Approved for public release; distribution unlimited.
The critical velocities of loads moving over floating ice plates have been determined by several authors. In all these analyses it was assumed that the in-plane force field in the ice cover is zero. However, due to constrained thermal strains, in-plane forces do occur in the field. The purpose of the present paper is to determine their effect upon the critical velocities of the moving loads. It is shown that a uniform compression force field reduces the critical velocity, whereas a tension force field has the opposite effect.
PREFACE

This report was prepared by Dr. Arnold D. Kerr, Visiting Professor, Department of Civil Engineering, Princeton University, under Grant DACA 89-73-0228 from the U.S. Army Cold Regions Research and Engineering Laboratory. The work was performed under DA Project 4A062103A894, Engineering in Cold Environments, Task 02, Engineering Design Criteria, Work Unit 005, Crossing of Water Barriers.

Technical review of this report was performed by Guenther Frankenstein and Dr. Donald Nevel of CRREL.
THE CRITICAL VELOCITIES OF A FLOATING ICE PLATE
SUBJECTED TO IN-PLANE FORCES AND A MOVING LOAD

by
Arnold D. Kerr

INTRODUCTION

It is well known that when a vehicle is moving on a floating ice sheet there is a certain velocity, denoted in the mechanics literature as the "critical velocity" $v_{cr}$, at which it may break through the ice. Methods for determining $v_{cr}$ for floating plates subjected to moving loads have been presented by Assur (1961), Kheishin (1963, 1967) and Nevel (1970). Kheishin and Nevel utilized the linear bending theory of plates to describe the response of the ice cover, and the equations of an ideal fluid to describe the response of the liquid base.

Recently, Kerr (1972) showed that an axial force in a beam on a Winkler base that is subjected to a moving lateral load may have a profound effect upon $v_{cr}$. Since axial in-plane forces also occur in floating ice covers, caused by constrained thermal strains, it is of interest to determine their effect upon $v_{cr}$. The purpose of the present paper is to study this phenomenon.

At first, we analyze some related problems: the magnitude of the critical in-plane compression forces for a uniform biaxial stress field, and then the propagation of free waves in the floating plate subjected to in-plane stresses. This is followed by the determination of $v_{cr}$ for a floating plate subjected to a moving load and an in-plane force field.

THE INSTABILITY OF A FLOATING INFINITE PLATE
SUBJECTED TO A BAXIAL FORCE FIELD

It is assumed that the governing equation for the determination of $N_{cr}$ is

$$D \nabla^4 w + N \nabla^2 w + \rho g w = 0$$

(1)

where

$$\nabla^4 = \frac{\partial^4}{\partial x^4} + 2 \frac{\partial^4}{\partial x^2 \partial y^2} + \frac{\partial^4}{\partial y^4}$$

(2)

$w(x, y)$ is the perturbation from the plane state, $D$ is the flexural rigidity of the plate, and $\rho g$ is the specific weight of the liquid base.
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

For a buckling mode of the form

\[ w(x, y) = w_0 \sin(\alpha_1 x) \]  (3)

where \( w_0 = \text{const.} \), eq 1 yields, setting \( \rho_0 \delta / D = \kappa^4 = 1/d^4 \).

\[
\left( \alpha_1^4 - \frac{N}{D} \alpha_1^2 + \kappa^4 \right) w_0 \sin(\alpha_1 x) = 0. \tag{4}
\]

Equation 4 is satisfied for a non-zero \( w \) when

\[
\alpha_1^4 - \frac{N}{D} \alpha_1^2 + \kappa^4 = 0 \tag{5}
\]

and thus when

\[
\frac{N}{D} = \frac{\alpha_1^4 + \kappa^4}{\alpha_1^2}. \tag{6}
\]

Since the right-hand side of eq 6 is \( > 0 \) it follows, as anticipated, that the deformation mode of the form shown in eq 3 is only possible when \( N \) is a compression field, as is shown in Figure 1.

