# A Fast Algorithm for Finding Dominators in a Flow Graph

**Author:** Thomas H. Lengauer & Robert E. Tarjan

This paper presents a fast algorithm for finding dominators in a flow graph. The algorithm uses depth-first search and an efficient method of computing functions defined on paths in trees. A simple implementation of the algorithm runs in \(O(m \log n)\) time, where \(m\) is the number of edges and \(n\) is the number of vertices in the problem graph. A sophisticated implementation runs in \(O(m \alpha(m, n))\) time, where \(\alpha(m, n)\) is a functional inverse of Ackermann's function. Both versions of the algorithm were implemented in Algol W at Stanford University and tested on an IBM 370/168. The programs were compared with an implementation by Purdom and Moore of a straightforward \(O(mn)\) -time algorithm, and with a bit vector algorithm, described by Moore. The fast algorithm beat the straightforward algorithm and the bit vector algorithm on all but the smallest graphs tested.
A Fast Algorithm for Finding Dominators
in a Flow Graph

Abstract.

This paper presents a fast algorithm for finding dominators in a flow graph. The algorithm uses depth-first search and an efficient method of computing functions defined on paths in trees. A simple implementation of the algorithm runs in $O(m \log n)$ time, where $m$ is the number of edges and $n$ is the number of vertices in the problem graph. A more sophisticated implementation runs in $O(m \alpha(m,n))$ time, where $\alpha(m,n)$ is a functional inverse of Ackermann's function.

Both versions of the algorithm were implemented in Algol W, a Stanford University version of Algol, and tested on an IBM 370/168. The programs were compared with an implementation by Purdom and Moore of a straightforward $O(mn)$-time algorithm, and with a bit vector algorithm described by Aho and Ullman. The fast algorithm beat the straightforward algorithm and the bit vector algorithm on all but the smallest graphs tested.

Keywords: depth-first search, dominators, global flow analysis, graph algorithm, path compression.

1. **Introduction.**

The following graph problem arises in the study of global flow analysis and program optimization [2,6]. Let \( G = (V,E,r) \) be a flow graph with start vertex \( r \).*/ A vertex \( v \) dominates another vertex \( w \neq v \) in \( G \) if every path from \( r \) to \( w \) contains \( v \). Vertex \( v \) is the immediate dominator of \( w \), denoted \( v = \text{idom}(w) \), if \( v \) dominates \( w \) and every other dominator of \( w \) dominates \( v \).

**Theorem 1** [2,6]. Every vertex of a flow graph \( G = (V,E,r) \) except \( r \) has a unique immediate dominator. The edges \( \{(\text{idom}(w),w) \mid w \in V-\{r\}\} \) form a directed tree rooted at \( r \), called the dominator tree of \( G \), such that \( v \) dominates \( w \) if and only if \( v \) is a proper ancestor of \( w \) in the dominator tree. See Figures 1 and 2.

[Figure 1]

[Figure 2]

We wish to construct the dominator tree of an arbitrary flow graph \( G \). Aho and Ullman [2] and Purdom and Moore [7] describe a straightforward algorithm for solving this problem. For each vertex \( v \neq r \), we carry out the following step:

**General Step:** Determine, by means of a search from \( r \), the set \( S \) of vertices reachable from \( r \) by paths which avoid \( v \). The vertices in \( V-\{v\}-S \) are exactly those which \( v \) dominates.

Knowing the set of vertices dominated by each vertex, it is an easy matter to construct the dominator tree.

*/ Appendix A contains the graph-theoretic terminology used in this paper.
To analyze the running time of this algorithm, let us assume that G has m edges and n vertices. Each execution of the general step requires $O(m)$ time, and the algorithm performs $n - 1$ executions of the general step; thus the algorithm requires $O(mn)$ time total.

Aho and Ullman [3] describe another simple algorithm for computing dominators. This algorithm manipulates bit vectors of length $n$. Each vertex $v$ has a bit vector which encodes a superset of the dominators of $v$. The algorithm makes several passes over the graph, updating the bit vectors during each pass, until no further changes to the bit vectors occur. The bit vector for each vertex $v$ then encodes the dominators of $v$.

This algorithm requires $O(m)$ bit vector operations per pass for $O(n)$ passes, or $O(mn)$ bit vector operations total. Since each bit vector operation requires $O(n)$ time, the running time of the algorithm is $O(n^2 m)$. This bound is pessimistic, however; the constant factor associated with the bit vector operations is very small, and on typical graphs representing real programs the number of passes is small (on reducible flow graphs [3] only two passes are required [4]).

In this paper we shall describe a faster algorithm for solving the dominators problem. The algorithm uses depth-first search [9] in combination with a data structure for evaluating functions defined on paths in trees [13]. We present a simple implementation of the algorithm which runs in $O(m \log n)$ time and a more sophisticated implementation which runs in $O(m \alpha(m,n))$ time, where $\alpha(m,n)$ is a functional inverse of Ackermann's function.
The algorithm is a refinement of earlier versions appearing in [10, 11, 12]. Although proving its correctness and verifying its running time require rather complicated analysis, the algorithm is quite simple to program and is very fast in practice. We programmed both versions of the algorithm in Algol W, a Stanford University version of Algol, and tested the programs on an IBM 370/168. We compared the programs with a transcription into Algol W of the Purdom-Moore algorithm and with an implementation of the bit vector algorithm. On all but the smallest graphs tested our algorithm beat the other methods.

