the \( y \) direction (relative to \( O \))

direction north perpendicular to the equator plane

position component in the \( z \) direction

velocity component in the \( z \) direction (relative to \( O \))

origin, which coincides with the center of the earth

Figure 1. Earth-Centered Inertial Reference System
2. CLASSICAL ELLIPTIC SYSTEM

The state vector in the classical elliptic system (Fig. 2) is given at

time $t$ by

$$S = S(a, e, i, \Omega, \omega, M)$$

**Figure 2. Classical Elliptic Reference Frame**
3. ORBIT-PLANE SYSTEM

The state vector in the orbit-plane system (Fig. 3) is given at time $t$ by

$$S = S(R, T, C, R', T', C)$$

Figure 3. Orbit-Plane Coordinate System

In this instance the point $P$, position of the vehicle in the ECI system, represents the origin of the orbit-plane system defined by the vectors $\hat{z}$, $\hat{r}$, $\hat{l}$, which are referred to as the radial, in-track, and cross-track directions, respectively. In the smaller sketch, it should be noted that the $\hat{z}$ axis is an extension of the geocentric radius vector. The $\hat{r}$ axis is both normal to the $\hat{z}$ axis and positive in the same general direction as the inertial velocity vector $\hat{r}$. Both lie in the instantaneous orbit plane. The $\hat{l}$ axis is normal to the orbit plane (defined by $\hat{z}$ and $\hat{r}$) and thus forms a right-hand orthogonal system.
The position and velocity of an alternate point \(Q\) relative to point \(P\) are then given by

\[ Q = Q(R, T, C, R', T', C') \]

where

- \(R\) = position component in the \(\hat{r}\) direction
- \(T\) = position component in the \(\hat{T}\) direction
- \(C\) = position component in the \(\hat{C}\) direction
- \(R'\) = velocity component in the \(\hat{r}\) direction
- \(T'\) = velocity component in the \(\hat{T}\) direction
- \(C'\) = velocity component in the \(\hat{C}\) direction

C. TRANSFORMATION EQUATIONS

The transformation of the state vector to the other systems involves the following equations.

1. FROM ECI TO THE CLASSICAL ELLIPTIC SYSTEM

To obtain the classical elements from ECI coordinates, the following equations are solved.

\[
\frac{1}{a} = \frac{2}{r} - \frac{V^2}{\mu} \\
\]

\[
r = |r| \\
V^2 = \hat{r} \cdot \hat{r} \\
C_e = 1 - \frac{r}{a} \\
S_e = \frac{\hat{r}}{aE} = \frac{r}{a} \frac{1}{(\mu a)^{1/2}}
\]
\[
\begin{align*}
    \dot{r} &= (\mathbf{r} \cdot \dot{\hat{r}})/r \\
    \dot{E} &= (1/r)(\mu/a)^{1/2} \\
    e^2 &= S_e^2 + C_e^2 \\
    U &= \{r/r\} \\
    W &= |(\mathbf{r} \times \dot{\hat{r}})/(\dot{\mathbf{r}} \times \hat{\mathbf{r}})| \\
    V &= W \times U \\
    \sin i &= \left(\frac{U_x^2 + V_z^2}{2}\right)^{1/2} \\
    \cos i &= \left[\left(U_x^2 + V_y^2\right) + (U_y - V_x)^2\right]^{1/2} - 1 \\
    \sin u &= U_z / \sin i \\
    \cos u &= V_z / \sin i \\
    \sin \iota &= (U_y - V_x)/(1 + \cos i) \\
    \cos \iota &= (U_x - V_y)/(1 + \cos i) \\
    \Omega &= \iota - u \\
    C_v &= p/r - 1 \\
    S_v &= r(p/\mu)^{1/2} \\
    p &= a(1 - e^2) \\
    \cos v &= C_v/e \\
    \sin v &= S_v/e \\
    \omega &= u - v \\
    M &= E - e \sin E
\end{align*}
\]
2. FROM ECI TO THE ORBIT-PLANE SYSTEM

The orbit-plane system is defined, given \( \mathbf{r}, \mathbf{\dot{r}}, \) ECI vectors, by the unit vectors:

\[
\hat{\mathbf{r}} = \frac{\mathbf{r}}{r} \\
\hat{\mathbf{\dot{r}}} = \frac{(\mathbf{r} \times \mathbf{\dot{r}}) / |\mathbf{r} \times \mathbf{\dot{r}}|}{r} \\
\hat{\mathbf{n}} = \hat{\mathbf{\dot{r}}} \times \hat{\mathbf{r}}
\]

Any ECI vector can be expressed in the orbit-plane system (RTC) by the following dot products (where \( \mathbf{q} \) and \( \dot{\mathbf{q}} \) are arbitrary ECI position and velocity vectors):

\[
R = \mathbf{q} \cdot \hat{\mathbf{r}} \\
T = \mathbf{q} \cdot \hat{\mathbf{n}} \\
C = \mathbf{q} \cdot \hat{\mathbf{\dot{r}}} \\
R' = \dot{\mathbf{q}} \cdot \hat{\mathbf{r}} \\
T' = \dot{\mathbf{q}} \cdot \hat{\mathbf{n}} \\
C' = \dot{\mathbf{q}} \cdot \hat{\mathbf{\dot{r}}}
\]

D. TRAJECTORY GENERATION EQUATIONS

Several sets of trajectory generation equations are used in TAP to compute the vehicle state vector \( S(\mathbf{r}, \mathbf{\dot{r}}, \mathbf{\ddot{r}}) \) at some base time \( t \). The mathematical formulations of these sets are now described.

1. COWELL FORMULATION

The direct numerical integration of the following vector equation of motion is referred to as the Cowell method:

\[
\mathbf{\ddot{r}} = -\mu \frac{\mathbf{r}}{r^3} + \sum \mathbf{\ddot{r}}_i \quad (i = 1, 2)
\]
where

\[ \vec{r} = [x, y, z] \]
\[ r = |\vec{r}| \]
\[ \Sigma \ddot{x}_i = \ddot{x}_1 + \ddot{x}_2 \]
\[ \ddot{x}_1 = \text{noncentral gravitation} \]
\[ \ddot{x}_2 = \text{atmospheric drag} \]

2. **ENCKE FORMULATION**

The numerical integration of the following deviation-vector equation, which relates the departure of the actual from some nominal position, is referred to as the Encke method:

\[ \ddot{\vec{r}} = \ddot{\vec{r}} - \ddot{\vec{x}}_n \]

\[ = -\mu \frac{\vec{r}}{r^3} - \frac{\vec{r}_n}{r_n^3} - L + \sum \ddot{x}_i \quad (i = 1, 2) \]

where

\[ \vec{p} = \vec{r} - \vec{x}_n \]
\[ \vec{x}_n = [x_n, y_n, z_n] \]

\[ L = \text{additive secular acceleration vector that accounts for the consideration of a non-two-body reference orbit.} \]

The nominal trajectory \( \vec{x}_n \) is the solution of

\[ \ddot{x}_n = -\mu \frac{x_n}{r_n^3} + L \]

If \( L = 0 \), then the classical Encke solution results.
The $\mu$-term in the above equation can now be manipulated into the O. K. Smith computational form (Ref. 2)

$$ -\mu \left[ \frac{r_n}{r^3} - \frac{r_n^3}{r^3} \right] = \frac{\mu}{r_n^3} \left\{ \frac{r_n^2}{r^2} \left[ 1 + \frac{\delta^2}{4 + \delta^2} \right] \left[ (r_n + r) \cdot \frac{p}{r} \right] - \rho \right\} $$

where $\delta = r_n / r$. Note that only time is expressed as the independent variable in this deviation-vector and that no prespecified rectification criterion or procedure is considered.