From \( \delta (N/D) / \delta \alpha_1 = 0 \), it follows that \( N = N_{\text{min}} \) when

\[
\alpha_1 = \kappa. \tag{7}
\]

Substituting eq 7 into eq 6, it follows that

\[
\frac{N_{\text{cr}}}{D} = 2\kappa^2 = 2 \sqrt{\frac{\rho_0 \delta}{D}} \tag{8}
\]

or, rewritten,

\[
N_{\text{cr}} = 2 \sqrt{\rho_0 \delta}. \tag{9}
\]

The corresponding wave length is

\[
\lambda_0 = \frac{2\pi}{\alpha_1} = \frac{2\pi}{\kappa} = 2\pi \sqrt{\frac{D}{\rho_0 \delta}}. \tag{10}
\]

THE PROPAGATION OF FREE WAVES

The liquid layer

Assuming that the liquid layer (Fig. 2) responds like an ideal fluid (Kheishin 1963), and that the ratio of amplitude to wave length is very small, the resulting equations, in terms of the velocity potential \( \Phi \), are:

\* The same result is obtained for \( w(x) = w_0 \sin(\alpha_1 x) \sin(\alpha_2 y) \). However then, instead of eq 7, \( \kappa^2 = \alpha_1^2 + \alpha_2^2 \).
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

Free surface

\[ \nabla_{x,y,z}^2 \Phi = 0 \quad \text{for} \ 0 \leq z \leq H \]  \hspace{1cm} (11)

\[ \left( \frac{\partial \Phi}{\partial z} - \frac{1}{\mu} \frac{\partial^2 \Phi}{\partial \alpha^2} \right)_{z=0} = 0 \]  \hspace{1cm} (12)

\[ \left( \frac{\partial \Phi}{\partial z} \right)_{z=H} = 0 \]  \hspace{1cm} (13)

\[ \nabla_{x,y,z}^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \]

Assuming

\[ \Phi(x, z, t) = A \phi(z) \cos \alpha (x - ct) \]  \hspace{1cm} (14)

and substituting it into eq 11, it follows that \( \phi(z) \) has to satisfy

\[ \frac{d^2 \phi}{dz^2} - \alpha^2 \phi = 0 \quad \text{for} \ 0 \leq z \leq H. \]

The general solution of the above differential equation is

\[ \phi(z) = B_1 e^{+az} + B_2 e^{-az}. \]

Noting boundary condition 13, it follows that

\[ \phi(z) = 2B_1 e^{aH} \cosh a (H - z). \]  \hspace{1cm} (15)

Substitution of eq 15 and 14 into the remaining boundary condition (12) yields

\[ 2AB_1 e^{aH} \left[ -a \sinh a (H - z) + \frac{\alpha^2 c^2}{\mu} \cosh a (H - z) \right]_{z=0} \cos a (x - ct) = 0. \]

The above equation is satisfied, for any amplitude of \( \Phi \), when

\[ c_t = \frac{\mu}{\alpha} \tgh (aH). \]  \hspace{1cm} (16)

Noting that \( \alpha = 2\pi/\lambda \) it follows that a solution of the form 14 will exist when the phase velocity \( c \) and the wave length \( \lambda \) are related by the dispersion relation:

\[ c_t = \sqrt{\frac{\mu}{2\pi} \tgh \left( \frac{2\pi H}{\lambda} \right)}. \]  \hspace{1cm} (16a)
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

Equation 16 is presented schematically in Figure 3. Thus, there exists a range of $0 \leq c < \infty$ and to each phase velocity there corresponds a wave length $\lambda$.

It may be shown (Lamb 1945) that to the above solution there corresponds a sinusoidal free surface wave of wave length $\lambda$ which travels in the $x$ direction with the velocity $c$. For additional comments the reader is referred to the literature on free waves in liquids.

The stressed plate (without base)

Assuming that the plate responds elastically and is subjected to a uniform in-plane force field $N$, the following plate equation is used for long waves:

$$D \nabla^4_{x,y} w + N \nabla^2_{x,y} w + \rho_p h \frac{\partial^2 w}{\partial t^2} = 0. \quad (17)$$

Assuming a traveling wave of the form

$$w(x,y,t) = w_0 \sin \alpha (x - ct) \quad (18)$$

and substituting it into the above differential equation, it follows that

$$[Da^4 - Na^2 - \rho_p h a^2 c^2] w_0 \sin \alpha (x - ct) = 0.$$

Thus, a wave of the form 18 can propagate in the plate when $N < Da^3$ and then $c, a$ and $N$ are related by the dispersion relation

$$c_{pl}^2 = \frac{Da^2 - N}{\rho_p h}. \quad (19)$$

Writing $N = na^2D$ where $n < 1$, eq (19) becomes

$$c_{pl}^2 = a \sqrt{(1 - n)D \rho_p h}. \quad (19a)$$

Equation 19a is presented schematically in Figure 4.