The paper consists of five sections. Section 2 describes the properties of depth-first search used by the algorithm and proves several theorems which imply the correctness of the algorithm. Some knowledge of depth-first search as described in [9] and Section 2 of [10] is useful for understanding this section. Section 3 develops the algorithm, using as primitives two procedures that manipulate trees. Section 4 discusses two implementations, simple and sophisticated, of these tree manipulation primitives. Some knowledge of Sections 1, 2, and 5 of [13] is useful for understanding this section. Section 5 presents our experimental results.
2. **Depth-First Search and Dominators.**

Suppose we perform a depth-first search on a flow graph \( G = (V,E,r) \) starting from vertex \( r \), and that we number the vertices of \( G \) from 1 to \( n \) as they are reached during the search. The search generates a spanning tree \( T \) rooted at \( r \), with vertices numbered in preorder \([5]\). See Figure 3.

![Figure 3](image)

The following **paths lemma** is an important property of depth-first search and is crucial to the correctness of the dominators algorithm.

**Lemma 1** \([9]\). If \( v \) and \( w \) are vertices of \( G \) such that \( \text{number}(v) < \text{number}(w) \), then any path from \( v \) to \( w \) in \( G \) must contain a common ancestor of \( v \) and \( w \) in \( T \).

As an intermediate step, the dominators algorithm computes a value for each vertex \( w \neq r \) called its semi-dominator, denoted by \( \text{sdan}(w) \) and defined by

\[
\text{sdan}(w) = \min \{ \text{number}(v) \mid \text{there is a path } v = v_0, v_1, \ldots, v_k = w \text{ such that } \text{number}(v_i) > \text{number}(w) \text{ for } 1 \leq i \leq k-1 \}.
\]

See Figure 3.

The following lemmas describe some basic properties of semi-dominators and immediate dominators.

**Lemma 2.** For any vertex \( w \neq r \), let \( v \) be the vertex such that \( \text{number}(v) = \text{sdan}(w) \). Then \( v \) is a proper ancestor of \( w \) in \( T \).
Proof. Let \( \text{parent}(w) \) be the parent of \( w \) in \( T \). Since \( (\text{parent}(w), w) \) is an edge of \( G \), by (1) \( \text{number}(v) = \text{sdom}(w) \leq \text{number}(	ext{parent}(w)) \leq \text{number}(w) \).

By (1) and the choice of \( v \), there is a path \( v = v_0, v_1, \ldots, v_k = w \) such that \( \text{number}(v_i) > \text{number}(w) \) for \( 1 \leq i \leq k-1 \). By Lemma 1, some vertex \( v_i \) on the path is a common ancestor of \( v \) and \( w \). But such a common ancestor \( v_i \) must satisfy \( \text{number}(v_i) \leq \text{number}(v) \). This means \( i = 0 \), i.e., \( v_i = v \), and \( v \) is a proper ancestor of \( w \).

Lemma 3. For any vertex \( w \neq r \), let \( v \) be the vertex such that \( \text{number}(v) = \text{sdom}(w) \). Then \( \text{idom}(w) \) is an ancestor of \( v \) in \( T \).

Proof. The tree path from \( r \) to \( w \) contains only ancestors of \( w \) in \( T \). Thus \( \text{idom}(w) \) is an ancestor of \( w \). The path consisting of the tree path from \( r \) to \( v \) followed by a path \( v = v_0, v_1, \ldots, v_k = w \) such that \( \text{number}(v_i) > \text{number}(w) \) for \( 1 \leq i \leq k-1 \) (which must exist by (1)) avoids all proper descendants of \( v \) which are also proper ancestors of \( w \). It follows that \( \text{idom}(w) \) is an ancestor of \( v \).

Corollary 1. For any vertex \( w \neq r \), \( \text{idom}(w) \rightarrow w \).

Lemma 4. Let vertices \( v, w \) satisfy \( v \rightarrow w \) in \( T \). Then \( v \rightarrow \text{idom}(w) \) or \( \text{idom}(w) \rightarrow \text{idom}(v) \).

Proof. Let \( x \) be any proper descendant of \( \text{idom}(v) \) which is also a proper ancestor of \( v \). By Theorem 1 and Corollary 1, there is a path from \( r \) to \( v \) which avoids \( x \). By concatenating this path with the tree path from \( v \) to \( w \), we obtain a path from \( r \) to \( w \) which avoids \( x \) .
Thus \( \text{idom}(w) \) must be either a descendant of \( v \) or an ancestor of
\( \text{idom}(v) \).

Using Lemmas 1-4, we obtain two results which provide a way to
compute immediate dominators from semi-domimaters.

**Theorem 2.** Let \( w \neq r \) and let \( v \) be the vertex such that \( \text{number}(v) = \text{sdom}(w) \). Suppose no vertex \( u \) satisfies
\( \text{number}(u) > \text{number}(v) \), \( u \rightarrow^* w \), and \( \text{sdan}(u) < \text{sdom}(w) \). Then
\( \text{idom}(w) = v \).

