Abstract

Two-dimensional inviscid, unsteady transonic flows with shock waves in asymmetric channels with arbitrary wall shapes are investigated, using the method of matched asymptotic expansions. With the exception of thin regions in the neighborhood of the channel throat and the neighborhood of the shock wave, solutions found using linearized governing equations are valid. In the regions enclosing the shock wave, an inner solution which satisfies the shock jump conditions and matches with the outer solutions, is presented. The shock shape is found as part of the solution, which is obtained numerically using the method of integral relations. A composite solution, uniformly valid throughout the channel, and the relation between the instantaneous shock wave position and back pressure far downstream are presented.
INTRODUCTION

The analysis of two-dimensional transonic channel flows with shock waves has recently been the subject of several papers, culminating in a description of solutions found for unsteady flows with arbitrary initial conditions and arbitrary wall shapes. However, the solutions, no matter whether the channels are symmetric or asymmetric, are valid for streamline curvatures small enough that, to the scale of the channel width, the shock waves are planar. In this paper, on the other hand, a lower order (larger) curvature is considered in an asymmetric channel, so that strong cross channel gradients in velocity and pressure are found in the lowest order solutions. As a result, the shock wave is not planar; its shape is unknown and must be found as part of the solution.

Two approaches have generally been used in constructing analytical solutions for transonic channel flows with shock waves. In one, similarity solutions of the transonic small-disturbance equation are sought through various transformations, resulting in solutions for steady or unsteady flows. The solutions thus obtained, however, satisfy only very special boundary conditions which may or may not correspond to the physical problem under consideration, and the solutions are valid in a thin neighborhood of the sonic line. In the other approach, the method of matched asymptotic expansions is used to derive governing equations for each order of approximation from the general inviscid flow equations, for various regions in the channel. Adamson, Messiter and Richey showed that in the main part of the channel, this method gives a systematic derivation of the power series
expansion solution postulated by Szaniawski and used, for example, in the paper by Kopystynski and Szaniawski. In this method, arbitrary wall shapes may be specified, and in the extension to unsteady flows, arbitrary initial conditions may be considered. It is this approach which is used in the present paper.

In the following, the flow is taken to be two-dimensional, compressible, and transonic. The gas is assumed to follow the perfect gas law and to have constant specific heats. Upstream of the shock wave the flow is considered to be irrotational, and the Reynolds number is taken to be large enough that viscous effects are negligible. The unsteadiness in the flow is assumed to arise as a result of disturbances impressed upon the flow downstream of the region under consideration. A more detailed description of the analysis which follows, may be found in Reference 7.

**CHANNEL FLOW SOLUTIONS**

The solution is written in terms of time dependent perturbations from a steady, uniform, irrotational, sonic flow. The coordinate system and notation used are illustrated in figure 1. Velocity components u and v and the sound speed a are made dimensionless with respect to \( \overline{a} \), the sound speed in the undisturbed flow (overbars indicate dimensional quantities), space variables x and y are referred to \( \overline{L} \), the channel half width at the minimum area, and the time T is made dimensionless with respect to \( \overline{L}/\overline{a} \). The pressure, density, and temperature, denoted by \( \hat{P} \), \( \hat{\rho} \), and \( \hat{T} \) respectively, are made dimensionless with respect to their
values in the undisturbed flow. The region being considered is that for which \( x = O(1) \) and \( y = O(1) \); that is, it extends downstream of the throat for distances of the order of the channel half width. We introduce a small parameter, \( \epsilon \ll 1 \), which is of the order of the typical percentage difference between the flow velocity and its critical sonic value. Thus \( u - 1 = O(\epsilon) \) for \( x = O(1) \). The flow entering the region under consideration is irrotational and boundary layer effects are negligible. Moreover, because the flow is transonic, shock waves are weak enough that it can be shown that one can define a velocity potential to the order considered here.

Unsteady flows may be characterized by prescribing the relative orders of the characteristic time associated with the imposed flow disturbance, \( T_{ch} \), and the characteristic flow time, \( L/a^* \). In this present work, the so-called slowly varying time regime is considered, where \( T_{ch} \gg L/a^* \).

Hence, a parameter \( \tau \) is introduced as follows,

\[
T = \tau t \quad \tau = \frac{T_{ch}}{(L/a^*)} \tag{1a,b}
\]

where \( \tau \gg 1 \), and \( t = O(1) \). The slowly varying time regime covers a range of values for \( T_{ch} \) which is found in many physical problems. The relationship between \( \tau \) and \( \epsilon \) depends upon the relative orders of \( T_{ch} \) and the time it takes a pulse to move upstream from the point at which a disturbance originates, to the location under consideration, e.g., the point at which a shock wave is located. Thus, a disturbance pulse travels upstream at sonic velocity relative to the flow and, therefore, at an absolute velocity \( u_p = 1 - u = O(\epsilon) \). Hence, the time required for the disturbance to travel a distance \( L \) is \( O(L/a^*) \) and the desired time ratio is \( T_{ch}/(L//\epsilon a^*) = \tau/\epsilon \).
It is seen, therefore, that if the two times are of the same order, \( \tau = O(\epsilon) \).

This is the case considered in reference 6. Here we consider the case where \( \overline{T_{ch}} \gg \frac{L}{(\epsilon \overline{a}^2)} \), and in fact define \( \tau \) as,

\[
\tau = (k \epsilon^2)^{-1}
\]

where \( k \) is a constant of order unity. Physically, this means that flow disturbances are communicated "instantaneously" to the shock wave.