The stressed plate resting on a liquid layer

Retaining the assumptions made in the two preceding sections, the resulting formulation is (Kheishin 1963):

$$D \nabla^4_{x,y} w + N \nabla^2_{x,y} w + \rho_p h \frac{\partial^2 w}{\partial t^2} + \rho_v \frac{\partial w}{\partial t} + \rho_f \frac{\partial \Phi}{\partial t} \bigg|_{z=w} = 0 \quad (20)$$
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

\[ \nabla^2_{x,y,z} \Phi = 0 \]  \hspace{1cm} (21)

\[ \left. \frac{\partial \Phi}{\partial z} \right|_{z=0} = \frac{\partial w}{\partial t} \]  \hspace{1cm} (22)

\[ \left. \frac{\partial \Phi}{\partial z} \right|_{z=H} = 0 \]  \hspace{1cm} (23)

and regularity conditions for \( w \) and \( \Phi \) as \( x^2 + y^2 \to \infty \).

It is assumed, as above, that

\begin{align*}
    w(x,y,t) &= w_0 \sin a(x - ct) \hspace{1cm} (18) \\
    \Phi(x,z,t) &= A_\phi(z) \cos a(x - ct). \hspace{1cm} (14)
\end{align*}

Note that to the assumed \( \Phi \) in eq 14 there corresponds in the liquid, and hence also at the plate/liquid interface, a sinusoidal wave of the type shown in eq 18.

It was shown before that differential equation 21 and the boundary condition 23 are satisfied when

\[ \phi(z) = 2B_1 e^{aH} \cosh a(H - z). \]  \hspace{1cm} (15)

Substituting expressions 15 and 18 into condition 22 yields

\[ 1 - 2AB_1 e^{aH} \left[ \sinh a(H - z) \right]_{z=0} + cw_0 \alpha \cos a(x - ct) = 0. \]

The above equation is satisfied when

\[ 2AB_1 = \frac{cw_0}{e^{aH} \sinh a(H - w)}. \]
Thus

\[
\Phi(x, z, t) = \frac{cw_0 \cosh a (H - x)}{\sinh a (H - w)} \cos a (x - ct) = \frac{cw_0 \cosh a (H - z)}{\sinh a H} \cos a (x - ct)
\]  

(24)

since usually \(w << H\).

Substitution of \(w(x, t)\) as given in eq 18 and of \(\Phi(x, z, t)\) as shown above into differential equation 20 yields, noting that \(w << H\),

\[
\left(Da^4 - Na^2 - \rho_p h a^2 c^2 + \rho_f \frac{a^2 c^2 \cosh a H}{\sinh a H}\right)w_0 \sin a (x - ct) = 0.
\]

The above equation is satisfied when

\[
a^2 \left(a^2 - \frac{N}{D}\right) + \frac{\rho_f \frac{a^2 c^2 \cosh a H}{\sinh a H}}{D} \left[\rho_p h + \frac{\rho_f}{a} \tanh (aH)\right] = 0.
\]

(25)

This is the dispersion relation for the stressed plate on a liquid base.

Thus,

\[
c_{pt}^2 = \frac{(Da^2 - N)}{a^2} \left[\frac{\rho_p h}{\rho_f} + \frac{\rho_f}{a} \tanh (aH)\right].
\]

(26)

As expected, when the plate is absent \((D = N = h = 0)\) eq 26 reduces to eq 16, and when the liquid is absent \((\rho_f = 0)\) eq 26 reduces to eq 19.

