ABSTRACT

This thesis describes the design, implementation and user interface for an Instructional Software Information System (ISIS). The existing volume and increasing rate of growth of computer software production suggests the need for a catalogue procedure to help programmers find existing software to reduce redundant programming.

The purpose of the ISIS is to provide an online software catalogue which does not require either prior instruction or familiarity with keyword lexicons. Using ISIS, a user may record the characteristics of new software, and make searches for existing software by specifying its characteristics. Characteristics are specified by selection from a succession of menus. ISIS is implemented on a PDP-11 computer operating under the UNIX operating system using the INGRES database management system. It is written in the QUEL query language embedded in the programming language C.
ACKNOWLEDGMENTS

I would like to express my sincere appreciation to all those who provided background material and shared their experience in this thesis, and in particular to Dr. C. E. Irvine for her help with the C language and the UNIX operating system. I am deeply grateful to my thesis advisor LCDR Stephen HOLL for his guidance, timely advice and help throughout this work. Finally, a very special thanks to my wife, Ayten, for her patience and understanding.

I. INTRODUCTION

A. INTRODUCTION TO THE PROBLEM

Today in the computer world there is an enormous amount of software, written on many different subjects. Sometimes it is feasible to adopt a program on hand to a given problem; sometimes it is not. Even when new software must be created, the job can often be made easier if advantage is taken of existing software tools or of example programs performing analogous functions.

The existing volume and increasing growth rate of computer software demands effective, easy to use catalogue procedures. When a programmer is tasked to write a new program, he should be able to begin by verifying that software performing the indicated tasks does not already exist.

Many computer firms supply on line or off line catalogued subroutine libraries. But these library catalogues are not general; they are catalogues on specific subjects. A general all-encompassing catalogue is desired, and it should be one which can be conveniently extended to include new software written or acquired locally.
Solutions to the problem can take two forms: an offline catalogue, or an online catalogue. After preparation, an offline catalogue is hard to update. An online catalogue is easy to use and maintain, but terminal access is required. In an educational environment this approach is especially appealing; it encourages the students to use software tools and gives them the ready access to a broad range of software which they would otherwise have only after gaining considerable programming experience. Learning to take advantage of software tools is most important for computer science students, especially during the later quarters of the curriculum.
II. APPROACH TAKEN

A. BASIC INITIAL SPECIFICATIONS

After the decision to use an online catalogue was made, the following questions needed to be addressed:

a. What functions must the system perform?
b. How should the system communicate with the user?

The answers to these questions are really basic functional specifications:

The system has to search system resident listings according to user commands. The user has to be able to add new listings and also to be able to change his listings.

The system has to be very easy to use: the user should have no trouble even the first time he uses it. The approach taken to accomplish this was to make the system entirely self-prompting. No command vocabulary is used; instead, the system asks questions and provides, with each question, a complete menu of responses. This philosophy is incompatible with the keyword approach which is a common feature of automatic cataloguing systems.
9. DATA STRUCTURES

At this point the question of how to design the structure of the data representing the listings was addressed. The characteristics of importance are:

(1). easy user understandability, or else usability without understanding.

(2). The ability to quickly identify listings whose characteristics include those specified by the user.

(3). Reasonable storage density.

Listing lookup was expected to occur much more frequently than the creation of new listings or the modification of old ones; consequently the rapidity and complexity of listing structure updating was not considered to be an important criterion for data structure choice.

The following alternatives were considered:

1. Tree type structure

In a tree form software directory, the leaves would be individual listings, and the nodes would each be a common ancestor of all listings with a common characteristic.

One finds listings by starting at the root and making choices at each node, until reaching the listings desired.

Advantage:

The mechanism is easy to understand.
Disadvantages:

(1) User is forced to answer the questions in a particular order.

(c) Pointer implementation is troublesome.

2. Table type structure

One table with two dimensions is created; rows would correspond to program listings; columns to characteristics. When a listing has a given characteristic, a mark is placed in the appropriate cell in the table.

Advantages:

(1) Easy for user to comprehend.

(2) User can specify characteristics in any order.

Disadvantages:

(1) A large volume of storage is required.

(2) A variable dimension table is required because both listings and characteristics may be added as the database grows.

