ABSTRACT

Strain energy expressions are obtained for rings of rectangular, T- and I- section. The expressions are intended for use in the dynamic analysis of ring stiffened cylindrical shells. The approach is essentially a generalization of the conventional, approximate analysis of straight beams, i.e. the influence of shear stresses, and of direct stresses at right angles to the axis of the beams is neglected.
1. INTRODUCTION

The results obtained in this study will facilitate the determination of the modes of free vibration and/or of the dynamic response of ring-stiffened cylindrical shells. Expressions for the potential energy of the stiffeners in their most general state of displacement will be derived. The strain energies are obtained on the basis of "beam theory," i.e. the expressions are generalizations of those conventionally used for straight beams when shear effects and stresses at right angles to the axis of the beam are ignored. The approach is similar to the treatment of straight beams of thin-walled section in Ref. 1, Chapter 5, where the sections are considered to be built up from a number of flat plates for each of which the strain energy from elementary beam theory is known. Making the assumption that the shape of the cross section does not change, the energy in each plate can be expressed by the global coordinates of the bar. Allowing for the continuity of strains wherever two of the plates are jointed, strain energy expressions and the location of the shear center are obtained.

In the present treatment the elements of which the bars consist are either not flat, or not straight. The sections shown in Figs. la, b, and c will be treated. The ring in Fig. la is of simple rectangular cross section; it is really a flat plate of annular shape. In Fig. lb the section is a T. The web is again an annular flat plate, while the flange is a short segment of a cylindrical shell. The third case, Fig. lc, consists of three parts of similar nature. Expressions for the strain
energies of the elements are derived in the Appendices, using appropriately simplified relations available from plate and shell theories. For deformation of the entire bar in the plane of curvature a generalization of conventional beam theory is used, which assumes that plane sections remain plane, and also at right angles to the deformed center line.

The expressions in the Appendices could also be used to treat nonsymmetric cases like U- or L- stiffeners, Figs. 1d, e. These cases are not included because their use seems rather unlikely.

The strain energy expressions \( V \) obtained may be used in various, fairly obvious ways. They may be utilized to find the boundary conditions at the stiffeners for the a priori known partial differential equations for vibrations of the shell by using Hamilton's principle,

\[
\int (V - T) dt = \text{extremum}
\]

and applying calculus of variation with respect to the shell coordinates \( x \) and \( \phi \), Fig. 2. \( V \) and \( T \) are the strain energy and the kinetic energy, respectively.

As an alternative, one can use a Raleigh-Ritz approach and introduce appropriate approximation for the shell displacements \( u, v, w \), Fig. 3, into Eq. (1).

As a further alternative, one may introduce into Eq. (1) the expressions
\[ u = U_n(x) \cos(n\phi + \alpha) \]
\[ v = V_n(x) \sin(n\phi + \alpha) \]
\[ w = W_n(x) \cos(n\phi + \alpha) \]  

(2)

where \( \alpha \) is a phase angle. This substitution reduces the partial differential equations of the shell to three ordinary, simultaneous ones in \( U, V \) and \( W \).

For either of the alternatives, a suitable expression for the strain energy of the cylindrical shell may be found in Ref. 2.
II. STIFFENING RINGS OF RECTANGULAR CROSS SECTION, FIG. 1a

Fig. 4a shows a portion of the shell of thickness $t$ and radius $a$ and an interior stiffener of depth $d$ and thickness $h$. The depth $d$ is a nominal one, measured from the center surface of the shell to the innermost edge of the stiffener, Fig. 4a. This figure also shows the centroid $0$ of the stiffener cross section, and the radius $R_0$ of the centroidal circle. Fig. 4b shows the original and the displaced center lines of shell and stiffener, and the displacements $u_0, w_0$ of the centroid 0 as well as the rotation $\beta$. The out-of-plane displacement is $v_0$, but cannot be indicated in Fig. 4b.

Using Eqs. (A-13) and (A-22) for the portions of the strain energy of the stiffener in and out of the plane of curvature, respectively,

$$
V = \frac{1}{2} \int \frac{EZ}{R_0^3} \left( \frac{\partial^2 w_0}{\partial \phi^2} + w_0 \right) + \frac{EA}{R_0} \left( w_0 + \frac{\partial v_0}{\partial \phi} \right)^2 + \\
+ \frac{EI_0}{R_0^3} \left( \frac{\partial u_0}{\partial \phi} + R_0 \beta \right)^2 + \frac{GJ_0}{R_0^2} \left( \frac{\partial u_0}{\partial \phi} - R_0 \frac{\partial \beta}{\partial \phi} \right)^2 \, d\phi
$$

where

$$
Z = \frac{hd^3}{12}, \quad A = hd, \quad I_0 = \frac{h^3 d}{12}, \quad J_0 = \frac{h^3 d}{3}, \quad R_0 = a - \frac{d}{2}
$$

The value of $Z$ is approximate, but suitable if $d \ll a$. The displacements $u_0, w_0$ and $\beta$ can be expressed from geometry by the shell displacements at point A, Figs. 4a, 4b,
\[ w_0 = w_A, \quad \beta = -\frac{\partial w_A}{\partial x}, \quad u_0 = u_A - \frac{d}{2} \beta = u_A + \frac{d}{2} \frac{\partial w_A}{\partial x} \tag{5} \]

The quantity \( v_0 \) appears in Eq. (3) only in the form \( \frac{\partial v_0}{\partial \phi} \).