Denoting,

\[
f^4 = \frac{D}{\rho_f \frac{a^2}{D}}, \quad \mu = \frac{\rho_p h}{\rho_f l}, \quad \nu^2 = \frac{c_{pt}^2}{a^2}, \quad \nu^2_{pt} = \frac{c_{pt}^2}{a^2}.
\]

eq 25 may be written as

\[
1 + (\mu l)^4 - N\frac{\nu^2}{D} (a l)^2 - \nu^2_{pt} \left[\mu (a l)^2 + a l \tanh \left(a l \frac{H}{l}\right)\right] = 0
\]

(25a)

and eq 26 as

\[
\nu^2_{pt} = \frac{1 + (\nu l)^2 \left[(\mu l)^2 - N\frac{\nu^2}{D}\right]}{(a l)^2} \frac{\tanh (aH)}{1 + \mu (a l) \tanh (aH)}.
\]

(26a)

A graphical presentation of eq 26 is shown in Figure 5 for \(H = \infty, \rho_f = 1 \text{ g/cm}^3, \rho_p = 0.92 \text{ g/cm}^3, E = 50,000 \text{ kg/cm}^2, \nu = 0.34\) and \(h = 30 \text{ cm}\) (thus, \(l = 454 \text{ cm}\) and \(\mu = 0.0609\)). The situation is similar to that of a beam on a Winkler base discussed recently by Kerr (1972). Namely for a given \(N < N_c\), a wave of the form
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

Figure 5.

18 cannot propagate for \( 0 < c < (c_{pf})_{min} \) and for each \( c > (c_{pf})_{min} \) two wave trains with different \( \lambda \) may propagate.

The findings of Kerr (1972) as well as those of Khechin (1967) suggest that \((c_{pf})_{min}\) may be the critical velocity of a load \( P \) which moves in the direction of the \( x \)-axis.

A necessary condition for locating \((c_{pf})_{min}\) for a given \( N \) is

\[
\frac{\partial c_{pf}}{\partial a} = 0.
\]

It yields, using eq 26, and then setting \( N/a^2 = n \) to simplify the presentation of the final result,

\[
[1 + (a\ell)^4 (1 - n)]aH - 2\mu (a\ell)^2 \left( 1 - (a\ell)^4 \right) \sinh^2 (aH) + \frac{1}{2} \sinh (2aH) \left[ (a\ell)^4 (3 - n) - 1 \right] = 0 \quad (27)
\]

or, rewritten,

\[
\frac{1 + (a\ell)^4 (n - 3)}{1 + (a\ell)^4 (1 - n)} = \frac{2aH}{\sinh (2aH)} \left[ 1 - (a\ell)^4 \right] 2\mu (a\ell) \tgh (aH) \quad (27a)
\]

It is of interest to note that eq 26a and 27a for the case \( N = 0 \) are the conditions for the determination of the critical velocity \( v_{cr} \) used by Nevel (1970).

The minimum value of \( N \) is obtained from the condition

\[
\left( \frac{\partial N}{\partial a} \right)_{c_{pf} = 0} = 0.
\]
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

It is found to take place at

\[ a = \sqrt{\frac{P_D}{D}}. \]

The corresponding

\[(N_{min})_D = 2\sqrt{\rho_I zD}. \quad (28)\]

Thus, it is equal to the critical compression force \( N_c \) given in eq 9.

THE STRESSED FLOATING PLATE SUBJECTED TO A MOVING LOAD \( P \)

It is assumed that the plate is subjected to a force \( P \) which moves with a constant velocity \( v_0 \) as shown in Figure 6. The governing equations are:

\[
\begin{align*}
D \nabla^4_{x,y} w + N \nabla^2_{x,y} w + \rho_p b \frac{\partial^2 w}{\partial t^2} + \rho_f \frac{\partial w}{\partial t} - \rho_f \frac{\partial \Phi}{\partial t} \bigg|_{z=w} &= P \delta(x - v_0 t) \delta(y) \\
\nabla^2_{x,y,z} \Phi &= 0
\end{align*}
\]

\[
\left\{ \quad (29) \right\}
\]

where

\[
\begin{align*}
\frac{\partial \Phi}{\partial z} \bigg|_{z=w} &= \frac{\partial w}{\partial t} \\
\frac{\partial \Phi}{\partial z} \bigg|_{z=0} &= 0
\end{align*}
\]

\[
\left\{ \quad (30), \quad (31) \right\}
\]

and regularity conditions for \( w \) and \( \Phi \) as \( x^2 + y^2 \to \infty \).
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