(3) Program purpose classification appears to be most conveniently organized as a tree.

(4) User needs to know the characteristic vocabulary in advance.
3. Hybrid structure

A compromise between the tree and tabular approaches was sought in the form of a hybrid structure. Here the user may picture a table of the form explained above, and he may think of the search process as one of choosing blocks of columns to omit and columns to save, successively refining the choices, until the listings are narrowed down to a small number satisfying the characteristics he needs. The selection of characteristic columns is organized in a tree, though the user need not be aware of this. His first choice - the first level of the tree - is this: from among all of the independent categories of software classifications he chooses those from among whose subdivisions he wishes to choose. For example a user whose goal is to find a sort for the IBM 360 will look over the first menu, containing "language", "hardware", ... and will specify hardware for further clarification, and may ignore language if any language will do. The subdivisions of each of the chosen major subdivisions of each of the chosen categories are presented for review - then the minor subdivisions - and so forth, and the user may refine his choice along any direction as long as he wishes until further subdivisions are exhausted.
The physical form chosen for this structure was a tree where each node contains a table of names of its subordinate node tables and names of software listings which have the characteristics of that node but are too general to be listed among the node's subordinate nodes. (Notice that a given listing will typically be referenced in several different parts of the characteristics tree, most likely once under each major subcategory of the root.)

The relational database model offered an easy mechanism for maintenance of these node tables.

At this point it was decided to use the INGRES database management system available on the NPS computer laboratory PDP-11 computer under the UNIX operating system.

C. LANGUAGE SELECTION

The system programs are written in QUEL (the INGRES query language) embedded in the programming language C.
U. CLASSIFICATION OF SOFTWARE

A plausible, intuitive software classification was sought but no existing system seemed to be entirely suitable; moreover, they differed widely suggesting that classification goodness may be in some degree relative to the environment in which the catalogue is to employed. So it was decided to implement a variable type of classification which each user agency can configure as it sees fit.

Here is an example classification:

1- Computer software tools
   Operating system
   Compiler
   Language
   Time sharing
   Microprogramming
   Debugging aids

2- Data manipulating tools:
   Text editing
   Sort
   Merge
   Database
   Test data generators
   Data structures like stack, queue etc.
3- Mathematics
   Math. functions
   Probability
   Operations research

4- Business applications
   Engineering
   Financial
   Inventory
III. DESIGN FEATURES

ISIS is implemented as an INGRES database. A tree structure is simulated using relations. A small demonstration database is shown in figure 1.

The root of the tree is the "maintable" relation which is loaded at system installation time and cannot be changed by the user. Maintainable tuples show the main branches of the tree: these are the independent categories of software characteristics, like language and hardware. Every node of the tree is a relation with two fields, rid (record ID) and cname (class record name). Rid is used as a key to all actions. If a rid is equal to zero, it means there is a relation with that name which further subdivides the current relation. If a rid is greater than zero, it means cname is the record name itself. One listing may (and usually will) be found recorded in more than one branch (relation). There is no information about the listings on the tree relations; only rids are shown. All other information about a specific listing can be found in the recordfile and wr (where) relations, which are in the example shown in figure 2.

IV. CODING AND TESTING PHASES

The ISIS system was designed in a top down manner. First the main frame of the system was designed, coded and tested. Then the primary function of the system, the search program, was designed, coded and tested. As the search program becomes large, some problems began to surface. The C compiler began to print errors about undeclared variables which were in fact declared. At this point the output of EQUEL precompiler was checked and it was seen that similar statements in different parts of the source code were translated into C as different codes. When the source was divided into smaller files, the EQUEL precompiler seemed to work correctly.

After compilation was accomplished the testing began to take much more time than anticipated. The author was unprepared for the deliberateness with which INGRES functioned.

When run time error messages surfaced, it was difficult to find out what exactly was wrong because two compilers and the INGRES system were all involved.
EQUEL does not allow declaration of integer arrays. For this reason the integer array used as the input buffer was declared as a C variable and then, when required, each value was taken one by one from the C array into an EQUEL variable for use.