The governing equations are the gas dynamic equation and the Bernoulli equation:

\[
(a^2 - \Phi_x^2) \Phi_{xx} + (a^2 - \Phi_y^2) \Phi_{yy} - 2 \Phi_x \Phi_y \Phi_{xy} - \Phi_x \Phi_{TT} - 2 \Phi_x \Phi_x T - 2 \Phi_y \Phi_y T = 0 \quad (3a)
\]

\[
\Phi_T + \frac{1}{2} (\Phi_x^2 + \Phi_y^2) + a^2/(Y - 1) = (Y + 1)/(2(Y - 1)) \quad (3b)
\]

where subscripts \( x, y \) and \( T \) indicate partial differentiation; it can be shown that the constant on the right hand side of equation (3b) is valid to and including terms of order \( \epsilon^2 \), the highest order terms needed here. Since the solutions are written in terms of perturbations from a uniform flow, it is convenient to write \( \Phi \) as,

\[
\Phi(x, y, T) = x + \phi(x, y, T) \quad (4)
\]

where \( \phi \) is the perturbation potential. Then, using equation (3b) for \( a^2 \) and equation (4) for \( \Phi \), equation (3a) may be written as follows:

\[
\phi_{yy} = (Y + 1) \left[ \left( \phi_x + \phi_y^2/2 \right) \phi_{xx} + \left( \phi_y^2/2 \right) \phi_{yy} \right] + 2 \left( \phi_x + \phi_y \phi_x \phi_y \right) + \frac{1}{2} \left( \phi_x^2 + \phi_y^2 \right) \phi_{xy} \]

\[
+ (Y - 1) \left[ \left( \phi_x + \phi_y^2/2 \right) \phi_{yy} + \left( \phi_y^2/2 \right) \phi_{xx} \right] + 2 (1 + \phi_x) \phi_x T \]

\[
+ (Y - 1) \phi_T (\phi_{xx} + \phi_{yy}) + 2 \phi_y \phi_T + \phi_{TT} \quad (5)
\]
The boundary conditions at the walls of the channel are, for stationary walls,

\[ \phi_y(x, y_w, T) = y_w' \left[ 1 + \phi_x(x, y_w, T) \right] \]  

(6)

where \( y_w' = \frac{dy_w}{dx} \). For the asymmetric channels under consideration, and with the coordinate system as shown in figure 1, the wall shape, \( y_w \) is written as

\[ y_w = \pm 1 + \epsilon f_1(x) \pm \epsilon^2 f_2(x) \]  

(7)

where \( f_1(0) = f_2(0) = f_1'(0) = f_2'(0) = 0 \) and where \( f_1''(x) \) and \( f_2''(x) \) are continuous and nonzero at \( x = 0 \). The upper and lower signs refer to the upper and lower walls, respectively. It is seen that \( y = \epsilon f_1(x) \) is the equation for the channel centerline and \( \pm (1 + \epsilon^2 f_2(x)) \) are terms which describe walls symmetric with respect to the centerline, so that \( \epsilon \) is a measure of the radius of curvature of the channel at \( x = 0 \), the channel throat. Thus, the channel curvature is an order of magnitude larger than that considered previously, and as will be seen, this leads to completely different flow structures and shock shapes.

An asymptotic expansion of \( \phi \) is written as follows:

\[
\phi(x, y, T) = \epsilon \phi_1(x, y, t) + \epsilon^2 \phi_2(x, y, t) + \epsilon^3 \phi_3(x, y, t) + \cdots
\]

(8)

Substitution of equations (1), (2) and (8) into equation (5) yields the following equations for \( \phi_1, \phi_2, \) and \( \phi_3 \):

\[ \phi_{1yy} = 0 \]  

(9a)

\[ \phi_{2yy} = \left[ (Y + 1) \phi_{1x}^2/2 + \phi_{1x}^2 \right]_{1y} \]  

(9b)

\[ \phi_{3yy} = \left[ (Y + 1) \phi_{1x} \phi_{1x} - 2 (\phi_{1y} \phi_{2x} + \phi_{2y} \phi_{1x} + k \phi_{1x}) + \frac{1}{3} \left( Y - \frac{1}{2} \right) (Y + 1) \phi_{1x}^3 \right. \]

[ + \frac{1}{3} \left( Y - \frac{1}{2} \right) (Y + 1) \phi_{1x}^3 \]  

(9c)
The boundary conditions for equations (9) are found by substituting equations (1), (2), (7) and (8) into equation (6). Thus, to first order, it is found that
\[ \phi_1(x, y, t) = f_1'(x) \] (10)
where the prime indicates differentiation with respect to \( x \). The solution to equation (9a) subject to the boundary conditions in equation (10) is
\[ \phi_1 = f_1'(x)y + h_1(x, t) \] (11)
where \( h_1(x, t) \) is a function of integration. If the solution for \( \phi_1 \), equation (11), is substituted into equation (9b), the resulting equation may be integrated to give a solution for \( \phi_2 \). Thus,
\[ \phi_2(x, y, t) = \frac{(Y + 1)}{12} f_1'' f_1''' y^4 + \frac{(Y + 1)}{6} (f_1'' h_{1x}) y^3 \]
\[ + \frac{1}{2} (f_1')^2 + \frac{(Y + 1)}{2} (h_{1x})^2 y^2 + g_2(x, t)y + h_2(x, t) \] (12)
where \( g_2 \) and \( h_2 \) are functions of integration. If the solutions for \( \phi_1 \) and \( \phi_2 \) are substituted into the boundary condition, equation (6), where it should be noted that evaluation of any function at \( y_w \) implies expansion using equation (7), then one finds equations for \( g_2 \) and \( h_{1x} \). Thus,
\[ g_2(x, t) = f_2 h_{1x} - \frac{(Y + 1)}{2} (f_1'' h_{1x}) \] (13a)
\[ h_{1x} = \pm \left\{ (2 f_2 - (f_1')^2)/(Y + 1) + \beta(t) - (f_1'')^2/3 \right\}^{1/2} \] (13b)
where the equation for \( h_{1x} \) has been integrated once, and \( \beta(t) \) is the resulting function of integration; \( f_1 \) and \( f_2 \) are both functions of \( x \) and defined in equation (7). It is seen from equation (12) that in order to complete the solutions to second order, it is necessary to find \( h_2(x, t) \). This is accomplished by substituting the solutions for \( \phi_1 \) and \( \phi_2 \) into equation (9c), integrating once to obtain \( \phi_3y \), and substituting the resulting equations into the boundary condition,
equation (6). One finds that

