### Abstract

A comparative performance evaluation of the UH-60A helicopter in the normal utility configuration and with the External Stores Support System (ESSS) fixed provision fairings configuration (ESSS wings removed) was conducted at Edwards AFB, California. A total of eight flights were flown between 30 August and 22 September 1983 for a total of 10.0 productive hours. The increase in equivalent flat plate area due to installation of the ESSS fixed provision fairings was 2.5 feet². With the ESSS fixed provision fairings installed at the out-of-ground
Perfect hover guarantee conditions of .95 percent intermediate rated power at 4700 feet pressure altitude on a 35°C day, the hover capability was reduced 466 pounds. Incorporating the weight of the airframe fixed provisions will reduce the payload by 596.6 pounds or the equivalent of eliminating two combat equipped troops and 117 pounds of fuel or equipment.

SEE DISTRIBUTION

1. The purpose of this letter is to establish the Directorate for Engineering position on the subject report. The subject evaluation was conducted to determine the increased drag due to the External Store Support System (ESSS) fixed provision fairings and hover performance with the ESSS fixed provision fairings installed. In August 1977, USAAEFA conducted an Airworthiness and Flight Characteristics (A&FC) evaluation of the normal utility configured UH-60A using aircraft, S/N 77-22716. Following development of the ESSS, AEFA conducted an A&FC evaluation of the ESSS configured UH-60A using aircraft S/N 77-22714, which included a comparison of the full ESSS and ESSS fixed provision hover performance. When the results of the hover performance tests of the UH-60A A&FC and ESSS A&FC were compared, a download penalty due to the ESSS fixed provisions of 5 percent of gross weight out of ground effect (HOGE) and 7.4 percent of gross weight in ground effect (HIGE) was shown. This appeared to be excessive and it was decided to conduct back to back tests using the UH-60A A&FC aircraft (S/N 77-22716). This back to back test (ESSS fixed provisions on vs ESSS fixed provisions off) is reported here.

2. The back-to-back test results reported herein show penalties of 0.5 percent of design gross weight HIGE, 2.7 percent of design gross weight HOGE and 2.5 ft$^2$ equivalent flat plate drag area in forward flight. The accuracy of these results is supported by AEFA's ability to exactly reproduce, in these tests, the UH-60A A&FC HOGE tests conducted on the same helicopter six years earlier. A review of the back-to-back tests reported here shows the test conditions were comparable (density altitude, temperature and rotor tip speed) for both configurations, ESSS fixed provisions on and off. There is very little scatter in the data, but there is a distinct difference between the data of the two configurations. However, these data differ significantly with the penalties predicted by the contractor's analysis of 0 percent design gross weight HIGE and HOGE and 1 ft$^2$ equivalent flat plate drag area in forward flight.
3. This Directorate agrees with the report conclusions and recommendations, except that the UH-60A operator's manual should not be updated until completion of the A&FC evaluation of the sixth year production UH-60A (AEFA Project No. 83-25). The A&FC of the sixth year UH-60A will strengthen the data base of performance measurements with ESSS fixed provisions on and off and clear up some anomalies in flight performance data (non-dimensional hover performance variation with density altitude and inflection points on advancing tip Mach number trends).

FOR THE COMMANDER:

RONALD E. GORMONT
Acting Director of Engineering

INTRODUCTION

BACKGROUND

1. The US Army has stated a requirement for self deployment capability for the UH-60A helicopter. To satisfy this requirement, Sikorsky Aircraft (SA), Division of United Technologies, has designed the External Stores Support System (ESSS), which consists of airframe fixed provisions and an external stores subsystem. The external stores subsystem can be removed and the UH-60A can be flown in this configuration with the fixed provision fairings installed.

2. In August 1983 the US Army Aviation Engineering Flight Activity (USAEEFA) was tasked by the US Army Aviation Systems Command (ref 1, app A) to evaluate aircraft performance with the fixed provision fairings.

TEST OBJECTIVES

3. The objectives of this test were to determine the increased drag due to the fixed provision fairings and to obtain hover performance data with fixed provision fairings installed.