The search program is composed of approximately 1000 lines. It may cause interactive problems if run concurrently with add, delete and modify programs. The search routine is the key component of ISIS. It is possible to operate a reduced ISIS by running just the search function, maintaining the database (adds, modifications and deletions) by using the INGRES query language QUEL.
A. SYSTEM CAPABILITIES

The system has the following capabilities:

1. Search:
   The system searches for resident listings according to user specified qualifications. The user can choose up to 25 qualifications for a given search.

2. Add:
   Any user can add a listing; there is no need to get "add" permission from the ISIS manager. The principle restriction for addition is that the depth of the tree can be a maximum of around 20 arcs. When a listing is created, the listing "owner" assigns a one letter password.

3. Modify:
   The owner of a listing can modify either the listing description and/or the "where found" information.

4. Delete:
   The owner of a listing can delete his listing.

Currently the ISIS system can has a maximum of 32767 listings because listings are assigned 2 bytes unique ID numbers. By changing all "rid" attributes to 14 in relation declarations, the system could hold up to 2,174,483,647 listings.

Further information may be found in the user's manual.
b. PROBLEMS WITH THE SYSTEM

Only one user should use the search program or add, delete, and modify program at a given time. If more than one user is using one of these, ISIS may not work correctly because some temporary ISIS information is stored in shared INGRES relations.

System response is very slow even when the listing database is miniscule. This is apparently a characteristic of the INGRES system.

It is impossible to print a hard copy of the system listings in catalogue form at present. Each branch point is embodied in a relation and all relations can be printed but it is hard to extract a catalogue form from them. By printing "recordfile" and "whr" relations all listings in the system can be seen as a list form.

It would be preferable to use a more efficient, faster database system to implement ISIS, or not to use a database system at all.
C. POSSIBLE OTHER USAGE AREAS

The ISIS system was designed with software cataloguing in mind; however the system could be used in many different applications, for example, the assignment of personnel to jobs. Personnel characteristics could be put into relations and when a person is needed for a specific job, he can be found through the search process.
APPENDIX A

USER'S REFERENCE MANUAL

The purposes of this manual are threefold:

1. To introduce the program to facilitate maintenance.

2. To provide information to the ISIS system manager to enable him to keep the system efficiently configured.

3. To provide the user with more detailed knowledge of the system and to list the error conditions.

Running the system is very easy and generally no previous experience is required. The first time user should not need to read this manual; he should simply log in as "isis" and then type "oo".

1. INTRODUCTION

Instructional Software Information System (ISIS) is an online catalogue especially designed for computer software. Using ISIS a user may record the existence and characteristics of a new program, and may make searches for existing software by citing the characteristics desired. Characteristics are specified by selection from a succession of menus.

ISIS is implemented on a PDP-11 computer operating under the UNIX operating system using the INGRES data base management system. It is written in the QUEL query language embedded in the programming language C.
II. ISIS PROGRAMS

A. GENERAL VIEW

The system is composed of three programs:

1. Main Program (isismain.c)

This program is written in the language C. Upon login as "isis", main is executed automatically. Then, according to user instructions, control is transferred to one of the programs in figure 3. Isismain.c is very straightforward and needs no explanation.

Figure 3. ISIS program heirarchy
2. Search Program ( src.q )

This program is written in QUEL (the INGRES query language) and C. It does a search of ISIS software listings according to user qualifications and displays the results.

3. Add-Delete-Modify Program ( adm.q )

This program is also written in QUEL and C. It allows a user to add new listings to the system. It also allows a listing originator to modify or delete an existing listing.

4. Data Structures

The principle ISIS data structures are described below:

a. The relation "recordfile" contains a master file of the listings, with each identified by name and unique ID number (RID).

b. Information about where to find the software corresponding to the listings is in the "whr" relation, identified by unique ID number.

c. The main software characteristic classes are the tuples of the "maintable" relation.

d. A variable set of "node" relations embodies the tree structure.
Each node relation contains:
1. Listing names and ID numbers.
and/or
2. The names of dependent node relations, identified by RID's of zero.

B. SEARCH PROGRAM

1. General View

The search program searches for listings of existing software meeting the characteristics specified by the user. The user specifies these by answering questions posed by ISIS.

System execution is slow even when the listing database is short; to prevent a long search over a short list, the user may be willing to scan a list of all of the records in the system. For this reason there is an option to display all records at the beginning.