\[ h_{2x} = 7(Y + 1)\left[\frac{\left(f_1''\right)^2 - f_1'y}{360} + \frac{f_1'y - f_1'}{6} - \frac{f_1'y}{2} - f_1'\right] + \left[\frac{3}{2} - \gamma\right]h_{1x}' - \gamma(yf_1'\right)'/3 + \left[\frac{2}{15}f_1''(f_1''h_{1x})_{xx} - \frac{2k}{(Y + 1)}h_{1t} + \beta_2(t)/h_{1x}\right] \]

where \( \beta_2(t) \) is, again, the function of integration. Finally, then, the solutions for \( u \) and \( v \) are, to second order,

\[
\begin{align*}
u &= \Phi_y = 1 + \epsilon f_1' + \epsilon^2 \left\{ (Y + 1) \left[\frac{\left(f_1''\right)^2}{24} + (Y + 1) \left(f_1''h_{1x}\right)_{xx} \right] y^3/6 + \left(f_1'y + f_1'h_{1x} - \frac{(Y + 1)}{2} \left(f_1''h_{1x}\right)_{xx} \right) y + h_{2x} \right\} + \cdots \\
u &= \Phi_y = 1 + \epsilon f_1' + \epsilon^2 \left\{ (Y + 1) \left[\frac{\left(f_1''\right)^2}{24} + (Y + 1) \left(f_1''h_{1x}\right)_{xx} \right] y^3/6 + \left(f_1'y + f_1'h_{1x} - \frac{(Y + 1)}{2} \left(f_1''h_{1x}\right)_{xx} \right) y \right\} + \cdots
\end{align*}
\]

where \( h_{1x} \) and \( h_{2x} \) are given by equations (13b) and (14) respectively, and \( \beta_1 \) and \( \beta_2 \) are to be determined from the initial conditions of the problem under consideration.

Before proceeding to the consideration of flows with shock waves, it is of interest to establish the range of flow patterns covered by the solutions represented by equations (15). First, it should be noted that in \( h_{1x} \) (equation (13b)), the term \( \beta_1 - \frac{\left(f_1''\right)^2}{3} \) cannot be negative since the remaining terms under the square root are zero at \( x = 0 \). If we first consider the case where \( \beta_1 - \frac{\left(f_1''\right)^2}{3} > 0 \) and also consider the solution for \( u \) (equation (15a)) only up to terms of order \( \epsilon \), then if the upper (+) sign is chosen for all \( x \) in equation (13b), the resulting flow is supersonic except
for a possible subsonic pocket existing in a region around $x = 0$, as shown in figure 2a. If, on the other hand, the lower (-) sign is chosen for all $x$ in equation (13b), one obtains a subsonic flow, except for a possible supersonic pocket around $x = 0$, shown in figure 2b. In both cases, the pocket enclosed by the sonic line grows as $\beta_1 - (f_1')^2/3$ decreases. Until $\beta_1 - (f_1')^2/3 = 0$, no sign change at $x = 0$ can be tolerated because the sonic line ($u = 1$) does not pass through $(0,0)$. When $\beta_1 - (f_1')^2/3 = 0$, depending upon whether the sign in equation (13b) changes or remains unchanged as $x$ passes through zero, the sonic line either returns to the same wall, figures 3a and 3b, or crosses the channel to the opposite wall, figures 4a and 4b. The gradients in velocity, and thus in pressure, temperature, etc., seen in these flow pictures illustrate the very interesting changes which take place in the flow when a radius of channel curvature of order $\epsilon^{-1}$ is considered as opposed to the radius of curvature of order $\epsilon^{-2}$ considered in reference 6.

It can be shown\(^7\) that for $x = 0(\epsilon)$, the terms of order $\epsilon$ and $\epsilon^2$ in $u$ may become of the same order, casting doubt upon the validity of the asymptotic expansions in this region. However, as shown in references 4 and 5, this possible lack of uniform validity for the asymptotic expansions is not a serious problem, the difficulty disappearing, for example, for walls which vary as $x^2$ in the region where $x = O(\epsilon)$. Hence the throat region will not be considered in this paper.

The solutions presented so far were derived for flows with no shock waves. It is of interest now to analyze cases where shock waves exist, to
ascertain if and at what order these solutions break down. We choose for
illustrative purposes those flows for which \( \beta_1 - (f'_1)^2 / 3 \equiv 0 \) shown in figures
3b and 4a. In these cases, in equation (13b), the upper (+) sign (supersonic
flow) is used downstream of the throat but upstream of the shock, with the
lower (-) sign (subsonic flows) holding downstream of the shock; the sign
upstream of the throat depends upon whether the flow is subsonic (accelerating,
figure 4a) or supersonic (decelerating, figure 3b). Similar results hold for
other sign combinations.

If the shock position is, to lowest order, \( x_s = x_0(t) + \ldots \), then from
equations (1a) and (2), it is seen that the shock velocity, \( dx_s / dt \), is of
order \( \epsilon^2 \). Hence, to order \( \epsilon \), the shock polar equation, which reduces to
the Prandtl relation, may be written in terms of absolute velocities. Thus,

\[ u_{id} = u_{iu} \tag{16} \]

where \( u_i = \phi_i \), and the subscripts \( u \) and \( d \) denote values immediately up-
stream and downstream of the shock wave, respectively. Now, if equations
(11) and (13b) are used to write \( u_{iu} \) and \( u_{id} \) at \( x_0 \), where the upper sign in
equation (13b) is used for \( u_{iu} \) and the lower for \( u_{id} \), it is seen that the shock
wave jump condition, equation (16), is not satisfied. Thus, even in first
order, the shock wave jump conditions are not satisfied, as opposed to the
case for flows with smaller curvature, and an inner region about the shock
must be considered.

