FOREWORD

This report presents the results of the reliability and maintainability analyses conducted during the FB-111A Category II test program. The FB-111A Category II flight test program was initiated by an Air Force Flight Test Center Project Directive 67-1, dated 13 July 1966. The flying portion of the program was accomplished between 31 August 1968 and 27 June 1972.

A major contribution to the FB-111A reliability and maintainability analysis was made by Senior Master Sergeant Earl H. Wilson, NCOIC, F-111 Joint Test Force Maintenance Analysis.

Foreign announcement and dissemination by the Defense Documentation Center are not authorized because of technology restrictions of the U.S. Export Control Acts as implemented by APR 300-10.

ABSTRACT

This report presents the results of the reliability and maintainability evaluation conducted during the FB-111A Category II test program. The aircraft demonstrated a 1.6-hour mean time between failures and a 1.5-hour mean time between aircrew writeups. The overall aircraft reliability was significantly degraded by the low reliability of the flight controls and most avionics subsystems. The reliability of most non-avionics subsystems was acceptable. The contractor predicted that 23.8 maintenance manhours per flying hour would be required, and 48.0 manhours were actually measured; the difference was attributed to low reliability. Except for excessive removal, bench check, and replacement of good components during troubleshooting, the maintainability of the FB-111A was good. The mode/status lights associated with some subsystems were of questionable value in detecting failures correctly.

INTRODUCTION

GENERAL

The FB-111A Category II systems test program began in August 1968 when FB-111A USAF S/N 67-159 was delivered to the AFPTC. The test program was extended to allow for aircraft subsystem updates and the delay caused by a wing inspection and modification program. The AFPTC was responsible for conducting the test program under the overall management of the F-111 System Program Office at the Aeronautical Systems Division, Wright-Patterson AFB, Ohio. The test aircraft used for the systems test program were FB-111A No. 1, USAF S/N 67-159; FB-111A No. 3, USAF S/N 67-161; FB-111A No. 44, USAF S/N 67-162; FB-111A No. 6, USAF S/N 67-7192; and FB-111A No. 27, USAF S/N 68-255.

This report presents the final results from the Category II reliability and maintainability evaluation. This evaluation used the data from the entire Category II test program which consisted of 1,308 flying hours accumulated during 504 missions (including 27 ground aborts).

Results of the FB-111A Category II test program have been or will be published in a series of reports. The titles for those reports are listed in references 1 through 11. A summary report (reference 12) containing an overall evaluation of the FB-111A aircraft will be published at the completion of the program.

PROGRAM OBJECTIVES

The primary objective of the FB-111A Category II systems evaluation was to insure that an operationally ready FB-111A system would be integrated into the SAC inventory in a minimum of time. The specific objectives of the Category II test program in accordance with APR 80-14 and the FB-111A System Package Program were to:

1. Provide input data for determination of compliance with contract specifications for maintainability and reliability.

2. Obtain necessary data from flight test results to complete the Flight Manual (reference 11).

3. Evaluate design changes as required before incorporation into the system.

4. Demonstrate in as realistic and complete an environment as practicable that the complete system was functionally operative, operationally effective, and compatible with the other systems and supporting equipment required for operational use.

5. Determine whether the system was capable of and suitable for meeting the contract requirements and design objectives.

6. Provide equipment familiarization, experience, and maximum possible training for SAC and ATC within the limitations of the test program.

7. Demonstrate in the most realistic environment practicable that the complete system was maintainable with minimum resource outlay.
8. Determine the qualitative adequacy of the aerospace ground equipment (AGE).

9. Verify and evaluate the personnel subsystem.

AIRCRAFT DESCRIPTION

The FB-111A is a two-place (side-by-side) long-range fighter-bomber built by General Dynamics, Fort Worth Division. The aircraft was designed for all-weather supersonic operation at both low and high altitude. Mission capabilities include long range attack missions utilizing conventional or nuclear weapons. An automatic low altitude terrain following system enhances penetration capability. Power is provided by two TF-30 axial-flow, dual-compressor turbofan engines equipped with afterburners. The wings, equipped with leading edge slats and trailing edge flaps, may be varied in sweep, area, and aspect ratio by the selection of any wing sweep angle between 16 and 72.5 degrees. A selective forward wing sweep provides takeoff and landing capabilities at minimum speeds. For all other regimes, the wings are manually swept in accordance with desired Mach number. This feature provides the aircraft with a highly versatile operating envelope. The empennage consists of a fixed vertical stabilizer with rudder for directional control and a horizontal stabilizer that is moved symmetrically for pitch control and asymmetrically for roll control. The stability augmentation system incorporates triple redundant features which enhance system reliability. The tricycle-type forward retracting landing gear is hydraulically operated. The main landing gear consists of a single common trunnion upon which two wheels are singly mounted and contains only one extending/retracting/locking system, which ensures symmetrical main gear operation. Also, ground loads imposed upon the gear tend to extend the drag strut to the locked position. Stores are carried in a fuselage-enclosed weapons bay and externally on both pivoting and fixed wing-mounted pylons. The fuel system incorporates both inflight and single-point ground refueling capabilities.
TEST AND EVALUATION

GENERAL

This section contains a qualitative and quantitative analysis of the reliability and maintainability of each subsystem in the FB-111A aircraft as determined during the Category II test program. These results are presented by individual subsystem and for the overall aircraft. Evaluations that did not involve a specific subsystem are discussed at the conclusion of this section.

The quantitative analysis describes how each individual subsystem compared to the contractor's R&M predictions. Various R&M statistics are presented and analyzed as to the significant reasons for differences between the contractor's predictions and the measured Category II test results. Additional R&M statistics are presented for those users requiring further analysis. Insufficient failure and maintenance data were obtained on the aerospace ground equipment (AGE) to quantitatively evaluate it.

During the Category II test period, the monthly flying hours obtained varied from zero to a high of 76 hours per month. Because of this extreme variation, two R&M statistics most sensitive to a varying utilization rate, hardware mean time between failures (MTBF) and MMH/FH, were calculated using the six months data which corresponded with most flying hours (15 November 1970 through 15 May 1971 - 392 flying hours). All other R&M statistics were calculated using data from the entire Category II test program.

DATA COLLECTION

The Systems Effectiveness Data System (SEDS) was used for the reliability and maintainability analysis conducted on all aircraft subsystems during the Category II test program. Operational maintenance data were recorded on three different forms by maintenance and system engineering personnel. The data were input to two master history files, an operational data file, and a maintenance data file. The formatted file system (FFS) was used as an integral part of SEDS for the storage and retrieval of the data. The SEDS included the numerous computerized programs used to analyze this data. A detailed discussion of the forms used for data gathering (AFSC Form 258 and AFPTC Form 0-294) is contained in appendix I.

PROCEDURES AND GROUND RULES

Functional (Mission) Reliability

A functional or mission reliability analysis was performed on all aircraft subsystems. The flight hours obtained from the aircraft debriefing records were taken as the total flight time of all missions during which the particular subsystem was used with no credit being given for any ground operating or equipment checkout time. A maximum of 1,308 flying hours were accumulated during the 504 mission (including 28 ground aborts) covered in this analysis. Many of the subsystems had less operating time (appendix I) than the total aircraft, thus limiting
confidence in this data. Only aircrew-discovered discrepancies were recorded on the Aircraft Debriefing form, figure 1. Aircrew write-ups that reflected known design deficiencies for which corrective action had previously been initiated were deleted from these data. When two or more components of the same subsystem failed during a given flight, only one failure was considered.