A general flowchart of the search program is given in figure 4. After the user specifies some qualifications, the system replies how many listings meet the qualifications; the user may then either see the listings which meet his qualifications or he may change his qualifications.

After one search has been finished, the user may continue with other searches or he may exit from the system.
Figure 4. The general flowchart of search program src.q.
Figure 5. The functional diagram of the search program.
The functional diagram of the search program is shown in figure 5.

The source code for the search program is contained in three files.

a. File src.q

The code in this file performs the actual search; it is composed of the following functions:

main : calls introd and mnsrch functions.
intro : prints the introduction and invokes INGRES using the ISIS database.
mnsrch : calls the search routine, then exits ISIS.
search: monitors the search process by calling functions.
count1: counts number of listings in the system.
dipl1 : displays all listings in the system.
main1: monitors the qualification process.
prels1: puts relations onto stack 1.
qsls1: one by one gets a relation name from stack 1, qualifies it and puts results onto stack 2.
main2: monitors the rest of the qualification.
cps2s1: copies stack 2 to stack 1.
prqual: prints current qualifications.
deletq: deletes qualifications from stack 1.
disp12: displays listings according to qualifications.
b. File encsrc.q

This file is included in src.q at compile time.

The reason the search program is separated into two files, src.q and encsrc.q, is that the EQUEL precompiler does not seem to work correctly for long source files.

This file provides the following functions:

diss : displays D type qualifications.
cnttb3: counts table3 tuples.
distb3: displays listings in table3.
getnm : gets a listing number from terminal.

c. File com.q

This file is common to both the search program and the Ada-Delete-Modify program. It provides the following functions:

cylbrc: evaluates the first usage of search program.
helpis : prints information helpful to a user who has "lost his way".
greadc: gets a character from terminal.
greadn: gets a maximum of ten integer numbers from terminal.
msgerr: prints an error message.
infohe: prints ISIS information of a general nature.

2. Specifications of the Search Program

A search is performed by specifying the characteristics of the sought for software. As the search continues, these characteristics are successively refined.
Search is done on a simulated tree structure. Every node of the tree is a relation. The root of the tree is the "maintable" relation. In order to begin the search process, a user must choose at least one branch.

The qualification process uses two qualification stacks, each 25 elements long, so the user can have a maximum of 25 qualifications at any one time. Stack 1 is used as the main stack; stack 2 is used as an auxiliary stack when changing qualifications.

Each stack record has two fields:

a. qualification name

b. qualification type, which has value M, W or D.

These codes are used to specify actions to be performed when the stack is processed.

M: this qualification shows miscellaneous tuples which are tuples with ID numbers greater than zero in the given relation.

W: Instruction to write all the tuples of a given relation which have an ID number greater than zero.

D: Instruction to display all tuples of this relation which are greater than zero; there exist here some tuples which have ID numbers equal to zero, meaning there are further subdivisions. So D, in effect, will cause branch records to be displayed also.
The display function (disp12) uses stack 1 records and according to the qualification type it employs different methods to find listings which meet all the specific qualifications.

To display V and U type qualifications, three table relations named table1, table2 and table3 are used. Table1 and table2 are used for listing ID's which meet one qualification. Note that the display process is an AND operation not an OR operation, so table3 identifies listings which meet all previously processed qualifications.

It is more difficult to display D type qualifications, which have branch relations, because it is also necessary to find out and evaluate all listings in the branches. For this reason, in addition to the three table relations mentioned above, two more relations named tabled1 and tabled2 are used. All listing rid's for a given qualification are saved in tabled1, and subbranch relation names are saved in tabled2. One tuple is taken from tabled2; if this tuple shows a branch, it is evaluated and the resulting listing ID's are put into tabled1; branches, if any, are put to tabled2 again, and the process continues until tabled2 is empty. At this time tabled1 has all listings which meet D type qualification.
Only one user at a time can employ this part of the program; otherwise these tables become confused. If this situation is suspected the user should check other terminals for a user using display; then wait and try again.