**Proof.** By Lemma 3, it suffices to show that \( v \) dominates \( w \). Consider
any path from \( r \) to \( w \). Let \( x \) be the last vertex on this path
satisfying \( \text{number}(x) < \text{number}(v) \). If there is no such \( x \), then \( v = r \)
dominates \( w \). Otherwise, let \( y \) be the first vertex following \( x \) on
the path and satisfying \( v \rightarrow^* y \rightarrow^* w \). All vertices \( z \) following \( x \) on
the path but preceding \( y \) must satisfy \( z > y \) by Lemma 1 and the
choice of \( x \) and \( y \). Thus \( \text{sdan}(y) \leq \text{number}(x) < \text{number}(v) = \text{sdom}(w) \).
By the hypothesis of the theorem, \( y \) cannot be a proper descendant of \( v \).
Thus \( y = v \) and \( v \) lies on the path. Since the path selected was
arbitrary, \( v \) dominates \( w \). □

**Theorem 3.** Let \( w \neq r \) and let \( v \) be the vertex such that
\( \text{number}(v) = \text{sdom}(w) \). Let \( u \) be a vertex for which \( \text{sdom}(u) \) is minimum
among vertices satisfying \( \text{number}(u) > \text{number}(v) \) and \( u \rightarrow^* w \). Then
\( \text{sdom}(u) \leq \text{sdan}(w) \) and \( \text{idom}(u) = \text{idom}(w) \).
Proof. Let $x$ be the vertex such that $v \rightarrow x \rightarrow w$. Then

$$\text{sdan}(u) \leq \text{sdan}(x) \leq \text{number}(v) = \text{sdom}(w).$$

By Lemma 3, $\text{idom}(w)$ is an ancestor of $v$ and thus a proper ancestor of $u$. Thus by Lemma 4, $\text{idom}(w) \rightarrow \text{idom}(u)$. To prove $\text{idom}(u) = \text{idom}(w)$, it suffices to prove that $\text{idom}(u)$ dominates $w$.

Consider any path from $r$ to $w$. Let $x$ be the last vertex on this path satisfying $\text{number}(x) < \text{number}(\text{idom}(u))$. If there is no such $x$, then $\text{idom}(u) = r$ dominates $w$. Otherwise, let $y$ be the first vertex following $x$ on the path and satisfying $\text{idom}(u) \rightarrow y \rightarrow w$.

All vertices $z$ following $x$ on the path but preceding $y$ satisfy $\text{number}(z) > \text{number}(y)$ by Lemma 1 and the choice of $x$ and $y$. Thus $\text{sdom}(y) \leq \text{number}(x)$. Since $\text{number}(\text{idom}(u)) \leq \text{sdom}(u)$ by Lemma 3, we have $\text{sdom}(y) \leq \text{number}(x) < \text{number}(\text{idom}(u)) \leq \text{sdom}(u)$.

By the definition of $u$, $y$ cannot be a proper descendant of $v$. Furthermore, $y$ cannot be both a proper descendant of $\text{idom}(u)$ and an ancestor of $u$, for if this were the case the path consisting of the tree path from $r$ to $\text{sdom}(y)$ followed by a path $\text{sdom}(y) = v_0, v_1, \ldots, v_k = y$ such that $\text{number}(v_i) > \text{number}(y)$ for $1 \leq i \leq k-1$ followed by the tree path from $y$ to $u$ would avoid $\text{idom}(u)$; but no path from $r$ to $u$ avoids $\text{idom}(u)$.

The only remaining possibility is that $\text{idom}(u) = y$. Thus $\text{idom}(u)$ lies on the path from $r$ to $w$. Since the path selected was arbitrary, $\text{idom}(u)$ dominates $w$.  □
Corollary 2. Let \( w \neq r \) and let \( v \) be the vertex such that 
\[
\text{number}(v) = \text{sdan}(w) .
\]
Let \( u \) be a vertex for which \( \text{sdan}(u) \) is
minimum among vertices satisfying \( \text{number}(u) > \text{number}(v) \) and \( u \rightarrow w \).
Then
\[
(2) \quad \text{idom}(w) = \begin{cases} 
  v & \text{if } \text{sdan}(w) = \text{sdan}(u), \\
  \text{idom}(u) & \text{otherwise}.
\end{cases}
\]

Proof. Immediate from Theorems 2 and 3. \( \square \)

The following theorem provides a way to compute semi-dominators.

