PREFACE

This volume describes the computer programs shown in figure 1. The system consists of 15 programs written in FORTRAN for operation on CNA's CDC 3600 computer and a standard statistical regression program, BIMED34. For simplicity, only the machine-readable output is shown in figure 1. Every program produces a printed output.

The description of each program consists of a statement of its purpose, a description of its logic, the definition of its dimensioned variables, a list of changes to be made to it as a result of changes to other programs and vice versa, and a listing of the program and subroutines. Whenever a program produces an output tape, its structure and format are also described. The appendix summarizes the effect of changes to the dictionary and data tapes on all the programs.

The reader should refer to volume I for a glossary of terms and a summary of the methodology, including the mathematical models that are the bases for certain programs. If a more detailed discussion of techniques and models is wanted, the reader should refer to CNA RC 291.
MAINTAINING THE DATA AND DICTIONARY TAPES

FIG. 1: FLOW CHART OF THE LOS SYSTEM OF PROGRAMS
MAINTAINING THE DATA TAPES

STRUCTURE OF THE DATA TAPES

There are three law of the sea databases. The first, on two reels, contains all data that has been extracted from the primary source documents, the second contains all data from the secondary source documents, and the third contains all inactive data from both primary and secondary sources. The first two databases are referred to as the active data base, and the third is referred to as the historical data base. For purposes of analysis only the active data base has been used.

The tapes are unblocked and 7-tracked. Each is organized by country number and, within country, numerically by theme number. The primary data tapes contain approximately 30,000 records, the secondary tape 12,000 records, and the historical tape 8,000 records.

A record is equivalent to an observation and is written in the following BCD format:

The eight fields contain: (1) country number, (2) regional flag, (3) repetition flag, (4) classification code, (5) reliability code, (6) document number, (7) theme number, and (8) letter associated with the theme number. For a detailed description of these entries, the reader should refer to appendix A of the users guide.

PROGRAM CHECK

Purpose

This program verifies that new observations have been accurately transcribed and keypunched. It produces a list of observations in the order in which they were extracted from the documents.

Method

The country names are read off the dictionary tape and stored in NACON. The input deck of observations is read a card at a time. A document header is produced whenever the document number changes and a country header is produced whenever the country number changes. Each observation is printed with its theme number and letter designation, if any.

Dimensioned Variable

NACON, dimensioned 149 by 2, contains a two field name for each country.
Operational Effects of System Changes

This program depends upon the current structure and format of a new observation (update card) and the country dictionary. If an update card is modified, format 2 and statement 10 may have to be changed. If the number of countries exceeds 149, MAXC must be increased and NACON redimensioned. If the country dictionary file is restructured or reformatted, format 1 may have to be changed.

Program Listing

The listing of program CHECK follows.

PROGRAM REMOVE

Purpose

This program extracts all data on specified theme numbers from an active data tape. Its primary function is to delete all observations on outdated or inactive themes and punch them in a format that can be used to add them to the historical tape. Its secondary function is to equivalence two or more theme numbers with the same substantive meaning to a single number by deleting all observations on the "duplicate" theme numbers and punching each with the permanent number.

Method

For each theme that is to be retired, a flag is set in THEME which distinguishes a lettered from a non-lettered theme to be retired. If the retired theme is lettered, its number and letter are stored in NSPEC.

For each theme to be equivalenced, a flag is set in THEME which distinguishes lettered from non-lettered equivalences as well as from retired themes. If either the duplicate or the permanent theme contains a letter, then both are stored in NSPEC.

The active data tape is read a record at a time. If the record does not refer to a theme number being changed, it is written on the output tape. If it refers to a non-lettered theme being retired or equivalenced, the observation is deleted and punched. If, on the other hand, the record refers to a theme number which has been flagged as a lettered change, NSPEC is searched for this record's number and letter. If it is found, the record is deleted and punched. If it cannot be found, because this record's version is not being changed, the record is written on the output tape.

Dimensioned variables

There are four dimensioned variables in program REMOVE:

1) THEME, dimensioned 1599, contains a field for each theme number. This array consists of a flag for each theme number to denote if and how it is being changed.

THEME (M):

- 0 if theme M is non-existent or unchanged
- M if all versions of theme M are being retired
- -M if only lettered versions of theme M are being retired
- K if all versions of theme M are being equivalenced to versions of theme K
- -K if a version of theme M is being equivalenced to a version of theme K.

(Either M or K or both refer to lettered themes.)
(2) MTEMP, dimensioned 4, contains the temporary storage of the retired or equivalenced theme being processed. When retired themes are being stored, only the first two fields are filled with the theme number and letter, if any. When equivalences are being stored, the theme number and letter of the duplicate theme are followed by the theme number and letter of the permanent theme.

(3) NSPEC, dimensioned 500 by 4, contains the permanent storage of lettered themes being retired or equivalenced. It takes on the values of MTEMP whenever MTEMP (2) or MTEMP (4) contains a letter.

(4) RECORD, dimensioned 5, contains all the information from the record being processed, namely, country number, special codes, document number, theme number, and letter, if any.

**Operational Effects of System Changes**

Any changes in basic format of the input data tape could affect the way RECORD is read and how its fields are interpreted. Less dramatic effects are that if the maximum theme number exceeds 1599, MAX must be increased and THEME redimensioned; and if the number of retired or equivalenced themes involving a letter exceeds 500, NSPEC and NLETTER must be increased.

**Program Listing**

PROGRAM UPDATE

Purpose

This program creates a new data tape by merging an existing one with an ordered card deck of additions and deletions. It preserves the basic structure of the data tape.

Method

A record and card are read and compared. The record is written on the output tape when any of the following conditions are met:

1. The record pertains to a smaller country number.
2. They both pertain to the same country
   (a) and the record refers to a smaller theme number;
   (b) and the same theme number, and the card is being added;
   (c) and the same theme number, and the record is not identical with the delete card.
3. End of file has been encountered in the card deck.

The addition card is written on the output tape when any of the following conditions are met:

1. The card refers to a smaller country number than the record.
2. They are referring to the same country, and the card is for a smaller theme number.
3. End of file has been encountered on the input tape.

A deletion is accomplished whenever the card and record match on country, theme, and document number.

Dimensioned Variables

The data on the tape is read into RECORD, dimensioned 5. The update card is read into CARD, dimensioned 6. Both arrays are composed of the following information:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Country number</td>
</tr>

MAINTAINING THE DICTIONARY TAPE

STRUCTURE OF THE DICTIONARY TAPE

The LOS dictionary tape consists of six files. Each program automatically accesses the file(s) it requires. The dictionary tape is written in BCD and is an unblocked, 7-track tape. The files are in the following order:

1. Country dictionary
2. Theme dictionary
3. Major/minor dictionary
4. Issue-variable dictionary
5. Lettered theme dictionary
6. Independent variable dictionary

For a detailed description of the format and structure of each of these files, see appendix B of the users guide.

PROGRAM SEARCH

Purpose

The primary function of program SEARCH is to locate specified themes within the major/minor and issue-variable dictionaries. It lists their assignments, but does not delete them. This program can be used to verify that every theme belongs to one and only one major and minor topic or to aid the user when retiring themes from the dictionary tape. It can process 1,000 themes in a single run.

Method

The program first reads the theme range selection cards. The array JCODE is filled with counters so that JCODE(M) = N when theme M is the Nth theme to be processed. The program produces an overflow message if there are more than 1,000 themes to be processed.

Then the major/minor dictionary is read. If the Nth theme being processed is located in the major and minor topic, LOCATE(N, major topic) is set equal to the minor topic number. After all topics are read, LOCATE is printed whenever its cell is non-zero. A message is produced when all of its cells are zero (no assignment to a major and minor topic) or when more than one cell is non-zero (assigned to more than one major and minor topic).

Finally the issue-variable dictionary is read. If the Nth theme being processed is located within the issue-variable, LOCATE(N, counter) is set equal to the issue-variable number. The counter is increased as the cells are filled. The assignments to
issue-variables are printed in numerical order by theme number after the entire issue-variable dictionary has been read.

**Dimensioned Variables**

Program SEARCH contains four dimensioned variables:

1. **JCODE** is dimensioned 1599, one field for each theme number. This array serves as a flag for the themes being processed. \( JCODE(M) = 0 \) if \( M \) is not being processed; \( JCODE(M) = N \) if \( M \) is the \( N \)th theme processed.

