PART I

DEFLECTION OF THICK BEAMS OF MULTIMODULAR MATERIALS

C.W. Bert and F. Gordaninejad
The University of Oklahoma, Norman, Oklahoma, USA 73019

SUMMARY

A transfer-matrix analysis is presented for determining the static behavior of thick beams of "multimodular materials" (i.e., materials which have different elastic behavior in tension and compression, with nonlinear stress-strain curves approximated as piecewise linear, with four or more segments). To validate the transfer-matrix method results, a closed-form solution is also presented for cases in which the neutral-surface location is constant along the beam axis. Numerical results for axial displacement, transverse deflection, bending slope, bending moment, transverse shear, axial force, and location of neutral surface are presented for multimodular and bimodular models of unidirectional aramid cord-rubber. The transfer-matrix method results agree very well with the closed-form solutions.

INTRODUCTION

In 1941 Timoshenko\(^1\) considered the flexural stresses in bimodular material, i.e., a bilinear material having different moduli in tension and in compression. Ambartsumy\(\text{a}^{2}\) in 1965, introduced the terminology, "bimodulus", and extended the concept to two-dimensional materials. Numerous static papers appeared after this work; Marin\(^3\) gave the effective modulus for stiffness.

\(^{2}\)Graduate Research Assistant.
of bimodular beam undergoing pure bending.

Small-deflection bending of Bernoulli-Euler beams of homogeneous, bimodular material was treated in References 4-12. Large static deflections of beams of bimodular material were analyzed in References 13-14. Kamiya\textsuperscript{15} considered transverse-shear-deformation effects on bimodular beams for the first time. Recently Tran and Bert\textsuperscript{16} treated bending of thick beams of bimodular materials and obtained both closed-form and transfer-matrix solutions. To the best of the present authors' knowledge, no previous work is available in the context of multimodular beams.

MODELING OF THE STRESS-STRAIN CURVE

Bert and Kumar\textsuperscript{17} recently presented experimental stress-strain curves for unidirectional cord-rubber materials. In the present work a stress-strain curve for aramid-rubber taken from \cite{17} has been linearly approximated by four segments (two segments in tension and two segments in compression). For choosing the 'break points' t and c (see Fig. 1) the area between two fitting lines and the experimental curve in each portion has been minimized (see Appendix A). To find comparable moduli for the bimodular case, one has to minimize the area between two straight lines and the experimental curve (also see Appendix A).

THEORY AND FORMULATION

Consider a rectangular-cross-section beam of thickness h and length l as shown in Fig. 2. The origin of the Cartesian coordinate system is located on the mid-surface of the beam with the z-axis being measured positive downward.
1. Displacement Field

The same displacement field used in classical Timoshenko beam theory is implemented here

\[ U(x,z) = u(x) + z\psi(x), \quad W(x,z) = w(x) \]  

(1)

where \( U \) and \( W \) are displacements in the \( x \) and \( z \) directions, respectively, \( u \) and \( w \) are corresponding displacements at the midplane, and \( \psi \) is the bending slope.

2. Stress Field

For a four-segment approximation of the normal stress-strain curve, considering the general case (i.e., when \( -\frac{h}{2} < a_c, a_t < \frac{h}{2} \)), the following stress field has been considered for the case of convex bending (see Figs. 1 and 3).

\[ \begin{cases} E_1^c \varepsilon_x^c + E_2^c(\varepsilon_x - \varepsilon_x^c) & -\frac{h}{2} \leq z \leq a_c \\ E_1^c \varepsilon_x & a_c \leq z \leq z_n \\ E_1^t \varepsilon_x & z_n \leq z \leq a_t \\ E_1^t \varepsilon_x^t + E_2^t(\varepsilon_x - \varepsilon_x^t) & a_t \leq z \leq \frac{h}{2} \end{cases} \]  

(2)

where \( E_1^c, E_2^c, E_1^t, E_2^t, G, \varepsilon_x^c, \) and \( \varepsilon_x^t \) are material constants, \( \varepsilon_x \) is the axial normal stress, \( \varepsilon_x^c \) is the axial normal strain, \( \gamma_{xz} \) is the transverse shear strain, \( \gamma_{xz} \) is the transverse shear stress, and \( z_n \) is the location of the neutral surface. It is noted that this material is linear elastic in shear. Comparison of Figs. 1 and 3 leads to

\[ \varepsilon_x = \kappa(z - z_n) \]  

(3)

\[ \varepsilon_x^c = \kappa(a_c - z_n) \]  

(4)
\[ \varepsilon_f^c = \kappa(-h/2 - z_n) \]
\[ \varepsilon_f^t = \kappa(h/2 - z_n) \]

where \( \varepsilon_f^c \) and \( \varepsilon_f^t \) are the final values attained at the respective compressive and tensile outer fibers and \( \kappa \) is the curvature.

Using linear strain measure and the strain field of equations (1), one obtains

\[ \varepsilon_x = U_x = u_x + z \psi_x, \varepsilon_\psi = 0 + z \psi_x \]
\[ \gamma_{xz} = W_{xx} + U_z = w_x + \psi \]

Comparison of equations (3) and (8) gives

\[ u_x = -\kappa z_n, \psi_x = \kappa \]

Note that \( \frac{d}{dx} \) denotes \( \frac{d(\ )}{dx} \).

3. Constitutive Relation

For the assumed beam, the normal and transverse shear stress resultants and moment, each per unit width, are defined as

\[ (N,Q) = \int_{-h/2}^{h/2} \sigma_{x,x} r_{xz} \, dz, \quad M = \int_{-h/2}^{h/2} z \sigma_{x,x} \, dz \]

Using the assumed stress and displacement field system of equations (10) can be written as the constitutive relation for a multimodular beam:

\[ \begin{bmatrix} N \\ M \\ Q \end{bmatrix} = \begin{bmatrix} A + C_N & B + C_B & 0 \\ B + C_B & D + C_D & 0 \\ 0 & 0 & S \end{bmatrix} \begin{bmatrix} u_x \\ \psi_x \\ w_x + \psi \end{bmatrix} \]
where $A$, $B$, $D$, and $S$ denote the respective extensional, flexural-extensional coupling, flexural, and transverse shear stiffnesses defined by

$$
\begin{align*}
(A,B,D) &= \int_{-h/2}^{h/2} (1,z,z^2)E_i(k)dz \\
&S = K^2 \int_{-h/2}^{h/2} G dz
\end{align*}
$$

(12)

Here, the stiffnesses $C^A_N$, $C^B_N$, $C^B_M$, and $C^D_M$ are not present in linear or bimodular materials, and are as defined in Appendix B. In equation (12) $t$ and $c$ denote tensile-strain and compressive-strain regions, respectively.

The quantity $K^2$ is a shear correction coefficient which is generally taken to be $5/6$ for static loading of a rectangular-section beam.