DESCRIPTION

4. The test helicopter was a UH-60A, US Army S/N 77-22716, the third production UH-60A. Primary mission gross weight (ref 2, app A) is 14,260 pounds and the present maximum alternate gross weight is 20,250 pounds. The UH-60A is powered by two General Electric T700-GE-700 turboshaft engines, each rated at 1553 shaft horsepower (shp) installed at sea level, standard-day static conditions. Installed dual-engine power was transmission limited to 2828 shp. In the ESSS configuration, the UH-60A is equipped with integral airframe fixed provisions and a removable external stores subsystem. With the external stores subsystem (wings) removed, a set of aerodynamic fairings (fixed provision fairings) are installed. The fixed provision fairings used during this evaluation were handmade and had significantly smoother surface texture and slight shape differences when compared to the 6th year production UH-60A fairings (photos 4 and 5, app B). A more detailed description of the UH-60A and the fixed provision fairings is included in appendix B.
5. The flight testing was performed at Edwards Air Force Base, California (2302 feet). A total of eight flights were conducted between 30 August and 22 September 1983 for a total of 15.6 flight test hours of which 10.0 were productive flight hours. USAAARFA calibrated and maintained the test instrumentation and performed all required maintenance on the helicopter. Personnel from SA installed the tested fixed provision fairings. Flight restrictions and operating limitations observed during the test are contained in the operator's manual (ref 3, app A). Testing was conducted in accordance with the test plan (ref 4, app A) at the conditions shown in table 1.

NOTES:

1 Tests were conducted at a mid lateral center of gravity (0.1 inch left) in two configurations: normal utility and ESSS fixed provision fairings.
2 Aircraft gross weight plus cable tension

TEST METHODOLOGY

6. A detailed listing of the test instrumentation is contained in appendix C. Established flight test techniques and data reduction procedures were used (ref 5, app A), and are described in appendix D. The flight test data were obtained from test
Instrumentation displayed on the instrument panel and recorded on magnetic tape installed in the aircraft. Real-time telemetry monitoring of selected data parameters was used during these tests.
RESULTS AND DISCUSSION

GENERAL.

7. Limited performance flight testing was conducted on the HH-60A helicopter to determine the comparative performance differences between the normal utility configuration, as described in USAF/FA Report No. 77-17 (ref 6, app A), and the ESSS fixed provision fairings configuration. The increase in equivalent flat plate area \( (F_e) \) due to installation of the ESSS fixed provision fairings was 2.5 feet\(^2\). At the out-of-ground effect (OGF) hover guarantee conditions of 95 percent intermediate rated power (IRP) at 4700 feet pressure altitude \( (H_p) \) on a 35°C day, the hover capability was reduced 466 pounds.

HOVER PERFORMANCE

8. Hover performance tests were conducted at Edwards AFB, CA at the conditions and configurations listed in table 1. A left main wheel height of 5.3 feet was used for in-ground effect (IGE) and 100 feet for OGF. The tethered hover method was used to obtain the majority of the data with a limited amount gathered using the free flight hovering method. A cable tensiometer was used to measure total thrust less gross weight. Variations in the coefficient of thrust \( (C_T) \) were attained by varying cable tension or rotor speed. Hover test results are presented in figures 1 and 2, appendix E. Test data with the fairings installed, compared to the normal utility configuration, indicate an increase in power required of approximately 1 percent to hover at 5.3 feet and 4 percent to hover OGF. This is a comparison made during a previous test (ref 7, app A), an increase in power required of 11 percent (IGE) and 7 percent (OGE) was noted. This difference between test results for the same configuration confirms the observation reported in the previous test, that the increase in power required was too great. Since test results presented in this report agree with the Airworthiness and Flight Characteristics Evaluation OGF test results in the normal utility configuration (ref 6), and a baseline was flown for each wheel height, the previous data should be disregarded. The increase in power required, to hover with the ESSS fixed provision fairings installed as reported herein, is representative and should be incorporated in the operator's manual.

9. The standard day OGF hover ceiling at the primary mission gross weight of 16,260 pounds using IRP was 11,200 feet in the normal utility configuration as published in USAF/FA Report...
No. 27-17 (ref 8, app A). With the fairings installed there was a decrease of 850 feet in the hover ceiling. At 5000 feet \( h_p \), on a 35°C day, the maximum gross weight of 17,721 pounds for 0GF hover in the normal utility configuration decreased 522 pounds to 17,199 pounds with the ESSS fixed provision fairings installed. At the hover performance guarantee condition of 95 percent BHP at 4700 feet \( h_p \), on a 35°C day, the hover capability was reduced 466 pounds from 16,570 to 16,104 pounds. Incorporating the weight of the airframe fixed provisions (130.6 pounds, table 1, app B) still reduce the payload by 596.6 pounds (466 + 130.6 pounds) or the equivalent of eliminating two combat equipped troops and 117 pounds of fuel or equipment.