More than one user may be doing the qualification process at once; only display must be done serially.
C. ADD-DELETE-MODIFY PROGRAM

1. General View

This program is used to add new listings into the system and to delete or modify existing listings. A general flowchart of the program is given in figure 6 and the functional diagram in figure 7.

The source code of the program is composed of the following files:

a. File adm.o

This file performs add, delete, and modify actions and invokes functions in the other files.

File adm.o contains the following functions:

main: calls infohe and branch functions, and invokes the database.

branch: branches to add, delete or modify processes.

add: monitors add process.

perpar: gets parameters for a listing from terminal.

aorwh: appends listings to recordfile and whr relations.

adirls: adds listings to relations by calling other functions.

curstr: outs relation name chosen by user on the stack.

curcl: prints current class and subcategories.
Figure 6. General flowchart of Add-Delete-Modify Program adm.q.
Figure 7. The functional diagram of Add-Delete-Modify program.
addcur: adds a listing to current relation.
newrec: adds a listing to a newly created subcategory relation.
exitrec: adds a listing to one of the existing branches.

b. File encadm.q

This file is included in adm.q at compile time. These two files were split for the same reason that the search routine was divided; the EQUEL precompiler seemed unable to process both at once.

File encadm.q has the following functions:
delmod: gets parameters, and monitors delete and modify processes.
detnum: gets a listing ID number from the terminal.
delete: beginning part of the delete process.
modlt: deletes a listing from a relation.
modify: beginning part of the modify process.
modwh: modifies listing description and where information.

b. File com.q

This file contains functions common to the search and Add-Delete-Modify programs. For more information refer to the search program on page 32.
2. Specifications of Add-Delete-Modify program

The ADD process user can enter his listing into existing characteristic relations or he can create new branch relations and put the listing into them.

The ADD process can stack up to a maximum of 25 relation names. This does not mean the user is restricted to putting his listings into fewer than 26 relations, but rather that he can not have more that 25 further divisions identified and pending at any one time.

When a new relation is created as a new branch, the save command must be performed. This is done in file adm.q by the newbrc (new branch) function. The date supplied to the SAVE command must be advanced periodically by the ISIS manager; otherwise, when the date is reached, the relations may be inadvertently purged. It is probably best if the save date is identical to that used to save other relations.

DELETE and MODIFY processes at the beginning use the same delmod function to identify the owner of the listing which is to be deleted or modified. For this reason the user gives a listing ID number and the system checks to find out if there is any record with that number. Afterwards the password is checked; the password was set up during the ADD process when the listing was created; it is one character. For example it may be "," (fullstop) or any letter or digit. After the correct password is received, the delete or modify process can begin.
DELETE PROCESS:

This process deletes a listing from "recordfile", the master listing relation, and from "whr", the where found, relation, and begins to search the branch relations starting at the root. When the listing is found recorded in a relation, the subbranches of that relation are ignored.

When a listing is deleted from a relation, if there are no more listings in that relation, the relation is also destroyed. If the parent has no entries other than the destroyed relation then the parent relation is also destroyed; otherwise the child relation name is deleted from the parent.

The delete process employs the same stack used by the add process. The function dumwr (dummy write), which prints the top 5 elements of the stack, was used in the testing phase of the program and was left in. It can be reactivated by removing the two slashes "//" (comment) previous to dumwr(). By changing 5 to 25 in the "for" statement in dumwr, all stack elements can be written during the delete and add processes.

MODIFY PROCESS:

It is only possible to modify listing description and where information. If the user needs to modify the tree entries for a listing he must first use DELETE to remove the listing entries and then use ADD to create revised ones.
III. SYSTEM GENERATION

This section explains how to install ISIS. ISIS requires the database management system INGRES which requires the UNIX operating system which runs on PDP/11 hardware.

A. DATABASE SETUP

The ACTUAL software database is named "isis0".

If a DEMONSTRATION database is desired, it should be named "isis1". A demonstration database is not necessary.

The database is created as follow.(The "%" sign is the UNIX prompt symbol)

First mount INGRES. At NPS this is done via a UNIX shell file, invoked as follows:

  % /usr/inesys/systmnt.sh

Now create database isis0:

  % creatdb isis0

Invoke INGRES operating on the newly created database:

  % ingres isis0

The INGRES prompt is "do *".