Three categories of functional discrepancies were used: aborts, function loss, and function degradation. An abort was a malfunction that resulted in the premature termination of the primary mission due to a critical subsystem failure or a safety of flight malfunction. A function loss could have been of the complete subsystem or just the loss of one required mode of the subsystem. A functional degradation was a maintenance malfunction or degraded operation of a subsystem that functioned, but required corrective maintenance action. These categories were cumulative in a computation of functional reliability statistics; that is, mean flight hours between function loss included both aborts and function losses but not function degradations.

The following mission reliability statistics (appendix I), and tables III through XXXI, were calculated using the formulae in appendix II:

1. Mean Flying Hours Between Function Degradations (MFHFBFD)
2. Mean Flying Hours Between Function Losses (MFHBFL)
3. Mean Flying Hours Between Aborts (MFHBA)

In addition, the statistically derived 90-percent lower confidence limits (LCL's) for the means were calculated. A 90-percent LCL (for a given parameter) is that value which the true value equals or exceeds for a given sample size with 90-percent probability. Thus, the proximity of the 90-percent LCL to the measured mean gives an indication of the certainty that should be attached to the measured mean. In other words, the closer the measured value is to the 90-percent LCL, the more certain it is that the measured value is the true value. The large difference between some of the measured probabilities and the associated LCL's was the result of low utilization rates and/or number of failures of some subsystems, which yielded less certainty in the measured results. The formulae and methods used in calculation of these statistics are presented in appendix II.

Appendix I contains the following statistics computed to show the probability that a system will be usable on any mission regardless of duration:

1. Probability of no functional degradation \( (P_{nd}) \)
2. Probability of no functional loss \( (P_{nl}) \)
3. Probability of no abort \( (P_{na}) \)

In addition, the associated LCL's are also presented. Formulae used are contained in appendix II.
Hardware Reliability

A hardware reliability analysis was performed on all aircraft subsystems. The flight hours for the aircraft were multiplied by the operating time to flight time ratios ("use factors") shown in table I so that each subsystem could be credited with ground operating and checkout time. The "use factors" shown in table I were derived using the Operating Time Report for Selected Items (AFTO Form 4) as explained in appendix II. All confirmed failures were included (both air and ground crew discovered). A failure was considered confirmed if the corrective maintenance action verified that a component required repair. For example, if a component replaced on the aircraft subsequently bench-checked satisfactorily, no failure was assessed.

Results of the hardware reliability analysis are presented in tables III through XXXI.

Maintainability

A maintainability analysis was performed on aircraft subsystems using data obtained from the maintainability master history file. The maintenance manhour per flying hour (MMH/FH) values were computed by retrieving the total maintenance manhours for each two digit WUC and dividing this value by the total flying hours for the same period. The MMH/FH computations were separated into line and shop maintenance actions, that is, organizational and field level maintenance. Support general maintenance actions were considered separately from non-support general maintenance. All maintenance actions except for special instrumentation were considered in these calculations, not just those maintenance actions that related to the aircrew-discovered discrepancies. These statistics are presented in tables III through XXXI (along with contractor predicted values from reference 16) and summarized in table XXXII.

The MMH/FH values are nonparametric statistics. By considering each maintenance event as a separate data point it was possible to calculate a distribution of maintenance events (DOME). These data points for each subsystem were statistically tested by the Kolomogorov-Smirnov (K-S) goodness-of-fit test to determine whether they fit an exponential, Weibull, or log normal distribution. This computerized program computed the probability of the data points fitting each of these distributions as well as the K-S "D" statistic which defined whether or not the data points represented the specific distribution tested. The parametric distribution parameters for each distribution tested and the nonparametric statistics of the mean, variance, median (50th percentile) and MMAX (90th percentile) were also computed (tables III through XXXI). All DOME statistics were tested for the line active hours, shop active hours, total active hours, line manhours, shop manhours, and total manhours. Many of these statistics were not determined because they did not fit any distribution tested or lacked adequate sample size. Active hours are the clockhours during which maintenance actions were actually being performed; that is, administrative and logistic delays were eliminated. Manhours were the active hours times the maintenance crew size. Mathematical formulations of the exponential, Weibull, and log normal distributions are contained in appendix II.

SUBSYSTEMS ANALYSIS BY WORK UNIT CODE

The following analyses by WUC compare the Category II test results with the contractor-predicted R&M figures of merit. A sample WUC listing is shown in table II. An explanation appears in appendix II.

Airframe (WUC 11000)

Reliability.

The relatively low hardware MTBF shown in table III was caused by minor component failures which were discovered between flights. As a result, the mission reliability (MFHBFL) shown in table III was good. The single repetitive failure mode consisted of 11 instances of wing tip cracks in 896 flying hours. After the incorporation of TCTO 1P111-B-A-578, which changed the wing tip structure, 396 flying hours were accumulated with no failures.
Maintainability.

The MMH/FH measured in Category II testing was lower than contractor predictions. Table III shows the average clock time for a maintenance task on the airframe as 4.0 hours and 90 percent of all actions were completed in less than 8.3 hours. The wing tip replacement task required 1.5 clockhours and 3.0 manhours. The largest single maintenance task involved repair of plastic delamination under panel 3323 which required 140 clockhours and 250 manhours. Shop (intermediate level) clock-hours and manhours were Weibull distributed.

Landing Gear (WUC 13000)

Reliability.

The hardware reliability of the landing gear was low when all failures were considered although the measured mission reliability (MFHBFL) was good (table IV). This was caused by a large number of minor component failures which were detected between flights. Of the two aborts charged to this subsystem, one occurred when a cut nose tire was discovered during aircrew walk-around. The other abort was caused by an "unsafe" light in the gear handle after engine start. This was corrected by resetting the emergency shuttle valve.

The main landing gear tires averaged 25 landings per tire while the nose tire required replacement after an average of 23 landings. The only other repetitive failure mode was leaking brakes. There were 8 brakes changed for leaks during a time period covering 645 landings.

Maintainability.

The line (organizational level) MMH/FH for this subsystem was higher than the contractor-predicted value while the shop (field level) MMH/FH met predictions (table IV). This was caused by the low hardware reliability which required line corrective maintenance. The most frequent maintenance task was removal and replacement of wheel and tire assemblies which required 0.3 clockhours and 0.6 maintenance manhours (MMH) for a nose wheel or 1.5 clockhours and 3.0 MMH for a main wheel. A brake change required 2.0 clockhours and 6.0 MMH. The nonparametric DOME statistics (table IV) show that the task times for this subsystem are quite reasonable.

Operating Hours/Flying Hours Ratio

1.3
Flight Controls (WUC 14000)

Reliability.

The flight controls subsystem demonstrated the lowest hardware reliability of any non-avionic subsystem (table V). The No. 5 flap/vane components presented the major problem. Originally, these failures were considered to be caused by the uneven airflow around the wing tip cameras installed on some Category II test aircraft. When aircraft without cameras experienced similar failures, it was apparent cameras were not causing, but rather accelerating the failures. Engineering Change Proposals (ECP's) 2263 and 2846 (TCTO's 1F111-B-A-902 and 1F111-B-A-618, respectively) were designed to correct the problems with No. 5 flap. Seventy flight hours were accumulated after these changes were incorporated on one aircraft (FB-111A No. 3). During that period, the only failures were a bent No. 5 van and a worn No. 5 air deflector door hinge. Discounting failures in the No. 5 flap/vane area increases the hardware MTBF to approximately 26 hours. This more reasonable figure will be obtained only if ECP's 2263 and 4863 are effective.