**SOLUTIONS IN THE SHOCK WAVE REGION**

In the inner region containing the shock wave, the solutions must
satisfy the jump conditions across the shock, and match with the outer
channel flow solutions in the appropriate limit. This region may be expected
to extend across the channel, but to be very thin in the flow direction. Then,
in the inner region, we define the independent variables as follows:

\[ x^* = \frac{x - x_0(t)}{(Y + 1)^{1/2} \epsilon^\sigma}, \quad y^* = y, \quad T^* = T = \tau t^* \]  

(17a, b, c)

where, again, \( x_0(t) \) is the shock location to lowest order, and \( \sigma \) is to be
determined. The inner region velocity potential is defined as,

\[ \Phi^* (x^*, y^*, T^*) = \Phi(x, y, T)/(Y + 1)^{1/2} \epsilon^\sigma - \dot{x}_0 x^* \]  

(18)

where \( \dot{x}_0 = \frac{dx_0}{dT} = k \epsilon^2 \frac{dx_0}{dt} \). That is,

\[ u^* = \frac{\Phi^*}{x^*} = u - \dot{x}_0, \quad v^* = \frac{\Phi^*}{y^*} = v/(Y + 1)^{1/2} \epsilon^\sigma \]  

(19a, b)

In view of the expansion for \( \Phi \), equation (4a), we write the expansion for \( \Phi^* \)
as follows:

\[ \Phi^* (x^*, y^*, T^*) = (1 - \dot{x}_0) x^* + \phi^* (x^*, y^*, T^*) + x_0/(Y + 1)^{1/2} \epsilon^\sigma \]  

(20)

where \( \phi^* (x^*, y^*, T^*) \) is the inner perturbation potential.

The proper form for the expansion of \( \phi^* \) results from the application
of three conditions which must be fulfilled. Since it is expected that the
fluid acceleration in the inner region is of importance and will be found in
the lowest order governing equation for \( \phi^* \), in order that changes intro-
duced by the shock may be accommodated, the first condition is that
\( \phi^*_{1x^*} \phi^*_{1x^*x^*} \) be of the same order as \( \phi^*_{1y^*y^*} \). The next condition is given
by the matching conditions which are to be met as \( |x^*| \rightarrow \infty \); they are found
by expanding the outer solutions, equations (15), about \( x = x_0 \) and sub-
stituting the resulting equations written in terms of inner variables, into
equations (19). The final condition is imposed by the boundary conditions
at the wall. Since \( y - y_w = 0 \) at the walls, then also the Eulerian derivative of this function, \( \frac{\mathcal{S}'(y - y_w)}{\mathcal{T}} = 0 \) at the walls. This equation, which may be used to derive equation (6), is transformed using equations (17), (19), (20), and equation (7) expanded about \( x_0 \), such that it is valid in the moving coordinate system associated with the inner region, and gives the desired boundary conditions. The three conditions lead to \( \sigma = 1/2 \) in equation (17a), and

\[
\phi^*_{,x_0} (x^*, y^*, T^*) = \varepsilon^{1/2} f_{x_0}^1 y^*/(Y + 1)^{1/2} + \varepsilon \phi^*_{,x_1} (x^*, y^*, t^*) + \varepsilon^{1/2} \phi^*_{x_0} (x^*, y^*, t^*) + \ldots \tag{21}
\]

where \( f_{x_0}^1 = f_{x_1}(x_0) \).

The governing equation for \( \phi^*_{,x} \) in the inner region may be derived from equation (5) by using equations (4a), (17), (20), (21), and (17) with \( \sigma = 1/2 \). Thus,

\[
\phi_{,x}^* \phi_{,x}^* x^* + \phi_{,y}^* y^* = 0
\]

The matching conditions to be used as \( |x^*| \to \infty \), found as described previously, are

\[
\phi_{,x}^* = f_{10}'' y^* + h_{1x}(x_0) \quad \phi_{,y}^* = f_{10}'' x^* \tag{23a,b}
\]

where \( h_{1x}(x_0) \) is given by equation (13b) with the upper (+) sign and where the upper and lower signs in equation (23) correspond to the conditions as \( x^* \to -\infty \) and \( x^* \to +\infty \) respectively. The boundary conditions at the wall, again found as described previously, are as follows:

\[
\phi_{,y}^*(x^*, \pm 1, t^*) = f_{10}'' x^* \tag{24}
\]

The final condition necessary before solutions in the inner region may be found are the shock wave jump conditions. Now, the shape of the shock,
\( x'_s(y^*, t^*) \), is given in the inner region by the equation

\[
\frac{\partial x'}{\partial y'} = -\frac{v^* - v^*}{u_d - u_d^*} \tag{25}
\]

In view of equation (21), it is seen that the first term in the expansion for \( x_s^* \) is of order unity and the next is of order \( \epsilon^1/2 \). In the inner and outer variables, then, the expression

\[
\frac{x_s(y, t) - x_0}{\epsilon^{1/2}(y + 1)^{1/2}} = x_s^*(y^*, t^*) = x_1(y^*, t^*) + \epsilon^{1/2}x_2(y^*, t^*) + \ldots \tag{26}
\]

where \( x_1(y^*, t^*) = x_1(y, t) \), etc., meets the necessary conditions and agrees with the relation used previously, that \( x_s = x_0 + \ldots \). The function \( x_1 \) is chosen such that \( x_1(-1, t) = 0 \); that is, \( x_0 \) gives the position of the intersection of the shock wave and the lower wall, and \( x_1 \) gives the variation of the shock shape from the normal (to the \( x \) axis) at that point. In order to find the jump conditions across the shock wave, it is necessary to write the shock polar equation relative to the moving shock. The velocity components relative to the shock wave are \( \hat{u} = u - u_{sh} \) and \( \hat{v} = v - v_{sh} \) where \( u_{sh} \) and \( v_{sh} \) are the components of the shock wave velocity. It can be shown that \( u_{sh} = \dot{x}_0 + O(\epsilon^{5/2}) \) and \( v_{sh} = O(\epsilon^{5/2}) \), and since \( \dot{x}_0 = \epsilon^2 k dx_0 / dt = O(\epsilon^2) \), it is seen that if \( u_1^* = \phi_{1x}^*, v_1^* = \phi_{1y}^*, \) etc., then

\[
\hat{u} = 1 + \epsilon u_1^* + \epsilon^{3/2} u_{3/2}^* + \ldots \tag{27a}
\]

\[
\hat{v} = (Y + 1)^{1/2} (\epsilon v_1^* + \epsilon^{3/2} v_{3/2}^* + \ldots) \tag{27b}
\]

That is, to the order desired, the shock wave velocity does not appear.

