In 1932 a posthumously published article by the Cambridge philosopher W.E. Johnson showed how symmetric Dirichlet priors for infinitely exchangeable multinomial sequences could be characterized by a simple property termed "Johnson's sufficiency postulate" by I.J. Good (1965). Johnson could prove such a result, prior to the appearance of de Finetti's work on exchangeability and the representation theorem, for Johnson had himself already invented the concept of exchangeability, dubbed by him the "permutation postulate" (see Johnson (1924, p. 183)). Johnson's contributions were largely overlooked by philosophers and statisticians alike until the publication of Good's 1965 monograph, which discussed and made serious use of Johnson's result.

Due perhaps in part to the posthumous nature of its publication, Johnson's proof was only sketched and contains several gaps and ambiguities; the major purpose of this paper is to present a complete version of Johnson's proof. This seems of interest both because of the result's intrinsic importance for Bayesian statistics and because the proof itself is a simple and elegant argument which requires little technical apparatus. Furthermore, it can be easily generalized to characterize both symmetric Dirichlet priors and finitely exchangeable sequences with posterior expectation of success linear in the frequency count, and the proof below is given in this generality.

After sketching the background to Johnson's result in Section 1, the generalization of his proof mentioned above is given in Section 2. Section 3 discusses a number of complements to the result and some open problems it raises, and Section 4 concludes with a historical note on Johnson and the reception of his work in the philosophical literature.

Professor Zabell is at Northwestern University.
1. **The Bayesian Background.** Let \( X_1, X_2, \ldots \) be an infinite exchangeable sequence of 0's and 1's (to be thought of as indicators of some event \( E \)), and let \( S_N = X_1 + \ldots + X_N \). Then, as first shown by de Finetti, it follows from exchangeability that the limiting frequency

\[
Z =: \lim_{N \to \infty} \frac{S_N}{N}
\]

exists almost surely, and that

\[
P(S_N = k) = \binom{N}{k} \int_0^1 p^k (1-p)^{N-k} \, dF(p)
\]

for every \( N \geq 1 \) and \( 0 \leq k \leq N \), where \( F(p) = P(Z \leq p) \) is the cumulative distribution function of \( Z \). If the parameter \( p \) is thought of as a propensity or "objective probability," then \( dF \) may be regarded as the degree of belief about or "subjective probability" of the true value of \( p \).

Traditionally, the "flat" prior \( dF(p) = dp \) was taken to express "complete ignorance" about \( p \), or the likelihood of the event \( E \) (for which the \( X_i \) serve as indicators). Bayes's own justification for this was to take \( P(S_N = k) = (N+1)^{-1} \) as quantifying complete ignorance about \( E \), observe that (1.2) gave precisely this result (for all \( k \) and \( N \)) when \( dF(p) = dp \), and then conclude that \( dF(p) \) is \( dp \).

Laplace justified the choice somewhat more directly by invoking the so-called principle of insufficient reason.
This principle came under strong criticism during the latter part of the 19th century, and some advocates of its use (Edgeworth (1884, p. 230), Pearson (1907)) adopted the position that taking $dF(p) = dp$ was often approximately justifiable on the basis of experience and background information; a position which suggests that other priors might equally well express and quantify states of knowledge previous to the receipt of sampling data. It was against this background that the actuary G.F. Hardy (1889) and the mathematician W.A. Whitworth (1897, pp. 224-225) both proposed the class of beta priors

$$B(\alpha, \beta) = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} p^{\alpha-1}(1-p)^{\beta-1}, \quad \alpha, \beta > 0,$$

as suitable for quantification of prior knowledge.

In 1778 Laplace proposed the obvious multinomial generalization of the Bayes-Laplace prior (Laplace (1781, §33); cf. De Morgan (1845, §48-49), Bachelier (1912, p. 503), Lidstone (1920)): if $X_1, X_2, ..., X_N$ are the outcomes of a $t$-category multinomial with unknown sampling vector $p = (p_1, ..., p_t)$, and frequency counts $n = (n_1, n_2, ..., n_t)$, then

$$(1.3) \quad P(n_1, ..., n_t) = \frac{N!}{n_1!} \sum_{p_1=1}^t \prod_{i=1}^t p_i^{n_i} dF(p)$$

with $dF(p) = dp_1 dp_2 \cdots dp_{t-1}$, which implies that

$$(1.4) \quad P(X_{N+1} \in \text{i-th category}|n) = \frac{n_i+1}{N+t}.$$

In 1924 W.E. Johnson gave a justification for (1.4) parallel to Bayes's: if all ordered $t$-partitions $n_1 + n_2 + \cdots + n_t$ of $N$ are
assumed to be a priori equally likely, then (1.4) must hold; it follows
(as observed by Good (1965, p. 25)) that the moments of \( d\Omega \), and hence
\( d\Omega \) itself, are uniquely determined.