To express this derivative, the equality of the strains in shell and stiffener at point A, Fig. 4a, is used

\[ \frac{1}{a} \frac{\partial v_A}{\partial \phi} + \frac{1}{a} w_A = \frac{w_0}{R_0} + \frac{1}{R_0} \frac{\partial v_0}{\partial \phi} - \frac{d}{2aR_0} (\frac{\partial^2 w_A}{\partial \phi^2} + w_A) \tag{6} \]

The left hand side of this equation is the membrane strain in the shell at point A, while the right hand side is obtained from Eq. (A-15) for \( \eta = d/2 \). Noting the relation between \( a \) and \( R_0 \) gives

\[ \frac{\partial v_0}{\partial \phi} = \frac{d}{2a} \frac{\partial^2 w_A}{\partial \phi^2} + \frac{R_0}{a} \frac{\partial v_A}{\partial \phi} \tag{7} \]

Substitution into Eq. (3) gives the strain energy in the ring stiffener in terms of \( u_A, v_A \) and \( w_A \),

\[ V = \frac{1}{2} \int \left[ \frac{EZ}{R_0^3} \left( \frac{\partial^2 w_A}{\partial \phi^2} + w_A \right)^2 + \frac{EA}{R_0} (w_A + \frac{d}{2a} \frac{\partial^2 w_A}{\partial \phi^2} + \frac{R_0}{a} \frac{\partial v_A}{\partial \phi})^2 + \right. \]

\[ + \frac{EI_0}{R_0^3} \frac{\partial^2 u_A}{\partial \phi^2} + \frac{d}{2} \frac{\partial^2 w_A}{\partial x^2} - R_0 \frac{\partial w_A}{\partial x}^2 \]

\[ + \frac{GJ_0}{R_0^3} \left( \frac{\partial u_A}{\partial \phi} + a \frac{\partial^2 w_A}{\partial x \partial \phi} \right)^2 d\phi \tag{8} \]

If desired, one could introduce the approximation \( R_0 = a \), but the resulting simplification is hardly worthwhile.
III. STIFFENING RINGS OF T-SECTION, FIG. 1b

Figure 5a shows the shell and an interior stiffener and all dimensions. The centroid of the stiffener is at a distance $e$ from the middle surface of the shell. Figures 5b and 5c show the web and flange in their original and in their displaced positions, respectively. Also shown are the centroids $O_w$ and $O_1$ and their displacements.

The strain energy of the entire stiffener due to displacements $w_0$ and $v_0$ is

$$V(v_0, w_0) = \frac{1}{2} \int \left( \frac{EZ_0}{R_0} \frac{\partial^2 w_0}{\partial \phi^2} + w_0 \right)^2 + \frac{EA_o}{R_0} (w_0 + \frac{\partial v_0}{\partial \phi})^2 \, d\phi \quad (9)$$

where $Z_0 = I_0$ and $A_0$ are the moment of inertia and the area of the section, respectively.

The strain energies due to the displacement in the $x$-direction and rotation for the web, $V_w$, and for the flange, $V_1$, are according to Eqs. (A-22) and (A-32), respectively,

$$V_w(u_w, \beta) = \frac{1}{2} \int \left( \frac{EI_w}{R_w} \frac{\partial^2 u_w}{\partial \phi^2} + R_w \beta \right)^2 + \frac{GJ_w}{R_w} \left( \frac{\partial u_w}{\partial \phi} - R_w \frac{\partial \beta}{\partial \phi} \right)^2 \, d\phi \quad (10)$$

$$V_1(u_1, \beta) = \frac{1}{2} \int \left( \frac{EI_1}{R_1} \frac{\partial^2 u_1}{\partial \phi^2} + R_1 \beta \right)^2 + \frac{GJ_1}{R_1} \left( \frac{\partial u_1}{\partial \phi} - R_1 \frac{\partial \beta}{\partial \phi} \right)^2 \, d\phi \quad (11)$$
where the section properties are defined by

\[
I_w = \frac{dh^3}{12}, \quad J_w = \frac{dh^3}{3}, \quad I_1 = \frac{t_1b^3}{12}, \quad J_1 = \frac{bt^3}{3}
\]  

(12)

The displacements \(w_o, u_1\) and \(u_w\) can be expressed by the equivalent quantities at point A. The relations are

\[
w_o = w_A, \quad u_w = u_A - \frac{d}{2} \beta, \quad u_1 = u_A - d \beta, \quad \beta = -\frac{\partial w_A}{\partial x}
\]

(13)

To express \(\frac{\partial v_0}{\partial \phi}\), the strain in the shell at point A, and the strain in the web at the same point are equated

\[
\frac{1}{a} w_A + \frac{1}{a} \frac{\partial v_A}{\partial \phi} = \frac{1}{R_0} (w_0 + \frac{\partial v_0}{\partial \phi}) - \frac{e}{R_0 (R_0 + e)} \left(\frac{\partial^2 w_0}{\partial \phi^2} + w_0\right)
\]

(14)

The right-hand side of this equation is Eq. (A-15) for \(\eta = e\).