3. ANALYTIC ALGORITHMS

Analytic algorithms give rise to closed form solutions for the nominal equation of motion $\ddot{r}_n = -\mu r_n/r^3 + L$. The three analytic methods of Pines, Kyner, and Escobal are of interest here.

2. Pines Method

Closed-form expressions for the $F$ & $G$ functions are utilized in the Pines method (Ref. 3) to evaluate the Keplerian state vector $S(r_n, \dot{r}_n, \ddot{r}_n)$ at some specified time $t$, given the initial state vector $S_o(r_o, \dot{r}_o, \ddot{r}_o)$ at initial time (epoch) $t_o$. The method can be summarized by the set of equations

$$ \dot{r}_n = f(t, r_o, \dot{r}_o, \ddot{r}_o) \cdot \dot{r}_o + g(t, r_o, \dot{r}_o, \ddot{r}_o) \cdot \ddot{r}_o $$

$$ \dot{\dot{r}}_n = \dddot{f}(t, r_o, \dot{r}_o, \ddot{r}_o) \cdot \dot{r}_o + \dddot{g}(t, r_o, \dot{r}_o, \ddot{r}_o) \cdot \ddot{r}_o $$

$$ \dddot{r}_n = -\frac{\mu r_n}{r_n^3} $$

with scalar functions

$$ f = (a/r_o)(\cos \theta - 1) + 1 $$

$$ g = t - [(\theta - \sin \theta)/n] = [\sin \theta - (\theta - M)]/n $$

-16-
\[ i = -\left(\frac{a^2}{\mu r_o}\right) \sin \theta \]
\[ \dot{g} = (a/r)(\cos \theta - 1) + 1 \]

and Kepler's equation relating the time \( t \) to the angular variable given by

\[ M = nt = \theta - \sin \theta \left(1 - \frac{r_o}{a}\right) - (\cos \theta - 1) \frac{r_o}{n_o} \cdot \frac{\dot{r}_o}{a^2} \]

where

\[ a^{-1} = \frac{2}{r_o} - \frac{V_o^2}{\mu} \]
\[ n = \frac{\mu^{1/2}}{a^{-3/2}} \]
\[ r_o = \left(\frac{r_o \cdot \dot{r}_o}{n_o}\right)^{1/2} \]
\[ V_o = \left(\frac{r_o \cdot \ddot{r}_o}{n_o}\right)^{1/2} \]

b. Kyner Method

The Kyner method (Ref. 4) evaluates a non-Keplerian state vector \( S(\tau_n, \dot{\tau}_n, \ddot{\tau}_n) \), which includes the first-order secular effects of the earth's oblateness. This technique utilizes the three rate parameters \( (\eta, \tau, \gamma) \), in the formulation of nominal \( \dot{\tau}_n \), where

\( \eta \) is the rotation rate of the major axis of the nominal ellipse

\( \tau \) is the rotation rate of the line of nodes of the nominal plane

\( \gamma \) is defined in terms of the nominal anomalistic mean motion

\[ \bar{n} = n_0 (1 - \gamma) \], where \( n_0 \) is the mean motion at epoch.
(1) Kyner Formulation I (KYNER 1)

The first formulation (Ref. 4) of the nominal \( \mathbf{r}_n \) is given by the vector equation

\[
\mathbf{r}_n = [R(\Omega, i, u)] \mathbf{r}_0
\]

that satisfies the differential equation \( \mathbf{r}_n = -\mu \mathbf{r}_n / r_n^3 + \mathbf{L} \) where

\[
\Omega = \tau (f-f_0) + \Omega_0 \quad \text{(longitude of the ascending node)}
\]

\[
i = i_0 \quad \text{(inclination)}
\]

\[
u = f + \omega \quad \text{(argument of latitude)}
\]

\[
\omega = \eta (f-f_0) + \omega_0 \quad \text{(argument of perigee)}
\]

\[
r_n = a_0 (1-e_0^2)/(1+e_0 \cos f) \quad \text{(length of } \mathbf{r}_n \text{)}
\]

where

\[
a = a_0 \quad \text{(semi-major axis)}
\]

\[
e = e_0 \quad \text{(eccentricity)}
\]

and the nominal true anomaly \( f \) is given as a function of time by the modified Kepler equation

\[
r_n (1-\gamma)t + M_0 = E - e_0 \sin E.
\]

-18-
Note that

\[ \tan(f/2) = \left[ \frac{1 + e}{1 - e} \right]^{1/2} \tan(E/2) \]

\[ M_o = \text{initial value of the mean anomaly} \]

\[ n_o^2 = \frac{3}{a_o^3} = \mu \]

rotation matrix \([R] = [D(\Omega)][C(\iota)][B(\omega)]\)

Thus the nominal trajectory \(r_n(t)\) depends on nine parameters, which are

- The six values \(a_o, e_o, i_o, \Omega_o, \omega_o, M_o\)
- The three arbitrary rate parameters \(\eta, \tau, \gamma\)

If the rate parameters are set equal to zero (that is, if \(L = 0\)), then the resultant nominal \(r_n\) is Keplerian.

(2) Kyner Formulation II (KYNER 2)

The second formulation [Ref. 5] of the nominal \(r_n\) is given by the vector equation

\[ r_n = F M + G N \]

where

- \(F, G = \text{Keplerian scalar functions}\)
- \(M, N = \text{Rotating vectors that are always in nominal orbital plane and maintain constant angles with the precessing line of apses of the nominal ellipse}\)
In detail, these scalar functions are described as

\[ F = \frac{1}{r_0} (r_n \cos \varphi) - \left( \frac{\dot{r}}{h} \right)_0 r_n \sin \varphi \]
\[ G = \left( \frac{r}{h} \right)_0 r_n \sin \varphi \]

where

\[ \varphi = f - f_0 \]
\[ h_0 = \left| \mathbf{r}_0 \times \dot{\mathbf{r}}_0 \right| \]

and the rotating vectors as

\[ M = \mathbf{r}_0 + [A] \mathbf{r}_0 \]
\[ N = \dot{\mathbf{r}}_0 + [A] \dot{\mathbf{r}}_0 \]

The matrix \([A]\) can be represented as a sum of constant matrices \([A_j]\) (evaluated at epoch) whose scalar coefficients are slowly varying functions of \(\varphi\) and the rate parameters \(\eta, \tau, \gamma\). That is

\[ [A] = [A(\varphi, \eta, \tau, \gamma, \Omega_0, \dot{i}_0, \dot{u}_0)] \]

\[ [A] = \sum_{j=1}^{6} a_j(\varphi) [A_j] \]
In summation, the state vector $S_t(\mathbf{x}_n, \mathbf{\dot{x}}_n, \mathbf{\ddot{x}}_n)$ is expressed as

$$\mathbf{x}_n = F[I+\mathbf{A}]\mathbf{x}_0 + G[I+\mathbf{A}]\mathbf{\dot{x}}_0$$

$$\mathbf{\dot{x}}_n = [F[I+\mathbf{A}] + F[I+\mathbf{A}] + \dot{\mathbf{g}}[I+\mathbf{A}] + \dot{\mathbf{g}}[\mathbf{A}]]\mathbf{x}_0$$

$$\mathbf{\ddot{x}}_n = -\mu\mathbf{x}_n/r^3 + \mathbf{L}$$

where

$$\mathbf{L} = (1 - (1 - \gamma)^2)\frac{\mu r_3}{r^3} + (\mathbf{F}(\mathbf{A})\mathbf{x}_0 + (\mathbf{G}(\mathbf{A})\mathbf{\dot{x}}_0$$

$$(\mathbf{p}, \mathbf{q}) = 2(\frac{\partial \mathbf{p}}{\partial t}) + (\frac{\partial \mathbf{q}}{\partial t}) + p(\frac{\partial^2 \mathbf{q}}{\partial t^2})$$ (differential operator)

where $\mathbf{p}$ and $\mathbf{q}$ are the arguments of the operator.