2. **THEMES**, dimensioned 500, contains the temporary storage of all themes in the minor topic or in the issue-variable being searched.

3. **LOCATE** is dimensioned 1,000 by 20. Each row represents a theme being processed (up to a current maximum of 1,000). The columns take on different meanings for the major/minor and issue-variable dictionaries. When the assignments to topics are being stored, LOCATE(N, major topic) is zero when the \( N \)th theme being processed is not assigned to this major topic and is equal to the minor topic when it is. When the assignments to issue-variables are being stored, LOCATE is filled across the row as the \( N \)th theme is located. The \( N \)th theme cannot belong to more than 20 issue-variables.

4. **KOUNT** is an array dimensioned 1,000. Each field corresponds to a theme being processed. KOUNT is the counter used to fill LOCATE with assignments of themes to issue-variables. KOUNT(N) is increased by 1 everytime the \( N \)th theme is located in the issue-variable dictionary.

**Operational Effects of System Changes**

Since this program is dependent upon the major/minor and issue-variable dictionaries, any change to their structure or format will have an operational effect. Numerous minor changes can be made easily. If the largest theme number in the theme dictionary is larger than 1599, NTHEME must be set equal to the new maximum and JCODE must be dimensioned at least as large. If the number of major topics is increased, NMAJ must be equal to the largest major topic and LOCATE must have at least as many columns as NMAJ. If the number of issue-variables is increased, NVAR must be equal to the largest issue-variable number. If themes are assigned to more than 20 issue-variables, LOCATE must be expanded. If more than 1,000 themes are to be processed in a single run, KOUNT and LOCATE must be expanded. If the number of themes assigned to any issue-variable or minor topic should ever exceed 500, THEMES must be expanded.

PROGRAM DTAPE

Purpose

This program and its subroutines update the six dictionary files. Any file can be left unchanged or have specified entries changed. The first five files can also be completely updated with a new card deck.

Method

DTAPE consists of a main calling program and seven subroutines. The calling program reads the main control card, which specifies if and how a file is to be changed. The files are then processed one at a time. When the first five files are processed, the calling program copies the file on the output tape if it is to be left unchanged; reads and writes the new card deck on the tape if it is to be completely updated by cards; or calls the appropriate file subroutine (ONE through FIVE) if specific entries are to be changed. When file six is processed, subroutine SIX is always called.

Subroutine ONE performs all changes to specified entries in file 1, country dictionary. Additions and deletions of countries are not allowed, since they would affect the data on the raw data tape. However, the name of a country and its abbreviation can be corrected.

File 1 and the deck of changes are organized numerically by country number. A card and a record are read and compared. If the card refers to a smaller country number, it is out of order and subroutine ERROR is called. If they refer to the same country number, the name and abbreviation from the card are substituted for the record and written on the output tape. If the card refers to a larger country number, the record is written.

If a change card requests anything but a substitution or if an EOF is encountered on the input file before it has occurred on the change deck, subroutine ERROR is called. When an EOF is found on the change deck, all remaining input records are written on the output tape.

Subroutine TWO performs all changes to specified entries in file 2, theme dictionary. Additions, deletions and substitutions are allowed as long as the theme number is less than 1,600.

File 2 and the deck of changes are organized numerically by theme number. A card and a record are read and compared. If the card refers to a smaller theme number and requests an addition, the card is written on the output tape; if it does not request an addition, it is out of order and subroutine ERROR is called. If the card and record refer to the same theme number and the card requests an addition, subroutine ERROR is
called; if it requests a substitution, the theme title on the card is written; if it requests a deletion, the record is deleted. If the card refers to a larger theme number, the record is written on the output tape.

If a change card attempts to modify or create a theme larger than 1599 or if an EOF is encountered on the input file (blank record precedes its EOF) before it has occurred in the change deck, subroutine ERROR is called. When an EOF is found on the change deck, all remaining input records are written on the output tape.

Subroutine THREE performs all changes to specified entries in file 3, major/minor dictionary. The titles of the topics and the themes assigned to them can be changed. New major or minor topics cannot be created, nor can existing ones be deleted. File 3 is organized numerically by major topic number and, within each major topic, by minor topic number, each being followed by a list of its themes in numerical order. The deck of changes is similarly ordered.

A card and record are read and compared. If the card refers to a smaller major topic number, it is out of order and subroutine ERROR is called. If it refers to a larger major topic number, the major topic record is written on the output, and all of its minor topics and themes are read and written. If they refer to the same major topic, its title is changed, if requested, and written. Then a comparison is made of the minor topic numbers. If the card change refers to a smaller minor topic, subroutine ERROR is called; if it refers to a larger minor topic number, the minor topic and its themes are copied off the input file. If they refer to the same minor topic, its title is changed, if requested. The change cards are then compared with the list of themes in the minor topic; the additions are made in the appropriate numerical location and deletions are made when they are located in the list. If deletions cannot be found or entries are out of numerical order, subroutine ERROR is called. Once all changes have been made, the minor topic title and the number of themes now assigned to it are written, followed by a list of these theme numbers.

If an EOF is encountered on the input file before it occurs on the change deck, subroutine ERROR is called. When all changes have been made, all remaining records are written on the output tape.

Subroutine FOUR performs all changes to specified entries in file 4, issue-variable dictionary. The titles of the issue-variables and the ranks and themes within them can be changed. Existing issue-variables can be deleted, which creates an unused number, and new issue-variables can be created for any of the unused numbers between 1 and 70.

File 4 is organized numerically by issue-variable number and, within each issue-variable, by rank of themes. The deck of changes is similarly ordered. This subroutine reads an issue-variable identification card and record. If the card refers to a smaller issue-variable number, it is out of order and subroutine ERROR is called, If
it refers to a larger issue-variable number, the record is written, all of its ranks and themes are read and written, and the next issue-variable identification record is read.

If the card and record refer to the same issue-variable, its title is changed, if requested. If only the title is being changed, the new title is written, and the existing ranks and themes are read and written.

If there are rank and theme changes to be made, the existing ones and changes are read. Then one at a time, a record and card entry are compared. The card additions are made in the appropriate rank order and deletions are made when they are located on the list. If deletions cannot be found or if a card entry is out of rank order, subroutine ERROR is called. Once all changes have been made, the issue-variable title and the number of themes now assigned to it are written, followed by a list of the ranks and themes.

If an EOF is encountered on the change deck, all remaining records on the file are copied onto the output tape. If an EOF occurs on the input file before it is encountered on the change deck, subroutine ERROR is called.

Subroutine FIVE performs all changes to specified entries in file 5, lettered theme dictionary. Additions, deletions and substitutions of lettered themes are processed by this subroutine. File 5 and the deck of changes are organized numerically by theme number and, within each theme number, alphabetically by letter.

A card and record are read and compared. If the card refers to a smaller theme number and is an addition, it is written on the output tape and another card is read; but if it is not an addition, it is out of order and subroutine ERROR is called. If the card refers to a larger theme number, the record is written on the output tape and the next record is read. If the card and record refer to the same theme, their letters are compared. If they do not match, the record is written and the next one processed. But if they do match and it is an addition, subroutine ERROR is called; if it is a deletion, the record is deleted and the next record and card are compared; if it is a substitution, the card title is substituted and written on the output tape, and the next record and card are compared.

When an EOF has been encountered on the change deck, all remaining records are written on the output tape. If an EOF is encountered on the input tape and changes still remain, the additions are placed on the output tape, but any deletions or substitutions call subroutine ERROR.

Subroutine SIX performs all operations on file 6, independent variable dictionary. If the file is to be left unchanged, it is copied. If a complete update is requested, a message is produced that the request is unacceptable and the file is copied unchanged. If specific entries are to be changed, a country's data is read off the input and compared with a card in the change deck. If the card refers to a smaller country number, an error message
is written and the entire file is left unchanged. If the card refers to a larger country number, the record is written on the output tape and the next country's data is read. If they refer to the same country the card entry is substituted for the record entry and another card is read.

If an EOF occurs on the change deck, all remaining records are copied onto the output tape. If an EOF is encountered on the input file before it is found on the change deck, an error message is produced, the changes are disregarded, and the entire file is copied unchanged.

Subroutine ERROR is called whenever a deck of changes is out of order or is incompatible with the above subroutines. This subroutine erases all work on a file, rewinds the input and output tapes and copies the file unchanged onto the output tape. Any remaining changes to this file are skipped over.