The low hardware reliability seriously affected mission reliability (MFHBFL, table V). The aircrew "squawked" the flight controls an average of once every 25 flight hours. There were eight aborts for flight controls problems. Of these aborts, 5 were caused by the No. 5 flap/vane components.

Maintainability.

The measured line (organizational level) MMH/FH (table V) was over three times greater than the contractor predictions. However, 0.7 MMH/FH were expended on the No. 5 flap/vane area and an additional 1.4 MMH/FH were required for TCTO accomplishment. An additional 0.1 MMH/FH were required for shop (field level) accomplishment of TCTO's. After discounting the No. 5 flap/vane and TCTO manhours, the total measured MMH/FH of 1.7 compares favorably with the predicted 1.6 MMH/FH. The line, shop, and total manhour statistics were found to be log-normally distributed while the shop clock hours were exponentially distributed.

Escape Capsule Crew Module (WUC 16000)

Reliability.

The reliability of this subsystem (table VI) was acceptable when all discrepancies were considered. There were four aircrew-discovered discrepancies; all of which were function degradations. The four function degradations were: flash curtain rollers missing, right seat inoperative, right seat would not raise or lower, and left canopy handle lock tab would not lock. There were numerous hardware failures discovered between flights or during phase inspections by the ground crews. The failures were random among the components with no particular item having a high failure rate.

Maintainability.

The MMH/FH of this subsystem was very high in comparison with contractor-prediction (table VI). The primary cause was that the majority of the manhours was expended on removal and replacement of time change items, windshields, and crew seats to facilitate other maintenance.

Propulsion (WUC 23000)

Reliability.

The hardware reliability for the propulsion subsystem (table VII) was quite reasonable. It should be noted that the 21.7-hour MTBF is for the propulsion subsystem (i.e., two engines) as are the mission reliability statistics. The majority of the maintenance required was for repair of engine instruments and most aircrew writeups were on the same components. Of the eight aborts charged to the subsystem, two were caused by the spike controls on FB-111A No. 1 and two were caused by a high turbine inlet temperature on start which required a new indicator in one case and could not be duplicated in the other instance. The other aborts were caused by a failed N₁ tach generator which caused an overspeed light, a failed fuel control which prevented afterburner operation, a failed air ejector valve which caused an oil hot light, and one instance of severe stalls which could not be duplicated.

Maintainability.

The propulsion subsystem MMH/FH (table VII) was consistently better than the contractor predicted. This was attributed to reasonable reliability and a good maintainability design. Engine removal required 2.0 clockhours and 6.0 manhours while reinstallation required 4.0 clockhours and 12.0 manhours. Clock and manhours for line and shop were log-normally distributed.

Air Conditioning, Pressurization and Surface Ice Control (WUC 41000)

Reliability.

The reliability of this subsystem was low when all discrepancies were considered (table VIII). There were 27 aircrew-discovered discrepancies, 25 function degradations, and two function losses. The 25 function degradations were: seven environmental control system (ECS) failures which caused the forward equipment hot light to illuminate, eight failures in the pressurization system, seven failures in the air-conditioning system, one failure in the anti-icing systems and two intermittent FCS discrepancies. There were a large number of minor component failures which were detected between flights and during phase inspections. These minor failures lowered the reliability of the subsystem even further.

Maintainability.

The line (organizational level) MMH/FH for this subsystem more than doubled the contractor-predicted value while the shop (field level) MMH/FH was lower than contractor predictions (table VIII). This was caused by the low hardware reliability which required line corrective maintenance. The most frequent tasks were the removal and replacement of components in the ECS and pressurization system. The nonparametric DOME statistics (table VIII) for line active and shop manhours were tested and found to be exponential and Weibull distributed, respectively. The values for these statistics were quite reasonable.

Electrical Power Supply (WUC 42000)

Reliability.

The reliability of this subsystem was acceptable (table IX). There were only four aircrew-discovered discrepancies; three function degradations, and one mission abort. The three function degradations were: two generator power contactor failures, and three circuit breakers popped. On one flight the generator power contactor caused electrical transients when the engine was shutdown, and the other generator power contactor caused the inertial navigation system (INS) to dump when transferring from ground power. There were several hardware failures that were discovered between flights while performing maintenance on other components: two generator failures, four external power monitor failures, and one generator power contactor failure. The four external power monitor failures prevented application of external power to the aircraft. One generator failure caused a ground abort after being overserviced by maintenance and was not used in the analysis of the data.

Maintainability.

The MMH/FH for this subsystem was 0.1, about equal to contractor predictions. Most of the maintenance was for removing and replacing external power monitors which required on an average of 4.0 MMH per failure and making battery inspections, which required 2.0 MMH per inspection. The DOME for line active and line manhours were tested and both found to be log-normally distributed (table IX).

Lighting System (WUC 44000)

Reliability.

The reliability of this system was considered acceptable (table X). There were 14 aircrew-discovered discrepancies, 10 function degradations, and 4 function losses. The 10 degradations were primarily burnt bulbs or illuminated warning lights. The four losses were: three rotating beacon failures, and both green lights in gear down indicator burned out.

There were numerous hardware failures discovered by the ground crews during preflight and postflight inspections. There were seven rotating beacon failures, five master caution light failures and two flasher failures which were discovered by the ground crew.

Maintainability.

The MMH/FH for the subsystem was 0.1 which was equal to the contractor predictions (table X). Most of the maintenance manhours were spent replacing burned out bulbs which required an average of 0.5 MMH per failure while removal and replacement of rotating beacon assemblies and master caution panels required an average of 1.0 and 2.0 MMH per failure, respectively. The DOME for line active and line manhours were tested and found to be log-normal and exponentially distributed (table X).

* NO PREDICTION
** STATISTIC NOT KNOWN
Pneudraulic Power Suppiy (WUC 45000)

Reliability.

The reliability of this subsystem was somewhat low when all discrepancies were considered (table XI). There were seven aircrew-discovered discrepancies, four function degradations, one function loss, and two mission aborts. The four function degradations were: three primary hydraulic pressure switches inoperative, and one hydraulic pressure transmitter caused indicator to read 3,300 psi with engines running and 200 psi with engine shutdown. One function loss was attributed to right engine primary hydraulic pump light illuminating. The two mission aborts were: complete loss of utility hydraulic system when a hydraulic expansion swivel joint broke and the other was when the utility hydraulic light came on in flight. There were numerous hardware failures discovered between flights or in phase inspections. The failures were random among the components in the hydraulic system with no particular component having a high failure rate.

Maintainability.

The MMH/FH for this system was below contractor-predicted values (table XI). The majority of the manhours were for removal and replacement of leaky parts throughout the system. The DOME for line active and line manhours were tested and found to be exponentially and Weibull distributed, respectively (table XI).

Fuel System (WUC 46000)

Reliability.

The hardware reliability of the fuel system was acceptable (table XII). There were 29 aircrew-discovered function degradations and 1 mission abort. In the function degradations there were: 7 failures in the distribution system, which caused the fuel distribution light to illuminate; 6 failures in the inflight-refueling system; 4 failures in the fuel quantity indication system; 11 failures in the fuel transfer system; and 1 failure in the fuel dump system.

In the fuel distribution system there were varying component failures that caused the distribution light to illuminate. All the problems related to the inflight refueling system involved making contact with the tanker. The fuel quantity tanker system had one bad indicator and the other failures involved calibration problems. This system also caused the only abort against the fuel system. The fuel transfer system had three transfer pump failures and random failures among switches and valves. Fuel dumped overboard on one instance when an engine was started. Retorquing a loose Wiggins coupling corrected the discrepancy. There were a large number of fuel leaks detected between flights and corrected by the ground crew.