c. Escobal Method

As in the Kynan method, the Escobal method (Ref. 6) evaluates a non-Keplerian state vector $S(\mathbf{x}_n, \mathbf{\dot{x}}_n, \mathbf{\ddot{x}}_n)$, which includes the first-order secular effects of the earth's oblateness. This technique utilizes the secular rates of change in the three elements

$$\dot{\Omega} = -\frac{3}{2} \frac{J_2}{P_o} \frac{n}{k} \cos i_0$$

$$\dot{\omega} = \frac{3}{2} \frac{J_2}{P_o} \left(2 - \frac{5}{2} \sin^2 i_0\right) \frac{n}{k}$$

$$\dot{\nu} = n_o (1 - \gamma)$$
where

\[
\gamma = -\frac{3}{2} J_2 \left( \frac{a}{a_o} \right)^2 \left( \frac{a}{r} \right)^3 (1 - 3 \sin^2 i_o \sin^2 u_o) \tag{1}
\]

\( J_2 \) = second harmonic coefficient

\( p_o \) = semi-parameter of the orbit at epoch

\( i_o \) = inclination of the orbit epoch

\( k \) = Gaussian or planetary constant

\( n_o = k[n]^{1/2} a_o^{-3/2} \) (mean motion at epoch)

\( \mu \) = sum of celestial-object mass and central mass

\( a_e \) = semi-diameter of the central mass

\( a_o \) = semi-major axis of the orbit at epoch

\( r_o \) = radius of object at epoch

\( u_o = f_o + \omega_o \) (argument of latitude at epoch)

\( \omega_o \) = argument of pericenter at epoch

\( f_o \) = true anomaly at epoch

Note that the formula for \( \gamma \) is not the one given in Reference 6. To insure that the rate parameter \( \gamma \) for mean motion is consistent with the first-order secular effects for \( \Omega \) and \( \omega \) at perigee, the secular effect for the anomalistic mean motion should be used; that is, the approximation of the Cunningham integral given in Eq. (1) above.
The state vector $S(\mathbf{x}_n, \dot{\mathbf{x}}_n, \ddot{\mathbf{x}}_n)$ can be expressed as

$$\mathbf{x}_n = x_\omega \mathbf{P} + y_\omega \mathbf{Q}$$

$$\dot{\mathbf{x}}_n = \left(\frac{d}{dt}\right) \{\mathbf{x}_n\} = \tau = k(t - t_0)$$

$$= k [x_\omega \mathbf{P} + y_\omega \mathbf{Q} + x_\omega \dot{\mathbf{P}} + y_\omega \dot{\mathbf{Q}}]$$

$$\ddot{\mathbf{x}}_n = \left(\frac{d}{dt}\right)^2 \{\mathbf{x}_n\}$$

$$= k^2 [x_\omega \ddot{\mathbf{P}} + 2 x_\omega \dot{\mathbf{P}} + \dot{x}_\omega \mathbf{P} + y_\omega \ddot{\mathbf{Q}} + 2 \dot{y}_\omega \dot{\mathbf{Q}} + \ddot{y}_\omega \mathbf{Q}]$$

where the unit vectors

$$\mathbf{P} = \mathbf{P}(\omega, \Omega, i)$$

$$\mathbf{Q} = \mathbf{Q}(\omega, \Omega, i)$$

$$\mathbf{W} = \mathbf{W}(\omega, \Omega, i)$$

with

$$\begin{bmatrix} \mathbf{P} \\ \mathbf{Q} \\ \mathbf{W} \end{bmatrix} = \begin{bmatrix} \cos \omega & \sin \omega & 0 \\ -\sin \omega & \cos \omega & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos i & \sin i \\ 0 & -\sin i & \cos i \end{bmatrix} x$$
\[
\begin{bmatrix}
\cos \Omega & \sin \Omega & 0 \\
-sin \Omega & \cos \Omega & 0 \\
0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
I \\
J \\
K
\end{bmatrix}
\]

\[I = [1, 0, 0] \]
\[J = [0, 1, 0] \]
\[K = [0, 0, 1] \]

\[
\Omega = \Omega_o + \dot{\Omega} \tau \\
\omega = \omega_o + \dot{\omega} \tau \\
n = \overline{n}
\]

and

\[
x_\omega = a_o (\cos E - e_o) \\
y_\omega = a_o (1 - e^2)^{1/2} \sin E \\
\overline{nt} + M_o = E - e_o \sin E \quad \text{(Kepler's equation)}.
\]
E. MISCELLANEOUS EQUATIONS

Following are equations for specific trajectory quantities.

Angular Momentum, $h$

$$h = \left| \mathbf{r} \times \dot{\mathbf{r}} \right|$$

Root-Sum-Square, rss

$$rss = (R^2 + T^2 + C^2)^{1/2}$$

where

- $R = \Delta r \cdot \hat{r}$
- $T = \Delta r \cdot \hat{T}$
- $C = \Delta r \cdot \hat{C}$
- $\Delta \mathbf{r} = \mathbf{r} - \mathbf{r}_c$

Keplerian Period, $P_k$

$$P_k = \frac{2\pi a^{3/2}}{\mu^{1/2}}$$

Kinetic Energy, K.E.

$$K.E. = \frac{v^2}{2} = \frac{\dot{r} \cdot \dot{r}}{2}$$

-25-
Potential Energy, P.E. (J₂ Only)

P.E. = - (\mu/r) \left[ 1 + (a_e^2 J_2/2r^2)(1 - 3 \sin^2 \delta) \right]

where

\sin^2 \delta = z^2/r^2

Total Energy, T.E.

T.E. = K.E. + P.E.

Gravitational Acceleration Due to the Noncentral Force Field of the Earth, \ddot{r}_1 (J₂ Effect Only)

\ddot{r}_1 = \frac{a_e^2}{r^3} J_2 \mu \left[ \frac{3}{2} \frac{r}{r^2} (-1 + \frac{3z^2}{r^2}) - \frac{r^*}{r^4} \right]

where

a_e = 1 earth radius

\begin{align*}
\vec{r}^* &= -\frac{3z}{r^4} \\
\begin{bmatrix}
xz^2 \\
yz^2 \\
-r^2 z (1 - \frac{z^2}{r^2})
\end{bmatrix}
\end{align*}
Noncentral Earth Gravitational Force, $\vec{a}_1$

The gravitational acceleration $\vec{a}_1$ due to the noncentral force field of the earth is derived from the generalized potential function

$$U = \frac{1}{r^2} \sum_{n=2}^{\infty} \left( \frac{a_e}{r} \right)^n \sum_{m=0}^{n} P_{nm}^m (\sin \varphi) \left( C_{nm} \cos m \lambda + S_{nm} \sin m \lambda \right)$$

where

$r, \varphi, \lambda$ are the geocentric distance, latitude, and East longitude of the vehicle

$a_e$ is the mean equatorial radius of the earth

$P_{nm}^m$ is the Legendre associated function of the first kind of degree $n$ and order $m$

$C_{nm}, S_{nm}$ are numerical coefficients.

Components of the acceleration vector $\vec{a}_1$ are expressed as

$$\vec{a}_1 = \begin{bmatrix} \vec{a}_{1x} \\ \vec{a}_{1y} \\ \vec{a}_{1z} \end{bmatrix} = T_{\varphi, \lambda} \begin{bmatrix} G_{Up} \\ G_{East} \\ G_{North} \end{bmatrix} = T_{\varphi, \lambda} \begin{bmatrix} G_{U} \\ G_{E} \\ G_{N} \end{bmatrix}$$
where

\[ T, \varphi, \lambda \] is the earth-fixed local horizontal system

\[ \text{transformation matrix} \]

\[ GLH \] is the gravitational acceleration due to the noncentral force field of the earth in the local horizontal system, in which the coordinate axes are directed Up (along the position vector), East, and North.