Theorem 4. For any vertex \( w \neq r \),
\[
(3) \quad \text{sdan}(w) = \min(\{\text{number}(v) | (v,w) \in E \text{ and } \text{number}(v) < \text{number}(w)\}) \\
\quad \quad \quad \quad \quad \cup \{\text{sdan}(u) | \text{number}(u) > \text{number}(w) \text{ and there is} \} \\
\quad \quad \quad \quad \quad \quad \quad \quad \text{an edge } (v,w) \text{ such that } u \rightarrow v \text{ in } T\}.
\]

Proof. Let \( l \) equal the right side of (3). We shall first prove that 
\( \text{sdan}(w) \leq l \). Suppose \( l = \text{number}(v) \) for some vertex \( v \) such that 
\( (v,w) \in E \) and \( \text{number}(v) < \text{number}(w) \). By (1) \( \text{sdan}(w) \leq l \). Suppose
on the other hand \( l = \text{sdan}(u) \) for some vertex \( u \) such that 
\( \text{number}(u) > \text{number}(w) \) and there is an edge \( (v,w) \) such that \( u \rightarrow v \).
Let \( x \) be the vertex such that \( \text{number}(x) = \text{sdan}(u) \). By (1) there is
a path \( x = v_0, v_1, \ldots, v_{j-1} = u \) such that 
\( \text{number}(v_i) > \text{number}(u) > \text{number}(w) \)
for \( 1 \leq i \leq j-1 \). The tree path \( u = v_0 \rightarrow v_{j+1} \rightarrow \cdots \rightarrow v_{k-1} = v \)
satisfies \( \text{number}(v_i) > \text{number}(w) > \text{number}(w) \) for \( j \leq i \leq k-1 \). Thus
the path \( x = v_0, v_1, \ldots, v_{k-1} = v, v_k = w \) satisfies \( \text{number}(v_i) > \text{number}(w) \)
for \( 1 \leq i \leq k-1 \). By (1), \( \text{sdan}(w) \leq \text{number}(x) = \text{sdan}(u) = l \).
It remains for us to prove that $\text{sdom}(w) > \ell$. Let $x$ be the vertex such that $\text{number}(x) = \text{sdom}(w)$, and let $x = v_0, v_1, \ldots, v_k = w$ be a simple path such that $\text{number}(v_i) > \text{number}(w)$ for $1 \leq i \leq k-1$. If $k = 1$, $(x, w) \in E$, and $\text{number}(x) < \text{number}(w)$ by Lemma 2. Thus $\text{sdom}(w) = \text{number}(x) \geq \ell$. Suppose on the other hand that $k > 1$.

Let $j$ be minimum such that $j \geq 1$ and $v_j \rightarrow v_{k-1}$. Such a $j$ exists since $k-1$ is a candidate for $j$.

We claim $\text{number}(v_i) > \text{number}(v_j)$ for $1 \leq i \leq j-1$. Suppose to the contrary that $\text{number}(v_i) < \text{number}(v_j)$ for some $i$ in the range $1 \leq i \leq j-1$. Choose the $i$ such that $1 \leq i \leq j-1$ and $\text{number}(v_i)$ is minimum. By Lemma 1, $v_i \rightarrow v_j$, which contradicts the choice of $j$. This proves the claim.

The claim implies $\text{sdom}(w) = \text{number}(x) \geq \text{sdom}(v_j) \geq \ell$. Thus whether $k = 1$ or $k > 1$ we have $\text{sdom}(w) > \ell$, and the theorem is true. \qed
3. **A Fast Dominators Algorithm.**

In this section we develop an algorithm which uses the results in Section 2 to find dominators. Earlier versions of the algorithm appear in [10,11,12]; the version we present is refined to the point where it is as simple to program as the straightforward algorithm [2,7] or the bit vector algorithm [3,4], similar in speed on small graphs, and much faster on large graphs.

The algorithm consists of the following four steps.

**Step 1.** Carry out a depth-first search of the problem graph. Number the vertices from 1 to \( n \) as they are reached during the search. For each vertex \( w \), determine the set \( \text{pred}(w) \) of vertices \( v \) such that \((v,w)\) is an edge and the vertex \( \text{parent}(w) \) which is the parent of \( w \) in the spanning tree generated by the search. Initialize the variables used in succeeding steps.

**Step 2.** Compute the semi-dominators of all vertices by applying Theorem 4. Carry out the computation vertex-by-vertex in decreasing order by number.

**Step 3.** Implicitly define the immediate dominator of each vertex by applying Corollary 2.

**Step 4.** Explicitly define the immediate dominator of each vertex, carrying out the computation vertex-by-vertex in increasing order by number.

Here is an Algol-like version of Step 1.

```algol
step1: n := 0;
for each \( v \in V \) do \( \text{pred}(v) := \emptyset \); \( \text{semi}(v) = 0 \)
DFS(r);
```
Step 1 uses the recursive procedure DFS, defined below, to carry out the depth-first search. The procedure assumes that \( \text{succ}(v) \) is the set of vertices \( w \) such that \( (v, w) \in E \). When a vertex \( v \) receives a number \( i \), the procedure assigns \( \text{semi}(v) := i \) and \( \text{vertex}(i) := v \).

**procedure DFS(vertex v);**

\[
\text{semi}(v) := n := n+1; \\
\text{vertex}(n) := v; \\
\text{comment initialize variables for steps 2, 3, and 4;}
\]

for each \( w \in \text{succ}(v) \) do

\[
\text{if semi}(w) = 0 \text{ then parent}(w) := v; \text{DFS}(w) \text{ fi; add v to pred}(w) \text{ od}
\]

end DFS;

After carrying out Step 1, the algorithm carries out Steps 2 and 3 simultaneously, processing the vertices \( v \neq r \) in decreasing order by number.