Finally, from the energy equation which holds in a moving coordinate system, it can be shown that the dimensionless critical speed of sound is, in this
system,

\[ \dot{a}^2 = 1 - 2(Y - 1)\dot{x}_0/(Y + 1) + \cdots \]  

(28)

The jump conditions are found, then, by expanding equations (27) about \( x^*_s \), using equations (26), and substituting these expansions and equation (28) with \( \dot{x}_0 = \epsilon^2 k dx_0/dt \), into the shock polar equation. The results are as follows:

\[ (v^*_1 - v^*_0)^2 - \frac{1}{2} (u^*_1 - u^*_0)^2 (u^*_1 + u^*_0) = 0 \]  

(29)

It may be noted that the form of expansion derived for \( u^* \) and \( v^* \) using boundary and matching conditions is also consistent with the shock jump conditions.

It is not difficult to show \(^7\) that upstream of the shock wave, the solutions for \( \phi^*_1 \) are simply the continuation of the outer solutions evaluated at the shock wave. That is, one obtains the physically correct result that no disturbances from the shock affect the supersonic flow upstream of the shock wave. Downstream of the shock, however, equation (22) must be solved with the boundary conditions given by the condition at the walls, equation (24), the matching condition as \( x^* \to \infty \), equation (23a), and the conditions immediately downstream of the shock wave, given by equations (25) and (29). Thus, since both \( u^*_0 \) and \( v^*_0 \) are found in the first order jump condition given by equation (29), the shock wave is not planar to this order, and another equation, (25), is necessary to relate the local shock slope to \( v^*_0 \) and \( u^*_0 \). It may be noted that this problem is therefore quite different from those solved previously for channels with smaller curvature, \(^6\) where the shock is planar to the lowest order. In that case, the boundaries
and normal derivatives of the potential at the boundaries were all given, and $v_{1d}^*$ was calculated, as was the higher order shock shape. In the present case, however, $u_{1d}^*$ and $v_{1d}^*$ are related to the shock shape which must be found as part of the first order solution.

It is convenient to write $\phi_1^*$ in terms of the difference between it and its limiting value as $x^* \to \infty$. Thus, we define $\zeta^*$ as follows:

$$\zeta^* = \phi_1^* - [f_{10}'' y^* - h_{1x} (x_0)] x^*$$

Then the governing equation and boundary conditions for the problem to be solved are

$$\left( f_{10}'' y^* - h_{1x} (x_0) + \xi_{x^*}^* \right) \xi_{x^*}^{x^*} - \xi_{y^*}^{x^*} = 0$$

$$\left\{ \begin{array}{l}
\xi_{x^*}^* = -2 f_{10}'' y^* + 2 \left( \frac{\partial x_1}{\partial y}\right)^2 \\
\xi_{y^*}^* = 2 \left( \frac{\partial x_1}{\partial y}\right) \left[f_{10}'' y^* + h_{1x} (x_0) - \left( \frac{\partial x_1}{\partial y}\right)^2 \right]
\end{array} \right.$$  

$$x^* = x_1$$

$$x^* \to \infty \quad \xi_{x^*}^* = 0$$

$$y^* = \pm 1 \quad \xi_{y^*}^* = 0$$

where

$$\frac{1}{(Y+1)^{\frac{1}{2}}} \epsilon^{\frac{1}{2}} \frac{\partial x_s}{\partial y} = \frac{\partial x_s^*}{\partial y^*} = \frac{\partial x_1}{\partial y} + O(\epsilon^{1/2})$$

$$\frac{\partial x_1}{\partial y} = -\frac{u_{1d}^* - v_{1u}^*}{u_{1d}^* - u_{1u}^*}$$

and equations (15) evaluated at the shock wave, and equations (19), have been used to write $u_{1u}^*$ and $v_{1u}^*$. Evidently, this problem must be solved numerically; specific example solutions are discussed later.

A composite solution, uniformly valid throughout the channel, may be constructed by adding the outer and inner solutions and subtracting those
(matching) terms common to both. In view of the definition of $\xi^*$, these composite solutions are thus, to first order,

$$
\begin{align*}
    u &= 1 + \epsilon (f_1'' y \pm h_{1x} + \xi^* x^*) + \cdots \\
    v &= \epsilon f_1' + \epsilon^{1/2} (y + 1)^{1/2} \xi^* y^* + \cdots
\end{align*}
$$

(33a)

(33b)

where $h_{1x}$ is given by equation (13b) with the plus sign, and $\xi^* = 0$ upstream of the shock, $x < x_5$. Also, for $x < x_s$, if the flow accelerates from subsonic to supersonic flow (with the sonic line passing through $(0, 0)$), then the upper sign is taken in equation (33a); if the flow is supersonic decelerating flow for $x < 0$ and accelerates for $x > 0$ with possibly a subsonic pocket in the region about $x = 0$, then the lower sign is taken for $x < 0$ and the upper for $x > 0$. For $x > x_s$, only the lower sign in equation (33a) is taken. It should be noted that for $x^* = O(1)$ equations (33) reduce to the inner solutions downstream of the shock, while as $x^* \to \infty$, $\xi^* \to 0$ and the outer solutions, to order $\epsilon$, are recovered.

Solutions for the pressure and density are written in terms of the solutions for the velocity components through equations derived from the conservation equations and the equation for the jump in entropy across the shock wave. Thus, from the inviscid energy equation, it can be shown that the stagnation or total enthalpy can be written as,

$$
\begin{align*}
    h_t &= \frac{T}{Y - 1} + \frac{1}{2} (u^2 + v^2) = \frac{Y + 1}{2(Y - 1)} + \epsilon^s h_{tl} + \cdots \\
    h_{tl} &= k \frac{dx_0}{dt} (\xi^* x^* + 2 h_{1x} (x_0)) \quad x > x_s \\
    h_{tl} &= 0 \quad x < x_s
\end{align*}
$$

(34a)

(34b)

(34c)

where $h_{1x} (x_0)$ is calculated from equation (13b) with the plus sign. The
pressure and density are related to the entropy and the temperature as follows:

\[ \frac{P}{\rho Y} = e^{(s-s_u)(Y-1)} \quad P = \rho \frac{A}{T} \]  