Note that

\[ GLH = \begin{bmatrix} G_{Up} \\ G_{East} \\ G_{North} \end{bmatrix} \]

so that

\[ G_{Up} = \frac{\partial U}{\partial r} = \sum_{n=2}^{\infty} K_n^1 (\varphi, \lambda) \]

\[ G_{East} = (1/r \cos \varphi)(\partial U/\partial \lambda) = \sum_{n=2}^{\infty} K_n^2 (\varphi, \lambda) \]

and

\[ G_{North} = (1/r)(\partial U/\partial \varphi) = \sum_{n=2}^{\infty} K_n^3 (\varphi, \lambda) \]

where

\[ K_n^1 (\varphi, \lambda) = - (\mu/r^2)(n+1)(a_e/r)^n \sum_{m=0}^{n} P_n^m (\sin \varphi) \left[ C_{nm} \cos m \lambda + S_{nm} \sin m \lambda \right] \]
\[ K_n^2 (\varphi, \lambda) = (\mu/r^2 \cos \varphi) (a_e/r)^n \sum_{m=0}^{n} m P_n^m (\sin \varphi) \left[ C_{nm} \sin m \lambda - S_{nm} \cos m \lambda \right] \]

\[ K_n^3 (\varphi, \lambda) = (\mu/r^2) (a_e/r)^n \sum_{m=0}^{n} \frac{P_n^{m'}}{(2m+1)} P_n^m (\sin \varphi) \cos \varphi \left[ C_{nm} \cos m \lambda + S_{nm} \sin m \lambda \right] \]

\( P_n^{m'} \) is the derivative of the Legendre function with respect to \( \sin \varphi \).

Two different optional normalizations of the Legendre functions are used. The alternate values for \( C_{nm} \) and \( S_{nm} \) coefficients (Ref. 7) are denoted by

\[ \overline{C}_{nm}, \overline{S}_{nm} \quad (APL \ \text{normalization}) \]

and

\[ \overline{\overline{C}}_{nm}, \overline{\overline{S}}_{nm} \quad (Kaula \ \text{normalization}) \]

where

\[ (\overline{C}_{nm}, \overline{S}_{nm}) = \left[ (n+m)!/(n-m)! \right]^{1/2} (C_{nm}, S_{nm}) \]

and

\[ (\overline{\overline{C}}_{nm}, \overline{\overline{S}}_{nm}) = \left[ (2n-1)(2-6m) \right]^{-1/2} (\overline{C}_{nm}, \overline{S}_{nm}) \]

with \( \delta_{ij} \) being the Kronecker delta function.
Atmospheric Drag Acceleration, $\ddot{r}_A$

$$\ddot{r}_A = -\rho(V_A/2)(C_D A/W) \dot{r}_A$$

where

$\rho$ = the density at height $h$ above an oblate earth (the only atmosphere model considered is the Lockheed-Jacchia)

$C_D A/W$ = the drag coefficient

$\dot{r}_A$ = vehicle velocity vector relative to a rotating atmosphere

$$\dot{r}_A = [\dot{x}_A, \dot{y}_A, \dot{z}_A]$$

$V_A = |\dot{r}_A|$

where

$\dot{x}_A = \ddot{x} + \omega_a y$

$\dot{y}_A = \ddot{y} - \omega_a x$

$\dot{z}_A = \ddot{z}$

$\omega_a$ = rotation rate of the atmosphere.
**Apsis Event Detection (between times \( t_i \) and \( t_{i-1} \))**

If \( \cos \beta_i \cdot \cos \beta_{i-1} > 0 \), there is no event. Otherwise, an event has occurred and

\[
\frac{\partial \cos \beta_i}{\partial t} = \frac{\mathbf{v}_i}{v_i^2} \cdot \mathbf{w}_i + \frac{\mathbf{v}_{i-1}}{v_{i-1}^2} \cdot \mathbf{w}_{i-1} \quad \text{for all } i.
\]

Since \( \cos \beta \) is a smooth monotonic function of \( t \) and \( \cos \beta \) is near zero, then

\[
\frac{\partial t}{\partial \cos \beta_i} = \left( \frac{\partial \cos \beta_i}{\partial t} \right)^{-1}
\]

and allows interpolation for the time \( t \) for which \( \cos \beta = 0 \), given

\[
\cos \beta_i, \cos \beta_{i-1}, t_i, t_{i-1},
\]

\[
\frac{\partial t}{\partial \cos \beta_i}, \frac{\partial t}{\partial \cos \beta_{i-1}}
\]

After \( t_{\cos \beta=0} \) is obtained, interpolation for the state vector yields

\[
S(\mathbf{x}, \mathbf{z}; t_{\cos \beta=0})
\]

given \( t_i, t_{i-1}, \mathbf{x}_i, \mathbf{x}_{i-1}, \mathbf{z}_i, \mathbf{z}_{i-1}, \mathbf{w}_i, \mathbf{w}_{i-1} \).

**Node Event Detection**

If \( z_i \cdot z_{i-1} \geq 0 \), there is no event; otherwise, an event has occurred.

Then assume that

\[
\frac{\partial t_i}{\partial z_i} = \left( \frac{\partial z_i}{\partial t_i} \right)^{-1}
\]
and interpolate for the time at which \( z = 0 \). After \( t_{z=0} \) is obtained, interpolation for the state vector yields

\[ S(x, \dot{x}; t_{z=0}). \]
SECTION IV
Cowell and Encke Implementation

Table I indicates the sequence of steps necessary to implement Cowell and Encke formulations.

### Table I. Schematic for Implementing Cowell and Encke Formulations

<table>
<thead>

C. PLOTTING FEATURES

Printer plots are given for prespecified orbital parameters versus time. The parameters considered are:

- **RSS** Root-sum-square of difference between Reference and Comparison
- **ENERGY** Difference in total energy \( TE = KE + PE \) between Reference and Comparison
- \( \xi(XI) \) Radial component of difference between Reference and Comparison
- \( \eta \) In-track component of difference between Reference and Comparison
- **\( r(R) \)** Radius of Reference
- **\( a(R) \)** Semimajor axis of Reference
- **\( e(R) \)** Eccentricity of Reference
- **\( i(R) \)** Inclination of Reference
- **\( \Omega(R) \)** Right ascension of the ascending mode of Reference
- **\( \omega(R) \)** Argument of perigee of Reference
- **\( M(R) \)** Mean anomaly of Reference
- **\( TE(R) \)** Total energy of Reference
- **\( h_z(R) \)** Polar component of angular momentum of Reference
- **\( r(C) \)** Radius of Comparison
- **\( a(C) \)** Semimajor axis of Comparison
- **\( e(C) \)** Eccentricity of Comparison
- **\( i(C) \)** Inclination of Comparison
- **\( \Omega(C) \)** Right ascension of the ascending mode of Comparison
- **\( \omega(C) \)** Argument of perigee of Comparison
- **\( M(C) \)** Mean anomaly of Comparison
- **\( TE(C) \)** Total energy of Comparison
- **\( h_z(C) \)** Polar component of angular momentum of Comparison
- **\( KE(C) \)** Kinetic energy of Comparison

Examples of a subset of these printer plots are given in Figures 5 through 8.