Maintainability.

The line (organizational level) MMH/FH for the fuel system was slightly higher than the contractor-predicted value while the shop (field level) MMH/FH met predictions (table XII). The largest consumer of MMH in the fuel system was repairing fuel cell leaks and trouble-

**Oxygen System (WUC 47000)**

**Reliability.**

The reliability of this system was considered acceptable (table XIII). There were two aircrew-discovered function degradations and numerous ground crew-discovered hardware failures. The function degradations were: right oxygen regulator inoperative, and the emergency oxygen regulator leaking. Some of the ground crew failures were: crimped oxygen hoses, leaking liquid oxygen converter, and several leaking valves and regulators.

**Maintainability.**

The MMH/FH for the oxygen system were equal to contractor-predicted values (table XIII). This did not include servicing which came under scheduled maintenance. The majority of manhours required were for time-change-items. The easy access (removal and replacement) of the liquid oxygen converter allowed it to be removed from the aircraft and taken to a liquid oxygen servicing cart for refilling while the aircraft was being fueled or having other maintenance performed. The DOME for both line active and line manhours were tested and found to be log-normally distributed (table XIII).

**Miscellaneous Utilities (WUC 49000)**

**Reliability.**

The reliability of this system was acceptable (table XIV). There were no aircrew-discovered discrepancies reported. There were six ground crew-discovered discrepancies, two fire detection control unit, and four sensing element failures. Repair involved removing and replacing the components. On the average, 2.0 MMH to change a control unit and 1.0 MMH to change a sensing element were required.

**Maintainability.**

The MMH/FH for this subsystem was below contractor-predicted values (table XIV). The majority of the manhours was expended replacing sensing elements in the fire detection system. The DOME for line active and line manhours was tested and found to be Weibull and exponentially-distributed, respectively (based on a very small sample size).

Instruments (WUC 51000)

Reliability.

The hardware MTBF shown in table XV resulted from scattered failures. No single component appeared to have a dominant failure mode. The instruments subsystem averaged one aircrew write-up every 18 flight hours. Of these write-ups, 35 percent were traced to problems with interfacing subsystems and 14 percent could not be duplicated. One abort was charged to the subsystem when a failed electronic control amplifier caused the primary altimeter to be inoperative.

Maintainability.

The MMH/FH required by the instrument subsystem was more than twice that predicted by the contractor (table XV). A contributing reason for this high statistic was the inability of the maintenance technician to isolate a failure to the correct line replaceable unit (LRU). In many instances, several LRU's had to be removed and bench-checked to determine which unit had failed. Of the total 1.8 MMH/FH measured, 0.3 MMH/FH were expended removing, bench-checking, and replacing good components. The remaining MMH/FH overage was attributed to low reliability.

Autopilot (WUC 52000)

Reliability.

The hardware reliability (table XVI) demonstrated by the autopilot subsystem was considered reasonable although the mission reliability was low. The majority of the aircrew-write-ups were considered functional degradations in that a loss or improper response of only one mode of autopilot was involved. Of the eight aborts charged to this subsystem, three were caused by the feel-trim assembly, and one each by the roll computer, roll rate gyro, and Central Air Data Computer. Six of the eight abort-causing failures were discovered during the pretaxi surface motion check.

Maintainability.

The measured MMH/FH (table XVI) exceeded predictions for the autopilot subsystem. Much of the maintenance was for intermittent or flight peculiar (that is, altitude-, temperature-, and g-related) discrepancies. A full 25 percent of the aircrew write-ups could not be duplicated and hence produced no positive corrective maintenance action. When a failure was duplicated there was difficulty isolating it to the correct LRU. A total of 0.4 MMH/FH was expended in removing, bench-checking, and replacing good units. Also, of the total MMH/FH shown in table XVI, 0.7 MMH/FH were due to TCTO accomplishment.

HF Communications (WUC 61000)

Reliability.

The reliability of the AN/ARC-123 HF Communications subsystem was very low. The Category II MTBF results were approximately one-tenth of the prediction (table XVII). There were 13 aircrew-discovered discrepancies, 6 function degradations, and 7 function losses. The six function degradations were: two control panel failures, two receiver-transmitter (R/T) unit failures, one amplifier and one coupler failure. The seven function losses were: four R/T unit failures, two failures which could not be duplicated, and one coupler failure.

Of the six R/T unit failures, two were reparable in the shop (field level) while the other four had to be sent to the depot for repair. The couplers and control panels were repaired locally except for one coupler and one control panel which were sent to the depot.

Maintainability.

The MMH/FH for this subsystem was double the predicted value (table XVII). The line (organizational level) maintenance was equal to the predictions, while the shop (field level) was three times greater than the predicted value (table XVII). The majority of the shop manhours was spent repairing or replacing modules in the R/T units. If module replacement did not solve the problem, the R/T units were sent to the depot for repair. The parametric statistics for all maintenance parameters were tested and found to be log-normally distributed.

UHF Communications (WUC 63000)

Reliability.

The relatively low hardware MTBF of the AN/ARC-109 communications subsystem shown in table XVIII was caused by numerous component failures. There were 44 aircrew-discovered discrepancies: 39 function degradations, 4 function losses, and 1 mission abort. The 39 function degradations were: 17 R/T unit failures, 1 UHF foot switch failure, 3 antenna coaxial switch failures, 5 antenna failures, and 13 write-ups that could not be duplicated. The four function losses were: three R/T unit failures and one antenna failure. The mission abort was a R/T unit failure.

There was a total of 21 R/T unit failures discovered by the aircrew. Of the 21 R/T unit hardware failures, five modules were replaced by the shop (field level). These modules were then sent to the depot for repair. The remaining 16 R/T unit failures required alignment and adjustments to modules within the R/T unit. After this was done, the R/T unit bench-checked as serviceable and returned to the aircraft.

Maintainability.

The MMH/FH for this subsystem was slightly lower than predictions (table XVIII). Even though the reliability of the hardware was low the time for repair was about equal to predictions. This was because most of the line MMH's were spent on removal and replacement of R/T units while troubleshooting discrepancies that could not be duplicated. The shop MMH's were slightly lower than predicted because most of the time

Interphone System (WUC 64000)

Reliability.

The reliability of the AN/AIC-25 interphone system was well below predicted values (table XIX). There were 13 aircrew-discovered discrepancies: 12 of which were function degradations and 1 a function loss. The function degradations were: 1 control panel with no hot mic at altitude, 1 control panel not secured in the cockpit, and 10 intermittent transmission and reception failures. The navigator foot switch was inoperative in the only function loss.

Maintainability.

The MMH/FH for the interphone system amounted to 0.1, about equal to the contractor predictions. Most of the maintenance was for troubleshooting or repairing interphone cords associated with the intermittent transmission and reception failures. The DOME for line active and line manhours were tested and both found to be log-normally distributed (table XIX).

Identification Friend or Foe (WUC 65000)

Reliability.

The reliability of the AN/APX-64V IFF was below the predicted value (table XX). There were 11 aircrew-discovered discrepancies, 5 function degradations and 6 function losses. The five function degradations were: three intermittent operations of IFF and two intermittent caution lights. The six function losses were: one IFF antenna lost inflight and five R/T unit failures. All R/T units were repaired in the shop (field level) by replacing various modules in three R/T units and repairing connectors in the other two R/T units. One power supply module and one generator module were not reparable this station and were sent to the depot level for repair.

Maintainability.