(35a, b)

The entropy change of importance is that across the shock wave, the gradients downstream of the shock being of high enough order that they are negligible. For transonic flow, across a shock

\[ S_d - S_u = \frac{2Y}{3(Y+1)} (M_u^2 - 1)^3 - \frac{2Y^2}{(Y+1)^3} (M_u^2 - 1)^4 + \ldots \]  

(36)

where, since the shock in this case is in motion, \( M_u \) is the relative normal Mach number of the incoming flow. For a shock described by equation (26),

\[ M_u^2 - 1 = \epsilon (Y+1) \left[ u_{1u} - \frac{\partial x_1}{\partial y} \right] \pmb{^2} \]  

(37)

where, as mentioned earlier, outer solutions are valid upstream of the shock wave. The expansions for \( P \) and \( \rho \) can then be found from equations (34a) and (35), where \( u \) and \( v \) are found from equations (4) and (8) with \( u_1 = \phi_{1x} \) and \( v_1 = \phi_{1y} \). Thus,

\[ P = 1 - \epsilon Y u_1 - \epsilon^2 Y (v_1^2/2 + u_2) - \epsilon^3 Y \left[ 2 (Y + 1) \left[ u_{1u} - \left( \frac{\partial x_1}{\partial y} \right)^2 \right] + 3 \right. \]
\[ - \left. h_{t1} - (Y+1)u_1^3/6 - u_1 v_1^2/2 + v_1 v_2 + u_3 \right] + \ldots \]  

(38a)

\[ \rho = 1 - \epsilon u_1 - \epsilon^2 \left[ (Y - 1)u_1^2/2 + v_1^2/2 + u_2 \right] - \epsilon^3 \left[ 2 Y (Y + 1) \left[ u_{1u} - \left( \frac{\partial x_1}{\partial y} \right)^2 \right] / 3 \right. \]
\[ - \left. h_{t1} - (Y - 1)u_1^2/3 + (Y - 1)u_1 u_2 - (2 - Y) u_1 v_1^2/2 + v_1 v_2 + u_3 \right] + \ldots \]  

(38b)

If the composite solutions are used for \( u_1 \) and \( v_1 \) (terms of order \( \epsilon \) in equations (33)), then equations (38) give solutions which are uniformly valid to order \( \epsilon \). A solution for \( \frac{A}{T} \) similar to those given for \( P \) and \( \rho \) is easily derived from equation (34a).
It should be noted that, if composite solutions are considered, then immediately upstream of the shock wave, \( P_y = -\epsilon Y f''_{10} \), while downstream of the wave, \( P_y = -\epsilon Y (f''_{10} + \xi_{*y*}^* + \cdots) \). Thus, downstream of the wave, if the wave is approached by first going to \( y^* = \pm 1 \), and then going to \( x^* = x_1 \), then at the wave \( P_y = -\epsilon Y f''_{10} \). However, if the wave is approached by going to \( x^* = x_1 \) first, at any \( y^* \), and then traveling along the wave toward \( y^* = \pm 1 \), then \( P_y = \epsilon Y f''_{10} + \cdots \). That is, from equations (31c) and (31e), \( \partial x_i/\partial y = 0 \) at \( y = \pm 1 \); hence, from equation (31b), \( \xi_{*x*y*}^* = -2f''_{10} \) at \( y = \pm 1 \). Thus, there is a change of sign in \( P_y \) across the shock, and since \( P_y \propto v_{*x*}^* \), the streamline curvature, this means that downstream of the shock wave, the limiting value of \( v_{*x*}^* \) at the intersection of the shock wave and the walls depends on the path of approach to the intersection. This singularity in the solution is similar to that analyzed by Messiter and Adamson.

SHOCK WAVE LOCATION

The unsteady perturbations in flow velocity and thermodynamic properties in the channel can be caused, for example, by pressure disturbances in a plenum downstream of the shock wave. Here, we consider the case where the disturbances have a characteristic time (inverse of characteristic frequency) of order \( \epsilon^{-2} \), and an amplitude of order \( \epsilon^2 \). As will be seen, this is sufficient to give shock motions with an amplitude of order unity.

Since only terms of order \( \epsilon^2 \) in \( P \) may vary with time, it is seen from equations (38a) that \( u_1 \) is independent of time; hence, \( h_1 = h_1 (x) \). In
fact, (equations (38a) and (15)) the time dependence first appears in $u_2$, through $h_2 = h_2(x, t)$. As a result, in equation (13b), $\beta_1$ is a constant, and the time dependence of $h_2$ and thus $u_2$ and indeed $\phi_2$ is through $\beta_2(t)$. Both $\beta_1$ and $\beta_2$ may have different values upstream and downstream of the shock wave. Since the time enters the solutions for $u$ only through the integration function, $\beta_2$, then to order $\epsilon^2$, the unsteady motion may be pictured as a sequence of steady state solutions for $u$, each with different downstream conditions. The velocity component $v$, to order $\epsilon^2$, is totally time independent, (equation (15b)). From equations (38a), (15), and (14), it is seen that specifying the second order variation in pressure at a downstream plenum location, is equivalent to setting $\beta_2(t)$ downstream of the shock, say $\beta_2 d$. The fact that time does not appear explicitly in the solutions valid downstream of the shock wave (e.g., see the composite solutions given in equations (33)) and appears only as a parameter, in $\beta_2$, is due to the fact that the disturbances travel upstream at a speed of order $\epsilon$ while the shock moves at a velocity of order $\epsilon^2$, and indeed, the order of the unsteady part of the fluid velocity is $\epsilon^2$. Thus, the disturbances travel upstream "instantaneously" compared with the characteristic times under study.

It should be noted, however, that as a result of the motion of the shock (i.e., since $x_0 = x_0(t)$) the first order pressure, velocity, etc., in the range of motion of the shock, do change as the shock moves back and forth; they jump between the steady state values upstream and downstream of a shock wave at the point in question.