APPENDIX A
NUMERICAL ACCURACY OF THE DEQ NUMERICAL INTEGRATOR

1. INTRODUCTION

In recent months, much experience has been gained at the Aerospace Mathematics and Computation Center with a particular numerical integrator (Ref. 8), referred to as DEQ and used principally for trajectory generation. Developed and written by James F. Holt of Aerospace, it is designed to numerically integrate a set of N simultaneous 2nd-order ordinary differential equations. A fourth-order Runge-Kutta method is used for its starting procedure and a Gauss-Jackson method (with eighth-order differences) is used for normal integration. Additional techniques allow a variable-step mode (halving and doubling) with automatic local truncation-error controls.

In trajectory generation, DEQ is used to integrate the equations of motion expressed in a Cowell and/or Encke formulation. The numerical accuracy of this integrator for typical geodetic orbits is of primary interest here. To investigate the solution accuracy, direct comparisons were made with known analytic solutions and integration closure tests were performed with augmented force models.

2. BASIC MODEL

A Cowell formulation of the equations of motion in vector form was used for testing where the total acceleration vector acting on a vehicle was represented as the sum of a primary gravitational term and total perturbative term. Table A-1 shows such a vector in an ECI coordinate system.
Table A-1. Cowell Integration Method

Problem: Numerically integrate second-order ordinary differential equations of the form

\[ \ddot{\mathbf{r}} = -\frac{\mu \mathbf{r}}{|\mathbf{r}|^3} + \sum_{i=1}^{N} \ddot{\mathbf{r}}^*_i \]

where

- \( \mathbf{r} \) = Position vector
- \( \mu \) = Newtonian Gravitational Constant
- \( \sum_{i=1}^{N} \ddot{\mathbf{r}}^*_i \) = Acceleration vector resulting from perturbing forces

Solution: DEQ = Floating-point Cowell (second sum) Runge-Kutta integration of second-order equations
- 4th-order Runge-Kutta method to start and halve the step-size during the integration
- Cowell "second-sum" (Gauss-Jackson) method based on 8th differences to continue the integration.

a. NUMERICAL ACCURACY

All numerical results presented here are as of 12 June 1967.

An example of the numerical accuracy of this integrator on three different computers - IBM 7094, CDC 3600, and CDC 6600 - is given in Figure A-1. Note the following respective word lengths (DP = double precision):

<table>
<thead>
<tr>
<th>Machine</th>

</tr>
<tr>
<td>CDC 6600</td>
<td>60 bits</td>
<td>14</td>
</tr>
</tbody>
</table>
Figure A.1. Accuracy of Numerical Integration
(Analytic Solution, Keplerian Model)
The root-sum-square (rss of the error) is the difference obtained from comparing a known analytic solution at each integration step and is plotted vs time by using a log-log scale. Note that a fixed step of one minute, using 6th-order differences with partial double precision (PDP) on the IBM 7094, gives a 100-ft error after one day; whereas the 8th-order method using single precision (SP) on the CDC 6600, gives an approximate 1/100-ft error, and only 2 ft after 10 days. Comparable results were obtained by using DP on the CDC 3600.

b. TEST CASES

The test cases chosen for this study are listed in Table A-II.

<td>240.3 (n mi)</td>
</tr>
</tbody>
</table>

A parametric relation between the error variation rss and the fixed-step size \( h \) for a particular time period can be utilized to investigate optimum step size. In Figure A-2(a) this technique is illustrated by plotting the relative maximum rss error vs the integration-step size for orbits A, B, and C. Note the roundoff error growth for Orbit B to the left of the optimum step (0.5 min) as \( h \) tends toward zero. On the other hand, the high eccentricity of this orbit causes sudden changes in acceleration near perigee and a very uniform acceleration at apogee, which results in a greater growth for \( h \) than 0.5 minute.
Figure A-2. Error Variation with Fixed Step Size
Optimum steps for C-bits A and C are 1.5 and 1.0 minutes, respectively. Thus, if the investigation time period is changed, the relative optimum step may also change; for example, Orbit C has a 1.5-minute optimum for a 1-day sample.

(1) **Variable Step Mode**

In general, the variable-step mode reduces the rss error (for a 10-day period). For example, for Orbit B in Figure A-2 (b), with \( h_0 = 0.5 \), it decreases the rss; and for \( h_0 = 1 \), it decreases the error from 25 to 8 ft. The behavior is the same at the end of 1 day.

(2) **Integration Closure Tests**

With this numerical integration method, closure tests were made on three augmented force models. A generalized potential function expansion for the aspherical earth was assumed, and the symbols Z, T, and R denoted zonal harmonics, zonal-plus-tesseral harmonics, and harmonics-plus-resonance, respectively. Relationships between closure error and fixed-step size permitted the desired 'best' step size to be chosen for a particular force model and orbit. Figure A-3 indicates that for a 1-day sample interval, \( h = 1.0 \) minute is optimum for the Z and T models, and \( h = 0.5 \) for the R model at the desired level of accuracy. In another example (Figure A-4 for Orbit C), \( h = 0.5 \) is necessary for both the T and R force models.

(3) **Constant Energy Considerations**

For simple conservative fields, such as spherical and Z models, both the magnitude of angular momentum and its polar component exhibited linear growth with time, but maintained an acceptable degree of significance as defined by computer word length.

(4) **Sample Running Times**

Table A-III gives sample running times for trajectory generation by using three augmented force models. All stated times are considered upper bounds.
Table A-III. Sample Running Times

Problem: Numerical Integration of Accelerations
Derived from Geopotential Model \( U = \sum_{n=0}^{N} \sum_{m=0}^{M} U_{nm} \)

APPENDIX B
KYNER II NON-TWO-BODY NOMINAL TRAJECTORY

1. FORMULATION

The formulation of the Kyner II non-two-body nominal trajectory is developed in Reference 5.

2. COMPUTATIONAL ALGORITHM FOR THE REFERENCE TRAJECTORY

To utilize the theoretical concepts presented in Section III.D, a computational algorithm is developed to evaluate the reference trajectory. The algorithm is composed of basic equations of the formulation, related formulas, and the computational scheme.

a. BASIC EQUATIONS OF THE FORMULATION

Given the initial position \( r_o \) and velocity \( \dot{r}_o \) vectors at epoch, the reference \( r \) can be written in terms of the \( F \) and \( G \) functions as

\[
\begin{align*}
\mathbf{r} &= \mathbf{F} \mathbf{M} + \mathbf{G} \mathbf{N} \\
\mathbf{M} &= r_o + \left[ A \right] r_o = \left[ I + \left[ A \right] \right] r_o \\
\mathbf{N} &= \dot{r}_o + \left[ A \right] \dot{r}_o = \left[ I + \left[ A \right] \right] \dot{r}_o \\
F &= (r/r_o) \cos \phi - (\dot{r}/h)_o r \sin \phi \\
G &= (r/h)_o r \sin \phi \\
\phi &= v + v_o \\
\left[ A \right] &= \sum_{i=1}^{8} a_i (\#) \left[ A_i \right]
\end{align*}
\]

where

\[
\begin{align*}
& F = (r/r_o) \cos \phi - (\dot{r}/h)_o r \sin \phi \\
& G = (r/h)_o r \sin \phi \\
& \phi = v + v_o \\
& \left[ A \right] = \sum_{i=1}^{8} a_i (\#) \left[ A_i \right]
\end{align*}
\]

[-65-]
$a_i$ are slowly varying scalar functions of $\phi$

$[A_i]$ are constant matrices evaluated at epoch

Thus Eq. (B-1) becomes

$$\vec{r} = F[I + [A]]\vec{z}_0 + G[I + [A]]\vec{z}_o$$  \hspace{1cm} (B-2)