Structure of the Output Tape

The six files that are on the output tape have the same format and structure as the input tape. (For a detailed description of the dictionary file structure, see the users guide.)

Dimensioned Variables

There are five dimensioned variables that appear in the calling program and the seven subroutines. Most of them take on different meanings depending on the subroutine. Their general meaning will be discussed here.

(1) NFILE, dimensioned 6, contains a change code for each file. If NFILE(M) is zero, file M is to be left unchanged; if it is 1, file M is to be completely updated with cards; if it is 2, specified entries are to be changed.

(2) INFO, dimensioned 500, contains all of the information from a record. The reader should refer to the users guide for a description of a record in each file.

(3) NINFO, dimensioned 500, contains all of the information from a change card. The reader should refer to the users guide for a description of the format and structure of the change cards for each file.

(4) VDATA, dimensioned 500 by 2, is used as temporary storage of the themes assigned to the minor topic being processed in subroutine THREE (only the first column is used) or the temporary storage of the ranks and themes assigned to the issue-variable being processed in subroutine FOUR.
(5) NVDATA, dimensioned 50 by 3, is used as temporary storage of changes to themes in the minor topic or issue-variable being changed. In subroutine THREE, the first two columns of NVDATA are filled with a + (addition) or - (deletion), followed by the theme number. In subroutine FOUR, the three columns are used to store the rank, + or -, and theme change.

Operational Effects of System Changes

If the format or structure of the dictionary tape is changed, all the programs in the system, especially this one, will have to be changed. DTAPE is not affected by changes in any other program, but all other programs depend upon its product, namely the dictionary files. Appendix A identifies how changes can affect each of the programs in the system.

PROGRAM CODEBK

Purpose

The purpose of this program is to produce a codebook.

Method

The program reads the first five files of the dictionary tape and lists them in a readable form. As the theme and issue-variable dictionaries are read, the array JCODE is used to distinguish between non-existent theme numbers, existing theme numbers not assigned to an issue-variable, and existing theme numbers that are assigned. A list of existing themes not in an issue-variable and non-existent theme numbers is then produced from the entries in JCODE.

Dimensioned Variables

Program CODEBK contains five dimensioned variables:

1. NACON, dimensioned 4, contains the country number, the country name (in 2 fields), and its international abbreviation.
2. TITLE, dimensioned 6, contains the title of the theme, major topic, minor topic or issue-variable currently being processed.
3. JCODE is dimensioned 2000, each field representing a theme number (currently 1599 would be required). JCODE(K) can take on three values:
   - 0 if K is a non-existent theme
   - 1 if K exists and is not in an issue-variable
   - 2 if K exists and is in an issue-variable.
4. NAME, a permanent matrix of theme names dimensioned 2000 by 6, stores a 6 field title for each theme. Unlike JCODE, NAME(K,...) contains the Kth theme title that exists.
5. THEMES, a temporary matrix of themes within a minor topic or issue-variable, is dimensioned 200 by 2, since no minor topic or issue-variable currently contains more than 200 themes. When the themes in minor topics are being stored, it contains the list of theme numbers in the order in which they appear in the dictionary. When the themes in issue-variables are being stored, it contains the rank and number of each theme in the order in which they are read off the dictionary tape.

Operational Effects of System Changes

Since this program's sole input is the dictionary tape, its operation is dependent upon the current format and structure of that tape. After every significant update of the dictionary, a review of the following variables is advised:
NMAJ must equal the maximum major topic number.
NVAR must equal the maximum issue-variable number.
NTHEME must equal the maximum theme number.
JCODE must be dimensioned at least as large as NTHEME.
NAME should be dimensioned as large as NTHEME by 6.
THEMES must be dimensioned at least twice as large as the maximum number of themes in a minor topic or issue-variable.

ORGANIZING THE DATA

PROGRAM MATRIX

Purpose

The primary function of this program is to convert the active data tapes into matrix form. The equivalent of a three dimensional matrix - country by theme by time period - is produced. The secondary function is to produce a retrieval printout which identifies the source of each theme.

Method

Before the matrix is created, the control cards specifying the criteria for selecting observations must be read. After the main problem card is read, the document range cards are read and NDOC is filled (see NDOC under Dimensioned Variables). Next the major topic selection card is read, if it exists, and array MAJOR is filled with a 1 when the topic is selected. Then the theme dictionary is read, and the first six fields of NAME are filled with the theme title. A row of NAME is left blank when the theme does not exist. If major topics are being selected for the retrieval printout, the major/minor dictionary is read next, and for each major topic selected, themes are given a flag of 1 in the 7th field of NAME. Lastly, the regional and lettered theme criteria for each time period is read.

The program then processes all data on a single country, filling NFREQ(theme no., time period) as observations are read. Each observation is checked against the regional, letter and document specifications and placed in NFREQ only when it meets all of the requirements. Simultaneously the retrieval printout is produced according to its specifications (i.e., all data from major topic selected, all data or only data on the matrix tape). After all the country's data from one input tape is read, all of its data from the second tape (if it exists) is read in the same manner. After all data for a country is read, NFREQ is buffered out on the tape and NFREQ is zeroed out and the next country's data is processed.

Structure of Input and Output Tapes

The primary data and secondary data tapes are each organized by country number and within country numerically by theme number. Each observation is a BCD record and the tapes are unblocked.

The matrix output tape is written in binary and organized by country. The number of records for each country depends upon the number of time periods created. The first record for a country contains the number of mentions the country has made of each of the 1599 themes during the first time period. This is followed by an equivalent record for the second time period, etc. This form is followed for all other countries.
Dimensioned Variables

There are eight dimensioned variables in program MATRIX:

(1) NDOC, dimensioned 999, has one field for each document number. NDOC(document number) equals the time period that the document number is assigned to by the document range cards or zero if it is not assigned to a time period.

(2) NAME, dimensioned 1600 by 7, is a matrix of theme titles and theme selection flags. The first six fields contain the title; the 7th contains a flag of 0 or 1, where a 1 means that the theme is assigned to a major topic selected for the retrieval output and a 0 means it is not. If major topics are not selected, all are assigned 1's. NAME(N, X) is blank whenever theme N does not exist.

(3) MAJOR, dimensioned 17, is an array of major topic flags. When major topics are selected, MAJOR(N) is 1 when topic N is selected, and is 0 otherwise. When major topics are not selected, all values are 1.

(4) NFREQ is the matrix of theme frequencies for the country being processed. It is dimensioned 1600 by 4, with one row for each theme and one column for each possible time period. This is the matrix that is written on the output tape. If major topics are selected, NFREQ is used earlier as temporary storage for themes within a minor topic.

(5) NACON, dimensioned 2, contains the two field name of the country being processed.

(6) NCLASS, dimensioned 2, is the two field classification title that is to appear at the top and bottom of each retrieval output page.

(7) MT, dimensioned 6, serves two functions. It is the temporary storage of the six field theme title before it is placed in NAME. During data processing, MT is used to store the regional flag codes for the four possible time periods. If MT(N) is 0, only non-regional remarks are included in time period N; if 1, only regional remarks; and if 2, both regional and non-regional remarks.

(8) NT, dimensioned 6, contains the letter/non-letter codes for each time period. If NT(N) is 1, only non-lettered themes are included in time period N; if 2, both letter and non-lettered themes are included; and if 3, only lettered themes are included.

Operational Effects of System Changes

This program depends upon the data tapes and the first three files of the dictionary. Assuming that their structure and format remain the same, the following changes to the dictionary files can be handled by changing these variables:

- If the number of countries exceeds 149, NCOUN must be increased.
- If the maximum theme number exceeds 1599, NMAX must be set equal to the maximum number and NAME and NFREQ must be redimensioned accordingly.
- If the number of major topics exceeds 17, MAJOR must be redimensioned and NTOPIC must be increased.

-42-
Apart from these changes to the dictionary file, the data tape may, in the future, contain observations from document numbers larger than 999. If this occurs, MDOC and NDOC must be increased. Furthermore, if it becomes desirable to have more than 4 time periods on a single matrix tape, MT, NFREQ and NT must be redimensioned and format 1 must be changed if there are more than 8 time periods. The programmer is cautioned that expanding the number of time periods increases substantially the amount of core required.

Program Listing

The listing of program MATRIX follows.