After simplification

\[
\frac{\partial v_0}{\partial \phi} = \frac{e}{a} \frac{\partial^2 w_A}{\partial \phi^2} + \frac{R_0}{a} \frac{\partial v_A}{\partial \phi}
\]

(15)

The total strain energy is the sum of Eqs. (9), (10) and (11). After substitution of Eqs. (13) and (15).
This expression can be somewhat simplified, if desired, by noting that $d \ll a$, and that for thin-walled sections $I_w \ll I_1$. Using also

$$R_O \approx R_1 \approx R_w \approx a - d \approx a - 2d \approx a$$

one obtains

$$V = \frac{1}{2\kappa^3} \int \left( \frac{E I_o}{R_o^3} \left( \frac{\partial^2 w_A}{\partial \phi^2} + \frac{\partial w_A}{\partial \phi} \right)^2 + \frac{E A_o}{R_o a^2} \left( \frac{\partial w_A}{\partial \phi} + e \frac{\partial^2 w_A}{\partial \phi^2} + R_o \frac{\partial v_A}{\partial \phi} \right)^2 + \right.$$  

$$+ \frac{E I_w}{R_1^3} \left[ \frac{\partial^2 u_A}{\partial \phi^2} + \frac{d}{2} \frac{\partial^3 w_A}{\partial x \partial \phi^2} - \left( a - \frac{d}{2} \right) \frac{\partial w_A}{\partial \phi} \right]^2 +$$

$$+ \frac{E I_1}{R_1^3} \left[ \frac{\partial^2 u_A}{\partial \phi^2} + \frac{d}{2} \frac{\partial^3 w_A}{\partial x \partial \phi^2} - \left( a - d \right) \frac{\partial w_A}{\partial \phi} \right]^2 +$$

$$G \left( \frac{J_w}{R_w^3} + \frac{J_1}{R_1^3} \right) \left( \frac{\partial u_A}{\partial \phi} + a \frac{\partial^2 w_A}{\partial \phi^2} \right)^2 \right) d\phi$$

(17)
IV. I-BEAM STIFFENING RINGS, FIG. 1c

Figure 6a shows a cross section of the shell and of the stiffening ring inside the shell. The centroid of the web and of the entire stiffener is at 0. The properties of the web and its displacements will carry the subscript 0. The two flanges are of equal dimensions, b by t₁, and their centroids are 0₁, 0₂, respectively. The displacements of the two centroids carry the subscripts 1, 2, respectively.

Just as in Sections I and II, the portion of the strain energy \( V(w₀, v₀) \) is given by Eq. (A-13),

\[
V(w₀, v₀) + \frac{1}{2} \int \left[ \frac{EZ}{R₀} \frac{\partial^2 w₀}{\partial \phi^2} + w₀ \right]^2 + \frac{EA}{R₀} \left( w₀ + \frac{\partial v₀}{\partial \phi} \right)^2 \right] d\phi \tag{18}
\]

where \( A \) and \( Z \) are the area, and the moment of inertia of the entire section.

The portion \( V₀ \) of the strain energy of the web due to the displacements \( u₀ \) and \( β \) is according to Eq. (A-22)

\[
V₀(u₀, β) = \frac{1}{2} \int \left[ \frac{EI₀}{R₀} \frac{\partial^2 u₀}{\partial \phi^2} + R₀ β \right]^2 + \frac{GJ₀}{R₀^3} \left( \frac{\partial u₀}{\partial \phi} - R₀ \frac{\partial β}{\partial \phi} \right)^2 \right] d\phi \tag{19}
\]

where

\[
I₀ = \frac{dh}{12}, \quad J₀ = \frac{dh}{3}, \quad R₀ = a - e - \frac{d}{2} \tag{20}
\]

The portions of the strain energy due to the displacements of the two flanges \( u₁ \) and \( β \) are, respectively, from Eq. (A-32)...
\[ V_1(u_1, \beta) = \frac{1}{2} \int \left[ \frac{EI}{R_1} \left( \frac{\partial^2 u_1}{\partial \phi^2} + R_1 \beta \right)^2 + \frac{GJ}{R_1^3} \left( \frac{\partial u_1}{\partial \phi} - R_1 \frac{\partial \beta}{\partial \phi} \right)^2 \right] d\phi \]  

(21)

\[ V_2(u_2, \beta) = \frac{1}{2} \int \left[ \frac{EI}{R_2} \left( \frac{\partial^2 u_2}{\partial \phi^2} + R_2 \beta \right)^2 + \frac{GJ}{R_2^3} \left( \frac{\partial u_2}{\partial \phi} - R_2 \frac{\partial \beta}{\partial \phi} \right)^2 \right] d\phi \]  

(22)

where \( u_1, u_2 \) are the displacements of the flanges 1 and 2, respectively, and

\[ I = \frac{t_1 b^3}{12}, \quad J = \frac{t_3 b^3}{3}, \quad R_1 = a - e, \quad R_2 = a - e - d \]  

(23)

Referring to Fig. 6b, the displacements, except \( v_i \), can be expressed by the displacements of the shell at point A,

\[ w_0 = w_A, \quad \beta = \frac{\partial w_A}{\partial x}, \quad u_0 = u_A - \left( \frac{d}{2} + e \right) \beta = u_A + \left( \frac{d}{2} + e \right) \frac{\partial w_A}{\partial x}, \]  

\[ u_1 = u_A - e \beta = u_A + e \frac{\partial w_A}{\partial x}, \quad u_2 = u_A - (d + e) \beta = u_A + (d + e) \frac{\partial w_A}{\partial x} \]  