4. Equilibrium Equations

The equilibrium equations for transverse distributed loading $q(x)$ can be written as

$$
N_{,x} = 0 ; \quad Q_{,x} + q(x) = 0 ; \quad M_{,x} - Q = 0
$$

(13)

By substitution of equation (11) into equations (13), one obtains the following equations of equilibrium in terms of the generalized displacements

$$
\begin{align*}
(A'u_{,x} + B'v_{,x}),x &= 0 \\
[S(w_{,x} + \omega)],x &= -q(x) \quad \text{and} \\
(B'u_{,x} + D'v_{,x}),x - S(w_{,x} + \omega) &= 0
\end{align*}
$$

(14)

where
A closed-form solution can be obtained only when the stiffnesses and thus neutral-surface position \( z_n \) do not depend on \( x \). Therefore, neutral-surface location [18] must be constant

\[
\frac{z_n}{x} = \text{constant} \tag{16}
\]

Using equation (11) one is able to express \( u \) in terms of \( N \), \( M \), and the stiffnesses as follows:

\[
\begin{aligned}
\begin{pmatrix} u_x \\ v_x \end{pmatrix} &= \frac{1}{B'B''-A'D'} \begin{pmatrix} -D' & B' \\ B'' & -A' \end{pmatrix} \begin{pmatrix} N \\ M \end{pmatrix} \\
\end{aligned} \tag{17}
\]

Combining equations (16) and (17), one obtains

\[
\frac{z_n}{x} = \frac{B'M - D'N}{A'M - B''N} \tag{18}
\]

It is obvious that \( z_n = \text{const.} \) when \( N = 0 \). Thus, for these special cases (see Appendix C)

\[
\frac{z_n}{x} = \frac{A'}{A'} = \text{constant} \tag{19}
\]

Now, equilibrium equations (14) can be simplified as follows [19]:

\[
\begin{aligned}
& A'u_{xx} + B'v_{xx} = 0 \\
& S(w_{xx} + \gamma_{xx}) = -q(x) \\
& B'u_{xx} + D'v_{xx} - S(w_x + \gamma_x) = 0 \tag{20}
\end{aligned}
\]
The general solution for equations (20) can be written as follows:

\[ u(x) = d_1 + d_2 x + \frac{3B'B}{A}C_4 x^2 + u_p(x) \]

\[ \psi(x) = -C_2 + \frac{6(B'B''-A'D')}{SA}C_4 - 2C_3 x + 3C_4 x^2 + \psi_p(x) \] (21)

\[ w(x) = C_1 + C_2 x + C_3 x^2 + C_4 x^3 + w_p(x) \]

where \( u_p, \psi_p, w_p \) are particular solutions (see Appendix D) and \( C_1, C_2, C_3, C_4, d_1, \) and \( d_2 \) are arbitrary constants determined by the boundary conditions of the beam. The following boundary conditions have been considered for closed-form solutions:

1. Hinged-Hinged (free to move axially at \( x = L \))
\[ u(0) = N(0) = 0 \quad ; \quad M(0) = M(0) = 0 \quad ; \quad w(0) = w(0) = 0 \]
2. Clamped-Free
\[ u(0) = N(0) = 0 \quad ; \quad \psi(0) = M(0) = 0 \quad ; \quad w(0) = Q(0) = 0 \]
3. Clamped-Clamped (free to move axially at \( x = L \))
\[ u(0) = N(0) = 0 \quad ; \quad \psi(0) = \psi(0) = 0 \quad ; \quad w(0) = w(0) = 0 \]

The values of constants \( C_1, C_2, C_3, C_4, d_1, \) and \( d_2 \) are listed in Appendix D.

**TRANSFER-MATRIX SOLUTION**

As it has been shown in [20,21], in the transfer-matrix approach, the beam is divided into \( N_s \) elements, each of which is assumed to be of mass \( m \) and concentrated at the center of mass of the element. The mass center of each element is called the station. The stations are separated by fields which are taken to be massless and contain all of the stiffnesses of the beam. At the end points of the beam there are two half fields of length \( \Delta / 2 \) (see
Fig. 4), and between these half fields there are $N_s$ stations separated by
$(N_s - 1)$ full fields of length, $\Delta z$, where $\Delta z = \lambda / N_s$ and $\lambda$ is the length of
the beam. By writing the equilibrium equations for each station and each
element and connecting the elements by transfer matrices, one transfers the
generalized displacements $(u, w, \gamma)$ and the forces $(N, Q, M)$ from the left side
of the beam to the right side.

Since the same procedure used in [16] has been used here to derive
transfer matrices and state vectors $(u, w, \gamma, N, Q, M)^T$, the readers are referred
to this reference. Note that since the present work deals with multimodular
material, some changes in the field matrix are necessary (see Appendix E).

In the calculation of the stiffnesses for the cases where the axial force is
not zero, the neutral-surface locations and the corresponding distances to the
"break points" in the $\alpha_x$ vs $z$ curve ($a_c$ and $a_t$) are not constant and not
known a-priori. Therefore, an iterative technique has been employed to com-
pute the neutral-surface locations $z_n$, also $a_c$ and $a_t$. One must first assume
$(2N_s + 2)$ sets of values of $z_n$, $a_c$, and $a_t$ and then compute the stiffnesses
and solve the governing equations for the state vector. Finally, by using
equations (18), (C.3), and (C.4), compute new values of $z_n$, $a_c$, and $a_t$.
Obviously, if the assumed and computed sets of $z_n$, $a_c$, and $a_t$ are in
sufficiently close agreement, the problem is solved; otherwise, assume the
calculated set $z_n$, $a_c$, and $a_t$ and repeat the procedure.

NUMERICAL RESULTS

In the following, numerical results are presented for a thick beam with
a rectangular cross section and constructed of multimodular material (see
Table 1): unidirectional aramid cord-rubber, which is used in the tire
industry. Various boundary conditions and loading conditions were investigated (see Tables 2 and 3). In the transfer-matrix analysis, twenty-five elements were used. Each element was of length 0.32 in. for dimensional cases and dimensionless length of 0.04 for nondimensional cases. The shear correction coefficient was taken to be 5/6.

For all cases considered, the computations are carried out for axial elongation $u$ (or $\bar{u} = uE_2^t/q_o$), transverse deflection $W$ (or $\bar{W} = W E_2^t/q_o$), bending slope $(\bar{\theta} = E_2^t/q_o)$ axial force $N$ (or $\bar{N} = N/q_o$), shear force $Q$ (or $\bar{Q} = Q/q_o$), bending moment $M$ (or $\bar{M} = M/q_o$) and neutral-surface location $z_n$ (or $\bar{z}_n = z_n/h$), where $u$, $W$, $\bar{\theta}$, $N$, $Q$, $M$, and $z_n$ are nondimensional parameters.

Due to lack of comparable results in the literature, comparisons are made between the closed-form solution (CFS) and the transfer-matrix solution (TMS) developed here. Excellent agreement between CFS and TMS for the twenty-five element model has been achieved and still it can be improved by increasing the number of elements. For most of the results, the error is less than 2%. Figure 5 contains the plots of the dimensionless transverse deflection ($\bar{W}$) versus dimensionless position ($\bar{X} = x/z$) for Case 11 for multimodular, bimodular, unimodular, and average-modular [i.e., $E = (E_b^t + E_b^c)/2$] cases, where $z/h = 10$.

As one can see, there is a considerable difference between transverse deflection of multimodular and bimodular models on one hand and unimodular and average modular models on the other. Note that Case 11 is a special case because both ends are not free to move and one expects axial force to be developed due to bending-stretching coupling caused by bimodular action. However, the computed axial force is close to zero which means $z_n$ is constant.
To validate TMS, in Figs. 6 through 9, a comparison is made between TMS and CFS. Behavior of Cases 1, 4, 10, and 11 was studied for the multimodular model considering different dimensionless parameters (\( \varepsilon/h = 5, 10, 15 \), \( \tilde{M}_1 = -1.0, \tilde{N}_1 = -1.0, \tilde{Q}_1 = -1.0 \)).

In Table 4, for a specific beam (see Table 1), dimensioned comparisons have been made between multimodular and bimodular models. Tables 5, 6, 7 and 9 again show the validity of TMS while they present the computed results for Cases 3, 5, 6, 7, and 8.