PROGRAM PTHEME

Purpose

The sole function of this program is to list all of the countries that have addressed specific themes and to specify their number of mentions.

Method

The program allows the user to select a set of themes for this profile by choosing ranges of theme numbers, choosing themes assigned to major topics and/or choosing themes assigned to issue-variables.

Depending on the option(s) chosen, the program reads the relevant cards and dictionary files. The array JCODE is filled with theme counters to the extent that JCODE(theme number) = N when this theme number is the Nth one to be processed in this run. A maximum of 600 themes can be processed at once. An error message occurs when more than 600 are requested and the job processes the first 600 it detects. After all the themes have been assigned values in JCODE, JCODE is reordered so that the counter is numerically increasing as the theme numbers increase.

The program then begins to process the data from the matrix tape. The program buffers in one country's data and one time period at a time.

If that time period was selected, the program processes one theme at a time and only if it is a selected theme does the program fill MATRIX.

MATRIX is dimensioned 160 by 100. Each row represents a country; each column represents 6 themes, hence the 600 maximum. When an observation occurs on a theme selected, the relevant column is determined by the index of this theme number, and the value entered depends upon the location of this theme number within the column. That is, if theme number 100 is the 7th theme being processed (JCODE(100) = 7) and the packing factor is 6, then theme 100 is located in the first portion of the second column. Thus, the index would be 2 and the value would be MOVE(1).

After all data is read off the matrix tape, MATRIX is decoded one column at a time (6 themes at a time). The 6 entries in a cell are stored in NEW. Once NEW has been filled with every country's data on the 6 themes, the titles of themes and their observations are listed. Then the program returns to process another column of data.
Dimensioned Variables

There are 11 dimensioned variables in program PTheme:

1. MATRIX contains the frequency of mention by each country of all themes being processed. The frequencies are packed within a column in conjunction with MOVE.

2. MOVE, an array dimensioned 6, must be consistent with the packing factor NPACK. MOVE defines the portion of a column where frequencies of each of the 6 themes are cumulated.

3. NAME, an array dimensioned 6, is temporary storage of the theme title being processed.

4. JCODE, dimensioned 1600, contains indices for the themes being processed. JCODE(theme number) is zero when the theme has not been selected and N when this theme is the Nth theme being processed.

5. NFREQ, dimensioned 1600, is temporary storage for data read off the dictionaries and the matrix tape and is also used during the decoding process. NFREQ stores the themes within the minor topics or variables when these options are used for theme selection. Later it stores all observations of a country in a particular time period. During the decoding process it stores the theme numbers being processed in such a way that NFREQ(K) = N, where the Kth theme being processed is theme number N.

6. NTIME, dimensioned 4, contains a flag for the 4 time periods that could exist on the matrix tape. If NTIME(t) = 1, time period t's data is included in the listing; otherwise it equals 0.

7. NCLASS, dimensioned 2, consists of the classification title to be written at the top and bottom of each page of the output.

8. NACON, a matrix 160 by 2, contains a two field name for each of the countries in the analysis.

9. NMAJOR, dimensioned 17, contains a flag for each major topic number. A 1 means that the themes in the major topic are to be included in the printout; a 0, that they are not.

10. NVARS, dimensioned 70, contains a flag for each issue-variable. A 1 means that the themes in the issue-variable are to be included; a 0, that they are not.

11. NEW is a matrix dimensioned 160 by 6. Each row represents a country and each column a theme number. NEW is the decoded form of a single column of MATRIX in which the entries have been unpacked. An entry is the frequency with which a country has made this remark under the conditions specified on the main problem card.
Operational Effects of System Changes

This program is dependent upon the matrix tape and the first four files of the dictionary tape. If minor modifications to the four files of the dictionary are made, the programmer is cautioned to change the following variables in this program:

If the maximum theme number should exceed 1599, NMAX must be set equal to the maximum number and JCODE and NFREQ must be dimensioned at least as large.

If the number of countries exceeds 149, NCOUN must be increased. If NCOUN is increased beyond 160, MATRIX, NACON and NEW must be increased accordingly.

If the number of major topics exceeds 17, NTOPIC and NMAJOR must be increased.

If the number of issue-variables exceeds 70, NVARB and NVARS must be increased.

If modifications are made to the matrix tape, such as increasing the number of time periods that can exist, NTIME must be dimensioned at least as large as the maximum number of time periods, and the format and read statements for the main problem card must be changed accordingly.

Apart from these tape changes, the programmer is cautioned to make certain that the number of observations by a single country on a theme under the criteria established on the main problem card never exceeds 128. If it does, the packing factor must be reduced, MOVE and NEW would have to be redimensioned, and the values of MOVE would have to be changed accordingly.

PROGRAM LETTER

Purpose

This program is a special case of program PTHEME and handles data on lettered themes. The sole function of LETTER is to list all the countries that have addressed particular lettered themes and to specify the number of mentions. A theme profile is produced for all lettered themes that were selected.

Method

Unlike PTHEME, this program reads the original data tapes. First, the main problem card is read and then the document numbers to be included in this printout are read from the document range cards. The array NDOCS is filled so that NDOCS(N) is 1 when observations from document N are to be included and 0 when they are not.

The lettered theme dictionary is read and the first 315 theme numbers with letters are identified. JCODE(theme no.) is assigned a disc number where this theme's data will be temporarily stored. Currently seven theme numbers, each with its various letter designates, are assigned to a disc unit 1 to 45, hence the 315 maximum.

Then the input data tape(s) are read an observation at a time. If the observation is on a lettered theme being processed in this run and it meets the document and regional code criteria, it is written on the disc unit that stores this theme number (and 6 others).

After all data has been read from the tape(s) and the appropriate observations have been stored on disc, the lettered theme dictionary is reread one theme number and letter at a time. The appropriate disc is searched for observations and as they are found they are written on the printout. The disc is then rewound and the next lettered theme is processed in the same manner.

Dimensioned Variables

Program LETTER has five dimensioned variables:

(1) NDOCS is dimensioned 999 with one field for each existing document number. If document N's data is to be included in the printout, NDOCS(N) = 1; otherwise it equals 0.

(2) NACON, a matrix dimensioned 160 by 2, contains a two field name for each country.

(3) JCODE is an array 1599 long with one field for each theme number. Beginning with the smallest theme number for this run as specified on the main problem card, JCODE is filled with a counter for each theme number with letters; that is, JCODE(theme number) = N whenever the theme number has lettered versions to it and it is the Nth such theme number found. JCODE is zero in all other cases.
(4) NCOUNT, an array dimensioned 45, one field for each temporary disc to be used, is merely the number of observations that exists on each disc.

(5) MT, dimensioned 6, contains a six field title of the theme being processed.

**Operational Effects of System Changes**

The normal operation of this program depends upon the current structure and format of the data tape, country dictionary, and lettered theme dictionary. The following minor modifications can be handled by changing the following variables:

If the number of documents exceeds 999, NDOCS will have to be redimensioned.

If the maximum theme number exceeds 1599, MAXT and JCODE must be at least as large as the maximum number.

If the number of countries exceeds 160, both MAXC and NACON must be increased.

This program will currently process 315 theme numbers with all of their lettered versions (i.e., 45 discs with 7 per disc). This handles all existing lettered theme numbers. If, in the future, it does not, NPACK could be increased and then more themes would be written on a single disc.

PROGRAM PROFILE

Purpose

This program and its subroutine produce one of four possible reports of the data on the matrix tape. Depending on the option selected, the program lists in numerical order:

- countries with their frequency of mention of themes by time period,
- countries with their data organized into major and minor topics by time period,
- themes with the number of mentions by all countries during each time period,
- countries with their data organized into selected issue-variables for each time period.

The last option, country profile by issue-variable, is the only one that continues the flow. It produces an output tape which converts the matrix input into observations on issue-variables for use by program SCORES. Up to 45 issue-variables can be processed at once.

Method

When producing any of the above four reports, the program reads the main problem card and then all selection cards in the following order. First, the country range selection cards, if any, are read and NACON(country number, 3) is set to 1 if the country is to be included and 0 if not. If there is no country selection card, all countries receive a 1. The theme range selection cards are read and JCODE(theme number) is set to 1 if the theme is selected and 0 if not. The same procedure as with country selection cards is then followed for the major topic selection cards and issue-variable selection cards, if they exist, and NTOPIC. But a country profile by issue-variable cannot have been requested when topic selection cards exist, and vice versa. Then the final control card, titles of time periods, is read, storing only those titles used in this job.