It is further assumed that after a time \( t \) a steady state will exist. This assumption allows the time variable to be transformed out by means of the simple transformation

\[
\xi = x - v_0 t, \quad \eta = y, \quad \zeta = z.
\]

The resulting formulation consists of differential equations

\[
D_{\xi,\eta}^4 w + N_{\xi,\eta}^2 w + \rho_p h v_0^2 \frac{\partial^2 w}{\partial \zeta^2} + \rho_f v_0 \frac{\partial \Phi}{\partial \zeta} \bigg|_{\zeta=w} = \rho \partial (\zeta) \delta(\eta) \tag{32}
\]

\[
N_{\xi,\eta,\zeta}^2 \Phi = 0 \tag{33}
\]

with the boundary conditions

\[
\frac{\partial \Phi}{\partial \zeta} \bigg|_{\zeta=w} = -v_0 \frac{\partial w}{\partial \zeta} \tag{34}
\]

\[
\frac{\partial \Phi}{\partial \zeta} \bigg|_{\zeta=H} = 0 \tag{35}
\]

and the regularity conditions for \( w \) and \( \Phi \) as \( x^2 + y^2 \to \infty \)

\[
\lim_{\zeta,\eta \to \infty} \left( w, \Phi, \frac{\partial w}{\partial \zeta}, \frac{\partial w}{\partial \eta}, \frac{\partial \Phi}{\partial \zeta}, \frac{\partial \Phi}{\partial \eta}, \ldots \right) = 0. \tag{36}
\]

The resulting formulation differs from the one used by Kheishin (1963, 1967) and Nevel (1970) in that it contains the term \( N_{\xi,\eta}^2 w \) in the first equation. To solve the posed problem we proceed according to Kheishin (1967) and Nevel (1970).

We introduce the double Fourier transforms

\[
\tilde{w}(\alpha, \beta) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} w(\xi, \eta) e^{i(\alpha \xi + \beta \eta)} \, d \xi d \eta \tag{37}
\]

\[
\tilde{\Phi}(\alpha, \beta, \zeta) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \Phi(\xi, \eta, \zeta) e^{i(\alpha \xi + \beta \eta)} \, d \xi d \eta. \tag{38}
\]

Multiplying eq 33 by \( e^{i(\alpha \zeta + \beta \eta)} \) and integrating it as indicated in eq 38 we obtain

\[
\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left( \frac{\partial^2 \Phi}{\partial \xi^2} + \frac{\partial^2 \Phi}{\partial \eta^2} + \frac{\partial^2 \Phi}{\partial \zeta^2} \right) e^{i(\alpha \xi + \beta \eta)} \, d \xi d \eta = 0.
\]

Using integration by parts, and noting regularity conditions 36 and definition 38, the above equation becomes

\[
\frac{\partial^2 \tilde{\Phi}}{\partial \zeta^2} - \psi^2 \tilde{\Phi} = 0 \quad \text{for} \ 0 \leq \zeta < \infty \tag{39}
\]
where
\[ \gamma^2 = \alpha^2 + \beta^2. \]  
(40)

The same transformation performed on the boundary conditions 34 and 35 yields
\[ \frac{\partial \Phi}{\partial \zeta} \bigg|_{\zeta = w} = -i\lambda w \]  
(41)
\[ \frac{\partial \Phi}{\partial \zeta} \bigg|_{\zeta = H} = 0. \]  
(42)

The general solution of eq 39 is
\[ \Phi = A_1 e^{-\gamma \zeta} + A_2 e^{+\gamma \zeta}. \]  
(43)

Noting the boundary conditions in eq 41 and 42, \( \Phi \) becomes
\[ \Phi(\alpha, \beta, \zeta) = \frac{i\lambda w}{\gamma} \frac{\cosh \gamma(H - \zeta)}{\sinh \gamma(H - w)}. \]  
(44)