When processing a vertex \( v \), the algorithm computes \( \text{sdom}(v) \) by applying Theorem 4. Each edge \((u, v)\) is examined. If \( \text{number}(u) < \text{number}(v) \), \( \text{number}(u) \) is a candidate for \( \text{sdom}(v) \). If \( \text{number}(u) > \text{number}(v) \), the algorithm finds a vertex \( x \) of minimum \( \text{sdom}(x) \) among vertices satisfying \( \text{number}(x) > \text{number}(v) \) and \( x \neq u \); \( \text{sdom}(x) \) is a candidate for \( \text{sdom}(v) \). The minimum of all the candidates is \( \text{sdom}(v) \). After computing \( \text{sdom}(v) \), the algorithm assigns \( \text{semi}(v) := \text{sdom}(v) \) and adds vertex \( v \) to the set \( \text{bucket}(u) \), where \( u \) is the vertex such that \( \text{number}(u) = \text{sdom}(v) \). This completes Step 2 for \( v \). Note that before \( \text{sdom}(v) \) is found, \( \text{semi}(v) = \text{number}(v) \), and after \( \text{sdom}(v) \) is found, \( \text{semi}(v) = \text{sdom}(v) \).
After the semi-dominator of $v$ is computed, the algorithm empties $\text{bucket}(\text{parent}(v))$. For each vertex $w \in \text{bucket}(\text{parent}(v))$, the algorithm finds a vertex $u$ of minimum $\text{sdom}(u)$ among vertices satisfying $\text{number}(u) > \text{number}(\text{parent}(v))$ and $u \neq w$. If $\text{sdom}(u) = \text{sdom}(w)$, then by Corollary 2 the immediate dominator of $w$ is $\text{parent}(v)$, and the algorithm assigns $\text{dom}(w) := \text{parent}(v)$. If $\text{sdom}(u) < \text{sdom}(w)$, then by Corollary 2, $u$ and $w$ have the same immediate dominator, and the algorithm assigns $\text{dom}(w) := u$. The intent of this assignment is to implicitly define the immediate dominator of $w$ to be the immediate dominator of a vertex with smaller semi-dominator than $w$. This completes Step 3 for vertices $w \in \text{bucket}(\text{parent}(v))$.

Both Step 2 and Step 3 require determining, for certain paths $v \rightarrow w$ in the spanning tree, a vertex $u$ on the path $v \rightarrow w$ having minimum $\text{sdom}(u)$. To find such vertices the algorithm uses a method described in [10]. The algorithm maintains a data structure which represents a forest with vertex set $V$ and edge set $\{(\text{parent}(v), v) | \text{sdom}(v) \text{ has been computed}\}$. To manipulate this data structure, the algorithm uses two procedures:

**LINK($v, w$):** Add edge $(v, w)$ to the forest.

**EVAL($v$):** If $v$ is the root of a tree in the forest, return $v$. Otherwise, let $r$ be the root of the tree in the forest which contains $v$. Return a vertex $u \neq r$ of minimum $\text{sdom}(u)$ on the path $r \rightarrow v$ in the forest.
Here is an Algol-like version of Steps 2 and 3 which uses LINK and EVAL.

```
comment initialize variables;
for i := n by -1 until 2 do
  v := vertex(i);
step2: for each u ∈ pred(v) do
  x := EVAL(u); if semi(x) < semi(v) then semi(v) := semi(x) od;
  LINK(parent(v), v);
  add v to bucket(vertex(semi(v)));
step3: for each w ∈ bucket(parent(v)) do
  delete w from bucket(parent(v));
  u := EVAL(w);
  dom(w) := if semi(u) < semi(parent(v)) then u
            else parent(v) fi od od;
```

Step 4 examines vertices in increasing order by number, filling in the immediate dominators not explicitly computed by Step 3. Here is an Algol-like version of Step 4.

```
step4: for i := 2 until n do
  v := vertex(i);
  if dom(v) ≠ vertex(semi(v)) then dom(v) := dom(dom(v)) od;
```

This completes our presentation of the algorithm except for the implementation of LINK and EVAL. Figure 4 illustrates how the algorithm works.

[Figure 4]

Appendix B contains a complete Algol-like version of the algorithm, including variable declarations and initialization. Using Theorem 4 and Corollary 2 it is not hard to prove that, after execution of the algorithm,
\[ \text{dom}(v) = \text{idom}(v) \] for each vertex \( v \neq r \), assuming that LINK and EVAL perform as claimed. The running time of the algorithm is \( O(m+n) \) plus time for \( n-1 \) LINK and \( m+n-1 \) EVAL instructions.
4. Implementation of LINK and EVAL.

Reference [13] provides two ways to implement LINK and EVAL, one simple and one sophisticated. We shall not discuss the details of these methods here, but merely provide Algol-like implementations of LINK and EVAL which are adapted from [13].

The simple method uses path compression to carry out EVAL. To represent the forest built by the LINK instructions (henceforth called the forest), the algorithm uses two arrays, ancestor and label. Initially \( \text{ancestor}(v) = 0 \) and \( \text{label}(v) = v \) for each vertex \( v \).

In general \( \text{ancestor}(v) = 0 \) only if \( v \) is a tree root in the forest; otherwise \( \text{ancestor}(v) \) is an ancestor of \( v \) in the forest.