Since closed-form solutions are not available for the complicated boundary conditions considered in Cases 9, 10, and 11, only transfer-matrix results are presented for these cases. In Figs. 10-13 the behavior of a clamped-free beam (with applied moment and axial and shear forces at the free end) and a clamped-clamped beam under a uniform load is investigated. See also Table 10. It is of particular interest to note that in Fig. 10, the sign of the deflection depends upon the \( \varepsilon/h \) ratio, the crossover point being at \( \varepsilon/h = 11 \).

For cases where axial force is zero, the neutral-surface location is constant; otherwise it varies along the beam length. In Figs. 14-17 the shapes of neutral-surface curves for multimodular and bimodular models have been shown for several cases.

**CONCLUSIONS**

Analyses of the bending deflection of multimodular thick beams with rectangular cross section based on shear-deformable-beam theory are presented. In this study, both dimensionless and dimensioned results of transfer-matrix, as well as closed-form, solutions for a rectangular multimodular beam of aramid-cord rubber are presented. The transfer-matrix and the closed-form solutions are found to agree very well.
Results of analysis of bimodular and multimodular models show that there is not a drastic difference between the two models. Although the multimodular model is a better one for approximating the stress-strain curve, the bimodular approximation is less complicated. Closed-form solutions are available only for a number of loading/boundary conditions (in which the axial force is identically zero), but the transfer-matrix method can be applied to more complicated geometry, loading, and boundary conditions. In this work, results for several boundary and loading conditions are investigated. The transfer-matrix method is found to be very effective in terms of computational time and also gives results which agree quite well with the closed-form solutions.

APPENDIX A
FITTING MINIMIZED CURVES TO THE STRESS-STRAIN CURVE

1. Multimodular Case
Consider the nonlinear stress-strain curve shown in Fig. A.1. For any arbitrary point \((\varepsilon^t, \sigma^t)\) in the tension region \((\varepsilon \geq 0)\), there are two straight lines such that

\[
g(\varepsilon) = \begin{cases} 
\left(\frac{\sigma^t}{\varepsilon^t}\right)\varepsilon & \text{for } \varepsilon > \varepsilon_f \\
\left[\left(\frac{\sigma^t - \sigma_f}{\varepsilon^t - \varepsilon_f}\right)/(\varepsilon - \varepsilon_f)\right](\varepsilon - \varepsilon_f) + \sigma_f & \text{for } \varepsilon \leq \varepsilon_f
\end{cases}
\] (A.1)

The equation of a stress-strain curve as expressed in [17] is

\[
\sigma(\varepsilon) = K\varepsilon^n ; \quad \varepsilon \geq 0
\] (A.2)

where \(K\) and \(n\) are constants depending on the material. To find the proper "break point" \((\varepsilon^t, \sigma^t)\), the area between the approximated curve \(g(\varepsilon)\) and the actual experimental curve \(\sigma(\varepsilon)\) has to be minimized. The mentioned area can be expressed

\[
A = \left| \int_0^{\varepsilon_f} \left[ g_1(\varepsilon) - \sigma(\varepsilon) \right] d\varepsilon \right| + \left| \int_{\varepsilon_f}^{\varepsilon^t} \left[ g_2(\varepsilon) - \sigma(\varepsilon) \right] d\varepsilon \right| \] (A.3)

Substitution of equations (A.1) and (A.2) into equation (A.3) and taking the integrations gives

\[
A = \left| \frac{1}{2} \varepsilon^t t - \frac{K}{n+1} (\varepsilon^t)^{n+1} \right| + \left| \frac{1}{2} (\varepsilon_f t + \sigma^t)(\varepsilon_f t - \varepsilon^t) - \frac{K}{n+1}[ (\varepsilon_f^t)^{n+1} - (\varepsilon^t)^{n+1} ] \right|
\] (A.4)

By searching in the region of \(\varepsilon \in (0, \varepsilon_f^t) \times (0, \varepsilon_f^t)\), one is able to find a point \((\varepsilon^t, \sigma^t)\) such that \(A\) is minimized locally. Note that a few other methods (e.g., least-squares method) have been tried but it turned out that
the absolute minimum point was outside of the region \( \Omega \).

2. Bimodular Case

For this case, the least-squares method has been used. As shown in Fig. A.2, there is a line such that

\[
I = \int_0^{\varepsilon_f} [E_b t_c - K_c n_c] d_c \tag{A.5}
\]

can be minimized in \( I \). Here, \( E_b t_c \) is the slope of that line. By taking the derivative of equation (A.5) and equating it to zero, one has

\[
\frac{dI}{dE_b} = 2 \int_0^{\varepsilon_f} [E_b t_c - K_c n_c] d_e = 0 \tag{A.6}
\]

By solving equation (A.6) for \( E_b t_c \), one obtains

\[
E_b t_c = \frac{3K}{n+2} (\varepsilon_f t)^{n-1} \tag{A.7}
\]

For example, for aramid-rubber in the tension region (see [17]), the following parameters are found:

\[
n_t = 1.22 \\
K_t = 1.1 \times 10^6 \text{ psi} \\
\varepsilon_f = 0.029 \\
E_b t_c = \frac{(3)(1.1 \times 10^6)}{1.22 + 2} (0.029)^{1.22-1} = 0.47 \times 10^6 \text{ psi}
\]

An analogous calculation can be applied for the compression side of the bend, i.e., \( E_b c \) can be found, provided that \( K_c, n_c, \) and \( \varepsilon_f c \) are known.
3. Unimodular Case

Using the same method as in Case 2 and assuming only one line, which passes through the origin, to approximate both tension and compression regions (Fig. A.3), one has

\[
I = \int_{\varepsilon_f}^{0} [K_c^n c - E_c^2] d\varepsilon + \int_{0}^{\varepsilon_f} [K_t^n t - E_t^2] d\varepsilon
\]

(A.8)

and, then

\[
\frac{dI}{dE} = 2\varepsilon_f [\int_{\varepsilon_f}^{0} (K_c^n c - E_c^2) d\varepsilon + \int_{0}^{\varepsilon_f} (K_t^n t - E_t^2) d\varepsilon] = 0
\]

(A.9)

Solving equation (A.9) for \(E\), one obtains

\[
E = 2[\frac{K_c}{n_c+1} (\varepsilon_f^n c)^{n_c+1} - \frac{K_t}{n_t+1} (\varepsilon_f^n t)^{n_t+1}] / [(\varepsilon_f^n c)^2 - (\varepsilon_f^n t)^2]
\]

(A.10)

NOTE: In the present computations, the values of \(\varepsilon_f^n c\) and \(\varepsilon_f^n t\) considered are as follows:

\[
\varepsilon_f^n c = 0.046 \quad ; \quad \varepsilon_f^n t = 0.029
\]

The constants \(K_c, K_t, n_c,\) and \(n_t\) are listed in [17].
APPENDIX B
THE BEAM STIFFNESSES FOR RECTANGULAR-SECTION BEAMS OF MULTIMODULUAR MATERIALS

For the assumed four-segment model, there are two different bending cases in general, convex downward and concave downward bending. In convex downward bending, the top layer of a beam is in compression and the bottom layer in tension. Conversely, in concave downward bending, the top layer of the beam is in tension and the bottom layer is in compression.

Depending on the location of \( z_n, a_c, \) and \( a_t \) in \( z \) vs \( z \), eight different cases might occur. For example, for convex downward bending, consider the case when \( z_n, a_c, \) and \( a_t \) are in the range of \(-h/2\) and \( h/2\) (see Fig. 3).