The equation from which the instantaneous shock wave location can be calculated is derived from the principle of mass conservation applied
to a control volume enclosing the shock wave. Thus, one surface of the
control volume, the sides of which are the channel walls, is located at \( x = 0 \),
the throat, and the other is at \( x = X_c \), somewhere downstream of the shock.

Then

\[
\frac{d}{dT} \left\{ \int_{y_w^-}^{y_w^+} \int_0^{X_c} \rho \, dx \, dy \right\} - \int_{-1}^{+1} \rho \, u \, dy + \int_{y_w^-}^{y_w^+} \rho \, u \, dy = 0
\]

(39)

where \( y_w^+ \) and \( y_w^- \) denote, respectively, the upper and lower walls. The
integral in the first bracket, from zero to \( X_c \), is evaluated in two parts,
one upstream of the wave (0 to \( x_s \)) and one downstream of the wave (\( x_s \) to \( X_c \))
with the composite solutions used for \( u_1 \) in the first order terms of equation
(38b). Since \( d/dT = O(\epsilon^2) \) and only terms up to third order are desired,
only the first order term in \( \rho \) is necessary. In the remaining integrals at
\( x = 0 \) and \( x = X_c \), equations (15) and (38b) are used. First order terms are
identically zero, and from the second and third order terms, one finds that

\[
\beta_{1u} = \beta_{1d} = \beta_1
\]

(40a)

\[
\frac{4k}{(Y+1)} \frac{dx_0}{dt} = (\beta_{2u} - \beta_{2d})/h_{10} - 2Y \left( (f_{10}^{'})^2 + (h_{10})^2 \right)/3 + G(x_0)
\]

(40b)

\[
G(x_0) = \frac{Y}{h_{10}} \int_{-1}^{1} \left( \frac{\partial x_1}{\partial y} \right)^2 [u_{1u}(x_0) - u_{1u}(x_0) \left( \frac{\partial x_1}{\partial y} \right)^2 + \frac{1}{3} \left( \frac{\partial x_1}{\partial y} \right)^4] \, dy
\]

(40c)

where \( h_{10}^{'}, dh_{1}/dx \) evaluated at \( x_0 \) and \( \beta_{2u} \) is a constant, while \( \beta_{2d} \) is a function
of time for the case under consideration where disturbances are imposed
downstream of the shock wave. If the shock wave has a higher order curva-
ture, \( \partial x_1/\partial y = 0 \), and \( G(x_0) \) vanishes; then equation (40b) is reduced to a form
equivalent to that given by Richey and Adamson. 6
Equation (40b) may be used in determining the shock location, \( x_0 = \text{constant} \), for a flow which is steady with a stationary shock wave. Thus, for a given (now constant) \( \beta_{zd} \) which is equivalent to a given pressure in a plenum downstream of the shock wave, the only unknowns in equation (40b), \( h'_{10} \) and \( G(x_0) \), are functions of \( x_0 \). Since \( \partial x_1 / \partial y \), which depends on \( x_0 \) as well as \( y \) as seen from equations (31), must be known if \( G(x_0) \) is to be calculated, this means that equations (31) and (40) must be solved simultaneously. In principle, therefore, \( x_0 \) may be calculated for a given \( \beta_{zd} \). However, it is much easier to choose a given \( x_0 \), solve equations (31) and in the process find \( x_1 \), calculate \( G(x_0) \) and \( h'_{10} \), and then use equation (40b) to calculate the \( \beta_{zd} \) which corresponds to the chosen \( x_0 \); after a series of such calculations, \( x_0 \) may be plotted as a function of \( \beta_{zd} \). If the downstream pressure varies with time in a prescribed manner, then \( \beta_{zd} = \beta_{zd}(t) \) is known and \( dx_0/dt \) and thus the shock velocity may in principle be calculated from equations (31) and (40b), with the shock position, \( x_0(t) \), being found then by integration of \( dx_0/dt \). The computations may be carried out by first solving equations (31) for a sequence of values for \( x_0 \), so that \( \partial x_1 / \partial y \), \( h'_{10} \) and thus \( G(x_0) \) are essentially known as functions of \( x_0 \). With \( \beta_{zd}(t) \) and the initial value of \( x_0 \) known, equation (40b) may then be integrated numerically, thus relating \( x_0 \) to \( t \); i.e., \( x_0(t) \) is obtained. Finally, with \( x_0(t) \) known, \( \xi^* \) and \( \partial x_1 / \partial y \), and thus \( u, P, \rho, x_1 \), etc., may be obtained as functions of time at any space point.

**NUMERICAL CALCULATIONS**

In the present work, equations (31) were solved using the method of integral relations proposed by Dorodnitsyn.\(^9\)\(^,\)\(^10\) Details of the computation
are available in reference 7, so only a brief description is given here. The inner region in which equations (31) are valid is composed of a region extending from $y^* = -1$ to $y^* = +1$ in the $y^*$ direction and from the curve $x^* = x_s^*$ to $x^* \to \infty$ in the $x^*$ direction; $x_s^* = x_1 + \ldots$ is to be found as part of the solution. This region is transformed into a finite region by the transformation $\hat{x} = e^{-x^*}$, and this finite region, between $\hat{x} = 0$ and $\hat{x} = \hat{x}_s = e^{-x_s^*}$, is divided into $N$ strips. Calculations of the shock shape made with $N = 2$ and compared with the calculation made with $N = 3$ showed very little difference, indicating that relatively accurate computations can be made with two strips. Equation (31a), written in terms of velocity components, and the corresponding irrotationality condition, $u_{1y}^* = v_{ix}^*$, are the governing equations integrated across each strip, using $N$th order polynomials in $\hat{x}/x_s^*$ for interpolation expressions for $u_1^*$ and $v_1^*$. In the present case, it was found that if $\lim_{x^* \to \infty} \xi_{x^*} = 0$ is used as a boundary condition and the method of integral relations applied, then $\xi_{y^*}$ is not zero as $x^* \to \infty$. That is, apparently due to the approximations inherent in the method and the effects of the singularity at the shock-wall interaction, there is an error in the $v$ velocity as $x^* \to \infty$. Rather than accept this error, the condition $\xi_{y^*} \to 0$ as $x^* \to \infty$ was enforced and the irrotationality condition was integrated once across the whole region rather than across each of the two strips separately.