The algorithm maintains the labels so that they satisfy the following property. Let \( v \) be any vertex, let \( r \) be the root of the tree in the forest containing \( v \), and let \( v = v_k, v_{k-1}, \ldots, v_0 = r \) be such that \( \text{ancestor}(v_i) = v_{i-1} \) for \( 1 \leq i \leq k \). Let \( x \) be a vertex such that \( \text{sdom}(x) \) is minimum among vertices \( x \in \{ \text{label}(v_i) \mid 1 \leq i \leq k \} \).

Then

\[ (*) \ x \text{ is a vertex such that } \text{sdom}(x) \text{ is minimum among vertices } x \]
\[ \text{satisfying } r \rightarrow x \rightarrow v \text{ in the forest.} \]

To carry out \( \text{LINK}(v,w) \), the algorithm assigns \( \text{ancestor}(w) := v \).

To carry out \( \text{EVAL}(v) \), the algorithm follows ancestor pointers to determine the sequence \( v = v_k, v_{k-1}, \ldots, v_0 = r \) such that \( \text{ancestor}(v_i) = v_{i-1} \) for \( 1 \leq i \leq k \). If \( v = r \), \( v \) is returned. Otherwise, the algorithm performs a path compression by assigning \( \text{ancestor}(v_i) := r \) for \( z \leq i \leq k \), updating labels to maintain \((*)\).

Then \( \text{label}(v) \) is returned. Here is an Algol-like procedure for EVAL.
vertex procedure EVAL(v);
    if ancestor(v) = 0 then EVAL := v
    else COMPRESS(v); EVAL := label(v) fi;

Recursive procedure COMPRESS, which carries out the path compression,
is defined by

procedure COMPRESS(v);
    comment this procedure assumes ancestor(v) ≠ 0;
    if ancestor(ancestor(v)) ≠ 0 then
        COMPRESS(ancestor(v));
        if semi(label(ancestor(v))) < semi(label(v)) then
            label(v) := label(ancestor(v)) fi;
        ancestor(v) := ancestor(ancestor(v)) fi;

The time required for n-1 LINKs and m+n-1 EVALs using this
implementation is \(O(m \log n)\) [13]. Thus the simple version of the
dominators algorithm requires \(O(m \log n)\) time.

The sophisticated method uses path compression to carry out the
EVAL instructions but implements the LINK instruction so that path
compression is carried out only on balanced trees. See [13]. The
sophisticated method requires two additional arrays, size and child.
Initially \(size(v) = 1\) and \(child(v) = 0\) for all vertices \(v\). Here
are Algol-like implementations of EVAL and LINK using the sophisticated
method. These procedures are adapted from [13].
vertex procedure EVAL(v);
  comment procedure COMPRESS used here is identical to that in the
  simple method;
  if ancestor(v) = 0 then EVAL := label(v)
  else COMPRESS(v);
  EVAL := if semi(label(ancestor(v))) > semi(label(v)) then label(v)
  else label(ancestor(v)) fi fi;

procedure LINK(v,w);
begin
  comment this procedure assumes for convenience that
  size(0) = label(0) = semi(0) = 0;
  s := w;
  while semi(label(w)) < semi(label(child(s))) do
    if size(s) + size(child(child(s))) ≥ 2 * size(child(s)) then
      parent(child(s)) := s; child(s) := child(child(s))
    else size(child(s)) := size(s);
    s := parent(s) := child(s) fi od;
  label(s) := label(w);
  size(v) := size(v) + size(w);
  if size(v) < 2 * size(w) then s,child(v) := child(v),s fi;
  while s ≠ 0 do parent(s) := v; s := child(s) od
end LINK;

With this implementation, the time required for p-l LINKs and m+n-l
EVALs is 0(m α(m,n)), where α is a functional inverse of Ackermann's
function [1], defined as follows. For integers i,j ≥ 0, let A(i,0) = 0
if i ≥ 0, A(0,j) = 2^j if j ≥ 1, A(i,1) = A(i-1,2) if i ≥ 1,
and A(i,j) = A(i-1,A(i,j-1)) if i ≥ 1, j ≥ 2. Then
α(m,n) = min{i ≥ 1 | A(i,⌊2m/n⌋) > log_2 n}. Thus the sophisticated
version of the dominators algorithm requires O(m α(m,n)) time.
5. **Implementation and Experimental Results.**

We translated both versions of the algorithm as contained in Appendix B into Algol W and ran the programs on a series of randomly generated program flow graphs. Table 1 and Figures 5 and 6 illustrate the results. The sophisticated version beat the simple version on all graphs tested. The relative difference in speed was between 5 and 25%, increasing with increasing $n$.

[Table 1]

[Figure 5]

[Figure 6]

We transcribed the Purdom-Moore algorithm into Algol W and ran it and the sophisticated version of our algorithm on another series of program flow graphs. Table 2 and Figure 7 show the results. Our algorithm was faster on all graphs tested except those with $n = 8$. The Purdom-Moore algorithm rapidly became non-competitive as $n$ increased. The trade-off point was about $n = 10$.