Substitution of equation (2) into equation (10) and using equations (3), (4), and (5) leads to

\[
N = \int_{-h/2}^{h/2} [\frac{\alpha}{E_1}(a_c - z_n) + \frac{\alpha}{E_2}(z - a_c)] dz + \int_{a_c}^{z_n} \frac{\alpha}{E_1}(z - z_n) dz + \int_{z_n}^{a_t} \frac{\alpha}{E_1}(z - z_n) dz + \int_{h/2}^{h/2} \frac{\alpha}{E_1}(a_t - z_n) dz + \int_{h/2}^{z_n} \frac{\alpha}{E_2}(z - a_t) dz
\]

and

\[
M = \int_{-h/2}^{h/2} [\frac{\alpha}{E_1}(a_c - z_n) + \frac{\alpha}{E_2}(z - a_c)] z dz + \int_{a_c}^{z_n} \frac{\alpha}{E_1}(z - z_n) z dz + \int_{z_n}^{a_t} \frac{\alpha}{E_1}(z - a_t) - \int_{h/2}^{h/2} \frac{\alpha}{E_1}(a_t - z_n) z dz + \int_{h/2}^{z_n} \frac{\alpha}{E_2}(z - a_t) - \int_{z_n}^{a_t} \frac{\alpha}{E_1}(z - z_n) z dz
\]
Equations (B.1) and (B.2) can be written in the following form

\[
N = (-\kappa z_n^2) \left[ \int_{-h/2}^{a_c} E_2^c dz + \int_{z_n}^{a_t} E_1^c dz + \int_{-h/2}^{a_t} E_1^t dz + \int_{h/2}^{a_c} E_2^t dz \right] \\
+ \left[ \int_{-h/2}^{a_c} E_2^c dz + \int_{z_n}^{a_t} E_1^c dz + \int_{-h/2}^{a_t} E_1^t dz - \int_{h/2}^{a_c} E_2^t dz \right]; \\
+ (\kappa) \left[ \int_{-h/2}^{a_c} E_2^c dz + \int_{z_n}^{a_t} E_1^c dz + \int_{-h/2}^{a_t} E_1^t dz + \int_{h/2}^{a_c} E_2^t dz \right] \\
+ \left[ \int_{-h/2}^{a_c} E_2^c dz - \int_{z_n}^{a_t} E_1^c dz - \int_{-h/2}^{a_t} E_1^t dz + \int_{h/2}^{a_c} E_2^t dz \right]; \\
\text{(B.3)}
\]

\[
M = (-\kappa z_n^2) \left[ \int_{-h/2}^{a_c} E_2^c dz + \int_{z_n}^{a_t} E_1^c dz + \int_{-h/2}^{a_t} E_1^t dz + \int_{h/2}^{a_c} E_2^t dz \right] \\
+ \left[ \int_{-h/2}^{a_c} E_2^c dz + \int_{z_n}^{a_t} E_1^c dz + \int_{-h/2}^{a_t} E_1^t dz - \int_{h/2}^{a_c} E_2^t dz \right]; \\
+ (\kappa) \left[ \int_{-h/2}^{a_c} E_2^c dz + \int_{z_n}^{a_t} E_1^c dz + \int_{-h/2}^{a_t} E_1^t dz + \int_{h/2}^{a_c} E_2^t dz \right] \\
+ \left[ \int_{-h/2}^{a_c} E_2^c dz - \int_{z_n}^{a_t} E_1^c dz - \int_{-h/2}^{a_t} E_1^t dz + \int_{h/2}^{a_c} E_2^t dz \right]; \\
\text{(B.4)}
\]

Combining equations (9) and (11), one gets
Comparison of equations (B.3) and (B.5) with equations (B.4) and (B.6) and considering equations (12) and (15), one finds that

\[ N = (-\kappa z_n)A' + \kappa B' \]  
(B.5)

\[ M = (-\kappa z_n)B'' + \kappa D' \]  
(B.6)

As mentioned before, eight cases may occur depending on the location of \( z_n' \), \( a_c' \), and \( a_t' \). These cases have been analyzed as the same as the general case as follows (for convex downward bending)

**Case 1:**

\[ x = E_1 t \varepsilon_1 + E_2 t (\varepsilon_x - \varepsilon_1) \]

\(-h/2 \leq z \leq h/2 \)  
(B.8)

\[ A' = hE_1 t \]

\[ B' = ha_t (E_1 t - E_2 t) \]  
(B.9)

\[ B'' = 0 \]

\[ D' = h^3 E_2 t / 24 \]
Case 2:

\[ \begin{align*}
\gamma_x &= \begin{cases} 
E_1 t_{x_1} + E_2 t_{(x - x_1)} & a_t \leq z \leq h/2 \\
E_1 t_{x_x} & -h/2 \leq z \leq a_t
\end{cases}
\end{align*} \]

(B.10)

\[ A' = E_1 t \]

\[ B' = - (E_1 t - E_2 t)(h/2 - a_t)^2/2 \]

(B.11)

\[ B'' = 0 \]

\[ D' = [h^3(E_1 t + E_2 t)/8 + a_t^3(E_2 t - E_1 t)^2]/3 + h^2 a_t(E_1 t - E_2 t)/8 \]

Case 3:

\[ \begin{align*}
\gamma_x &= \begin{cases} 
E_1 t_{x_1} + E_2 t_{(x - x_1)} & a_t \leq z \leq h/2 \\
E_1 t_{x_x} & z_n \leq z \leq a_t \\
E_1 t_{c_x} & -h/2 \leq z \leq z_n
\end{cases}
\end{align*} \]

(B.11)

\[ A' = h(E_1 c + E_1 t)/2 + z_n(E_1 c - E_1 t) \]

\[ B' = [h^2(E_2 t - E_1 c)/2 + a_t(h - a_t)(E_1 t - E_2 t) + z_n^2(E_1 c - E_1 t)]/2 \]

(B.12)

\[ B'' = (E_1 t - E_1 c)(h^2/4 - z_n^2)/2 \]

\[ D' = [h^3(E_1 c + E_2 t)/8 + a_t^3(E_2 t - E_1 t)^2]/3 + z_n^3(E_1 c - E_1 t)/3 \]

+ h^2 a_t(E_1 t - E_2 t)/8

Case 4:

This case is the general case (see Fig. 3) which has been discussed in detail earlier in this Appendix.

Case 5:

\[ \begin{align*}
\gamma_x &= \begin{cases} 
E_1 t_{c_x} & z_n \leq z \leq h/2 \\
E_1 t_{c_x} & a_c \leq z \leq z_n \\
E_1 c_{1} + E_2 c_{(x - x_1)} & -h/2 \leq z \leq a_c
\end{cases}
\end{align*} \]

(B.13)
\[ \text{A'} = h(E_1^t + E_1^c) + z_n(E_1^c - E_1^t) \]
\[ \text{B'} = [h^2(E_1^t - E_2^c)/4 + z_n^2(E_1^c - E_1^t) + a_c(a_c + h)(E_1^c - E_2^c)]/2 \]
\[ \text{B''} = (E_1^t - E_1^c)(h^2/4 - z_n^2)/2 \]
\[ \text{D'} = [h^3(E_1^t + E_2^c) + z_n^3(E_1^c - E_1^t) + a_c^3(E_1^c - E_2^c)/2]/3 \]
\[ - h^3 a_c(E_1^c - E_2^c)/8 \]