LEVEL FLIGHT PERFORMANCE

10. Level flight performance tests were conducted at the conditions listed in table 1 to determine power required and fuel flow at various airspeeds. The method used maintained the ratio of gross weight to pressure altitude ratio \((W/h)\) and referred rotor speed ratio of rotor speed to ambient temperature ratio \((S_{r}/S_{t})\) constant resulted in a constant \( C_{p} \). This was accomplished by increasing altitude as fuel was consumed and adjusting rotor speed for changes in ambient temperature. Each test was flown in ball-centered flight by reference to a calibrated lateral accelerometer. Level flight test results in the normal utility configuration are presented in figures 3 through 5, appendix F, and with the ESSS fixed provision fairings installed in figures 6 through 8. The baseline power required and inherent sideslip curves shown in these figures were derived from USAerea Final Report No. 81-16 (ref 8, app A). With the ESSS fixed provision fairings installed on the UH-60A helicopter, \( F_e \) increased 2.5 feet\(^2\) which reduces the level flight airspeed by 2 knots at maximum continuous power.
CONCLUSIONS

II. Based on this limited evaluation, installation of the ES 88 fixed provision fairings on the UH-60A helicopter resulted in the following conclusions:

a. Power required to hover was increased compared to test results of the normal utility configured UH-60A (para 8).

b. Power required to hover was decreased compared to previous test results of an ES 88 fixed provision fairings configured UH-60A (para 3).

c. Drag in level flight increased by 2.5 feet² of equivalent flat plate area (para 10).
RECOMMENDATIONS

12. The following recommendations are made:

a. The hover performance data obtained during USAAFFA Project No. 82-15, dated December 1983, should be disregarded (para 8).

b. The increase in power required with the ESSS fixed provision should be incorporated in the operator's manual (para 8).
APPENDIX A. REFERENCES

APPENDIX B. AIRCRAFT DESCRIPTION

GENERAL

1. The Sikorsky UH-60A (Black Hawk) is a twin turbine engine, single-main-rotor helicopter capable of transporting 11 combat troops plus a crew of three. It is equipped with 3 nonretractable conventional wheel-type landing gear. A movable horizontal stabilator is located on the lower portion of the tail rotor pylon. The main and tail rotors are both four-bladed with a capability of manual main rotor blade and tail pylon folding. The cross-beam tail rotor with composite blades is attached to the right side of the pylon and is canted 20 degrees upward from the horizontal. A complete description of the aircraft is contained in the operator’s manual (ref 3, app A) and the aircraft general information manual (ref 9).

EXTERNAL STORES SUPPORT SYSTEM (ESSS) FIXED PROVISION FAIRINGS

2. In the ESSS configuration, the UH-60A is equipped with integral airframe fixed provisions and a removable external stores subsystem. With the external stores subsystem removed, a set of aerodynamic fairings (fixed provision fairings) (photos 1 through 4) are installed. The fixed provision fairings used during this evaluation were handmade (fiberglass) and when compared to the 6th year production UH-60A fairings, significant surface texture and slight shape differences were noted. Photo 5 is a top view side-by-side comparison of both fixed provision fairings. Photo 5, a top view of a 6th year production UH-60A fairing, shows the rough surface texture. Table 1 is a detailed weight description of the airframe fixed provisions provided by the Aviation Systems Command.

AIRSPEED/STABILATOR MODIFICATIONS

3. The airspeed/stabilator system on the test aircraft included five modifications from the original production aircraft in an attempt to eliminate pitch oscillations during takeoff, improve pitch handling qualities, and reduce large position error during various airspeed regimes. Three changes were incorporated in the pilot-static pressure systems and two changes were electrical circuit modifications to the stabilator amplifiers in the stabilator system. Major features of this system are summarized in Table 2 and are described in detail in the Preliminary Airworthiness Evaluation of UH-60A with an Improved Airspeed System (ref 14, app A).

ENGINES

The primary power plants for the HH-60A helicopter are General Electric T700-GE-700 front drive turboshaft engines, rated at 1553 shaft horsepower (shp) at a power turbine speed 20,900 rpm (sea level, standard day installed). The engines are mounted in nacelles on either side of the main transmission. Each engine has four modules: cold section, hot section, power turbine section, and accessory section. Design features include an axial-centrifugal flow compressor, a through-flow combustor, a two-stage air-cooled high pressure gas generator turbine, a two-stage uncooled power turbine, and self-contained lubrication and electrical systems. Pertinent engine data are shown below.

APPENDIX C. INSTRUMENTATION

1. The test instrumentation was installed, calibrated and maintained by the US Army Aviation Engineering Flight Activity personnel. A test boom with a swiveling pitot-static tube and angle of attack and sideslip vanes, was installed at the nose of the aircraft. The data acquisition system utilized pulse code modulation encoding on magnetic tape onboard the aircraft, and to the ground for real time monitoring through telemetry transmission. Data was displayed or recorded as indicated below.