(24)

The equality of the hoop strains at A in the shell and in the stiffener, with \( \eta = e + d/2 \) gives

\[ \frac{1}{a} \left( w_A + \frac{\partial v_A}{\partial \phi} \right) = \frac{1}{R_0} \left( w_0 + \frac{v_0}{\partial \phi} \right) - \frac{d + ze}{R_0 (2R_0 + d + 2e)} \left( \frac{\partial^2 w_0}{\partial \phi^2} + w_0 \right) \]  

and after simplification

\[ \frac{\partial v_0}{\partial \phi} = \frac{d + 2e}{2a} \frac{\partial^2 w_A}{\partial \phi^2} + \frac{R_0}{a} \frac{\partial v_A}{\partial \phi} \]  

(25)
Using Eqs. (24) and (25), the four Eqs. (18), (19), (21) and (22) become

\[ V(w_0, v_0) = \frac{1}{2} \int \left[ \frac{Ez}{R_0} \left( \frac{\partial^2 w_A}{\partial \phi^2} + \frac{w_A}{2} \right)^2 + \frac{EA}{R_0} \left( w_A + \frac{d+2e}{2a} \left( \frac{\partial^2 w_A}{\partial \phi^2} + \frac{2a}{2a} \left( \frac{\partial v_A}{\partial \phi} \right)^2 \right) \right] d\phi \]

\[ V_0(u_0, \beta) = \frac{1}{2} \int \left[ \frac{Ez}{R_0} \left( \frac{\partial^2 u_A}{\partial \phi^2} + \frac{d+2e}{2} \left( \frac{\partial^2 w_A}{\partial \phi^2} - \frac{R_0}{2} \frac{\partial w_A}{\partial x} \right)^2 + \frac{GJ}{R_0} \left( \frac{\partial u_A}{\partial \phi} + a \frac{\partial^2 w_A}{\partial x \partial \phi} \right)^2 \right] d\phi \]

\[ V_1(u_1, \beta) = \frac{1}{2} \int \left[ \frac{Ez}{R_1} \left( \frac{\partial^2 u_A}{\partial \phi^2} + e \frac{\partial^2 w_A}{\partial \phi^2} - R_1 \frac{\partial w_A}{\partial x} \right)^2 + \frac{GJ}{R_1} \left( \frac{\partial u_A}{\partial \phi} + a \frac{\partial^2 w_A}{\partial x \partial \phi} \right)^2 \right] d\phi \]

\[ V_2(u_2, \beta) = \frac{1}{2} \int \left[ \frac{Ez}{R_2} \left( \frac{\partial^2 u_A}{\partial \phi^2} + (d+e) \frac{\partial^2 w_A}{\partial \phi^2} \right) - R_2 \frac{\partial w_A}{\partial x} \right)^2 + \frac{GJ}{R_2} \left( \frac{\partial u_A}{\partial \phi} + a \frac{\partial^2 w_A}{\partial x \partial \phi} \right)^2 \right] d\phi \]

(26)

The entire strain energy \( V \) is the sum of the four terms, Eqs. (26). However, some approximations seem permissible. The first term in the relation for \( V_0 \) contains the factor \( I_0 = dh^3/12 \), which is very small in comparison to the similar terms in \( V_1 \) and \( V_2 \), where \( I = t_1 b^3/12 \). For thin-walled sections the term multiplied by \( I_0 \) is negligible. Further \( e = \frac{t + t_1}{2} \) is small compared to \( d \) or \( R \). Using \( e \approx 0 \) is thus a reasonable approximation. Assuming further that \( d \ll a \), one may use approximately \( R_0 \approx R_1 \approx R_2 \approx a \).

The end result is
\[
V = \frac{1}{2a^3} \int \left[ E \left( \frac{\partial^2 w_A}{\partial \phi^2} + w_A \right)^2 + E_a a^2 A(w_A + \frac{d}{2a} \frac{\partial^2 w_A}{\partial \phi^2} + \frac{\partial v_A}{\partial \phi})^2 + \right. \\
+ E\left( \frac{\partial^2 u_A}{\partial \phi^2} - a \frac{\partial w_A}{\partial \phi} \right)^2 + E\left( \frac{\partial^2 u_A}{\partial \phi^2} + d \frac{\partial^3 v_A}{\partial x \partial \phi^2} - a \frac{\partial w_A}{\partial x} \right)^2 + \\
+ G(J_0 + 2J) \left( \frac{\partial u_A}{\partial \phi} + a \frac{\partial^2 w_A}{\partial x \partial \phi} \right)^2 d\phi 
\] (27)
V. SUMMARY

Strain energy expressions have been obtained for ring stiffeners of the types shown in Figs. 1a, b and c. The results are, respectively, given by Eqs. (8), (17) and (27). The stiffeners shown in Fig. 1 are all on the inside of the shell. However the results obtained are also applicable to stiffeners of the same type on the outside of the shell. In such cases the quantities d and e occurring in Eqs. (8), (17) and (27) must be replaced by \(-d, -e\), respectively.