**Case 6:**
\[ \sigma_x = \begin{cases} 
E_1^c \varepsilon_x & \text{for } a_c \leq z \leq h/2 \\
E_1^c \varepsilon_1^c + E_2^c(\varepsilon_x - \varepsilon_1^c) & \text{for } -h/2 \leq z \leq a_c
\end{cases} \tag{B.15} \]

\[ \text{A'} = hE_1^c \]
\[ \text{B'} = (E_1^c - E_2^c)(h/2 + a_c)^2/2 \]
\[ \text{B''} = 0 \]
\[ \text{D'} = [h^3(E_1^c + E_2^c)/8 + a_c^3(E_1^c - E_2^c)]/3 - h^2 a_c(E_1^c - E_2^c)/8 \]

**Case 7:**
\[ \sigma_x = E_1^c \varepsilon_1^c + E_2^c(\varepsilon_x - \varepsilon_1^c) \quad \text{for } -h/2 \leq z \leq h/2 \tag{B.17} \]

\[ \text{A'} = hE_1^c \]
\[ \text{B'} = h a_c(E_1^c - E_2^c) \]
\[ \text{B''} = 0 \]
\[ \text{D'} = h^3 E_2^c/24 \tag{B.18} \]

**Case 8:**
\[ \sigma_x = \begin{cases} 
E_1^t \varepsilon_x & \text{for } z_n \leq z \leq h/2 \\
E_1^c \varepsilon_x & \text{for } -h/2 \leq z \leq z_n
\end{cases} \tag{B.19} \]
\[ A' = h(E_1 t + E_1 c) + z_n (E_1 c - E_1 t) \]
\[ B' = (E_1 t - E_1 c)(h^2/4 - z_n^2)/2 \]
\[ B'' = (E_1 t - E_1 c)(h^2/4 - z_n^2)/2 \]
\[ D' = [h^3(E_1 t + E_1 c)/8 + z_n^3(E_1 c - E_1 t)]/3 \]  

For concave downward bending, one is able to derive similar equations for stiffnesses by converting as follows:

\[ E_2 c \rightarrow E_2 t \quad E_1 t \rightarrow E_1 c \quad a_c \rightarrow a_t \]
\[ E_1 c \rightarrow E_1 t \quad E_2 t \rightarrow E_2 c \quad a_t \rightarrow a_c \]

**APPENDIX C**

**COMPUTATION OF \( z_n \), \( a_c \), AND \( a_t \)**

For multimodular beams, the following equation is not sufficient to determine the neutral-surface location \( z_n \)

\[ z_n = \frac{B'M - D'N}{A'M - B''N} \]  
\[ \text{(C.1)} \]

even for cases where \( N = 0 \)

\[ z_n = B'/A' \]  
\[ \text{(C.2)} \]

Two more equations are needed for computing \( z_n \) because the stiffnesses are not only dependent on \( z_n \) but they are functions of \( a_c \) and \( a_t \) as well.

Dividing equation (4) by equation (6) and equation (5) by equation (7) and solving for \( a_c \) and \( a_t \), one can get (for the convex downward case)

\[ a_c = (\frac{c}{t}) (h/2 + z_n) - z_n \]  
\[ \text{(C.3)} \]
\[ a_t = (\frac{c}{t}) (h/2 - z_n) + z_n \]  
\[ \text{(C.4)} \]
For the concave downward case

\[ a_c = \left( \frac{\epsilon_1 c}{\epsilon_f c} \right) (h/2 - z_n) + z_n \quad (C.5) \]

\[ a_t = \left( \frac{\epsilon_1 t}{\epsilon_f t} \right) (h/2 + z_n) - z_n \quad (C.6) \]

The system of nonlinear equations (C.1), (C.3), and (C.4) for the convex downward case, or equations (C.1), (C.5), and (C.6) for the concave downward case, can be solved by using iteration of the Gauss-Seidel type [22].

APPENDIX D

ARBITRARY CONSTANTS AND PARTICULAR SOLUTIONS

The values of constants \( C_1, C_2, C_3, C_4, d_1, \) and \( d_2 \) for the various boundary conditions considered are listed below.

1. Hinged-Hinged (free to move axially at \( x = L \))

\[ C_1 = - u_p(0) \]

\[ C_2 = - (C_3 + C_4 z^2) - [w_p(z) - w_p(0)]/z \]

\[ C_3 = [v_{p,x}(z)/2 - 3C_4] \]

\[ C_4 = \frac{A^t}{B (A^t D - B^t B')} : B' \left[ u_{p,x}(z) - u_{p,x}(0) \right] + D' [v_{p,x}(z) - v_{p,x}(0)] \]

\[ d_1 = - u_p(0) \]

\[ d_2 = - [u_{p,x}(z) + (5B^t/A^t)C_4 z] \]

2. Clamped-Free

\[ C_1 = - w_p(0) \]

\[ C_2 = - w_{p,x}(z) - v_p(z) + v_p(0) \]

\[ C_3 = \frac{v_{p,x}(z)/2 + A^t S}{2 (B^t B - A^t D')} [w_{p,x}(z) + v_p(z)] \]

\[ C_4 = \frac{A^t S}{6 (B^t B - A^t D')} \left[ C_2 - v_p(0) \right] \]
\[ d_1 = -u_p(0) \]
\[ d_2 = -u_p(x) + \frac{B'S}{B'B'' - A'D'} [w_p(x) + \varphi_p(x)] \]

3. Clamped-Clamped (free to move axially at \( x = L \))
\[ C_1 = -w_p(0) \]
\[ C_2 = \frac{6(B'B'' - A'D')}{SA'} C_4 + \varphi_p(0) \]
\[ C_3 = [u_p(0) - u_p(x) - (3B'/A')C_4 - 2]/2 \]
\[ C_4 = \frac{SA'}{SA''} - \frac{1}{2} [B'B'' - A'D'] \left\{ \varphi_p(0) + w_p(x) - 2[w_p(0) - w_p(x)]/2 \right\} \]
\[ d_1 = -u_p(0) \]
\[ d_2 = [u_p(0) - u_p(x) - (3B'/A')C_4 - 2]/2 \]

The particular solutions for uniform and sinusoidal normal load are as listed below.

For uniform normal load \( q(x) = q_o \):
\[ u_p(x) = \frac{B'o}{6(A'D'' - B'B''')} x^3 \]
\[ \varphi_p(x) = -\frac{A'o}{3} x - \frac{4A'o}{6(A'D'' - B'B''')} x^3 \]
\[ w_p(x) = \frac{A'o}{24(A'D'' - B'B''')} x^4 \]

For normal load \( q(x) = q_o \sin \omega x \), where \( \omega \equiv n/\pi \):
\[ u_p(x) = \frac{B'o}{\omega^2(A'D'' - B'B''')} \cos \omega x \]
\[ \varphi_p(x) = -\frac{A'o}{\omega^2(A'D'' - B'B''')} \cos \omega x \]
\[ w_p(x) = \frac{q_o}{\omega} \left[ \frac{1}{5} + \frac{A'o}{\omega^2(A'D'' - B'B''')} \sin \omega x \right] \]
For normal load \( q(x) = q_0 \cos \alpha x \):

\[
\begin{align*}
    u_p(x) &= -\frac{B'q_0}{(A'D' - B'B'')} \sin \alpha x \\
    \varphi_p(x) &= \frac{A'q_0}{\alpha^2(A'D' - B'B'')} \sin \alpha x \\
    w_p(x) &= \frac{q_0}{\alpha^2} \left[ \frac{1}{R'} + \frac{A'}{\alpha^2(A'D' - B'B'')} \right] \cos \alpha x
\end{align*}
\]

\[(D.6)\]