The dictionary files are read next, first the country dictionary and then the theme dictionary. If major topics are being selected, this dictionary is read, the titles are stored in NAMEM, and the themes within selected topics are stored on disc units. The same procedure is followed for reading the issue-variable dictionary when issue-variables are being selected and a country profile by issue-variable has been requested.

At this point, the type of profile requested will determine the remaining logic to follow. If the selection is:

1. A country profile with theme frequency, all time period data on the matrix tape for a given country is buffered into NFREQ(theme number, time period). If this country has been selected as one to process, the themes are taken one at a time in numerical order.
If a theme is one that was selected and this country has data on it, this theme is listed with this country’s frequency of mentions in each of the selected time periods. Once all themes have been processed, the next country’s data is buffered in.

(2) A country profile by major/minor topic, all existing time period data for a given country is buffered into NFREQ(theme number, time period). If this country has been selected as one to process, the major topics are processed one at a time. For each selected major topic, minor topic themes are read off the disc. If this country has data on any of these themes, the theme is listed with the frequency of mention in each of the selected time periods. Once all minor topics from selected major topics have been processed in this manner, the next country’s data is buffered in.

(3) A theme profile with total number of mentions, all data from the tape (for selected countries) is buffered into NFREQ(theme number, time period) and cumulated. The selected themes are listed in numerical order with number of mentions across all countries in the selected time periods.

(4) A country profile by issue-variable, all time period data for a given country is buffered into NFREQ(theme number, time period). If the country has been selected, the issue-variables are taken one at a time. (A maximum of 45 variables can be processed.) For each selected issue-variable, themes are read from the disc. If the country has data on these themes, they are listed with the frequency of mention in each of the selected time periods. Simultaneously, each mention of a theme within a selected issue-variable is buffered out to the output tape. (See Structure of Issue-Variable Data Output Tape below.) Once all selected issue-variables have been processed, the next country’s data is buffered in.

All four types of profile call subroutine HEADER, which prints the classification on the bottom of each retrieval output page and a continuation heading on the top of the next page.

Structure of Issue-Variable Data Output Tape

This binary output tape is created whenever a country profile by issue-variable is requested. This tape is necessary to continue the flow through the remaining programs. It contains all the data listed in the country profile printout, but each mention of a theme is written on a separate record. It is organized by country and within country by issue-variable. Within an issue-variable the observations on themes are listed in the order in which they appear in the variable, with the first time period’s data on a given theme appearing before the second, etc. A record has the following field interpretations:

1) country number
2) issue-variable number
3) theme number
4) rank of this theme in this issue-variable
5) time period of this observation.
Dimensioned Variables

There are 15 dimensioned variables in this program:

(1) NACON is dimensioned 160 by 3, with one row for each country. The first two columns contain the country name and the third serves as a flag for selecting countries. If it is 1, the country is processed; if it is 0, the country is skipped.

(2) JCODE, dimensioned 1800, contains theme number flags. If JCODE(N) is 1, theme number N exists and is included in the analyses. If JCODE(N) is 0, either it does not exist or it is excluded from the analysis.

(3) NTOPIC, dimensioned 70, contains flags for either selected topics or selected issue-variables, depending on the type of profile requested. If NTOPIC(N) is 1, topic or variable N is included; if 0, it is excluded from the analysis.

(4) MT, 6 fields long, is the temporary storage of the theme title being processed prior to its being stored in NAME.

(5) NAME, dimensioned 1800 by 6, is a matrix of theme titles. NAME(N, 1-6) contain the title for theme number N.

(6) NAMEM, dimensioned 170 by 5, is a matrix of titles of either topics or issue-variables, depending on the type of profile requested. If it contains topic titles, they appear in the order they are read, i.e., major topic 1 followed by its various minor topics, then major topic 2, etc. If it contains issue-variable titles, they appear in numerical order. In either case, the first four columns are the title and the fifth is the number of minor topics in the major topic or themes in a minor topic or variable.

(7) KTHEME, a matrix 170 by 2, is the temporary storage of theme numbers and their ranks in the issue-variable being processed. In each case, the rank fills the first column and the theme number the second.

(8) KNT, dimensioned 17, contains a counter that locates the beginning of major topics in the matrix NAMEM. If KNT(3) = 10, the major topic 3 title appears in the 10th row of NAMEM followed by its minor topic titles.

(9) NCLASS is a two field array of the classification to be written at the top and bottom of every page of the printout.

(10) NFREQ is the working matrix of frequency of mention of a theme number in a given time period. It is dimensioned 1800 by 4 with a row for each theme and a column for each of 4 possible time periods. For country profiles, each cell contains the frequency for the country being processed. For a theme profile, it contains the cumulative frequency for all countries.

(11) NTIME, dimensioned 4, contains flags for the time periods selected. Originally, it is read as a series of 1's and 0's so that NTIME(N) = 1 when the Nth time period is selected. During most of the program, NTIME(N) = J, which means that the Nth time period being processed is the Jth time period on the input tape.
(12) FLAG, dimensioned 20, contains a 0 or 1 flag for each minor topic of the major topic being processed. If FLAG(N) is 0, minor topic N's title has not been written on the printout; a 1 means that it has been.

(13) NMAJOR, dimensioned 90, contains the temporary storage of the theme numbers within the minor topic being processed.

(14) NAMET, dimensioned 4, is an array of time period titles for all the time periods on the input tape. After they have been read, the titles are consolidated so that NAMET contains only the titles of selected time periods and they appear in the first available cell; i.e., NAMET(N) contains the title of the Nth time period that has been selected.

(15) MCOUNT, dimensioned 1800, is the temporary storage of frequency of mentions by a country in a time period. It is used when a theme profile is produced. This array is later cumulated in NFREQ.

Operational Effects of System Changes

Program PROFILE depends upon the matrix tape and the first four files of the dictionary tape. Assuming that their structure and format remain the same, the following changes to the dictionary files can be handled by changing these variables:

If the number of countries exceeds 149, NCOUN must be increased. If it exceeds 160, NACON must be redimensioned.

If the maximum theme number exceeds 1599, NMAX must be set equal to the new maximum number. If this new maximum should exceed 1800, JCODE, NAME, NFREQ, and MCOUNT must be redimensioned.

If the number of major topics exceeds 17, NMAJ must be changed and KNT must be redimensioned. If it exceeds 70, NTOPIC must be increased.

If the total number of major and minor topics ever exceeds 170, NAMEM must be increased.

If the number of minor topics in a major topic ever exceeds 90, NMAJOR must be increased.

If there are more than 20 minor topics in a major topic, FLAG must be redimensioned.

If the number of issue-variables exceeds 70, NVAR must be increased and NTOPIC redimensioned. If it should exceed 170, NAMEM must be redimensioned.

If the number of themes in an issue-variable ever exceeds 170, KTHEME must be redimensioned.
Apart from these changes to the dictionary files, the matrix tape could in the future contain more than 4 time periods. If this occurs, NFREQ, NTIME, and NAMET must be increased.

Finally, if it becomes desirable to process more than 45 issue-variables at once, the logic of this program will have to be changed. Currently, each issue-variable is assigned to a separate disc and only 45 discs are available.

PROGRAM SCORES

Purpose

The primary purpose of this program is to calculate national scores (weighted averages of the remarks a state has made) for selected issue-variables. It allows the user to change any data on the issue-variable tape and to select the time periods and their weights for a specific analysis. Program SCORES must be run for each special analysis of up to 45 issue-variables.

The secondary purpose is to produce a tape of observation in a format that can be used by the BIMED34 regression package and to produce a tape of national scores for input into the MBLOC and VMODEL programs.

Method

The main problem card is read followed by the variable selection card that selects up to 45 issue-variables on which national scores are to be calculated (these issue-variables must exist on the issue-variable input tape). Then the time period weights are read. These operate for all issue-variables in this run. (See WEIGHT under dimensioned variables.) Finally, the themes that appear in more than one issue-variable being selected are read into MUSE. After these control cards are read, the dictionary files are read. The country names are read into NACON, the issue-variable titles into NAME, and the independent variables into NBLOC. Finally, the changes to the input data are read and NACON(N, 3) is flagged with a 1 whenever there is a change to country N's data.