For \( w \ll H \), the above equation simplifies to
\[ \Phi(\alpha, \beta, \zeta) \approx \left[ \frac{i\lambda w}{\gamma} \frac{\cosh \gamma(H - \zeta)}{\sinh \gamma(H - w)} \right] \bar{w}(\alpha, \beta). \]  
(45)

The same transformation performed on differential equation 32 yields
\[ \left[ D(\alpha^4 + 2\alpha^2 \beta^2 + \beta^4) - N(\alpha^2 + \beta^2) - \rho_0 \nu \alpha^2 + \rho \nu \bar{w} + i \rho_0 \nu \alpha \Phi \right] \zeta = w = P. \]  
(46)

Since according to eq 45, for \( w \ll H \),
\[ \Phi \bigg|_{\zeta = w} \approx \frac{i\lambda w}{\gamma t g h y H} \bar{w} \]  
eq \text{eq 46 becomes, noting eq 40,}
\[ \left[ D\gamma^4 - N\gamma^2 + \rho \Phi - \nu^2 \left( \rho_0 h h \alpha^2 + \frac{\rho_0^2}{\gamma t g h y H} \right) \right] \bar{w} = P. \]  
(47)

Denoting
\[ l^4 = \frac{D}{\rho \Phi}, \quad \mu = \frac{\rho_0 h h}{\rho \Phi}, \quad \nu^2 = \frac{\nu^2}{\Phi}, \quad \nu_0 = \frac{\nu^2}{\Phi} \]  

eq 47 may be rewritten as follows:
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

\[ \bar{w} = \frac{P}{\rho g \left( 1 + \frac{N \ell \sqrt{y}}{D} - \frac{V_0^2}{\mu} \left[ (-a \ell)^2 + \frac{(a \ell)^2}{g \ell \tan \gamma} \right] \right)} \]

Inverting \( \bar{w} \), it follows that

\[ w(\xi, \eta) = \frac{P}{4\pi^2 \rho g} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{e^{i(\alpha \xi + \beta \eta)}}{a - b \alpha^2 / \gamma^2} \, da \, d\beta \]

where

\[ a = 1 + \frac{N \ell \sqrt{y}}{D} - \frac{V_0^2}{\mu} \left[ (-a \ell)^2 + \frac{(a \ell)^2}{g \ell \tan \gamma} \right] \]

\[ b = V_0^2 \left[ (a \ell)^2 + g \ell \tan \gamma \left( y \frac{H}{I} \right) \right] \]

It may be shown, as done by Nevel (1970), that \( w(\xi, \eta) \to \infty \) when

\[ a = b \]

and

\[ \frac{\partial a}{\partial \gamma} = \frac{\partial b}{\partial \gamma} \]

Nevel used these two conditions to determine the critical velocity \( V_0 \).

It should be noted that these two conditions are identical to eq 25a and eq 27a, when the variable \((\gamma \ell)\) is replaced by \((a \ell)\) and the parameter \( V_0 \) by \( V_{pf} \). Since the variables \((\gamma \ell)\) or \((a \ell)\), determined from eq 52 or 27a, are identical, it follows that eq 52 for the determination of \( V_0 \) and eq 25a for the determination of \( V_{pf} \) are identical. Thus, as expected, the critical velocity \( V_0 \) is the same as \((c_{pf})_{min}\). Hence, the dependence of the critical velocities \( v_{cr} \) upon the axial force field \( N \) is as shown in Figure 5 for \((c_{pf})_{min}\) and is shown in Figure 8 for \( h = 30 \text{ cm} \) and \( 90 \text{ cm} \). The dependence of \( v_{cr} \) upon \( N \) and \( h \) was obtained by numerically evaluating eq 26 and 27 for \( H = \infty \), noting that \((c_{pf})_{min} = v_{cr}\). The obtained results are shown in Figure 9.
CRITICAL VELOCITIES OF LOADS MOVING OVER FLOATING ICE PLATES

CONCLUSION

The effect of a uniform in-plane force field in a floating plate upon the critical velocities of a moving load has been studied. For an increasing compression force field, the critical velocity decreases, approaching the value zero as $N \rightarrow N_{cr}$, for an increasing tension force field $v_{cr}$ increases.