[Table 2]

[Figure 7]

We implemented the bit vector algorithm using a set of procedures for manipulating multi-precision bit vectors. (Algol W allows bit vectors only of length 32 or less.) Table 3 gives the running time of this algorithm on the second series of test graphs, and Figure 8 compares the running times of the bit vector algorithm and the sophisticated version of our algorithm. The speed of the bit vector algorithm varied depending upon the number of passes required, but it was always slower than the fast algorithm.
There are several ways in which the bit vector algorithm can be made more competitive. First, the bit vector procedures can be inserted in-line to save the overhead of procedure calls. We made this change and observed a $33 - 45\%$ speed-up. The corresponding change in the fast algorithm, inserting LINK and EVAL in-line, produced a $20\%$ speed-up. These changes made the bit vector algorithm almost as fast as our algorithm on graphs of less than 32 vertices, but on larger graphs the bit vector algorithm remained substantially slower than our algorithm. See Table 1, Table 4, and Figure 9.

Second, the bit vector procedures can be written in assembly language. To provide a fair comparison with the fast algorithm it would be necessary to write LINK and EVAL in assembly language. We did not try this approach, but we believe that the fast algorithm would still beat the bit vector algorithm on graphs of moderate size.

Third, use of the bit vector algorithm can be restricted to graphs known to be reducible. On a reducible graph only one pass of the bit vector algorithm is necessary, because the only purpose served by the second pass is to prove that the bit vectors don't change, a fact guaranteed by the reducibility of the graph. We believe that a one-pass in-line bit vector algorithm would be competitive with the fast algorithm on reducible graphs of moderate size, but only if one ignores the time needed to test reducibility.
The bit vector algorithm has two disadvantages not possessed by the fast algorithm. First, it requires $O(n^2)$ storage, which may be prohibitive for large values of $n$. Second, the dominator tree, not the dominator relation, is required for many kinds of global flow analysis \[8,14\], but the bit vector algorithm computes only the dominator relation. Computing the relation from the tree is easy, requiring constant time per element of the relation or $O(n)$ bit vector operations total. However, computing the tree from bit vectors encoding the relation requires $O(n^2)$ time in the worst case.

We can summarize the good and bad points of the three algorithms as follows: the Purdom-Moore algorithm is easy to explain and easy to program but slow on all but small graphs. The bit vector algorithm is equally easy to explain and program, faster than the Purdom-Moore algorithm, but not competitive in speed with the fast algorithm unless it is run on small graphs which are reducible or almost reducible. The fast algorithm is much harder to prove correct but almost as easy to program as the other two algorithms, competitive in speed on small graphs, and much faster on large graphs. We favor some version of the fast algorithm for practical applications.

We conclude with a few comments on ways to improve the efficiency of the fast algorithm. One can speed up the algorithm by rewriting DFS and COMPRESS as non-recursive procedures which use explicit stacks. One can avoid using an auxiliary stack for COMPRESS by instead using a trick of reversing ancestor pointers; see \[12\]. A similar trick allows one to avoid the use of an auxiliary stack for DFS. One can save some additional storage by combining certain arrays, such as parent and ancestor. These modifications save running time and storage space, but only at the expense of program clarity.
Appendix A: Graph-Theoretic Terminology.

A directed graph \( G = (V, E) \) consists of a finite set \( V \) of vertices and a set \( E \) of ordered pairs \((v, w)\) of distinct vertices, called edges. If \((v, w)\) is an edge, \( w \) is a successor of \( v \) and \( v \) is a predecessor of \( w \). A graph \( G_1 = (V_1, E_1) \) is a subgraph of \( G \) if \( V_1 \subseteq V \) and \( E_1 \subseteq E \). A path \( p \) of length \( k \) from \( v \) to \( w \) in \( G \) is a sequence of vertices \( p = (v = v_0, v_1, \ldots, v_k = w) \) such that \((v_i, v_{i+1}) \in E \) for \( 0 \leq i < k \). The path is simple if \( v_0, \ldots, v_k \) are distinct (except possibly \( v_0 = v_k \)) and the path is a cycle if \( v_0 = v_k \).

By convention there is a path of no edges from every vertex to itself but a cycle must contain at least two edges. A graph is acyclic if it contains no cycles. If \( p_1 = (u = u_0, u_1, \ldots, u_k = v) \) is a path from \( u \) to \( v \) and \( p = (v = v_0, v_1, \ldots, v_l = w) \) is a path from \( v \) to \( w \), the path \( p_1 \) followed by \( p_2 \) is \( p = (u = u_0, u_1, \ldots, u_k = v = v_0, v_1, \ldots, v_l = w) \).