The reference velocity $\dot{\vec{r}}$ is then obtained by differentiating Eq. (B-2) as

$$\dot{\vec{r}} = [\dot{F}[I + [A]] + F[A]]\vec{z}_0 + [\dot{G}[I + [A]] + G[A]]\vec{z}_o$$  \hspace{1cm} (B-3)

where

$$\dot{F} = (r/r_o)(\dot{r} \cos \phi - r \sin \phi \dot{\phi}) - (\dot{r}/n_o)(\dot{r} \sin \phi + r \cos \phi \dot{\phi})$$

$$\dot{G} = (r/h_o)(\dot{r} \sin \phi + r \cos \phi \dot{\phi})$$

$$\dot{\phi} = \frac{n}{r^2}$$

$$\dot{r} = a \Delta E \left[ C_e \sin \Delta E + S_e \cos \Delta E \right]$$

$$\Delta \dot{E} = \ddot{\eta} a/r$$

$$[\dot{A}] = \sum_{i=1}^{8} \dot{A}_i (r, \phi) [A_i]$$

The differential equation satisfied by $\vec{r}$ then becomes

$$\ddot{\vec{r}} = -\mu \frac{\vec{r}}{r^3} + \frac{\vec{L}}{r}$$  \hspace{1cm} (B-4)
where

\[ L = \left[ 1 - (1 - \gamma)^2 \right] \mu T^3 + \left( F; [A] \right) \varepsilon_0 + \left( G; [A] \right) \varepsilon_0 \]

where

\[ \gamma = \frac{3}{2} J \frac{\left( \frac{a}{a_0} \right)^2 \left( \frac{a}{r} \right)^3}{(1 - 3 \sin^2 i_o \sin^2 u_o)} \]

\[ (p; q) = 2 \frac{dp}{dt} \frac{dq}{dt} + \frac{d^2 q}{dt^2} \] (differential operator)

and \( p \) and \( q \) are arguments of the operator.

b. RELATED FORMULAS

(1) Kepler's Equation in Differenced Form

The independent variable is expressed in difference form \( \Delta = t - t_o \) (time), \( \Delta = v - v_o \) (true anomaly), or \( \Delta = E - E_o \) (eccentric anomaly). It is therefore convenient to express the fundamental angle-time relationship (Kepler's equation) as

\[ M - M_o = (E - E_o) + 2 S_e \sin^2 (E - E_o)/2 - C_e \sin (E - E_o) \]  \hspace{1cm} (B-5)

where

\[ M - M_o = \overline{n} (t - t_o) \]

\[ C_e = (e \cos E)_o \]

\[ S_e = (e \sin E)_o \]
(2) True Anomaly and Eccentric Anomaly Relationships

Difference forms relating the true anomaly and the eccentric anomaly are necessary to evaluate \( r, \hat{r}, \) and \( \ddot{r}. \) These are

\[
\cos (v - v_o) = 1 - \frac{a^2}{r r_0} \left(1 - e^2\right) \left[1 - \cos (E - E_o)\right]
\]

\[
\sin (v - v_o) = \frac{a^2}{r r_0} \frac{1}{2} \left[(M - M_o) - (E - E_o) + \sin (E - E_o)\right]
\]

\[
\sin (E - E_o) = \frac{r}{\frac{1}{r_0}} \sin (v - v_o) - \frac{1}{p} \left[1 - \cos (v - v_o)\right] S_e
\]

\[
\cos (E - E_o) = 1 - \frac{r r_0}{ap} \left[1 - \cos (v - v_o)\right]
\]

(3) Expressions for \( r, \hat{r} \) and \( \Phi \)

If \( \Delta = t - t_o, \) or \( \Delta = E - E_o, \) then the reference position distance is given in difference form by

\[
r = \left[1 - C_e \cos (E - E_o) + S_e \sin (E - E_o)\right] \quad \text{(B-6)}
\]

If \( \Delta = v - v_o, \) then

\[
r = p \left[1 + C_v \cos (v - v_o) - S_v \sin (v - v_o)\right]^{-1}
\]

where

\[
C_v = (e \cos v)_o
\]

\[
S_v = (e \sin v)_o
\]

Differentiation of Eq. (B-6) gives

\[
\dot{r} = a \Delta \dot{E} \left[C_e \sin (E - E_o) + S_e \cos (E - E_o)\right]
\]

-68-
where

\[ \Delta E = \frac{1}{2} a / r \]

If \( \Phi = v - v_o \), then

\[ \dot{\Phi} = \frac{\Omega}{r^2} \]

where

\[ \Omega = \frac{n}{a^2} \left( 1 - \frac{1}{e^2} \right) = \frac{(\pi/n_o)}{r} \]

c. COMPUTATIONAL SCHEME

If the initial position vector \( \mathbf{r}_o \) and velocity vector \( \mathbf{v}_o \) are given at epoch time \( t_o \), the following procedure will establish a means of determining the reference position \( \mathbf{r} \), velocity \( \mathbf{v} \), and acceleration \( \mathbf{a} \) vectors at time \( t \). Two computational phases, initialization and evaluation, are presented in detail.

(1) Initialization Phase

All initial orbital parameters, rate parameters, coefficients, and time invariant matrices are evaluated at epoch by the following equations.

(a) Initial Orbital Parameters

The desired set of orbital parameters is

\[ (r_o, a, C_o, S_o, e, i, w_o, \Omega_o, C_v, S_v, v_o, w) \]
where

\[ r_0 \] is the geocentric radius distance at epoch
\[ a \] is semimajor diameter of the conic at epoch
\[ C_e, S_e \] are coefficients evaluated at epoch
\[ e \] is the eccentricity of the conic at epoch
\[ i \] is the inclination of the conic at epoch
\[ \omega_o \] is the argument of latitude at epoch
\[ \Omega_o \] is the longitude of the ascending node at epoch
\[ C_v, S_v \] are coefficients evaluated at epoch
\[ v_o \] is the true anomaly at epoch
\[ \omega_o \] is the argument of perigee at epoch

Equations for the orbital parameters are

\[ r_0 = \frac{1}{(r_o \cdot i_o)^2} \]
\[ i_o = \frac{(r_o \cdot i_o)}{r_o} \]
\[ 1/a = \frac{2}{r_o} - \frac{(i_o \cdot i_o)}{\mu} \]
\[ C_e = 1 - r_o/a \equiv (e \cos E)_o \]
\[
\begin{align*}
\mathbf{r}_0 &= (1 + r_0)(\mu/a)^{1/2} \\
\mathbf{r}_0^\prime &= a \hat{\mathbf{e}}_0 \equiv (e \sin E) \mathbf{e}_0 \\
e &= \left(\frac{C_e^2 + S_e^2}{2}\right)^{1/2} \\
U_0 &= \mathbf{r}_0 / \omega_0 \\
W_0 &= (\mathbf{r}_0 \times \hat{\mathbf{e}}_0) / |\mathbf{r}_0 \times \hat{\mathbf{e}}_0| \\
V_0 &= W_0 \times U_0 \\
\sin i &= \left[\frac{u_{oz}^2 + v_{oz}^2}{2}\right]^{1/2} \\
\cos i &= \left[\left(U_{ox} + V_{oy}\right)^2 + \left(U_{ox} - V_{oy}\right)^2\right]^{1/2} - 1 \\
i &= \tan^{-1} (\sin i / \cos i) \\
\sin u_o &= U_{oz} / \sin i \\
\cos u_o &= V_{oz} / \sin i \\
u_o &= \tan^{-1} (\sin u_o / \cos u_o) \\
\sin l_o &= (U_{ox} + V_{oy}) / (1 + \cos i) \\
\cos l_o &= (U_{oy} - V_{ox}) / (1 + \cos i) \\
l_o &= \tan^{-1} (\sin l_o / \cos l_o) \\
\tilde{n}_o &= \hat{\mathbf{e}}_0 - u_o \\
p &= a(1 - e^2) \\
C_v &= p / r_o - 1 \equiv (e \cos v) \mathbf{e}_0
\end{align*}
\]
\[
S_v = \frac{1}{p/\mu(\sin v)^2} = (\sin v)^
\]

\[
\sin v_0 = S_v/e
\]
\[
\cos v_0 = C_v/e
\]
\[
v_0 = \tan^{-1} (\sin v_0 / \cos v_0)
\]