The MMH/FH for this subsystem came to 0.1 which was about equal to predictions (table XX). The majority of the maintenance manhours was for troubleshooting intermittent discrepancies and for shop (field level) repair of the R/T units. The DOME for line active and shop active hour statistics were found to be Weibull distributed, while line and shop manhour statistics were found to be log-normally distributed.

Radio Navigation (WUC 71000)

Reliability.

The reliability of the subsystem was about half of the predicted value (table XXI) for the tacan only. There were no instrument landing approach system (ILAS) failures during this data span so no MTBF value could be derived. The Category II MTBF result is for the tacan only.

There were 22 aircrew-discovered discrepancies, 17 discrepancies against the tacan system, and 5 discrepancies against the ILAS system.

Of the 17 tacan discrepancies, 12 were function degradations, and 5 were function losses. The 12 function degradation were: 9 R/T unit failures and 3 discrepancies that could not be duplicated. The five function losses were all R/T unit failures.

Repair of the R/T unit failures required the removal and replacement of modules within the R/T unit of all failures except one which bench-checked as satisfactory. There were four modules that had a high failure rate. These were: 10 bearing module failures, 6 range mechanical module failures, 4 RF modulator module failures and 3 power supply module failures. All the module failures were not repairable at the field level and were sent to depot for repair.

The five ILAS discrepancies were four function degradations and one function loss. The four function degradation could not be duplicated by the maintenance crew, while the one function loss was attributed to a broken antenna coaxial cable. The reliability of this subsystem could not be adequately evaluated from this data due to the low utilization rate of this subsystem.

Maintainability.

The MMH/FH of table XXI are for tacan subsystem only as there were no ILAS discrepancies during that time period. The line (organizational level) MMH/FH for this subsystem was slightly higher than the predicted value while the shop (field level) more than doubled the predicted value. This was caused by the low hardware reliability which required shop corrective maintenance. The shop repairs consumed the largest amount of manhours primarily after the removal and replacement of a module within the R/T unit required realignment of the R/T unit.

The total MMH/FH of the radio navigation subsystem more than doubled the predicted value (table XXI) primarily because of shop repairs. The line-active and shop-active DOME parametric statistics were tested and found to be log-normally and Weibull distributed, while line manhours and shop manhours were both found to be Weibull distributed.

Bombing Navigation (WUC 73000)

Reliability.

Both the mission and hardware reliability for the bombing navigation subsystem were considered low (table XXII). In subsequent analyses, the predicted MTBF's were qualification test statistics that applied to MIL-STD-781A testing (reference 17) and were obtained from a Program Reliability Review (reference 18). Some degradation in reliability must be expected between the environments specified in MIL-STD-781A and the actual flight environment, but these predicted MTBF's are used as a basis for comparison.

Maintainability.

The measured MMH/FH was over twice that predicted by the contractor (table XXII). This overage was attributed to both low reliability and low maintainability. The majority of the line MMH was required for troubleshooting. Once a faulty component was isolated, removal and replacement were easily accomplished. Further contributing to the problems of maintaining the subsystem was the difficulty in duplicating altitude-, temperature-, or g-related failures. Over the entire test program, 37 percent of the aircrew write-ups could not be duplicated, and a writeup that could not be duplicated invariably required more manhours than if a failure had been found.

It should be noted that aircrew debriefing was and will be a critical maintenance function for this subsystem. Subsystem functions were often written up by the aircrew as malfunctioning when in fact another subsystem function had failed and provided an inaccurate input to the subsystem function reported as failed.

Radar Altimeter Set (WUC 73C00)

Reliability.

The reliability of the AN/APN-167 radar altimeter was extremely low. The MTBF was far below the predicted value (table XXIII). There were 14 aircrew-discovered discrepancies, 13 function degradations, and one function loss. The 13 function degradations were: 4 indicator failures, 5 R/T unit failures and 4 discrepancies that could not be duplicated. The four indicator failures were not repairable in the shop (field level) and were sent to the depot for repair. The five R/T unit failures were required by alignment for two R/T units and by replacement of modules in the other three R/T units. The modules were then sent to the depot for repair. The one function loss was caused by an indicator failure which was sent to the depot for repair. The "could not duplicate" rate was 20 percent of all discrepancies for this subsystem.

Maintainability.

The Category II MMH/FH results for this subsystem are quite reasonable, but there are not predicted values for comparison (table XXIII). The line (organizational level) and shop (field level) MMH/FH values were the same.

The DOME parametric statistics for line active, line manhours, shop manhours were found to be log-normally distributed; while shop active,

Inertial Navigation System (WUC 73H00)

Reliability.

The INS includes the IRU, the navigation computer unit (NCU), two general purpose computers (GPC's), the converter, and other smaller components. Both the mission and hardware reliability of the INS were very low (table XXIV). Earlier in this series of reports, the IRU, GPC, and converter were identified as reliability problems. After that time, the IRU did not demonstrate as much reliability growth as the GPC and converter. TCTO IF-111-B-A850 changed the IRU from the -91 to the -111 configuration in an attempt to improve reliability. During Category II testing, the -91 IRU measured 95 hours MTBF's are based on a small sample size (three failures for the -91 and six failures for the -111). The data indicates that TCTO IF-111-B-A-850 may be ineffective in improving IRU reliability.

Maintainability.

The MMH/FH for this subsystem was considered high (table XXIV). While part of this MMH/FH was due to low reliability, there was a maintainability problem with the avionics status/warning lights associated with this subsystem. A full 60 percent of the maintenance actions were initiated because those lights (and possibly other symptoms) did not actually indicate corresponding hardware failures. Some of these maintenance actions may have been software failures that were corrected when the computers were bench-checked and reloaded with programs. The exact percentage was not known, but was suspected to have been a minority of those instances.

Illumination of status/warning lights that could not be duplicated cause considerable unneeded maintenance. An investigation should be conducted to determine the feasibility of improving the accuracy of status/warning lights (R1).1

Attack Radar (WUC 73J00)

Reliability.

Both mission and hardware reliability of the AN/APQ-114 attack radar were excellent (table XXV). The majority of the aircrew write-ups concerned function degradations and seldom seriously impacted the missions. Of all write-ups, approximately 22 percent concerned the clock and camera. Further, 35 percent of all aircrew write-ups could not be duplicated by maintenance personnel. It was suspected that the majority of these problems originated with equipments interfacing with the attack radar.

Maintainability.

Although the contractor made no predictions for the attack radar, the MMH/FH shown in table XXV is considered quite reasonable. This figure may increase somewhat in operational use since very little shop (field level) maintenance was done during Category II testing. In most instances, the failed unit was returned to the contractor because of AGE unavailability.

1Boldface numerals preceded by an R correspond to the recommendation numbers tabulated in the Conclusions and Recommendations section of this report.
The shop active and manhours was tested and found to fit the Weibull distribution while line man, total active, and total manhours were log-normally distributed.

Terrain Following Radar (WUC 73K00)

Reliability.

The mission and hardware reliability (table XXVI) of the AN/APQ-128 terrain following radar (TFR) was low when compared to MIL-STD-781A statistics. The TFR averaged 1 aircrew write-up every 17 flight hours and about half of these write-ups were considered hardware failures. The remaining write-ups were "cleared" by adjustments or could not be duplicated.

Maintainability.

Although the contractor did not make MMH/FH predictions, the measured MMH/FH (table XXVI) was considered excessive. The line portions of the MMH/FH was high because of the low system reliability while the shop MMH/FH was attributed both to low reliability and troubleshooting difficulties.

The DOME for line active, line man, total active, and total manhours was tested and found to be log-normally distributed. The shop active and shop manhours were Weibull distributed.