Possible applications for the strain energy expressions are indicated in the Introduction. The suggested uses require an expression for the strain energy of shell panels adjoining the stiffeners. Such an expression is available in Ref. 2.

Defining the shell displacements \(u, v\) and \(w\) as shown in Fig. 3, the strain energy of a panel is

\[
U = \frac{E}{2(1-\nu^2)} \left( \int \left[ \frac{h^2}{a} \int \left[ a_2 u_x^2 + (v_\phi + w)^2 + 2avu_x (v_\phi + w) + \frac{1-\nu}{2} (u_\phi + av_x)^2 \right] dx d\phi \right.ight.
\]

\[
+ \frac{E}{24(1-\nu^2)} \left. \int \left[ \frac{h^3}{a^3} \int \left[ a_4 w_{xx}^2 + (w_\phi + w)^2 + \frac{1-\nu}{2} (aw_{x\phi} + u_\phi)^2 \right] dx d\phi \right. \right.
\]

\[
+ \frac{3(1-\nu)}{2} \frac{a^2}{2} (v_x - w_{x\phi})^2 + 2va^2 w_{xx} (w_\phi - v_\phi) - 2a^3 u_x w_{xx} \right] dx d\phi \right)
\]

where \(t\) is the shell thickness, and the subscripts \(x\) or \(\phi\) indicate partial derivatives with respect to \(x\) or \(\phi\). The double integrals extend over the area of the shell panel.
APPENDIX 1.

Strain energy of a circular curved bar due to deformation v, w in the plane of curvature, Fig. A-1.

Consider an element of a curved bar, Fig. A-2, the cross section of which is symmetric to the plane of curvature. The element is stressed by a moment M and a direct force N, both in the plane of curvature. The small deflections of a point P in the location φ can be described by the radial component w and the tangential component v, Fig. A-1. Figs. A-1 and 2 show I-beams with unequal flanges, which are generalizations of the three specific cases, Figs. 1a, b and c, needed in the body of the report.

The approach used is a generalization of the simple Navier-Euler theory in straight beams, which assumes that only stresses in the axial direction contribute materially to the strain energy. Stresses in the radial direction and shear stresses, both of which must exist, are thus assumed to contribute only negligibly to the strain energy. The assumption that plane cross sections remain plane and at right angles to the deformed center line of the bar, leads to the distribution of bending stresses as obtained in the classical treatment of Winkler-Resal. The following is not concerned with a re-derivation of the equations for the stresses, but with the formulation of strain energy expressions in terms of derivatives of v and w. Such expressions seem not to be available in the literature.
Consider an element of the bar of length $ds$ in its original and in its distorted shape, Fig. A-2. The centroidal axis of original length $ds$ will be lengthened by $\Delta ds$, and the angle between the two faces will change, as shown in the same figure, by $\frac{\Delta ds}{R} + \Delta d\phi$.

Considering an element $dA$ at a radial distance $\eta$ from the centroid, one can compute strain and stress in the element as function of $\Delta ds$ and $\Delta d\phi$

$$\sigma = E \left( \frac{1}{R} \frac{\Delta ds}{d\phi} + \frac{n}{R + \eta} \frac{\Delta d\phi}{d\phi} \right)$$

(A-1)

As usual, the quantity $Z$ is introduced

$$Z = R \int \frac{n^2}{R + \eta} dA = -R^2 \int \frac{n dA}{R + \eta}$$

(A-2)

If the depth of the bar is small compared to the radius $R$, the value of $Z$ is practically identical to the moment of inertia $I$.

In the body of the report, it will be assumed that $Z \approx I$.

Comparing the resultants of the stresses given by Eq. (A-1), and $M$ and $N$, one can determine $\Delta ds$ and $\Delta d\phi$,

$$\frac{\Delta d\phi}{d\phi} = \frac{R^3 M}{EZ}$$

(A-3)

$$\frac{\Delta ds}{d\phi} = \frac{R}{EA} (N + \frac{M}{R})$$

The strain energy $dV$ in the element of length $ds = Rd\phi$ being equal to the work done by the forces $M$ and $N$ during the distortion of the element, one finds
\[ V = \int dV R d\phi = \frac{1}{2} \int \left[ \frac{Ez}{R} \left( \frac{\Delta d\phi}{d\phi} \right)^2 + \frac{EA}{R} \left( \frac{\Delta ds}{d\phi} \right)^2 \right] d\phi \tag{A-4} \]

The quantities \( \frac{\Delta d\phi}{d\phi} \) and \( \frac{\Delta ds}{d\phi} \) are to be expressed in terms of \( v \) and \( w \), which are the components of the displacement of the centroid \( O \) of the cross section. Figure A-3 shows the original and the distorted element superimposed on each other. Using polar coordinates, \( \rho(\phi) = R + w(\phi) \), the curvature of the original center line is \( 1/R \), while the curvature \( 1/R_1 \) of the distorted center line is, with \( \rho = R + w \),

\[
\frac{1}{R_1} = \frac{\rho^2 + 2(\frac{d\rho}{d\phi})^2 - \rho \frac{d^2\rho}{d\phi^2}}{[\rho^2 + (\frac{d\rho}{d\phi})^2]^{3/2}} = \frac{1}{R+w} - \frac{1}{(R+w)^2} \frac{d^2w}{d\phi^2} \tag{A-5}
\]