If \( e = 0 \), set \( v_0 = 0 \). Then

\[
\omega_0 = u_0 - v_0
\]

(b) Initial Rate Parameters

The initial value of the rate parameters discussed in Reference 4 are evaluated from the equations

\[
\gamma = -\frac{3}{2} J_2 (a_e/a)_0^2 (a/r)_0^3 (1 - 3 \sin^2 i_0 \sin^2 u_0)
\]
\[
\eta = \frac{3}{4} J_2 (a_e/a)_0^2 (1 - e_0^2)^{-2} (4 - 5 \sin^2 i_0)
\]
\[
\tau = -\frac{3}{2} J_2 (a_e/a)_0^2 (1 - e_0^2)^{-2} \cos i_0
\]
\[
\bar{n} = n(1 - \gamma)
\]

where

\[
n = (\mu/a^3)^{1/2}
\]

-72-
c. F and G Coefficients

The F and G functions have initial coefficients $F_1$, $F_2$, and $G_1$, which are evaluated at epoch as

$$F_1 = (1/r)_o$$

$$F_2 = -(t/h)_o$$

$$G_1 = (r/h)_o$$

d. Time Invariant Matrices

The constant orientation matrices $\{A_j\}$ ($j = 1, \ldots, 8$) discussed in Section III.D.3.b are given as

$$[A_1] = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

$$[A_2] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

$$[A_3] = [D(\Omega_0)] [C(i_o)] [A_2] [C(-i_o)] [D(-\Omega_o)]$$

$$[A_4] = [D(\Omega_0)] [C(i_o)] [A_4] [C(-i_o)] [D(-\Omega_o)]$$

where

$$[D(\Omega)] = \begin{bmatrix} \cos \Omega & -\sin \Omega & 0 \\ \sin \Omega & \cos \Omega & 0 \\ 0 & 0 & 1 \end{bmatrix}$$
\[
[C(i)] = \begin{bmatrix}
1 & 0 & 0 \\
0 & \cos i & -\sin i \\
0 & \sin i & \cos i
\end{bmatrix}
\]

\[
[A_5] = [A_1] [A_3]
\]

\[
[A_6] = [A_2] [A_4]
\]

\[
[A_7] = [A_2] [A_3]
\]

\[
[A_8] = [A_1] [A_4]
\]

(2) **Evaluation Phase**

To obtain the nominal state \( S \left( \mathbf{r}_{n}, \mathbf{i}_{n}, \mathbf{v}_{n}, L \right) \) for some given value of the independent variable (time \( t \), true anomaly \( \nu \), or eccentric anomaly \( E \)), the following equations are solved.

First determine the value of the true anomaly difference

\[ \Phi = \nu - \nu_0. \]

If time is the independent variable \( (\Delta = \text{elapsed time from epoch}) \), then \( M - M_0 = \pi \Delta \), and Kepler's equation

\[ M - M_0 = (E - E_0) + 2S_e \sin^2 \left( \frac{E - E_0}{2} \right) - C_e \sin (E - E_0) \]

is solved for \( E - E_0 \). Thus

\[ r = a \left( 1 - C_n \cos (E - E_0) + S_e \sin (E - E_0) \right) \]

\[ \cos \Phi = 1 - \frac{a^2 (1 - e^2)}{rr_0} \left( i - \cos (E - E_0) \right) \]
\[
\sin \phi = \frac{a^2 (1 - e^2)^{1/2}}{r r_0} \left( (M - M_0) - (E - E_0) + \sin (E - E) \right)
\]

\[
\Phi = \tan^{-1} \left( \frac{\sin \phi}{\cos \phi} \right).
\]

Now apply a monotonicity adjustment on \( \Phi \) (see Section B.3.f of this Appendix). If true anomaly is the independent variable \( \Delta = \Phi \equiv \nu - \nu_0 \), then compute eccentric anomaly difference \( E - E_0 \) from

\[
\sin (E - E_0) = \frac{r}{(ap)^{1/2}} \sin \phi - \left( \frac{r}{p} \right) (1 - \cos \phi) S_e
\]

\[
\cos (E - E_0) = 1 - rr_0 (ap)^{-1} (1 - \cos \phi)
\]

where

\[
r = p/(1 + C_v \cos \phi - S_v \sin \phi)
\]

Thus

\[
M - M_0 = (E - E_0) + 2S_e \sin^2 \left( \frac{(E - E_0) / 2}{2} \right) - C_e \cos (E - E_0).
\]

Now apply a monotonicity adjustment on \( M - M_0 \) (see Section B.3.f) and compute the corresponding elapsed time from epoch as

\[
\Delta = t - t_0 = \frac{(M - M_0)}{\bar{\mu}}.
\]
If eccentric anomaly is the independent variable $\Delta = E - E_o$, then compute $\mathbf{M} - M_o$ and $t - t_o$ as above and proceed with Eq. (B-7).

Evaluate the $F$ & $G$ functions and scalar coefficients $a_j$ of the rotation matrix $[A]$ as follows.

$$F = \frac{r}{r_o} \cos \phi - (\frac{i}{h})_o \ r \sin \phi$$

$$G = (\frac{r}{h})_o \ r \sin \phi$$

$$\hat{F} = (\frac{r}{r_o}) (\frac{r}{r_o} \cos \phi - r \sin \phi) - (\frac{i}{h})_o (\frac{r}{r_o} \sin \phi + r \cos \phi)$$

$$\hat{G} = (\frac{r}{h})_o (\frac{r}{r_o} \sin \phi + r \cos \phi)$$

where

$$\hat{r} = \frac{1}{a (\Delta E)} \left( C_e \sin (E - E_o) + S_e \cos (E - E_o) \right)$$

$$\Delta E = \frac{a}{r}$$

$$\hat{\phi} = \frac{h}{r^2} \quad h = (1 - \gamma) h_o$$

and $(a_j)_{j=1}^{8}$ and $(\hat{a}_j)_{j=1}^{8}$ are as given in Eq. (B-8) in Section B.3.f.

Now

$$[A] = \sum_{j=1}^{8} a_j [A_j]$$

-76-
and

\[ [\hat{A}] = \sum_{j=1}^{8} \hat{a}_j [A_j]. \]

Form the \([F]\) and \([G]\) matrices as

\[ [F] = F[I + A] \]
\[ [G] = G[I + A] \]
\[ [\hat{F}] = [F[I + A] + F[\hat{A}]] \]
\[ [\hat{G}] = [G[I + A] + G[\hat{A}]] \]

Evaluate the nominal state \(S(\mathbf{r}_n', \mathbf{r}_o', \mathbf{\dot{r}}_n', \mathbf{\dot{r}}_o)\) by

\[ \mathbf{r}_n = [F] \mathbf{r}_o + [G] \mathbf{\dot{r}}_o \]
\[ \mathbf{\dot{r}}_n = [\hat{F}] \mathbf{r}_o + [\hat{G}] \mathbf{\dot{r}}_o \]
\[ \mathbf{\ddot{r}}_n = -\mu \frac{\mathbf{r}_n}{r_n^3} + \mathbf{L} \]

\[ \mathbf{L} = \left( \frac{n^2_o - n^2}{r^2_o} \right) \mu \frac{\mathbf{r}_n}{r_n^3} + (F; [A]) \mathbf{r}_o + (G; [A]) \mathbf{\dot{r}}_o. \]