APPENDIX D. TEST TECHNIQUES AND DATA ANALYSIS METHODS

AIRCRAFT WEIGHT AND BALANCE

1. The aircraft was weighed in the test configuration with full oil and all fuel drained prior to the start of the program. The initial weight of the aircraft was 14,750 pounds with the longitudinal center of gravity (cg) located at fuselage station (FS) 359.5 with the cg of the empty ballast cart located at FS 301. The fuel cells and external sight gauges were calibrated on a previous evaluation. The measured fuel capacity using the gravity fueling method was 364 gallons. The fuel weight for each test flight was determined prior to engine start and after engine shutdown by using the external sight gauge to determine the fuel volume and measuring its specific gravity. Aircraft cg was controlled by a moveable ballast system which was manually positioned to maintain a constant cg while fuel was burned. The moveable ballast system was a cart (2000 pound capacity) attached to the cabin floor by rails and driven by an electric screw jack with a total longitudinal travel of 72.3 inches.

PERFORMANCE

General

2. Helicopter performance was generalized through the use of nondimensional coefficients as follows using the 1968 US Standard Atmosphere:

a. Coefficient of Power (Cp):

\[ \text{SHP (350)} \]
\[ Cp = \frac{\rho a (\text{QDR})^3}{(1)} \]

b. Coefficient of Thrust (Cf):

\[ \text{CM + CABLP TENSION} \]
\[ Cf = \frac{\rho a (\text{QDR})^2}{(2)} \]

c. Advance Ratio (u):

\[ \nu_T (1.6878) \]
\[ u = \frac{V_T}{(3)} \]
Where:

- **W**<sub>oh</sub> = Engine output shaft horsepower (total for both engines)
- **q** = Ambient air density (lb·sec<sup>2</sup>/ft<sup>4</sup>)
- **A** = Main rotor disc area = 2262 ft<sup>2</sup>
- **Ω** = Main rotor angular velocity (radians/sec)
- **R** = Main rotor radius = 26.833 ft
- **GW** = Gross weight (lb)
- **Cable Tension** = Tension of tether hover cable (lb)

\[
V_T = \text{True airspeed (kt)} = \frac{V_F}{1.6878\sqrt{\rho/\rho_0}}
\]

1.6878 = Conversion factor (ft/sec-kt)

\[
\rho_0 = 0.0023769 \text{ (lb·sec}^2/\text{ft}^4)\]

\[
V_F = \text{Equivalent airspeed (ft/sec)} = \left(20.7262 \frac{P_a}{\rho_a} \right)^{1/2} \left( \frac{\rho}{\rho_0} \right)^{7/7} \left( \frac{\rho}{\rho_0} + 1 \right)^{-1/7}
\]

20.7262 = Conversion factor (lb/ft<sup>2</sup>-in.-Hg)

\[
\rho_a = \text{Dynamic pressure (in.-Hg)}
\]

\[
P_a = \text{Ambient air pressure (in.-Hg)}
\]

At the normal operating rotor speed of 25.7 (100%), the following constants may be used to calculate \(C_p\) and \(C_T\):

- \(C_p = 724.685\)
- \((\varepsilon \cdot R)^2 = 525,168.15\)
- \((\varepsilon \cdot R)^3 = 381,581,411.2\)

1. The engine output shaft torque was determined by use of the engine torque sensor. The power turbine shaft contains a torque.
sensor that measures the total twist of the shaft. A concentric reference shaft is secured by a pin at the front end of the power turbine drive shaft and is free to rotate relative to the power turbine drive shaft at the rear end. The relative rotation is due to transmitted torque, and the resulting phase angle between the reference teeth on the two shafts is picked up by the torque sensor. This torque sensor was calibrated in a test cell by the engine manufacturer. The output from the engine torque sensor was recorded on the on-board data recording system. The output SHP was determined from the engine's output shaft torque and rotational speed by the following equation.

\[
\text{SHP} = \frac{0(N_p)}{5252.113} \quad (4)
\]

Where:

- **0** = Engine output shaft torque (ft-lb)
- **Np** = Engine output shaft rotational speed (rpm)
- **5252.113** = Conversion factor (ft-lb-rev/min-SHP)

The output SHP required was assumed to include 13 horsepower for daynight operations of the aircraft electric system, but was corrected for the effects of test instrumentation installation. A power loss of 1.87 horsepower was determined for electrical operation of the instrumentation.