The approximate result is obtained by using the fact that \( (\frac{d^2w}{d\phi^2})^2 \ll (R+w)^2 \). Forming the expression \( 1/R_1 - 1/R \), and allowing for \( w \ll R \), and \( ds = Rd\phi \), one finds

\[
\frac{1}{R_1} - \frac{1}{R} = -\frac{w}{R(R+w)} - \frac{1}{2} \frac{d^2w}{(R+w)^2} \frac{d^2\phi}{d\phi^2} \ll -\frac{1}{2} R^2 (\frac{d^2w}{d\phi^2} + w) \tag{A-6}
\]

In addition to above relation there is a geometric one between \( R, R_1, \Delta ds \) and \( \Delta d\phi \), which can be read from Fig. A-3. The total length of the distorted axis, \( ds + \Delta ds \), must equal the new radius \( R_1 \) multiplied by the angle \( \alpha \) enclosed by the two faces of the deformed element. Thus
\[ R_1^\alpha \equiv R_1 \left( \frac{ds}{R} + \Delta d\phi + \frac{\Delta ds}{R} \right) = \Delta s + \Delta ds \] (A-7)

Rearranging and dividing by \( R_1 R \, d\phi \) gives

\[ \frac{1}{R_1} - \frac{1}{R} = \frac{1}{R} \frac{\Delta d\phi}{d\phi} + \frac{\Delta ds}{d\phi} \frac{R_1 - R}{2R_1} = \frac{1}{R} \frac{\Delta d\phi}{d\phi} \] (A-8)

The approximation in Eq. (A-8) is permissible because \( (R_1 - R)/R \) is inherently a small quantity in comparison to unity. Equations (A-6) and (A-8) furnish

\[ \frac{\Delta d\phi}{d\phi} = -\frac{1}{R} \left( \frac{d^2 w}{d\phi^2} + w \right) \] (A-9)

In conjunction with Eq. (A-3) this relation leads to the well-known differential equation for the radial displacement \( w \), see Ref. (3).

An additional geometric relation can be obtained from Fig. A-4. The end points \( A \) and \( B \) of the element \( ds \) displace to \( A' \) and \( B' \), respectively. The distances \( \overline{CA'} \) and \( \overline{CB'} \) follow from Fig. A-4, where quantities which are small of higher order are neglected.

\[ \overline{CA'} = dw - vd\phi - d\phi d\phi = dw - \frac{1}{R} \, vds \] (A-10)

\[ \overline{CB'} = Rd\phi + wd\phi + dv + d\phi d\phi = ds + \frac{1}{R} \, wds + dv \]

Further

\[ \frac{1}{ds} \overline{A'B'} = 1 + \frac{\Delta ds}{ds} = \sqrt{(1 + \frac{w}{R} + \frac{dv}{ds})^2 + \left( \frac{dw}{ds} - \frac{v}{R} \right)^2} \] (A-11)
Expanding the square root by the binomial law and neglecting higher order terms gives

\[ \frac{\Delta s}{d\phi} = w + \frac{dv}{d\phi} \quad (A-12) \]

Substitution into Eq. (A-4) gives finally the strain energy expression

\[ V = \frac{1}{2} \int \left[ \frac{Ez}{R^2} \left( \frac{d^2w}{d\phi^2} + w \right)^2 + \frac{EA}{R} (w + \frac{dv}{d\phi})^2 \right] d\phi \quad (A-13) \]

It is noted that the second Eq. (A-3) and Eq. (A-12) give the differential equation

\[ \frac{w + \frac{dv}{ds}}{R} = \frac{1}{EA} \left[ N + \frac{M}{R} \right] \quad (A-14) \]

Conventional texts contain only an approximation of the equation where the term M/R does not appear.

It will also be necessary to have an expression for the strain in a location \( \eta \), Fig. A-2. Using Eqs. (A-1), (A-9) and (A-12) one finds

\[ \varepsilon_\phi = \frac{1}{R} \frac{\Delta s}{d\phi} + \frac{\eta}{R+\eta} \frac{\Delta s}{d\phi} = \frac{1}{R}(w + \frac{dv}{d\phi}) - \frac{\eta}{R(R+\eta)} \left( \frac{d^2w}{d\phi^2} + w \right) \quad (A-15) \]
APPENDIX 2.

Strain energy of a thin annular plate, displaced at right angles to its middle plane, Fig. 5.

The web of a ring stiffener of a shell, Fig. 1a, b or c, may be considered as an annular plate. An expression for the strain energy of such a plate in polar coordinates can be found in Ref. (4 p. 346, Eq. (0)). This expression is a double integral over three major terms. The sum of the first two terms can be recognized as due to the direct stresses, while the third is due to the shear stresses. Let \( V = V_1 + V_2 \), and using the symbol \( \bar{u} \) for the normal displacements of the plate,

\[
V_1 = \frac{D}{2} \iint \left[ \left( \frac{2}{r} \frac{\partial^2 \bar{u}}{\partial r^2} + \frac{1}{r} \frac{\partial \bar{u}}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \bar{u}}{\partial \phi^2} \right)^2 - 2(1-v) \frac{2}{r^2} \left( \frac{1}{r} \frac{\partial \bar{u}}{\partial r} + \frac{1}{r} \frac{\partial^2 \bar{u}}{\partial \phi^2} \right)^2 \right] r dr d\phi \]  
\tag{A-16a}

\[
V_2 = \frac{D}{2} \iint 2(1-v) \left( \frac{1}{r} \frac{\partial^2 \bar{u}}{\partial r \partial \phi} - \frac{1}{r^2} \frac{\partial^2 \bar{u}}{\partial \phi^2} \right)^2 r dr d\phi \]  
\tag{A-16b}