Evaluate the rotation matrix \([A]\)

\[
[A] = \sum_{j=1}^{8} a_j(\Phi) [A_j]
\]

Evaluate the \([F]\) and \([G]\) matrices

\[
[F] = F[I + A] \\
[G] = G[I + A]
\]

(620) Evaluate the reference position vector \(r\)

\[
\bar{r} = [F] \bar{r}_0 + [G] \bar{r}_0
\]

Evaluate the \(F\) and \(G\) function coefficients

\[
\Delta E = \bar{n} a / r \\
\bar{r} = a \Delta E [C_e \sin (E - E_0) + S_e \cos (E - E_0)]
\]

\[
-sin \Phi = -\frac{a^2 (1 - e^2) \sin (E - E_0) \Delta \bar{r}_{o} - \bar{r}_o \hat{r} (1 - \cos (E - E_0))}{(\bar{r}_o)^2}
\]

\[
cos \Phi = \left[ \frac{a^2 (1 - e^2)^{1/2}}{(\bar{r}_o)^2} \right] \left[ (\bar{n} - \Delta E (1 - \cos (E - E_0))) \bar{r}_o \right. \\
- (M - M_0) - (E - E_0) + \sin (E - E_0)] \bar{r}_o \hat{r}
\]

\[
\hat{\Phi} = [(\sin \Phi \hat{\Phi})^2 + (\cos \Phi \hat{\Phi})^2]^{1/2}
\]

\[
F = F_1 \hat{r} \cos \hat{\Phi} + F_1 \hat{r} (- \sin \hat{\Phi}) + F_2 \hat{r} \sin \hat{\Phi} + F_2 \hat{r} (\cos \hat{\Phi})
\]

\[
G = G_1 \hat{r} \sin \hat{\Phi} + G_1 \hat{r} (\cos \hat{\Phi})
\]

Evaluate the scalar coefficients \(\hat{a}_j\) (\(j = 1, \ldots, 8\)) of the rotation matrix \([\hat{A}]\)

\[
\hat{a}_1 = \tau \hat{\Phi} (a_{-1} + 1) \\
\hat{a}_2 = \tau \hat{\Phi} (-a_1)
\]
\[ \dot{a}_3 = \eta \phi (a_4 + 1) \]
\[ \dot{a}_4 = \eta \phi (-a_3) \]
\[ \dot{a}_5 = \dot{a}_1 a_3 + a_2 \dot{a}_3 \]
\[ \dot{a}_6 = \dot{a}_2 a_4 + a_2 \dot{a}_4 \]
\[ \dot{a}_7 = \dot{a}_2 a_3 + a_2 \dot{a}_3 \]
\[ \dot{a}_8 = \dot{a}_1 a_4 + a_1 \dot{a}_4 \]

Evaluate the rotation matrix \([\dot{A}]\)

\[ [\dot{A}] = \sum_{j=1}^{8} \dot{a}_j (\phi, \dot{\phi}) [A_j] \]

Evaluate the \([\hat{F}]\) and \([\hat{G}]\) matrices

\[ [\hat{F}] = \left[ \hat{F} [I + A] + F [\dot{A}] \right] \]
\[ [\hat{G}] = \left[ \hat{G} [I + A] + G [\dot{A}] \right] \]

(660)

Evaluate the reference position vector \(\hat{x}\)

\[ \hat{x} = [\hat{F}] x_0 + [\hat{G}] \xi_0 \]

Evaluate the differential operator \( (\quad) \)

\[ (r \cos \phi; a_j) \quad (j = 1, \ldots, 8) \]
\[ (r \sin \phi; a_j) \quad (j = 1, \ldots, 8) , \]

where \((p; q) = 2 (dp/dt) (dq/dt) + p \ d^2q/dt^2\)

Evaluate the \([\hat{F}]\) and \([\hat{G}]\) matrices

\[ \hat{F} = \sum_{j=1}^{8} \left[ F_1 (r \cos \phi; a_j) + F_2 (r \sin \phi; a_j) \right] [A_j] = (F; [A]) \]

\[ \hat{G} = \sum_{j=1}^{8} \left[ G_1 (r \sin \phi; a_j) [A_j] = (G; [A]) \right. \]

-87-
Evaluate the $L$ vector
\[ L = \left( \frac{n_0^2 - n^2}{n_0^2} \right) \mu \frac{r}{r^3} + (F; [A]) \mathbf{r}_o + (G; [A]) \mathbf{t}_o \]

Evaluate the reference acceleration $\ddot{r}$
\[ \ddot{r} = -\mu \frac{r}{r^3} + L \]

Go to (900).

(900) Exit.

g. KEPLER'S EQUATION SOLVER

The first approximation for the solution of Kepler's equation is
\[ (E - E_o) = (M - M_o) + e \sin (M - M_o) + \frac{e^2}{2} \sin 2(M - M_o) + \frac{e^3}{8} [(3 \sin 3(M - M_o) - \sin (M - M_o)) \]

Kepler's equation in differenced form is given by
\[ (M - M_o) \equiv \overline{n}(t - t_o) = (E - E_o) + 2S_e \sin^2[(E - E_o)/2] - C_e \sin (E - E_o) \]

where
\[ C_e = 1 - \frac{r_o}{2} \]
\[ S_e = \frac{r_o \mathbf{t}_o}{(\mu a)^{1/2}} \]
\[ r_o \mathbf{t}_o = r_o \cdot \mathbf{t}_o \]

An iterative solution of the differenced Keplerian form is computed by the following scheme. Compute
\[ \Delta E = (E - E_o)_{i+1} - (E - E_o)_i \]
that is,

\[ \Delta E = - \frac{f(E - E_o)}{f'(E - E_o)} \]  
(\text{Newton-Raphson method})

Use the first approximation of \((E - E_o)\) given above as an initial guess, where

\[ f(E - E_o) = (M - M_o) - (E - E_o) - 2 S_e \sin^2 \left[ \frac{(E - E_o)}{2} \right] + C_e \sin (E - E_o) \]

and

\[ f'(E - E_o) = -1 - 2 S_e \sin \frac{(E - E_o)}{2} \cos \left[ \frac{(E - E_o)}{2} \right] + C_e \cos (E - E_o) \]

give

\[ \Delta E = \frac{(M - M_o) - (E - E_o) - 2 S_e \sin^2 \left[ \frac{(E - E_o)}{2} \right] + C_e \sin (E - E_o)}{1 + S_e \sin (E - E_o) - C_e \cos (E - E_o)} \]

Until \(\Delta E \leq \epsilon \ (10^{-8})\), this procedure yields a solution \((E - E_o)\).
**Trajectory Analysis Program (TAP)**

The Trajectory Analysis Program (TAP) is designed specifically for use on the CDC 6000 series machine as a computational tool to generate trajectories by different mathematical formulations and to compare the results. In particular, the reference trajectory is the result of numerical integration of the equations of motion in a Cowell formulation with time as the independent variable; whereas, the comparison trajectory selected is achieved by an analytic (Pines, Kyner, or Escobal) or a numerically integrated Encke (classical or modified) formulation. A comprehensive description is presented of the algorithms implemented in TAP with emphasis on characteristics such as logic flow, equations, numerical techniques, comparison differencing, and plotting. A basic usage guide is included with complete instructions for input data preparation and explanations of output tables. (...
### KEY WORDS

- Analytic (Pines, Kyner, Escobal) Formulation
- Cowell Formulation
- Encke (Classic and Modified) Formulation
- FORTRAN
- Noncentral Gravitation
- Printer Plots
- Reference Systems and Equations
- Trajectory Comparison