APPENDIX E
TRANSFER MATRICES

The equilibrium equations for each station can be written in matrix notation as follows

\[
\begin{bmatrix}
    U \\
    W \\
    \varphi \\
    N \\
    Q \\
    M \\
    1
\end{bmatrix}^R = \begin{bmatrix}
    1 & 0 & 0 & 0 & 0 & 0 & 0 \\
    0 & 1 & 0 & 0 & 0 & 0 & 0 \\
    0 & 0 & 1 & 0 & 0 & 0 & 0 \\
    0 & 0 & 0 & 1 & 0 & 0 & 0 \\
    0 & 0 & 0 & 0 & 1 & 0 & 0 \\
    0 & 0 & 0 & 0 & 0 & 1 & 0 \\
    0 & 0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix} \begin{bmatrix}
    U \\
    W \\
    \varphi \\
    N \\
    Q \\
    M \\
    1
\end{bmatrix}^L
\]

\[(E.1)\]

where \( q_s \) is the concentrated load at each station. In more compact form equation (E.1) is

\[
[S]_i^R = [T_s]_i^L [S]_i
\]

\[(E.2)\]

The matrix \([T_s]_i\) is known as the station matrix. In matrix notation the equilibrium equation for each field under a distributed load \( q(x) \) is
\[ \begin{pmatrix} U \\ W \\ V \\ N \\ Q \\ M \\ 1 \\ i+1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & \frac{B'(\Delta z)^2}{\gamma} & \frac{B'(\Delta z)^2}{2\gamma} & -\frac{D'(\Delta z)^2}{\gamma} & -\frac{B'(\Delta z)}{2\gamma} & K_m \\ 0 & 0 & -\frac{A'(\Delta z)^2}{2\gamma} & \frac{[A'(\Delta z)]^2}{2\gamma} & -\frac{B'(\Delta z)^2}{2\gamma} & -\frac{A'(\Delta z)}{2\gamma} & \frac{K_m - \Delta z}{2S} & K_q \\ 0 & 0 & 1 & -\frac{A'(\Delta z)}{\gamma} & -\frac{A'(\Delta z)^2}{2\gamma} & B'(\Delta z) & \frac{A'(\Delta z)}{2\gamma} & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & -K_q & 0 \\ 0 & 0 & 0 & 0 & \Delta z & 0 & -K_m & M \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \end{pmatrix} \begin{pmatrix} U \\ W \\ V \\ N \\ Q \\ M \\ 1 \\ i+1 \end{pmatrix} \]

where

\[ \gamma = B'B'' - A'D' \]

\[ K_q = \int_{0}^{z} q(\xi) d\xi \]

\[ K_m = \int_{0}^{z} q(\xi) d\xi \]

Values of \( K_m \) and \( K_q \) for various loadings are listed in Table 2. Equation (E.4) also can be written as

\[ [S]^L_{i+1} = [T_j]^R_i [S]^L_i \]

The matrix \([T_j]^R_i\) is called the field matrix.

Abstract - Many materials have quite different stress-strain relations in tension and compression. Examples include such diverse materials as rock, cast iron, concrete, tire cord-rubber, and soft biological tissues. It is shown by analysis in this paper that DBTC (different behavior in tension and compression) has a profound effect on the flexural strength as predicted by application of fundamental continuum mechanics relations. The theory is applied to a non-linear material model which is shown to be applicable to two widely different materials: concrete, which has more strength degradation in tension than in compression, and steel cord-rubber, which has strength which is enhanced in tension by cord strengthening and degraded in compression by cord microbuckling.
1. INTRODUCTION

It has long been known that certain materials behave significantly differently in tension than in compression. For example, this was recognized by Saint-Venant [1], who analyzed the pure bending behavior of a beam having different non-linear stress-strain curves in tension and compression. Specific experimental evidence of DBTC has been reported for cast iron by Gilbert [2], cord-rubber by Clark [3], polymers by Zemlyakov [4], concrete by Seefried et al. [5], cortical bone by Siskin and Robin [6], various kinds of rock by Haimson and Tharp [7], and soft biological tissue by Pearsall and Roberts [8]. Of course, the specific micromechanisms responsible for DBTC vary from one class of material to another. Stiff, brittle solids are weakened in tension by microcracks, while soft fiber-reinforced materials are weakened in compression by fiber microbuckling.

In this paper, a general theory is presented for the prediction of the maximum bending moment achievable in unidirectional pure bending for an arbitrary material with DBTC. Subsequently, the general theory is applied to a simple model which is suitable for widely different materials: concrete using a continuous damage mechanics model for the tensile behavior, and cord-rubber.

2. GENERAL THEORY

The theory developed here is an extension of the basic theory of unidirectional bending developed by Bach and Baumann [9]; see Nadai [10], section 22-1. The material is assumed to be subjected to a unidirectional pure bending moment, i.e., there is no applied direct tension or compression. The beam cross section and loading are assumed to be symmetric about the same axis, so that bending takes place in a single plane (no twisting or warping).
Poisson-type lateral contraction effects are neglected* and the beam cross section is assumed to be sufficiently compact that cross-sectional distortion (ovalization and warping) and buckling do not occur. Plane sections are assumed to remain plane so that the axial strain $\varepsilon$ is given

$$\varepsilon = kz$$

(1)

where $z$ is the normal position coordinate, measured positive downward from the neutral-surface position, and $k$ is the bending curvature.

The beam material may have arbitrary uniaxial stress-strain behavior in the longitudinal direction, i.e.,

$$\sigma = \begin{cases} 
\sigma_t(\varepsilon) & \varepsilon > 0 \\
\sigma_c(\varepsilon) & \varepsilon < 0 
\end{cases}$$

(2)

where $\sigma$ is the axial normal stress and $\sigma_t(\varepsilon)$ and $\sigma_c(\varepsilon)$ are arbitrary continuous functions.

In the absence of direct axial loading, equilibrium of forces in the axial direction requires

$$\int_{-C_c}^{0} \sigma_c(kz)b(z)dz + \int_{0}^{C_t} \sigma_t(kz)b(z)dz = 0$$

(3)

Here the respective compressive and tensile outer-fiber distances are denoted by $C_c$ and $C_t$ and the cross-sectional width at distance $z$ is denoted by $b(z)$; see Fig. 1. Substituting specific expressions for $b(z)$, $\sigma_c(kz)$, and $\sigma_t(kz)$ into (1), integrating, and using the following geometric relation (see Fig. 1) allows determination of $C_c$ and $C_t$:

$$C_c + C_t = H$$

(4)

Equilibrium of the internal moment due to the stress distribution with the externally applied bending moment $M$ gives

*This assumption is more reasonable for bending than for tension loading, and more reasonable for brittle materials, such as concrete and rock, than for ductile metals such as considered by Bert et al. [11].
The ultimate bending moment is found by using differential calculus to determine the relative maximum, i.e.

\[ M = M_{\text{max}} \text{ when } \frac{dM}{dp} = 0 \]  (6)

where \( p \) is any convenient parameter which can be used as a measure of deformation.

In principle, the general theory can be applied to any material (provided that it has continuous but different stress-strain curves in tension and compression) with any singly-symmetric cross section. The similarity with the theory of ductile failure by plastic tensile instability originated by considerations [12] is readily apparent; c.f., Nadai [10], section 8-1.