The observations are buffered in one at a time from the input tape. If the observation is on an issue-variable being processed, the program first determines whether it is a potential change. If it is, the list of changes is searched and the observation corrected in the manner specified. The way in which the observation is handled depends upon the weight of its time period if it is not a change and the frequency of mention if it is a change. By whichever method used, the observation is cumulated in VALUE, SIZE, MEAN, and SUM. If it is not a change and it refers to a multiply used theme, the observation may also be cumulated in NDOBL.

After all observations have been read off the input tape, any remaining changes are handled. The only changes that would remain are observations for countries that never addressed the issue-variables on the input tape. These are handled in the same manner as other changes.
The national score is then calculated for each country on each issue-variable. Simultaneously the mean and standard deviation are calculated for each issue-variable. A BCD regression tape and a binary national scores tape are written if they have been requested on the main problem card. Finally, the national scores are printed by country and/or issue-variable depending upon the user's request.

**Structure of the Output Tapes**

Two tapes are produced by this program - a BCD regression tape and a binary national scores tape. The regression tape is written in a format acceptable to BIMED34. Seventy files are written, one for each variable; but as a restriction in program SCORES only 45 variables could have data. Each file contains a different number of records; the number depends upon the number of countries with national scores for this issue-variable. The records are organized by country number. For each country with data, a record containing 36 entries is written. The first entry is its national score, the second through 35th are its discrete independent variables (see the users guide for a description of the 6th file of the dictionary, particularly its first 34 entries), and the 36th entry is the number of remarks by the country used to calculate its national score. This tape is written in the format F6:2,34F3.1, F5.1.

The national scores tape has two files. The first file consists of the national scores of all countries on all the issue-variables followed by the frequencies of mention. The issue-variables appear in numerical order with two records each. The first record contains the national scores of all countries; the second, the frequencies. The second file consists of one record which contains the number of times each country has mentioned a multiply used theme. The countries' frequencies on the first theme appear before the frequencies on the second, etc.

**Dimensioned Variables**

There are 16 dimensioned variables in program SCORES:

(1) **VALUE** is a matrix dimensioned 149 by 45. A row represents a country and a column one of the issue-variables being processed. It contains the national score of a country on an issue-variable. As the observations are being cumulated, VALUE(N,M) contains the sum of the ranks of themes country N has mentioned on the Mth issue-variable being processed. This is later divided by the number of observations by this country (SIZE) to obtain a national score.

(2) **SIZE** is a matrix dimensioned 149 by 45. A row is a country and a column is one of the issue-variables being processed. It contains the number of observations a country has made on each of the issue-variables.
(3) MEAN, dimensioned 45, contains the mean of each of the 45 possible issue-variables. As the observations are being read, MEAN(M) contains the sum of all ranks of themes mentioned by countries on the Mth issue-variable being processed. This is later divided by the total number of observations (SUM) to obtain a mean.

(4) STD, dimensioned 45, is used to calculate the standard deviation of each of the 45 possible issue-variables. As the observations are read, STD(M) contains the squared sum of the ranks on the Mth issue-variable being processed. This is later used to calculate the standard deviation.

(5) NVAR, dimensioned 70, contains a flag for selecting up to 45 of the 70 issue-variables. If NVAR(M) is 1, variable M is selected; if it is 0, M is not selected.

(6) NAME, dimensioned 70 by 4, is a matrix of issue-variable titles. For each issue-variable, a four field title is stored.

(7) NBLOC is dimensioned 149 by 35. A row represents a country and a column represents one of the discrete independent variables. For a discussion of these variables, see appendix B of the users guide, and particularly note the first 35 variables in file 6.

(8) NCHANGE, dimensioned 300 by 4, is a matrix of changes to the data. It allows up to 300 changes to be read in. Each change has four entries: (1) country number, (2) issue-variable number, (3) rank within issue-variable, and (4) number of mentions. After a change has been processed, the fourth field is set to -9 as a flag that it has been computed.

(9) NACON, dimensioned 149 by 3, is a matrix of country names and country change flags. For each country, the first two fields contain its name and the third field is a 1 if at least one change will be made to the country's data and a 0 otherwise.

(10) WEIGHT, dimensioned 4, represents the weight to be assigned the four possible time periods on the input tape. If WEIGHT(J) is 0, all data from time period J is excluded from this analysis. If WEIGHT(J) is 1, all data from time period J is included. If WEIGHT(J) is 2 (e.g.), all data will be included, but it will be entered twice (e.g.). Any positive integer or zero weight can be assigned.

(11) SUM, dimensioned 45, represents the total number of observations on each of the 45 possible issue-variables being processed.

(12) MUSE, dimensioned 10 by 2, contains up to 10 multiply used themes. For each theme, the number is followed by one of the issue-variables being processed that this theme is in.

(13) NDOBL is dimensioned 149 by 10. A row represents a country and a column represents one of the 10 possible multiply used themes. The matrix contains the number of times a country has said one of these themes.

(14) JCODE, dimensioned 1600, serves two purposes. First, it is temporary storage of the themes within issue-variables and their ranks. Second, it flags the themes that are used more than once. JCODE(M) is 1 when theme M is a multiply used theme and 0 otherwise.

-74-
MCOUNT, dimensioned 5, is the temporary storage of the five components of an
observation that is buffered in from the input tape. The five entries are (1) country number,
(2) issue-variable number, (3) theme number, (4) rank of the theme within this issue-variable,
and (5) time period in which this remark was made (1-4).

BLANK, dimensioned 149, contains a zero in each field. It is used to fill the national
scores output tape with a zero for each issue-variable not processed.

Operational Effects of System Changes

This program depends upon the issue-variable tape (produced by PROFILE) and four
dictionary files - country, theme, issue-variable and independent variable files. Assuming
that their structure and format remain the same, the following changes to the dictionary
files can be handled by changing these variables:

If the number of countries exceeds 149, VALUE, SIZE, NBLOC, NACON,
and NDOBL must be redimensioned.

If the number of issue-variables exceeds 70, LMAX and KVAR must be
increased and NVAR and NAME must be redimensioned.

If the maximum theme number exceeds 1600, MAXTHM will have to be
increased and JCODE redimensioned.

If the number of independent variables exceeds 34 or others are to be used,
MAXB may have to be increased, NBLOC redimensioned, and formats 6 and 38 changed.

Apart from dictionary file changes, it is possible that in the future the input tape will
contain more than 4 time periods. If this occurs, MTIME will have to be increased,
WEIGHT redimensioned, and format 1 perhaps changed. An increase in time periods
means that programs MATRIX and PROFILE would have been expanded as well.

In addition, there are internal changes that do not affect other programs. If more
than 300 changes are required, NCHANGE can be redimensioned without affecting other
programs. If the number of multiply used themes exceeds 10, MUSE and NDOBL will
have to be redimensioned and program MAXPAC changed slightly.

PROGRAM BIMED34

BIMED34 is a standard statistical program available at CNA which estimates a multiple linear regression equation in a stepwise manner. BIMED34 was selected because it provides numerous features that are necessary for an LOS issue analysis. It allows regression problems on different data bases to be stacked back to back; it can compute a weighted regression; it can force the regression equation through the origin; and it produces machine-readable output.

The version of BIMED34 used by the LOS project differs from the CNA version in the way in which the independent variable numbers are punched on the output cards. The CNA version assigns variable numbers 1-N to its N output cards. The LOS version assigns the original variable number. That is, if independent variable 3 is in the equation, the LOS version will punch a 3 as its variable number, whereas the CNA version will punch a K when variable 3 is the Kth variable in the equation.

Since MBLOC and VMODEL will read these output cards and match the variable numbers punched with the corresponding independent variable data, the LOS version is essential to normal operations of these two programs. Any modifications to BIMED34 should be made to the LOS version.

If a listing of BIMED34 is requested, a CNA systems programmer should be consulted. The program is on a load and go tape.

PROGRAM MBLOC

Purpose

The functions of this program are to calculate regression estimates and preferred positions for all countries, to calculate mean preferred positions and standard deviations for the 34 blocs or groups, and to produce a series of summary reports of group positions on selected issue-variables. As many as 45 variables can be processed in a single run.

Method

After the main problem and issue-variable selection cards are read, the deck of beta coefficients is read and placed in BETA. Then the names of blocs are read. Finally, the country and independent variable files are read off the dictionary tape.

---

For a selected issue-variable, the national scores and frequencies of mention for all countries are buffered in from the input tape and placed in MATRIX(country no., 1 and 4). Then a regression estimate and a preferred position are calculated for each country and placed in MATRIX(country no., 2 and 3).