**Shaft Horsepower Available**

4. Shaft horsepower available for the T700-GF-700 engine installed in the UH-60A was obtained from data received from Aviation Systems Command and presented in USAFPA Report No. 77-17 (Ref 5, app A). This data was calculated using the General Electric engine data sheet number 80024, dated 26 February 1981 with a power turbine shaft speed of 20,900 rpm. The installation losses used were based on 0.25 degree C engine inlet temperature rise in a hover, exhaust losses as obtained from the Sikorsky Aircraft Document Number SER-70410, Revision 2, dated 8 March 1979, inlet ram pressure recovery as obtained from the Sikorsky Prime Item Development Specification, and an inlet temperature rise in forward flight assuming an adiabatic rise referenced to a zero degree rise in a hover.
Hover Performance

Hover performance was obtained by the tethered hover technique. Additional free flight hover data were accumulated to verify the tethered hover data. All hover tests were conducted in winds of less than 3 knots. Tethered hover consists of restraining the helicopter to the ground by a cable in series with a load cell. An increase in cable tension, measured by the load cell, is equivalent to increasing gross weight. Free-flight hover tests consisted of stabilizing the helicopter at a desired height using the radar altimeter as a height reference. All hovering data were reduced to nondimensional parameters of $C_p$ and $C_T$ using equations 1 and 2, respectively. Adjustments in $C_p$ for changes in density altitude as presented in reference 5, and $\lambda$, were required for dimensional comparisons.

FREIGHT PERFORMANCE

Each speed power was flown in ball centered flight by reference to a calibrated lateral accelerometer at a predetermined $C_T$ and referred rotor speed ($N_R/\sqrt{T}$). To maintain the ratio of gross weight to pressure ratio $(W/\rho)$ constant, altitude was increased as fuel was consumed. To maintain $N_R/\sqrt{T}$ constant, rotor speed was decreased as temperature decreased.

Where:

$$ \lambda = \frac{\text{Temperature ratio}}{} = \frac{\text{OAT} + 273.15}{288.15} $$

OAT = Ambient air temperature (°C)

$N_R$ = Rotor speed (rev/min)

$$ \rho = \frac{\text{Pressure ratio}}{} = \frac{P_A}{P_{ao}} $$

$P_{ao} = 29.9^\prime 12$ in.-Hg

Changes to equivalent flat plate area were determined from the following equation:

$$ \frac{N_R}{2A} $$

(5)
The effects of external instrumentation drag were determined by the following equation, where the $\Delta F_e$ was estimated to be 0.833 ft$^2$.

$$\Delta F_e = (\rho/\rho_0)(V_T)^3$$

$$\text{SHP}_{\text{Instr drag}} = \frac{\Delta F_e}{96254}$$  \hspace{1cm} (6)

Where:

$96254 = \text{Conversion factor (ft}^2\text{-kt}^3/\text{SHP})$

Power required for level flight at the test day conditions was determined using the following equation.

$$\text{SHP}_t = \text{SHP} - \Delta \text{SHP}_{\text{Instr drag}} - 1.82$$  \hspace{1cm} (7)

7. Test-day (measured) level flight data was corrected to average test day conditions by the following equations.

$$\frac{N_R}{\sqrt{\delta}} = \left(\delta_s/\delta_s\right)_s$$

$$\text{SHP}_s = \text{SHP}_t \frac{N_R^3}{\sqrt{\delta}}$$  \hspace{1cm} (8)

$$\frac{N_R}{\sqrt{\delta}} = \left(\delta_t/\delta_t\right)_t$$

$$\text{SHP}_s = \text{SHP}_t \frac{N_R^3}{\sqrt{\delta}}$$  \hspace{1cm} (9)

$$\frac{V_T}{\sqrt{\rho}} = \left(V_P/\sqrt{\rho}\right)_t$$

$$\text{VTS}_s = \text{VTS}_t \frac{V_T}{\sqrt{\rho}}$$  \hspace{1cm} (9)

Where:

Subscript $t$ = Test day

Subscript $s$ = Average test day
The specific range (SR) data were derived from the test level flight power required and fuel flow (\(W_{Ft}\)). Selected level flight performance SR and fuel flow data for each engine were referred as follows.

\[
\text{SR}_{\text{REF}} = \frac{\text{SR}_{t}}{\delta \phi^{0.5}}
\]

\[
W_{FREF} = \frac{W_{Ft}}{\delta \phi^{0.5}}
\]

A curve fit was subsequently applied to this referred data and was used as the basis to correct \(W_F\) to standard day fuel flow using the following equation.

\[
W_{Fs} = W_{Ft} + W_{F}
\]

Where:

\(W_F\) = Changes in fuel flow between \(\text{SR}_{t}\) and \(\text{SR}_{s}\)

The following equation was used for determination of specific range.

\[
\text{SR} = \frac{W_{Fs}}{W_{Fs}}
\]