Consistent with the assumption that the only stresses contributing materially to the strain energy \( V_1 \) of bending are direct stresses \( \sigma_\phi \), the term \( D \) in (A-16a) is to be evaluated for \( v = 0 \), while the value \( v \neq 0 \) is retained in Eq. (16-b) for shear effects. Further, as in elementary beam theory, it is assumed that the radial axis of the cross section remains a straight line.
\( \ddot{u}(r) \equiv \ddot{u}(\eta) = u + \eta \beta \) \hspace{1cm} (A-17)

where \( u \) is the displacement of the centroid and \( \beta \) the rotation of the cross section. Using \( r = R + \eta, \; dr = d\eta \), and Eq. (A-17), one has the relations

\[
\frac{\partial^2 u}{\partial r^2} = \frac{\partial^2 u}{\partial \eta^2} = 0, \quad \frac{\partial u}{\partial r} = \frac{\partial u}{\partial \eta} = \beta
\]

(A-18)

After substitution of these relations into Eqs. (A-16) one can integrate with respect to \( \eta = r - R \). Using the fact that \( d/R \) is small compared to unity, the various integrals can be approximated

\[
\int \frac{dr}{r} = \ln \frac{1 + d/2R}{1 - d/2R} \approx \frac{d}{R}, \quad \int \frac{dr}{r^2} = \frac{1}{R^2 - d^2/4} \approx \frac{1}{R^2}, \quad \int \frac{dr}{r^3} = \frac{1}{2(R + d/2)^2} + \frac{1}{2(R - d/2)^2} \approx \frac{d}{R^3}
\]

(A-19)

One obtains thus

\[
V_1 = \frac{1}{2} \frac{Edh}{12} \int \frac{1}{R^3} \left( \frac{\partial^2 u}{\partial \phi^2} + 2\beta \right)^2 d\phi
\]

(A-20)
and

\[ V_2 = \frac{1}{2} \frac{G\delta h^3}{3} \int \frac{1}{R} \left( \frac{\partial u}{\partial \phi} - R \frac{\partial \beta}{\partial \phi} \right)^2 d\phi \]  

(A-21)

As a check on the adequacy of the simplifications made in Eqs. (19) consider a rigid body rotation of the annular plate with respect to the axis \( \phi = + \pi/2, \phi = - \pi/2 \), where \( u = \Delta \cos \phi \), \( \beta = \frac{\Delta}{R} \cos \phi \) and \( \Delta \) is the displacement at \( \phi = 0 \). Substitution into Eqs. (A-20, 21) indicates that for this displacement \( V_1 = V_2 = 0 \), as required for a rigid body displacement.

The total strain energy for out-of-plane displacements is thus

\[ V = \frac{1}{2R^3} \int \left[ \frac{Edh^3}{12} \left( \frac{\partial u}{\partial \phi} + R\beta \right)^2 + \frac{G\delta h^3}{3} \left( \frac{\partial u}{\partial \phi} - R \frac{\partial \beta}{\partial \phi} \right)^2 \right] d\phi \]  

(A-22)

The two coefficients appearing in the integrand are the values \( EI \) and \( GJ \) appearing in the equivalent expressions for a straight beam. For \( R \to \infty \), Eq. (A-22) thus furnishes the conventional value for \( V \) for a straight beam.
APPENDIX 3.

Strain energy stored in the flanges of rings of T- and I-Sections

Let the displacements of an arbitrary point $P$ on the middle surface of a flange, Fig. 7, be designated by the symbols $u_p, v_p, w_p$ while the displacements of the centroid $O$ of the undeformable, rectangular cross section are $u, v, w$ and the rotation is $\beta$.

Only sections which are symmetric to the plane of curvature are treated so that the strain energy separates into the sum of two terms

$$V = V_1(w,v) + V_2(u,\beta)$$  \hspace{1cm} (A-23)

one term depending only on $w$ and $v$, the other on $u$ and $\beta$. The term $V_1$ has already been obtained in Appendix 1, Eq. (A-13) and the associated strain in Eq. (A-15).

The second term, $V_2$, for T- or I-sections will be derived in the body of the report, using an expression for the web alone derived in Appendix 2, in conjunction with a relation to be derived here, treating flanges of rectangular cross section, $b \times t$, as short pieces of cylindrical shells. See Fig. A-7.