For each bloc, the data from all its members is cumulated in MBLOK and a mean and a standard deviation are calculated from their national scores alone, estimates alone and preferred positions. These statistics are then printed in a summary table in which the blocs appear in increasing order by mean preferred position. At this point in the program, a more detailed report by bloc can be produced; if requested, the members of each bloc are listed in order of their preferred positions. Then the program returns to process another selected issue-variable.

### Dimensioned Variables

There are eight dimensioned variables in program MBLOC:

1. **KVAR**, an array dimensioned 45, contains the numbers of the issue-variables being processed. The variables are listed in numerical order.

2. **BETA** is a matrix dimensioned 45 by 34. Each row represents an issue-variable being processed; each column represents a discrete independent variable (or bloc affiliation). The matrix contains the beta coefficient from BIMED34 for the issue-variable and bloc.

3. **BNAME**, an array dimensioned 34, contains a one field name for each of the independent variables or blocs.

4. **NACON**, dimensioned 149 by 2, is a matrix of country names. Each name is assigned two fields.

5. **BLOC** is a matrix 149 by 34. A row represents a country and a column an independent variable or bloc. This matrix contains a 1 if the country is a member of the bloc and a 0 otherwise.

6. **MATRIX**, dimensioned 149 by 4, contains all the data on the issue-variable being processed. There are four entries for each country: (1) national score, (2) regression estimate, (3) preferred position, and (4) frequency of mentions.

7. **MBLOK**, a three dimensional matrix 34 by 4 by 2, contains all the aggregate statistics of the 34 blocs on the issue-variable being processed. For each bloc J, MBLOK is as follows:

   - \((J, 1, 1)\) = mean of the national scores of its members
   - \((J, 1, 2)\) = standard deviation of the national scores of its members
   - \((J, 2, 1)\) = mean of the regression estimates of its members
   - \((J, 2, 2)\) = standard deviation of the regression estimates of its members
   - \((J, 3, 1)\) = mean of the preferred positions of its members
(J, 3, 2) = standard deviation of the preferred positions of its members  
(J, 4, 1) = number of members with national scores  
(J, 4, 2) = total number of members.

(8) NORDER, dimensioned 149, serves as a flag when blocs or countries are reordered.  
If NORDER(K) is 1, bloc or country K has been written on the printout. If it is 0, bloc or  
country K will be printed whenever it becomes the next in the order list.

Operational Effects of System Changes

This program depends upon the national scores tape from program SCORES and the  
country and independent variable files of the dictionary tape. Assuming that their  
structure and format remain the same, the following modifications can be handled in this  
program by changing these variables:

If the number of countries exceeds 149, BLOC, MBLOK, MATRIX, NACON,  
and NORDER will have to be redimensioned.

If the number of discrete independent variables exceeds 34, BLOC, MBLOK,  
BETA, and BNAME will have to be redimensioned and NB increased. Furthermore,  
format 11, which reads independent variables off the dictionary tape, will have to be  
changed. (Note: If format is changed, SCORES and BIMED34 must be changed  
accordingly.)

It is possible that in the future the regression analysis may involve continuous as well  
as discrete variables. If so, MBLOC must be changed substantially followed by corresponding  
changes in SCORES, BIMED34, and VMODEL.

FORECASTING OUTCOMES

PROGRAM VMODEL

Purpose

This program forecasts outcomes on selected individual issue-variables. For each issue-variable, medians, best and worst cases, and the preferred choice within a pair of alternatives can be produced. In addition, the program produces a tape that is used by program MAXPAC to analyze packages of issues.

Method

After the main problem and issue-variable selection cards are read, the country and independent variable files are read off the dictionary tape. For each of the selected issue-variables, the beta coefficient deck and input records containing the national scores and frequencies of mention for all countries are read. These enable the program to calculate a regression estimate, a residual (the difference between a country’s national score, if it exists, and its estimate), and a preferred position for each country. If the estimate exceeds the bounds of the issue-variable, the estimate is set equal to the upper or lower bound. The output table contains all of these statistics and medians of the national scores, estimates and preferred positions. The program returns to process the next selected issue-variable. The program then turns to best and worst cases. For each case, the program calculates the number of countries with preferred positions within the range specified. It lists the countries with their preferred positions and a tally of the number of states.

Then the matrix ISSUE, which contains the preferred position and frequency of mentions for each country on each of the selected issue-variables, is standardized by subtracting the mean of the issue-variable from each of the preferred positions and dividing this difference by the standard deviation of the issue-variable. This is printed and then written on the output tape in binary. From this point on in the program, ISSUE represents the normalized or standardized preferred positions.

The last section of this program calculates the outcome on an issue when countries are forced to choose between two alternatives. For each such forecast, the two alternatives are read and then standardized in the manner described above. A utility equation is used to determine which of the two alternatives each country prefers. After utility scores have been calculated for all countries, a summary outcome table is produced and, if requested, a list of countries with their utility scores is printed. This list of countries is ordered by intensity of preference. The program returns to process another pair of alternatives on this or another issue-variable.

For a discussion of the formulas used throughout this program and the way in which the results are interpreted, the programmer should refer to the users guide.
Structure of the Output Tape

The output tape from this program is used as input to MAXPAC, which analyzes packages of issues, and VALID, which compares the forecasts with 'outside' forecasts. It is written in binary and contains four kinds of records. The first record, 70 fields filled with 0's or counters, contains a list of the issue-variables selected for this run. The second record contains the number of issue-variables and countries processed in this program that will appear on this output tape. The third record contains a mean and a standard deviation for each of the selected issue-variables. The fourth series of records contains the matrix ISSUE (which is seen under Dimensioned Variables).

Dimensioned Variables

There are 12 dimensioned variables in program VMODEL:

(1) BLOC, a matrix dimensioned 149 by 35, contains the country number followed by the 34 discrete independent variables for each of the 149 countries. For a definition of these 34 variables, see the discussion of dictionary file 6 in the users guide.

(2) BETA, an array dimensioned 35, contains the beta coefficients for the issue-variable being processed.

(3) MEDIAN, an array dimensioned 3, contains the median national score, median estimate and median preferred position for the issue-variable being processed.

(4) NOBS, an array dimensioned 45, contains the number of countries with national scores on each of the 45 possible issue-variables that can be processed in a single run.

(5) KVAR has 70 fields, one for each existing issue-variable number. It contains flags for selecting issue-variables for this run. Originally it is read as a series of 0's and 1's, where a 1 means that the issue-variable is selected and a 0 that it is not. However, the program converts all the 1's to counters so that KVAR(N) = J when issue-variable N is the Jth one selected for processing.

(6) NACON, dimensioned 149 by 2, is a matrix of country names. Each country is assigned a two field name from the country dictionary.

(7) MEAN, dimensioned 45, is used in the calculation and ultimately the storage of the means of the 45 possible issue-variables.

(8) STD, dimensioned 45, is used in the calculation and ultimately the storage of the standard deviations of the 45 possible issue-variables.

(9) VOTE, an array dimensioned 3, contains the number of states that prefer alternative 1, that are indifferent, and that prefer alternative 2.

(10) CURMIN, an array dimensioned 3, is used in the calculation of the median national score, median estimate and median preferred position. In each case, CURMIN represents the current minimum score found in the list.
(11) SCORE, an array dimensioned 149, contains the scores for all 149 countries that were stored on the disc. The scores could be national scores, estimates, or preferred positions, depending upon the disc from which they were taken.

(12) ISSUE, a three dimensional matrix 149 by 2 by 45, contains the standardized preferred position and frequency of mentions of each country on each of the 45 possible issue-variables being processed. These two statistics appear as a set for all countries on one issue-variable at a time.

Operational Effects of System Changes

Program VMODEL depends upon the national scores tape and the country and independent variable files of the dictionary tape. Assuming that their structure and format remain the same, the following minor changes to the dictionary files can be handled by changing the following variables:

If the number of countries exceeds 149, ISSUE, BLOC, NACON, and SCORE will have to be redimensioned.

If the number of independent variables used in the regression analysis exceeds 34 or the variables in the regression are not the 34 discrete independent variables listed in the 2nd through the 35th position in the sixth file of the dictionary, format 4 must be changed. Furthermore, if more than 34 variables were processed through BIMED34, MAXB must be set equal to the number of variables plus 1 and BLOC and BETA must also be dimensioned one more than the number of variables processed.