A flow graph \( G = (V, E, r) \) is a directed graph \((V, E)\) with a distinguished start vertex \( r \) such that for any vertex \( v \in V \) there is a path from \( r \) to \( v \). A program flow graph is a flow graph such that each vertex has exactly two successors. A (directed, rooted) tree \( T = (V, E, r) \) is a flow graph such that \(|E| = |V|-1\). The start vertex \( r \) is the root of the tree. Any tree is acyclic, and if \( v \) is any vertex in a tree \( T \), there is a unique path from \( r \) to \( v \). If \( v \) and \( w \) are vertices in a tree \( T \) and there is a path from \( v \) to \( w \), then \( v \) is an ancestor of \( w \) and \( w \) is a descendant of \( v \) (denoted by \( v^\ast w \)). If in addition \( v \neq w \), then \( v \) is a proper ancestor of \( w \) and \( w \) is a proper descendant of \( v \) (denoted by \( v^{\ast\ast} w \)). If \( v^\ast w \) and \((v, w)\) is an edge of \( T \) (denoted by \( v - w \)), then \( v \) is the parent of \( w \) and \( w \) is a child of \( v \). In a tree each vertex has a unique parent.
(except the root, which has no parent). If \( G = (V, E) \) is a graph and \( T = (V', E', r) \) is a tree such that \((V', E')\) is a subgraph of \( G \) and \( V = V' \), then \( T \) is a spanning tree of \( G \).
Appendix B: The Complete Dominators Algorithm.

This appendix contains a complete listing of both versions of the dominators algorithm. The algorithm assumes that the vertex set of the problem graph is \( V = \{v \mid 1 \leq v \leq n\} \).

procedure DOMINATORS(integer set array succ(l::n); integer r,n; integer array dom(l::n));
begin
integer array parent, ancestor, [child,] vertex (l::n);
integer array label, semi [size] (0::n);
integer set array pred, bucket (l::n);
integer u,v,x;
procedure DFS(integer v);
begin
semi(v) := n := n+1;
vertex(n) := label(v) := v;
ancestor(v) := [child(v) :=] 0;
[size(v) := 1];
for each \( w \in \text{succ}(v) \) do
if semi(w) = 0 then parent(w) := v; DFS(w) fi;
add v to \( \text{pred}(w) \) od
end DFS;

procedure COMPRESS(integer v);
if ancestor(ancestor(v)) \neq 0 then
COMPRESS(ancestor(v));
if semi(label(ancestor(v))) < semi(label(v)) then
label(v) := label(ancestor(v)) fi;
ancestor(v) := ancestor(ancestor(v)) fi;

integer procedure EVAL(integer v);
if ancestor(v) = 0 then EVAL := v
else COMPRESS(v); EVAL := label(v) fi;

24
procedure LINK(integer v, w);
ancestor(w) := v;

step 1: for v := 1 until n do
pred(v) := bucket(v) := \emptyset; semi(v) := 0 od;
n := 0;
DFS(r);
[size(0) := label(0) := semi(0) := 0;]
for i := n by -1 until 2 do
v := vertex(i);

step 2: for each u \in pred(v) do
x := EVAL(u); if semi(x) < semi(v) then semi(v) := semi(x) od;
LINK(parent(v), v);
add v to bucket(vertex(semi(v)));

step 3: for each w \in bucket(parent(v)) do
delete w from bucket(parent(v));
u := EVAL(w);
if semi(u) < semi(parent(v)) then u
else parent(v) fi od od;

step 4: i := 2 until n do
v := vertex(i);
if dom(v) \neq vertex(semi(v)) then dom(v) := dom(dom(v)) od
end DOMINATORS;

The simple version of the algorithm consists of the procedure above, with everything in brackets deleted. The sophisticated version of the algorithm consists of the procedure above, with everything in brackets included, and the following procedures substituted for EVAL and LINK.

integer procedure EVAL(integer v);
if ancestor(v) = 0 then EVAL := label(v)
else COMPRESS(v);
EVAL := if semi(label(ancestor(v))) \geq semi(label(v)) then label(v)
else label(ancestor(v)) fi fi;
procedure LINK(integer v, w);
    begin integer s;
        s := w;
        while semi(label(w)) < semi(label(child(s))) do
            if size(s) + size(child(child(s))) ≥ 2 * size(child(s)) then
                ancestor(child(s)) := s; child(s) := child(child(s))
            else size(child(s)) := size(s);
                s := ancestor(s) := child(s) fi od;
        label(s) := label(w);
        size(v) := size(v) + size(w);
        if size(v) < 2 * size(w) then s, child(v) := child(v), s fi;
        while s ≠ 0 do ancestor(s) := v; s := child(s) od
    end LINK;

Figure 3. Depth-first search of flow graph in Figure 1.
Solid edges are spanning tree edges, dashed edges are non-tree edges.
First number in parentheses is vertex number, second is semi-dominator.
Figure 11. Forest maintained by LINK and EVAL during steps 2 and 3 of the dominators algorithm. (Trees in the forest consisting of single vertices are not shown.)

(a) Before vertex H is processed. Candidates for $sdom(H)$ are $9 = \text{number}(E)$ and $1 = \min \{sdom(v) | B \rightarrow v \rightarrow L \}$. 

(b) Before vertex E is processed. Candidates for $sdom(E)$ are $8 = \text{number}(B)$ and $1 = \min \{sdom(v) | E \rightarrow v \rightarrow H \}$. After $sdom(E) = 1$ is computed, $\text{bucket}(B)$ is unloaded. At this time $D$ is the only element of $\text{bucket}(B)$. $A$ is the vertex such that $sdom(A) = \min \{sdom(v) | B \rightarrow A \rightarrow D \}$. Since $sdom(A) = 1 < sdom(D) = 8$, $dom(D)$ is assigned $dom(D) := A$. Note that $idom(D) = idom(A) = R$.

(c) After E is processed.