Assuming that the cross section does not change its shape, the displacements of a point $P$ in the location $\eta, z = 0$, Fig. A-7, are

$$w_p = -\eta \beta, \quad u_p = u \quad v_p = -\frac{\eta}{R} \frac{\partial u}{\partial \phi}$$  \hspace{1cm} (A-24)
The strain energy $V_2(u, \beta)$ can be divided in a portion due to hoop strains $\epsilon_S$, and one due to shear strains $\gamma V_2 = V_{2\epsilon} + V_{2\gamma}$. Allowing again for the fact that direct stresses other than $\sigma_S$ are negligible, the value of Poisson's ratio in $V_{2\epsilon}$ is assumed to vanish

$$V_{2\epsilon} = \frac{E}{2} \int\int \epsilon_S^2 d\eta dz (R + z)d\phi$$  \hspace{1cm} (A-25)$$

while the usual value of $\nu$ is retained in

$$V_{2\gamma} = \frac{G}{2} \int\int \gamma^2 d\eta dz (R + z)d\phi$$  \hspace{1cm} (A-26)$$

When evaluating Eq. (A-25) it is assumed that the bending strains do not vary significantly through the thickness, $t << d$, $t << R$, so that

$$V_{2\epsilon} = \frac{Et}{2} \int\int \epsilon_S^2 d\eta (R + z)d\phi \approx \frac{Et}{2} \int \epsilon_S^2 d\eta d\phi$$  \hspace{1cm} (A-27)$$

where the value $\epsilon_S$ at $z = 0$ is to be used. Reference [5, Eq.(5-b) on p. 209] gives for $z = 0$, after substitution of Eqs. (A-24)

$$\epsilon_S = \frac{1}{R} \frac{3}{3} \frac{3}{3} + \frac{u}{R} = - \frac{n}{R^2} \frac{3}{3} \frac{3}{3} - \frac{R}{R} \beta$$

Equation (A-27) gives thus finally

$$V_{2\epsilon} = \frac{1}{2} \frac{Et d^3}{12} \int \int \frac{1}{3} \left( \frac{3}{3} \frac{3}{3} \left( \frac{3}{3} \frac{3}{3} + R \beta \right) \right)^2 d\phi$$  \hspace{1cm} (A-28)$$
The above integral vanishes, as required, for the rigid body motion \( u = \Delta \cos \phi, \beta = \frac{\Delta}{R} \cos \phi \).

To evaluate the integral in Eq. (A-26) use is made of Ref. [5, Eq. (5-c)]. The value of the shear strain at an arbitrary point \( A \), Fig. A-7, is expressed by the values at points \( P \) on the center plane

\[
\gamma_A = \frac{1}{R+z} \frac{\partial u}{\partial \phi} + \frac{R+z}{R} \frac{\partial v}{\partial \phi} - \frac{\partial^2 W}{\partial \phi^2} \left( \frac{z}{R} + \frac{z}{R+z} \right)
\]  

(A-29)

Substitution of Eqs. (A-24) gives

\[
\gamma_A = \gamma = -z \frac{2R+z}{R^2(R+z)} \frac{\partial u}{\partial \phi} + z \frac{2R+z}{R(R+z)} \frac{\partial \beta}{\partial \phi} = -2z \left( \frac{1}{R} \frac{\partial u}{\partial \phi} - \frac{1}{R} \frac{\partial \beta}{\partial \phi} \right)
\]  

(A-30)

The approximation used utilizes the fact that \( \max z = t/2 \ll a \).

The value of the integral in Eq. (A-26) becomes thus

\[
V_{2\gamma} = \frac{1}{2} \frac{\text{Gbt}^3}{3 \rho} \int \frac{1}{R^3} \left( \frac{\partial u}{\partial \phi} - R \frac{\partial \beta}{\partial \phi} \right)^2 \, d\phi
\]  

(A-31)

As necessary, this value vanishes for the rigid body motion tested on Eq. (A-28).

The total value of \( V_2(u, \beta) \) is

\[
V_2(u, \beta) = \frac{1}{2} \frac{\text{Et}d^3}{12} \int \frac{1}{R^3} \left( \frac{\partial^2 u}{\partial \phi^2} + R \beta \right)^2 \, d\phi + \frac{1}{2} \frac{\text{Gbt}^3}{3 \rho} \int \frac{1}{R^3} \left( \frac{\partial u}{\partial \phi} - R \frac{\partial \beta}{\partial \phi} \right)^2 \, d\phi
\]  

(A-32)

In the limit, \( R \to \infty \), Eq. (A-32) furnishes the usual expression for the strain energy of a straight bar.

<table>
<thead>
<tr>
<th>SECURITY CLASSIFICATION</th>
</tr>
</thead>
</table>

INSTRUCTIONS

1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.

2. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.

3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.

4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial, if military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. REPORT DATE: Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.

7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.

8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.

8b. & 8c. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.

9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.

9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originator or by the sponsor), also enter this number(s).

10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:

   (1) "Qualified requesters may obtain copies of this report from DDC."

   (2) "Foreign announcement and dissemination of this report by DDC is not authorized."

   (3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified users shall request through ________"

   (4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through ________"

   (5) "All distribution of this report is controlled. Qualified DDC users shall request through ________"

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.

12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.

13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS). (S). (C). or (U).

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, roles, and weights is optional.

Stiffening Rings

Strain Energy
Strain energy expressions are obtained for rings of rectangular, T- and I- section. The expressions are intended for use in the dynamic analysis of ring stiffened cylindrical shells. The approach is essentially a generalization of the conventional, approximate analysis of straight beams, i.e. the influence of shear stresses, and of direct stresses at right angles to the axis of the beams is neglected.