If the number of issue-variables ever exceeds 70, MAXV must be increased and KVAR redimensioned.

Apart from these changes to the dictionary files, it may become desirable in the future to process more than 45 issue-variables in a single run. If this is to be done, ISSUE, NOBS, MEAN, and STD would have to be redimensioned and MAXI increased. The programmer is cautioned that expanding the number of issue-variables would serve little purpose without a corresponding change in programs PROFILE, SCORES, MBLOC, and MAXPAC.

PROGRAM MAXPAC

Purpose

This program and its subroutine perform two functions. First, they forecast outcomes on packages of issues, by providing a tally of the number of countries preferring each of the two input packages and a measure of how intense states' preferences are. Second, they produce a series of packages that are more popular than the input package, to the voting body as a whole and to the United States in particular.

Method

After the main problem card is read, the normalized tape from VMODEL is buffered in. If unclassified frequencies of mention are to be used, the national scores tape from SCORES is buffered in, and if multiply used themes are involved, the second file is buffered in from the national scores tape. Then the country dictionary is read and the scores and frequencies of all countries on the issue-variables being processed are printed.

Then, a set of packages at a time, the program reads the issue-variables it includes and the positions of both packages on these issues. These positions are normalized and subroutine PREFER is called.

After the epsilons have been read, the program turns to its second function, producing more popular packages than the one input. It processes one such package at a time, normalizing it and then calculating the normalized direction cosine of each country on each issue in the package. After a composite direction cosine has been calculated for each issue, the program generates a series of packages that move away from the input package in the direction calculated. The series is produced by moving in that direction at different distances (epsilons). For each epsilon tested, subroutine PREFER is called.

Subroutine PREFER calculates a utility score for each state for the two packages being compared. The sign of the score determines which package the state prefers and the magnitude determines the intensity of its choice. The results are printed, if requested, so are the utility scores (in decreasing order).

Dimensioned Variables

There are 15 dimensioned variables in this program and its subroutine:

(1) KVAR has 70 fields, one for each existing issue-variable number. Each contains a flag for the issue-variables on the input tape; i.e., KVAR(N) = J when issue-variable N is the Jth one on the input tape and is 0 when N is not on the tape.
(2) MEAN, dimensioned 45, contains the means of the 45 possible issue-variables on the input tape.

(3) STD, dimensioned 45, contains the standard deviations of the 45 possible issue-variables on the input tape.

(4) ISSUE, a three dimensional matrix 149 by 2 by 45, stores the standardized preferred position and frequency of mention of each country on each of the 45 possible issue-variables.

(5) NACON, dimensioned 149 by 2, serves two functions. It is temporary storage of the unclassified national score and frequency of mention for each country on the variable being processed. During most of the program, it contains a two field name for each country.

(6) DOUBL is dimensioned 149 by 10. A row represents a country and a column represents one of the 10 possible multiply used themes. The matrix contains the number of times a particular country has said one of these themes.

(7) WEIGHT, dimensioned 10, contains the proportion of mentions of each of the multiply used themes that is to be assigned to the issue-variable being processed.

(8) PACK, dimensioned 45 by 2, contains the positions on the 45 possible issue-variables for the two packages being processed.

(9) PVAR, dimensioned 45, stores the numbers for the 45 possible issue-variables in the packages being processed.

(10) VOTE, an array dimensioned 4, contains the number of states that (1) strongly prefer package 1, (2) marginally prefer package 1, (3) marginally prefer package 2, and (4) strongly prefer package 2.

(11) SCORE, a matrix dimensioned 149 by 3, contains the utility score for package 1, that for package 2, and the difference between the two, for each country.

(12) THETA, dimensioned 45, contains the composite direction cosines for the 45 possible issue-variables in the package being maximized.

(13) Z, a matrix 45 by 149, stores the direction cosine for each country on each of the 45 possible issue-variables in the package being maximized.

(14) ESPLN is an array containing up to 16 user specified intensity weights which in combination with THETA produce various maximized packages.

(15) NUM, dimensioned 45, stores the direction cosines for the 45 possible issue-variables in the package being maximized for the United States.
Operational Effects of System Changes

This program is dependent upon the output tape from VMODEL, the country dictionary, and possibly the national scores tape from SCORES. If their structure and format remain the same, the following modifications to them can be handled by changing the following variables:

If the number of countries exceeds 149, ISSUE, NACON, DOUBL, SCORE, and Z will have to be redimensioned.

If the number of existing issue-variables ever exceeds 70, KVAR, MEAN, and STD will have to be redimensioned and MAXV will also have to be increased.

If the number of issue-variables being processed through VMODEL exceeds 45, ISSUE, PACK, THETA, NUM, Z, and PVAR will have to be redimensioned.

If more than 10 multiply used themes are processed through SCORES, DOUBL and WEIGHT will have to be redimensioned.

If more than 16 intensity weights are necessary, ESPLN will have to be increased.

PROGRAM VALID

Purpose

This program calculates a crude measure of the degree of similarity between CNA's forecasts and 'outside' forecasts. Comparisons can be performed on 45 issue-variables in a single run.

Method

After the normalized tape (output from VMODEL) has been buffered in, the 'outside' forecasts are read and normalized. For each issue being processed, states' preferred positions are compared with the 'outside' forecast and the number of countries with preferred positions less than the forecast is calculated. This is converted to a percentage and a crude similarity measure calculated through the following formula:

\[
\log \left( \frac{\text{percent}}{1-\text{percent}} \right)
\]

This measure is printed and the next issue processed.

Dimensioned Variables

This program contains five dimensioned variables:

1. MEAN, dimensioned 45, contains the means of the 45 possible issue-variables on the input tape.

2. STD, dimensioned 45, contains the standard deviations of the 45 possible issue-variables on the input tape.

3. ISSUE, a three dimensional matrix 149 by 2 by 45, contains the preferred position and frequency of mention for each country on each of the 45 possible issue-variables.

4. KVAR has 70 fields, one for each existing issue-variable number. It contains counters for the issue-variables included on the input tape; i.e., KVAR(N) = J when issue-variable N is the Jth issue-variable listed on the tape and is 0 if N is not on the tape.

5. PVAR, dimensioned 45, contains the 'outside' forecast for each of the 45 possible issue-variables on the input tape.
Operational Effects of System Changes

This program depends entirely upon the structure of the binary tape produced by VMODEL. If any changes are made to it, the four read statements must be changed. If these changes increase the number of countries, processed issue-variables, or existing issue-variables, the following dimensions must be changed:

If the number of countries exceeds 149, ISSUE will have to be enlarged.

If the number of issue-variables being processed through VMODEL exceeds 45, MEAN, STD, ISSUE, and PVAR will have to be redimensioned.

If the number of existing issue-variables exceeds 70, MAXV will have to be increased and KVAR redimensioned.

APPENDIX A

PROGRAMS AFFECTED BY
CHANGES TO DICTIONARY AND DATA TAPES
APPENDIX A

PROGRAMS AFFECTED BY CHANGES TO DICTIONARY AND DATA TAPES

This appendix provides the programmer with a cross-reference guide that summarizes the effect of changes to the dictionary and data tapes on all programs in the system. It should be used whenever there is a change to the structure or format of these tapes or whenever the dictionary tape is expanded.

Table A-1 identifies the dictionary files that are used by each of the programs. When changes are made to any of these files, the programmer should refer to the section "Operational Effects of System Changes" for each of the programs checked.

Table A-2 identifies the data tapes that are used or created by each of the programs. When changes are made to any of these tapes, the programmer should refer to the sections "Method" and "Dimensioned Variables" for each of the programs checked.

In addition there are five possible areas of expansion that affect more than one program in the system:

- If the number of time periods included in an analysis ever exceeds 4, programs MATRIX, PROFILE, PTHEME, and SCORES will have to be changed.
- If the number of documents from which raw data is extracted exceeds 999, programs MATRIX and LETTER will have to be changed.
- If the structure of an update card changes, programs CHECK and UPDATE will have to be changed.
- If more than 45 issue-variables need to be processed in a single run, programs MAXPAC, MBLOC, PROFLEx, SCORES, and VMODEL will have to be changed.
- If two or more variables to which more than 10 multiply used themes have been assigned in common need to be processed in a single run, programs SCORES and MAXPAC will have to be changed.