Doppler Radar (WUC 73L00)

Reliability.

The reliability of the AN/APN-185 Doppler radar was lower than the predicted MTBF value (table XXVII). There were 18 aircrew-discovered discrepancies, 8 function degradations, and 10 function losses. The eight function degradations were: one Doppler antenna failure, one electronic unit failure, and six discrepancies that could not be duplicated by the ground crew. The electronic unit failure accounted for all 10 of the function losses.

The electronics units of the Doppler system had the highest failure rate of any component. There were a total of 11 electronic units that failed of which only one was repaired at the line (organizational level), two were repaired at the shop (field level), and eight were sent to the depot for repair. Approximately 30 percent of all discrepancies could not be duplicated by the ground crew.

Maintainability.

The Category II MMH/FH results for this subsystem were quite reasonable, but there are no predicted values for comparison (table XXVII). The line (organizational level) and shop (field level) MMH/FH values were the same. The reason for this is primarily because the electronic unit was the component that failed and very few repairs could be made locally on this unit. The DOME parametric statistics for all types of maintenance except shop manhours were found to be log-normally distributed, while shop manhours was found to be Weibull distributed.

Astrotracker (WUC 73M00)

Reliability.

The reliability of the AN/ASQ-119 astrocompass was extremely low. The MTBF was nowhere near the predicted value (Table XXVIII). There were 22 aircrew-discovered discrepancies: 13 function degradations, and 9 function losses. The 13 degradations were: 5 tracker unit failures, 4 electronics unit failures and 4 discrepancies that could not be duplicated by the ground crew. The nine function losses were: six electronics unit failures, one tracker unit failure, and two discrepancies that could not be duplicated by the ground crew.

There were six tracker unit failures all of which had to be sent to the depot for repair except one which was repaired by replacing several modules. The modules were then sent to the depot for repair. There were 10 electronics unit failures all of which were sent to the depot for repair except for two which were repaired locally. The astrocompass was considered unreliable due to a low hardware reliability, and the utilization rate was not high enough to get an accurate prediction of the reliability of the subsystem.

Maintainability.

The high MMH/FH was due to low hardware reliability. There were many MMH's spent troubleshooting the system by the line (organizational level), and the MMH's for the shop (field level) were also high. The DOME parametric statistics for line active, total active, and total man-hours were found to be log-normally distributed; shop active and shop manhours were found to be Weibull distributed, and line manhours were found to be exponentially distributed.

Weapons Delivery (WUC 75000)

Reliability.

Both the hardware and mission reliability of the weapons delivery subsystem was low (Table XXIX). Occurring failures were approximately split between the weapons suspension components (pylons and bay) and the weapons control components. The weapons suspension failures were normally discovered between flights and had little impact on mission success. The weapons control failures were usually discovered by the aircrew and were considerably more serious. As a result of control failures there were two aborts for inadvertent releases, two aborts for "no-release" failures, and one abort for a bay door that would not open.

Maintainability.

The measured MMH/FH was twice that predicted (Table XXIX). This overage was attributed to low reliability and to difficulties in maintaining the system. A full 37 percent of the aircrew write-ups could not be duplicated and hence produced no positive corrective maintenance action. Following the two inadvertent releases, complete weapons delivery subsystem checkouts were accomplished. One checkout required 160 manhours and the other required 230 manhours.

Reliability.

The reliability of this subsystem was extremely low (table XXX). There were 15 aircrew-discovered discrepancies: 12 function degradations, 2 function losses, and 1 mission abort.

During the test program, the penetration aids subsystem demonstrated a MTBF of 12.4 flying hours. The associated 90-percent confidence limit was 8.9 flying hours. A further breakdown of equipment reliability is shown below, where the flying hours, MTBF, and associated 90-percent lower confidence limit are listed for each system within the penetration aids subsystem.

</tbody>
</table>

Maintainability.

Because of the nonrepresentative maintenance performed during testing, no attempt at a quantitative maintainability analysis was made. From a qualitative standpoint, the majority of the maintainability problems encountered were with the AN/ALQ-94.

A large problem area exists in the ability of the go/no-go test on this component. On three flights over instrumented ranges, ground instrumentation determined that the ALQ-94 was not working satisfactorily, but no indication of difficulty was presented to the aircrew. Subsequently, both systems which exhibited these symptoms failed within the next 10 flight hours.

OVERALL AIRCRAFT

Reliability

Hardware Reliability.

The overall reliability of the FB-111A aircraft in terms of hardware failures was 1.6 hours MTBF (table XXXI). This figure is optimistic because not all subsystems were operated during a significant percentage of the accumulated flight hours. The subsystems that only accumulated a small percentage of the total flight hours biased the hardware MTBF value.

Because of the multiple configurations of most subsystems and the widely varying size and utilization rate of Category II fleet, it was not possible to determine if any substantial reliability growth existed during Category II test. The lack of contractor predictions for hardware reliability made it impossible to measure the aircraft against any design goals.

Mission Reliability.

During the Category II test program the aircraft demonstrated a MFHBFD of 1.5 flight hours. The number of ground-crew-discovered hardware failures was approximately the same as the number of aircrew write-ups that did not yield a hardware failure. As a result, the hardware MTBF was about equal to the MFHBFD. The aircraft demonstrated a Mean Time Between Function Losses of 5.0 flight hours. Again, these statistics were biased upwards by the low flight hours accumulated on some subsystems. Appendix I shows the flight hours accumulated on each subsystem and also summarizes the mission reliability statistics by subsystem.

Maintainability

Support General (Scheduled) Maintenance.

The contractor predicted 6.3 MMH/FH for support general maintenance (WUC groups 01 through 09) and 22.9 MMH/FH would be required during Category II testing. Any comparison of support general MMH/FH's must consider the following usage restrictions (abstracted from: Maintainability Specification for Model FB-111A Weapon System, reference 19):

"Military usage in excess of 2.8 MMH/FH shall not be chargeable to the contractor MMH/FH requirement. Military usage shall include all labor expended under WUC's 02, 05, 06, 07, 08, 09, that portion of code 01, Ground Handling and Service (ground handling only) and that portion of code 04, Special Inspections (Special Inspection for Modification, Test Flight, After Fire, Excessive 'g', Hand Loading and Hot Start; Engine Time, Weight and Balance, Compass Swing, Accident/Incident Investigation, Reclamation, Emergency Equipment Check DD 780 Inventory)."

Censoring the Category II data to meet this restriction yielded a measured MMH/FH of 13.0. The remaining difference is attributed entirely to unrealistic contractor predictions.

Nonsupport General (Unscheduled) Maintenance.

The contractor predicted 17.5 MMH/FH for nonsupport maintenance (WUC's 11 through 99), and 25.8 MMH/FH was required during Category I testing. Of the measured value, 4.6 MMH/FH was required for TCTO accomplishment. Even if TCTO requirements decrease as the weapons system matures, a remaining difference of 3.7 MMH/FH would be expected. Since the nonavionics subsystems (with the flight controls excepted) generally met contractor predictions and the avionics subsystems (with the communications subsystems excepted) exceeded predictions, reliability improvements in the flight controls and avionics subsystem should allow the air vehicle to meet maintainability predictions for unscheduled maintenance. Table XXXII shows the measured MMH/FH by Work Unit Code.