3. A NON-LINEAR MATERIAL MODEL

The following mathematical relationship is proposed to approximate the stress-strain behavior of a variety of actual materials:

\[
\sigma(t) = \begin{cases} 
E_c \varepsilon + F_c \varepsilon^2 & ; \varepsilon < 0 \\
E_t \varepsilon + F_t \varepsilon^2 & ; \varepsilon > 0 
\end{cases}
\]  (7)

where \( E_c \) and \( E_t \) are the Young's moduli in compression and tension and \( F_c \) and \( F_t \) are also material constants. This model can be considered to be a generalization of Krajcinovic's model for plain concrete [14]. In this case,

\[ E_c = E_t = E, \quad F_c = 0, \quad F_t = -E^2/D_e \]  (8)

where \( D_e \) is a tensile-nitrocrack-damage modulus (\( D_e > 0 \)) related to Takan and Hilt's linear version [15] of Kachanov's concept of continuum damage mechanics.

*The case of damage induced instability in beam bending for materials having the same continuous damage in tension and compression was considered by Bostrom [13].
For an excellent review of CDM, the reader is referred to Hult [17].

The present model is an improvement on the Krajcinovic model in that it also includes compressive non-linearity as suggested by British Standard CP110 [18]:

\[ F_c = -\frac{E^2}{4f_{cu}} \]  

where \( f_{cu} \) is the material's ultimate strength in uniaxial compression (see Appendix A2).

To apply equation (7) to unidirectional cord-rubber, using experimental data for cord rubber reported by Bert and Kumar [19], one has \( E_t = E_c \), \( F_c = F_t > 0 \).

If one assumes a rectangular beam of width \( B \), application of equation (7) in equation (3) yields:

\[ \frac{1}{2} B \kappa (E_t C_t^2 - E_c C_c^2) + \frac{1}{3} B \kappa^2 (F_t C_t^3 + F_c C_c^3) = 0 \]

or

\[ \kappa = \frac{3}{2} \frac{E_c C_c^2 - E_t C_t^2}{E_t C_t^3 + F_c C_c^3} \]  

\[ (10) \]

Integrating equation (5), using equation (7), one obtains

\[ M = \frac{1}{3} B \kappa (E_t C_t^3 + E_c C_c^3) + \frac{1}{4} B \kappa^2 (F_t C_t^4 - F_c C_c^4) \]  

\[ (11) \]

Substituting the expression for \( \kappa \) from equation (10) into equation (11) and using equation (4) to eliminate \( C_c \), one finally obtains the following expression for \( M \) as a function of \( C_t \):

\[ M = \frac{3}{2} \left\{ \frac{[E_c(H-C_t)^2 - E_t C_t^2][E_t C_t^3 + E_c(H-C_t)^3]}{F_t C_t^3 + F_c(H-C_t)^3} \right\} \]

\[ + (9B/16) \frac{[F_t C_t^4 - F_c(H-C_t)^4][E_c(H-C_t)^2 - E_t C_t^2]^2}{[F_t C_t^3 + F_c(H-C_t)^3]^2} \]  

\[ (12) \]

Of course, the ultimate bending moment \( (M_u) \) can be found as a function of \( B, H, E_c, E_t, F_c \), and \( F_t \) by either direct substitution or use of differential calculus \( (dM/dC_t = 0) \).
4. APPLICATION TO PLAIN CONCRETE

Bert and Kumar [20] showed that for Krajićinović's [14] material \( E_c = E_r, \)
\( F_c = 0, \) and \( F_E \) given by equation (8)), equation (12) takes a form that
can be expressed as

\[
M = 6\left[1 - \frac{(15/8)K_c}{(3/4)K_c^2}\right]\left[\frac{K_c}{2} - \frac{1}{(2)K_c^2}\right]
\]

where \( M \) is \( 6\text{E}K_c^2 \) and \( K_c \equiv C/H. \) Bert and Kumar showed that the ultimate
value of \( M, M_u, \) is 0.407 at \( K_c = 0.5875. \) These values are both slightly
higher than the values \( M = 0.354 \) at \( K_c = 0.5505 \) obtained by Krajićinović, who
used the following failure criterion, which is appropriate only for failure in
uniform uniaxial tension

\[
\frac{d\sigma}{dc} = 0
\]

It is traditional to report ultimate strength data in bending in terms of
bending rupture strength defined as the maximum tensile stress at ultimate
bending moment calculated according to the simple, purely elastic formula

\[
f_{bu} = \frac{M_u C}{I}
\]

where

\[
I = BH^3/12 \quad ; \quad C = H/2
\]

It is to be emphasized that the value obtained by use of equation (15) is not
a stress value; it is just an index of moment-carrying ability expressed in
units of force per unit area.

Combining the definition of \( M_u (\equiv 6M_u / D_c B^2) \) with equations (15) and
(16), one can easily show that

\[
f_{bu} = D_c M_u
\]

It is shown in Appendix VI that use of the criterion \( d\sigma/dc \) for uniform
axial loading leads to the following expression for the ultimate tensile
strength:

\[
f_{tu} = D_c / 4
\]
Thus,

\[ \frac{f_{bu}}{f_{tu}} = 4m_u \]  \hspace{1cm} (19)

Fig. 2 shows a comparison among the experimental data of Gonnerman and Shuman [21] and of Brooks and Neville [22] (both wet and dry stored) and the theoretical prediction of Krajcinovic [14] and of Bert and Kumar [20].

It is noted that the Krajcinovic and Bert and Kumar predictions both are \( f_{bu} \) vs. \( f_{tu} \) relations that are straight lines starting at the origin (with slopes of 1.42 and 1.63, respectively). However, the experimental curves are straight lines shifted upward so that they have \( f_{bu} \) intercepts. Apparently this upward shift is due to statistical considerations, such as considered by Weil and Daniel [23], for instance, using the Weibull distribution [24] and by Jayatilaka [25], using a different approach.

It is well known that concrete has a stress-strain non-linearity in compression, although less pronounced than the one in tension. This was recognized in British Standard CP110 [18]; see also Refs. [26-30]. This non-linearity is represented by the term in equation (7) with a coefficient \( F_c \). To obtain a quantitative value for \( F_c \), one must know either

1. the mean compressive stress-strain curve to failure
2. the mean compressive strength (\( f_{cu} \)), for it is shown in Appendix A2 that \( F_c = E^2/D_c \) where \( D_c = 4f_{cu} \).
3. the ratio of mean compressive strength to mean tensile strength for \( D_c/D_t = f_{cu}/f_{tu} \).

Since the author has not yet been able to obtain a copy of Ref. [21], it is necessary to consider typical values of \( f_{cu}/f_{tu} \). (Ref. [22] had \( f_{cu}/f_{tu} = 15 \)). From statistical considerations, for various values of the Weibull parameter and sample size, Jayatilaka [25], Table 5.13, gave values of \( f_{cu}/f_{tu} \) ranging from 3 to 20. However, the ratio \( f_{bu}/f_{tu} \) predicted by the present theory is not strongly affected by \( f_{cu}/f_{tu} \), as can be seen in Table 1.
Piechnik and Pachla [31] proposed a power-law damage function to describe the tensile behavior of plain concrete. An analysis using this damage function to predict failure in bending and in tension is presented in Appendix B. For $n = 4$, the value recommended by Piechnik and Pachla, $\sigma_{bu}/D = m = 0.715$ at a value of 0.529 for $k_k$ for the bending case. For tension, a value of 0.669 is attained for $\sigma_{tu}/D$. Thus,

$$\frac{\sigma_{bu}}{\sigma_{tu}} = 0.715/0.669 = 1.07$$

This value of 1.07 is considerably lower than is consistent with the experimental results of Refs. [21] and [22]. The explanation for this discrepancy may be any one of the following factors or a combination of them:

2. Increase in measured $\sigma_{bu}/\sigma_{tu}$ due to a brittle failure mechanism and statistical size effects as discussed previously.