Now create the main listing and location relations and the "root" relations for the attribute tree:
create recordfile(rid=i2, rname=c12, rdes=c50, pswrd=c1)
create whr(rid = i2, rdes = c50)
create maintable(curname = c12)

Now "MAINTABLE", the root relation, must be loaded with the names of its direct descendants.

For example,
append to maintable(curname = "computer")

Now, "computer" is appended. Branch names have a maximum of 12 characters.

After filling the main table, create the corresponding node relations.

For example:
create computer(rid = i2, curname = c12)

Certain other relations which are used by ISIS as temporary storage during execution must also be created, as follows:
create table1(rid = i2)
create table2(rid = i2)
create table3(rid = i2)
create tabled1(rid = i2)
create tabled2(crename = c12)
All the essential relations have now been created. DO NOT FORGET to "save" relations up to a reasonable date, for example 1 year ahead. For example:

save relationname until jan 30 1979

Repeat this command for each relation which has been created.

Now the database isis0 is ready. If it is desired to create the isis1 demonstration database, the procedure is repeated as above, except that the first command would be

%create isis1
8. COMPILATION OF PROGRAMS

To compile the main program in file isismain.c use the command:

```
% cc isismain.c
```

Now rename the output "isis":

```
% mv a.out isis
```

To compile the search program:

First use the EQUEL precompiler for the files which are used by search:

```
% equel src.o
```

The output is in file src.c

```
% equel encsrc.o
```

The output is in file encsrc.c

```
% equel com.o
```

The output is in file com.c

These are all C files. Compile them using the EQUEL library:

```
% cc src.c -1q
```

The output is in file a.out; rename it "isissrc", as follows:

```
% mv a.out isissrc
```

"isissrc" is an executable file which, when invoked, performs an isis search.
To compile the Add-Delete-Modify program:

First, use the equel precompiler for the files which are used by this program.
% equel adm.q
The output is in file adm.c
% equel encadm.q
The output is in file encadm.c

The file com.c was already created during search compilation.
Now compile the program, using the EQUEL library.
% cc adm.c -1q
The output is in file a.out.
Rename it "isisadm", as follows:
% mv a.out isisadm
Now, "isisadm" is an executable file which, when invoked, performs isis add, modify, and delete operations.

Now remove unnecessary files:
% rm src.c encsrc.c com.c adm.c encadm.c

Isis is now ready to use.
C. SIMPLE TUTORIAL

This tutorial is prepared to give the user a general idea of how the system interacts with the user. This tutorial covers the search process only; it does not change the system resident data. It uses the ISIS demonstration database named "isis!" whose relations and linkage schema are shown in figure 1 on page 16.

Type one of the following numbers in " "
"1" to SEARCH ISIS records
"2" to ADD new ISIS, DELETE or MODIFY existing ISIS records
"3" to QUIT ISIS

go >

1

ISIS means Instructional Software Information System written at APS

*** when you need help, at some key point

type "h" to get HELP ***

good luck

For more information type "yes"

Otherwise push return key on > yes

This program is an online software dictionary
There are two major programs:
1. SEARCH program:

User can find existing software by conversing with the computer.
2. ADD, DELETE, MODIFY program:

User can advertise his own software by listing it with the system. Provisions for modifying and deleting a listing are included. Both programs are easy to use. They do not need previous experience. Just type answers after "go >" marks.

The programs are written in data sublanguage QUEL, supported by INGRES database management system, and the programming language C.

0. ERROR MESSAGES

The INGRES system may print EQUEL error messages with error numbers and a little information during run time. Explanations of them can be found in reference o. EQUEL errors arise when the system relations are not in proper form. For example in one relation there may be a tuple referencing a nonexistent dependent relation. This condition may occur if the computer goes down or if the user gives up in the middle of the add process. In order to fix the system, the relations must be checked by the manager using INGRES directly. (The UNIX command "RESTORE database name" should be issued whenever a crash occurs during an INGRES operation.)

There are other error messages which are printed by ISIS itself due to wrong arguments given by the user. These are all self explanatory, and give the user another chance to type a correct argument. In some places, if the user types the same wrong argument three times the system terminates.
main() { /* forks one of the two ISIS programs */