AVAILABILITY

Aircraft availability is a measure of the degree to which an aircraft is in the operable and commitable state at the start of the mission, when the mission is called for at an unknown (random) point in time. Inherent availability is a function of aircraft reliability, the effectiveness of maintainability design, and the adequacy of the contractor-recommended number of maintenance personnel, spares, AGE, and technical orders, but not the operational environment. Inherent availability can be expressed by the formula:

\[ A_i = \frac{\text{Total Time} - \text{Active Repair Time}}{\text{Total Time}} \]

For ease of computing the active repair time the following formula was used:

\[ A_i = \frac{\text{AH/MON} - \frac{\text{MART}}{\text{FLT}} \frac{\text{FH}}{\text{MON}} \frac{\text{FLT}}{\text{FH}} + \frac{\text{MAPT}}{\text{PI}} \frac{\text{PI}}{\text{FH}} \frac{\text{FH}}{\text{MON}}}{\text{AH/MON}} \]

where,

\[ A_i = \text{inherent aircraft availability} \]

\[ \text{AH/MON} = \text{active hour per month that the aircraft was available for flying and/or maintenance} \]

\[ \text{MART/FLT} = \text{mean active hours to repair the aircraft between successive flights} \]

\[ \text{MAPT/PI} = \text{mean active hours required to complete a phase inspection.} \]

\[ \text{FLT/FH} = \text{number of flights per hour.} \]

\[ \text{FH/MON} = \text{number of flight hours per month.} \]

\[ \text{PI/FH} = \text{number of phase inspections per flight hour.} \]

The MART/FLT and the MAPT/PI were calculated using only active maintenance times, since administrative and logistic delays were a function of the maintenance management at each operational unit and therefore must be excluded from any calculation of inherent availability.

The following calculations use:

\[ \text{MAPT/FLT} = 4.0 \text{ active hours per flight} \]

\[ \text{MAPT/PI} = 36.0 \text{ active hours per phase inspection} \]

and the following assumptions:

\[ \text{AH/MON} = 16 \text{ hours per day for 22 days per month} \]
\[ = 352 \text{ active hours per month} \]
FH/MON = 30 flight hours per month

FLT/FH = 0.5 flight per flight hour (2-hour average flight deviation)

PI/FH = 0.04 phase inspection/flight hour (a constant)

Giving:

\[ A_i = \frac{352 - [(4.0)(30)(0.5) + (36.0)(0.04)(30)]}{352} \]

\[ = \frac{352 - (60.0 + 43.2)}{352} \]

\[ = 70.5 \text{ percent.} \]

Because the above assumptions may be unrealistic for an operational unit, figures 1, 2, and 3 are presented. Each graph plots \( A_i \) as a function of active hours per day with separate curves for average flight durations of 2, 4, and 6 hours. Figure 1 assumes 20 flight hours per month while figures 2 and 3 assume 30 and 40 flight hours per month respectively.

Figures 1, 2, and 3 are on the following pages
Figure 2

For 30 Flight Hours Per Month (FH/MON)

- O Three Hour Mean Mission Duration
- ▲ Five Hour Mean Mission Duration

Active Hours Per Day (AH/DAY)
CONCLUSIONS AND RECOMMENDATION

RELIABILITY

The overall reliability of the FB-111A aircraft in terms of hardware failures was 1.6 hours MTBF. This figure is optimistic because not all subsystems were operated during a significant percentage of the accumulated flight hours. The subsystems that only accumulated a small percentage of the total flight hours biased the hardware MTBF value.

During the Category II test program the aircraft demonstrated a mean flying hours between function degradation of 1.5 flight hours. The number of ground-crew-discovered hardware failures was approximately the same as the number of aircrew writeups that did not yield a hardware failure. As a result, the hardware MTBF was about equal to the MFHBFD. The aircraft demonstrated a Mean Time Between Function Losses of 5.0 flight hours. Again, these statistics were biased upwards by the low flight hours accumulated on some subsystems.

With the exception of the flight controls subsystem, the reliability of the nonavionics subsystems was considered acceptable. Should modifications incorporated into the aircraft prove effective, the flight controls subsystems should approach satisfactory reliability.

The reliability of the avionics subsystems was low (with the exception of the attack radar) when compared with qualification test statistics that applied to MIL-STD-781A testing.

Because of the multiple configurations of most subsystems and the widely varying size and utilization rate of Category II fleet, it was not possible to determine if any substantial reliability growth existed during Category II test. The lack of contractor predictions for hardware reliability made it impossible to measure the aircraft against any design goals.

MAINTAINABILITY

The contractor predicted that an MH/FH of 6.3 would be required for support general maintenance (WUC groups 01 through 09); 22.9 MMH/FH was required during Category II testing.

Censoring the Category II data to meet restrictions on military usage as defined in the text (page 306) yielded a measured MNH/FH of 13.0. The remaining difference is attributed entirely to unrealistic contractor predictions.

The contractor predicted 17.5 MMH/FH for nonsupport maintenance (WUC's 11 through 99), and 25.8 MMH/FH was required during Category II testing. Of the measured value, 4.6 MMH/FH was required for TCTO accomplishment. Even if TCTO requirements decrease as the weapons system matures, a remaining difference of 3.7 MMH/FH would be expected. Since the nonavionics subsystems (with the flight controls excepted) generally met contractor predictions and the avionics subsystems (with the communications subsystems excepted) exceeded predictions, reliability improve-
ments in the flight control's and avionics subsystem should allow the air vehicle to meet maintainability predictions for unscheduled maintenance.

There was a high "cannot duplicate" rate for some subsystems due to altitude, temperature, or g-related malfunctions.

Within the inertial navigation subsystems, 60 percent of the maintenance actions initiated because of status-warning lights (and possibly other symptoms) did not trace to a hardware failure.

1. An investigation should be conducted to determine the feasibility of improving the accuracy of status/warning lights (page 40).

APPENDIX II
DATA COLLECTION AND FORMULAE

OPERATIONAL DATA SYSTEM

Reliability data were collected by use of the Aircraft Debriefing Record (APFTC Form 0-294), figure 4. The reliability and maintainability (R&M) engineer or his designated representative recorded the crewmember's analysis of subsystem deficiencies and malfunctions that occurred during the mission on the APFTC Form 0-294. These reliability codes were used to record debriefing of the aircrew:

No entry System was not used.
1 System operated satisfactorily.
2 System malfunctioned (was of degraded operation requiring corrective maintenance action), but was still capable of performing its intended function to a level at which the mission objectives for this subsystem were still accomplished.
3 System was completely inoperative or a required mode of operation was inoperative (in the minimum specified performance of the subsystem was not attained), but the failure did not cause an abort.
4 System failure as defined by 3 above that caused an abort.
5 Mission was flown with a known system discrepancy. If a new unrelated discrepancy occurred or system operation was satisfactory except for the known discrepancy, the appropriate code was entered.

The following definitions of mission effectiveness were used:

1. Ground Abort - Anytime the engine was shut down after engine start. Anytime maintenance was required before the pilot would take the aircraft, for example, adjustment of the system to obtain a usable presentation.

2. Air Abort - Anytime the aircraft was landed before normal mission completion for any safety-of-flight reason. Whenever the primary preplanned mission could not be performed due to a subsystem failure.

This form was also used to summarize the maintenance actions required to correct flight discrepancies. The R&M engineer evaluated each discrepancy after maintenance action was completed to determine whether it was a valid failure, discrepancy, etc., before including the information in the master history file.

Next the forms were keypunched and entered into the reliability master history file and a computerized listing of all data by mission was output. The R&M engineer edited this data product and corrected any data errors before performing any analysis on this file.