3. Possibility that the material damage relation for concrete has a threshold effect, as suggested by Young [33] and Bert and Kumar [20], rather than the 1.07 power-law damage function suggested in [31].

5. APPLICATION TO CORD-REINFORCED RUBBER

It was shown in the recent experiments of Bert and Kumar [19] that the stress-strain relations of this class of materials is strongly dependent upon the type of cord. For example, aramid-rubber loaded in the cord direction ($\theta = 0^\circ$) has a drastic discontinuity in slope at the origin ($E_c > E_s$), yet the same material loaded at $90^\circ$ to the cord direction is very nearly linearly through ($E_c = E_s$, $F_c = F_s = 0$). As an example of the application of the
generalized model presented in Section 3, steel cord-rubber specially made to have highly waved cords is considered. Then \( E_c = E_t = E \) and \( F_c = F_t = F > 0 \). Then equation (12) simplifies to

\[
\frac{M}{BH^2} = \frac{E^2}{F} \left( 1 - 2K_t \right) \left[ 3 - \frac{27}{8} \left( 1 - 2K_t + 2K_t^2 \right) \left( \frac{1 - 2K_t}{3K_t - 3K_t + 1} \right)^2 \right]
\]  

(20)

It can be shown that the maximum value of dimensionless bending moment is 
\( 6\mu F/BE^2H^2 = 0.433 \) at a value of 0.380 for \( K_t \). Now due to the monotonically increasing slope of the tension portion of the stress-strain curve, it does not exhibit a maximum-load phenomenon. (Tensile failure is obviously due to another mechanism, probably cord failure.) Thus, in this case, it is necessary to ratio the bending strength to the compressive strength rather than the tensile strength. From Appendix A2, one has

\[
\sigma_{cu} = -\frac{E^2}{4F}
\]  

(21)

Thus,

\[
\left| \frac{\sigma_{tu}}{\sigma_{cu}} \right| = \frac{6\mu/BH^2}{E^2/4F} = 1.73
\]

This indicates that \( \sigma_{tu} \) is 1.73 times the compressive strength. In reality, the tension portion of the steel-cord rubber is even steeper than indicated by a power of two. Thus, \( \sigma_{tu} \) would be expected to be even greater. This could not be verified experimentally due to the extremely flexible nature of the material, i.e. its flexural stiffness is too low to measure in practice.

6. CONCLUSIONS

A general theory was developed for predicting the maximum bending moment that can be carried by beams having arbitrary compact cross sections and constructed of material having an arbitrary non-linear stress-strain curve that is different in tension and in compression. As an application of the theory, it was applied to rectangular-cross-section beams of plain concrete and of cord-rubber.

APPENDIX A: RELATIONS BETWEEN TENSILE AND COMPRESSIVE STRENGTHS AND MATERIAL DAMAGE

1. Tension Loading

Using

\[
\sigma = E \varepsilon + \frac{F_t \varepsilon^2}{2} \quad ; \quad \varepsilon > 0
\]

it is obvious that material instability cannot occur unless \( F_t < 0 \). Then the Considère criterion [12] is

\[
\frac{d\sigma}{d\varepsilon} = 0
\]

or

\[
2 = 2F_t \varepsilon^2 = 0
\]

Thus, the strain at which tensile instability occurs is

\[
\varepsilon_{ti} = \frac{-E}{2F_t}
\]

and the tensile strength is

\[
\sigma_{tu} = -\frac{E^2}{2F_t} + \frac{E^2}{4F_t} = -\frac{E^2}{4F_t} = D_t/4
\]

2. Compression Loading

Using

\[
\sigma = E \varepsilon + \frac{F_c \varepsilon^2}{2} \quad ; \quad \varepsilon < 0
\]

it is obvious that material instability cannot occur in this situation unless \( F_c > 0 \). Again using the Considère criterion, equation (A2), one obtains the following expression for the instability strain:

\[
\varepsilon_{ci} = -\frac{E}{2F_c}
\]

and the predicted compressive strength is
\[ \sigma_{cu} = -\frac{E^2}{2F_c} + \frac{E^2}{4F_c} = -\frac{E^2}{4F_c} = D_c/4 \]  
(A7)

**APPENDIX B: EFFECT OF POWER-LAW TENSILE-DAMAGE FUNCTION ON BENDING STRENGTH OF CONCRETE**

1. **Bending Loading**

In the continuum damage theory [17], the nominal stress \( \sigma \) is related to the net or true stress \( S \) by the following relation

\[ \sigma = (1 - \omega)S \]  
(31)

Here \( \omega \) is called the damage.

Piechnik and Pachla [30] proposed the following power-law damage function for concrete in tension:

\[ \omega = \left(\frac{S}{D_t}\right)^n \]  
(B2)

Here \( n \) and \( D_t \) are material constants. Based on limited test data, Piechnik and Pachla recommended a value of 4 for \( n \). Thus, the following expressions for \( \omega \) are used here:

\[ \omega = \begin{cases} 
(S/D_t)^n & \text{for } S > 0 \\
0 & \text{for } S \leq 0 
\end{cases} \]  
(B3)

Since

\[ S = E\varepsilon \]  
(B4)

we obtain the following expression for the stress distribution

\[ \sigma_c(E) = E\varepsilon \]  
\[ \varepsilon < 0 \]  
(33)

\[ \sigma_t(E) = E\varepsilon - E(E/D_t)^n\varepsilon^{n+1} \]  
\[ \varepsilon > 0 \]  
(B5)

It is readily apparent that this model is a generalization of the linear-damage model hypothesized by Krajcinovic [14].

Use of equation (B5) in equation (3) leads to the following relationship between the curvature \( \kappa \) and the dimensionless tensile-outer-fiber distance \( (K_t \equiv C_t/H) \):

\[ \kappa = \left(\frac{D_t}{E^K_t}\right)[1 + (n/2)]^{1/n}(2K_t^{-1} - K_t^{-2})^{1/n} \]  
(B6)
Similarly, substitution of equation (35) into equation (5) and integration gives
\[ \frac{3M}{32\pi kH^3} = k_t^3 + (1-k_t)^3 - \frac{3(2+n)/(2(3+n))}{2}k_t^2 - k_t \]  
(37)

Finally, substitution of equation (36) into equation (37) yields
\[ n = \frac{6M/BD_tH^2}{2(1+(n/2))^{1/n} (2k_t^{-1} - k_t^{-2})^{1/n} + (3-2n)k_t} \]  
(38)

Obviously, for the case of linear damage (n = 1), equation (38) reduces to equation (13).

3. Tension Loading

Applying the tensile instability criterion, equation (A2) to \( \sigma_c(E) \) as given by equation (B5), one obtains the following expressions for the instability strain and ultimate tensile strength:
\[ \varepsilon_{t} = (D_t/E)(n+1)^{-1/n} \]  
(39)
\[ \sigma_{tu} = D(n+1)^{-1/n} [1-(n+1)^{-n+1}] \]  
(40)

20. Abstract (cont'd)

Numerical results for axial displacement, transverse deflection, bending slope, bending moment, transverse shear, axial force, and location of neutral surface are presented for multimodular and bimodular models of unidirectional aramid cord-rubber. The transfer-matrix method results agree very well with the closed-form solutions.

In part II, it is shown by analysis that different behavior in tension and compression has a profound effect on the flexural strength as predicted by application of fundamental continuum mechanics relations. The theory is applied to a nonlinear material model which is shown to be applicable to two widely different materials: concrete, which has more strength degradation (modeled by continuum damage mechanics) in tension than in compression, and steel cord-rubber, which has strength which is enhanced in tension by cord strengthening and degraded in compression by cord microbuckling.