Using the two strip method, one finds a nonlinear differential equation for the shock shape; since time enters only as a parameter, this equation may be treated as an ordinary differential equation. Thus, if $z(y) = \partial x_1/\partial y$, one finds that
\[
(f_1'' y + h_{10} - 3 z^2) z'' - \left[ 6 z z' - 2 R z + f_{10}'' h_{10}' (1 - y^2) - 2 f_{10}'' y \right] z'
\]
\[
- \left[ 2 R^2 + (3 h_{10}' + 2 f_{10}'' y) R - 2 f_{10}'' h_{10} y \right] z
- \left[ f_{10}'' h_{10}' (1 - y^2) + 3 f_{10}'' y \right] R - 2 f_{10}'' y - f_{10}'' h_{10} = 0
\]
\[
R = \left[ (f_{10}'' y + f_{10}' h_{10}' y + (h_{10}')^2 + f_{10}'' h_{10}' (1 - y^2) z - f_{10}'' z \right.
\]
\[
- (f_{10}' y + h_{10}' - 3 z^2) z']^{1/2}
\]
where \( h_{10}' = h_1'(x_0) \), etc. The boundary conditions for equations (44) are
\[
z(\pm 1) = 0
\]
Equation (41a) was solved numerically using a fourth-order Runge-Kutta method, yielding \( z(y) \). Then \( z(y) = \partial x_1 / \partial y \) was integrated, using the condition that \( x_1(-1) = 0 \), to give the shock shape, \( x_1 \). Since both \( f_{10}'' \) and \( h_{10}' \) are time dependent, because \( x_0 = x_0(t) \), the coefficients in equations (41) have different values at different times and it is seen that the shock shape varies with time.

The wall shapes chosen for the calculations are as follows:
\[
y_w = \pm 1 + \epsilon \ x^2/2 \pm \epsilon^2 \left[ 1 + 20 \ (Y + 1)/9 \right] x^2/2
\]
where the wall shape functions, \( f_1(x) \) and \( f_2(x) \) are found by comparing equations (7) and (43). In order to make the calculations as simple as possible, \( x_0(t) \) is prescribed here and the corresponding \( \beta_{2d} \) (and thus pressure in the downstream plenum) is calculated from equations (40b) and (40c). That is, one can prescribe \( \beta_{2d}(t) \) and find the resulting \( x_0(t) \), or prescribe \( x_0(t) \) and find the necessary \( \beta_{2d}(t) \). The latter problem demands less computing time and is used here for illustration. Thus, we set
\[
x_0(t) = 1.5 + (\sin t)/2
\]
and perform calculations for $\gamma = 1.4$, $\epsilon = 0.1$, and $\beta_{2u} = 0$. The wall shapes given by equations (43) with these values for $\epsilon$ and $\gamma$, are those seen in figures 2 to 4.

Velocity profiles showing the first order inner solutions downstream of the shock wave are shown at $x^* = x_1$ in figure 5a, and at $x^* = x_1 + 0.69$ in figure 5b, each at three different times, $t = \frac{\pi}{2}$, $\pi$, and $\frac{3\pi}{2}$. The corresponding $x_0$ is found from equation (44). These figures thus illustrate the temporal variations in the velocity components at the indicated inner region stations. The relatively large spatial variations which occur in the inner region at a given time, are illustrated in figure 6, at $t = 0$. The change in $u_1^*$ from its values immediately behind the shock to the linear profile associated with subsonic flow for the given wall shapes, is indicative of the large accelerations and decelerations which take place in the inner region.

The shock shape, $x_5 = x_0 + \epsilon^{1/2} (\gamma + 1)^{1/2} x_1 + \ldots$, is shown in figure 7, as a function of time. It is seen that as a result of the curvature of the walls and the attendant gradients in the incoming flow, the shock wave has a pronounced curvature; for the direction of curvature chosen for the walls, the shock starts normal to the lower wall, inclines in the flow direction and then turns back toward the upper wall so as to become normal to it also. As the shock moves closer to the throat of the channel, it becomes weaker and has more curvature.

The values of $x_0$, for each time at which calculations were made, the corresponding $\beta_{2d}(t)$ calculated from equation (40b), and the equivalent change in back pressure at a downstream plenum from its value at $t = 0$, $\Delta P_b = P_b(t) - P_b(0)$, are given in table 1. Finally, the pressure on the upper and lower
walls at these same times, to order $\epsilon$, are shown in figure 8. In this figure, the solid lines indicate the calculated pressure distributions upstream of the shock wave, the pressure jump across the shock, and outer pressure distributions downstream of the shock. The large dots indicate the pressures calculated in the inner region, and the dashed lines show a curve drawn through these points and faired into the outer pressure distribution, to show an approximate pressure distribution. Since only two strips were used in the inner region computations, only one data point within the inner region is available.

CONCLUSIONS

The methods used in this study enable one to study unsteady flows with shock waves in relatively highly curved asymmetric channels with arbitrary wall shapes and impressed disturbances of arbitrary form. It is shown that the shock wave is not planar and that its shape must be obtained as part of an inner solution which involves a numerical solution of the nonlinear small disturbance transonic equation, the unknown shock shape forming one of the boundaries of the region in question. It proves to be relatively easy to use the method of integral relations to obtain approximate but very useful solutions. The solutions allow one to calculate the shock shape and velocity, as well as fluid velocity and thermodynamic property distributions, as functions of time.

Two-dimensional inviscid, unsteady transonic flows with shock waves in asymmetric channels with arbitrary wall shapes are investigated, using the method of matched asymptotic expansions. With the exception of thin regions in the neighborhood of the channel throat and the neighborhood of the shock wave, solutions found using linearized governing equations are valid. In the regions enclosing the shock wave, an inner solution which satisfies the shock jump conditions and matches with the outer solutions, is presented. The shock shape is found as part of the solution, which is obtained numerically using the method of matched asymptotic expansions.
method of integral relations. A composite solution, uniformly valid throughout the channel, and the relation between the instantaneous shock wave position and back pressure far downstream are presented.