**DESCRIPTION OF DISCREPANCY**

1 NOTE:

a Obtain Block Number from front of this form.

b Obtain Job Control Number. When Discovered Code, Work Unit Code, How Malfunctioned Code, and Action Taken Code from AFSC Form 258-AFTO Form 349 as applicable, which shows the primary cause of failure.

Figure 4 Aircraft Debriefing Record (Concluded)
The Operating Time Report for Selected Items (AFTO Form 4), figure 5, recorded the elapsed time indicator (ETI) readings for each item so equipped during each scheduled phase inspection. These readings were compared to aircraft flight hours to obtain a ratio of the subsystem operating hours to the aircraft flight hours. The final cumulative ratio of these times is presented in table I. The value presented for those subsystems which did have ETI's represented the R&M engineer's estimate of this ratio from known run-up time, maintenance times, etc.
MAINTENANCE DATA SYSTEM

Maintainability data were collected by use of the Maintenance Discrepancy/Production Credit Record (AFSC Form 258 and 258-4), figure 6, which was completed by maintenance personnel. All maintenance actions were recorded by maintenance personnel using work unit codes (WUC's) to identify the specific hardware item being worked on and to identify the type of maintenance performed. WUC's were five-digit alpha/numeric codes specified in the WUC Manual (Technical Order 1F-111/B(Y)A-06), reference 14. The first two digits designated the aircraft system, for example 73 denoted the bombing navigation system (table II). The third digit identified subsystems within the system; for example, 73H denoted the inertial navigation system. The fourth and fifth digits designated assemblies and components within the subsystem; for example, 73HA0 denoted the inertial reference unit (IRU) of the inertial navigation system and 73HAA denoted the parameter memory instrument of the IRU.

Maintenance actions were further defined as support general or nonsupport general maintenance events. Support general maintenance such as preflights, servicing and other schedule maintenance tasks were denoted by WUC's 01XXX through 09XXX. Non-support general maintenance was unscheduled maintenance, such as repair of malfunctions discovered during flight, and were denoted by WUC's 11XXX through 97XXX.

After the AFSC Form 258's were completed by the man who had performed the maintenance, the forms were checked for accuracy by the maintenance supervisor and then system effectiveness personnel at two different levels before being keypunched. The data cards were put through a validation program which checked for errors that had not been previously detected or which had been introduced during keypunching. Computerized cards were output from this program in AF Form 349 (Maintenance Data Collection Record) format so that the maintenance data could be processed through the AFM 66-1 (Maintenance Management) system (reference 15), thus satisfying standard maintenance management requirements. After all detectable errors were eliminated, the data were put into the maintenance master history file. A computerized listing of all input data was edited at two levels in the system engineering section as a final check on data accuracy.

The maintenance data were now on computer tape and could be used for limited maintainability analysis. However, even though the maintenance actions had been documented and entered into the master history file, these actions were often not grouped together as a complete maintenance event. Therefore, all maintenance actions pertaining to a particular malfunction were "bridged" together into one corrective maintenance event. By use of this technique, a much more detailed analysis was possible than would have been permitted using standard maintenance data collection procedures as defined by AFM 66-1. This new maintenance master history file permitted the maintainability analysis conducted during Category II testing and presented in this report.

**Figure 6 Maintenance Discrepancy/Production Credit Record**
FUNCTIONAL RELIABILITY FORMULAE

The mission reliability statistics were calculated using the formulae;

\[
\text{MFHBD} = \frac{\text{FH}}{N_d + N_1 + N_a} \quad ; \quad \text{MFHBFL} = \frac{\text{FH}}{N_1 + N_a} \quad ; \quad \text{MFHBA} = \frac{\text{FH}}{N_a} \quad (1)
\]

where:

\[
\begin{align*}
\text{FH} & = \text{flight hours} \\
N_d & = \text{number of degradations recorded against the subsystem} \\
N_1 & = \text{number of losses recorded against the subsystem} \\
N_a & = \text{number of aborts recorded against the subsystem} \\
\text{MFHBD} & = \text{mean flight hours between function degradation} \\
\text{MFHBFL} & = \text{mean flight hours between function loss} \\
\text{MFHBA} & = \text{mean flight hours between aborts.}
\end{align*}
\]

The Chi-square (\(X^2\)) distribution using fixed truncation time for the tests was the method used to determine the lower confidence limits for mean flight hour statistics

\[
90\text{-percent LCL} = \frac{2 \text{FH}}{\chi^2 (a, 2 N_f + 2)} \quad (2)
\]

Where:

\[
\begin{align*}
\text{FH} & = \text{flight hours} \\
N_f & = \text{number of no-abort failures} \\
a & = \text{acceptable risk of error (10 percent, 1 - confidence level = 1-90).} \\
\chi^2 & = \text{the critical value for the chi-square distribution with risk, } a, \text{ and degrees of freedom, } 2 N_f + 2.
\end{align*}
\]

To calculate the probability that a subsystem would be usable on any mission regardless of duration, the following formulae were used:

\[
\begin{align*}
\text{P}_{\text{nd}} & = \frac{N_s}{N_s + N_d + N_1 + N_a} \quad (3) \\
\text{P}_{\text{nl}} & = \frac{N_s + N_d}{N_s + N_d + N_1 + N_a} \quad (4) \\
\text{P}_{\text{na}} & = \frac{N_s + N_d + N_1}{N_s + N_d + N_1 + N_a} \quad (5)
\end{align*}
\]
Where:

\( P_{nd} \) = probability of no function degradation
\( P_{nl} \) = probability of no function loss
\( P_{na} \) = probability of no abort
\( N_s \) = number of successful missions recorded for the subsystem.

The 90-percent LCL's for these probabilities were computed using the binomial distribution

\[
\frac{N}{i} \sum_{i=N}^{i=p} (1-p)^{N-i} = \alpha
\]

Where:

\( N \) = sample size
\( P \) = LCL probability (90 percent)
\( \alpha \) = acceptable risk of error (10 percent)

**MAINTAINABILITY FORMULAE**

In addition to the nonparametric maintainability statistics computed, the data points obtained were tested by the Kolmogorov-Smirnov (K-S) statistical goodness-of-fit test to determine which of three probability distribution might fit the data. The distributions tested and their mathematical formulation are:

Log normal distribution where \( t \) is the time and \( \mu \) and \( \sigma \) are the distribution parameters,

\[
f(t|\mu,\sigma) = \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{(\log_e(t) - \mu)^2}{2\sigma^2}}
\]

Exponential distribution with the parameter \( \theta \),

\[
f(t|\theta) = \frac{1}{\theta} e^{-\frac{t}{\theta}}
\]

Weibull distribution with parameters \( \theta_1 \) and \( \theta_2 \),

\[
f(t|\theta_1,\theta_2) = \theta_1 \theta_2 t^{\theta_2-1} e^{-(\theta_1 t)^{\theta_2}}
\]

BIBLIOGRAPHY

Maintainability Program Requirements (For Systems and Equipment), MIL-STD-470, Department of Defense, 21 March 1966.

This report presents the results of the reliability and maintainability evaluation conducted during the FB-111A Category II test program. The aircraft demonstrated a 1.6-hour mean time between failures and a 1.5-hour mean time between aircrew writeups. The overall aircraft reliability was significantly degraded by the low reliability of the flight controls and most avionics subsystems. The reliability of most non-avionics subsystems was acceptable. The contractor predicted that 23.8 maintenance manhours per flying hour would be required, and 48.0 manhours were actually measured; the difference was attributed to low reliability. Except for excessive removal, bench check, and replacement of good components during troubleshooting, the maintainability of the FB-111A was good. The mode/status lights associated with some subsystems were of questionable value in detecting failures correctly.