It was against this background that Johnson, not entirely satisfied
with his equiprobability (or "combination") postulate, proposed another,
more general one (his "sufficientness" postulate), which had the conse-
quence of forcing \( d\Omega \) to be a member of the Dirichlet family

\[
\text{Dir}(k_1, \ldots, k_t) = \frac{1}{B(k_1, \ldots, k_t)} p_1^{k_1-1} \cdots p_t^{k_t-1} \prod_{i=1}^t dp_i \prod_{i=1}^{t-1} dp_{i+1}
\]

\((k_i > 0, \text{ all } i)\).
2. Finite Exchangeable Sequences. Let $X_1, X_2, \ldots, X_{N+1}$ be a sequence of random variables, each taking values in the set $\mathcal{X} = \{1, 2, \ldots, t\}$, $N > 1$ and $t < \infty$, such that

\[(2.1) \quad P(X_1 = i_1, \ldots, X_{N+1} = i_{N+1}) > 0, \quad \forall (i_1, \ldots, i_{N+1}) \in \mathcal{X}^{N+1}.
\]

Let $n = n(X_1, \ldots, X_N)$ denote the $t$-vector of frequency counts, i.e. $n = (n_1, n_2, \ldots, n_t)$, where $n_i = n_i(X_1, \ldots, X_N) = \#(X_j = i)$. Johnson's

sufficiency postulate assumes that

\[(2.2) \quad P(X_{N+1} = i | X_1, \ldots, X_N) = f_i(n_1),
\]

that is, the conditional probability of an outcome in the $i$-th cell given $X_1, \ldots, X_N$ only depends on $n_i$, the number of outcomes in that cell previously. (Note that (2.2) is well-defined because of (2.1).) If $X_1, \ldots, X_{N+1}$ is exchangeable, $f_i(n_1) = P(X_{N+1} = i | n_1) = P(X_{N+1} = i | n_1).

**Lemma 2.1:** If $t > 2$ and (2.1), (2.2) hold, then there exist constants $a_i > 0$ and $b$ such that for all $i$,

\[(2.3) \quad f_i(n_1) = a_i + bn_i.
\]

**Proof:** First assume $N \geq 2$. Let

$$n_1 = (n_1, \ldots, n_i, \ldots, n_j, \ldots, n_k, \ldots, n_t)$$

be a fixed ordered partition of $N$, with $i, j, k$ three fixed distinct indices such that $0 < n_i, n_j$ and $n_k < N$, and let

$$\ldots$$
\( n_2 = (n_1, \ldots, n_i + 1, \ldots, n_{j-1}, \ldots, n_k, \ldots, n_c) \)
\( n_3 = (n_1, \ldots, n_i, \ldots, n_{j-1}, \ldots, n_k + 1, \ldots, n_c) \)
\( n_4 = (n_1, \ldots, n_i - 1, \ldots, n_j, \ldots, n_k + 1, \ldots, n_c) \)

Note that for any \( n \),
\[
(2.4) \quad \sum_{n \in n} f_k(n_k) = 1 ,
\]
hence taking \( n = n_1, n_2, n_3, n_4 \), we obtain
\[
(2.5) \quad f_i(n_i + 1) - f_i(n_i) = f_j(n_j) - f_j(n_j - 1)
\]
\[
= f_k(n_k + 1) - f_k(n_k)
\]
\[
= f_i(n_i) - f_i(n_i - 1) .
\]

Thus
\[
f_i(n_i) = a_i + b n_i ,
\]
where \( a_i = f_i(0) > 0 \), (because of (2.1)), and \( b = \Delta f_i(n_i) \) is independent of \( i \) (because of (2.5)).

If \( N = 1 \), let \( c_i = f_i(1) \); it then follows from (2.4) that for any \( j \neq i \), \( a_i + c_j = a_j + c_i \), hence \( c_i - a_i = c_j - a_j = b \) .

Let \( A = \sum_i a_i \). It follows from (2.3), (2.4) that
\[
(2.6) \quad A + b N = 1 ,
\]
hence \( A < \infty \) and
\[
(2.7) \quad b = (1 - A) / N .
\]
Suppose \( b \neq 0 \). Then letting \( k_i = a_i/b \) and \( K = \sum k_i \), we see from (2.6) that

\[
b^{-1} = N + A/b = N + K,
\]

hence

\[
f_i(n_i) = a_i + b n_i = \frac{k_i + n_i}{b^{-1}} = \frac{n_i + k_i}{N + K}.
\]

**EXAMPLE 2.1** (Sampling without replacement.) Let \( X_1, \ldots, X_{N+1} \) denote a random sample drawn from a finite population with \( m_i \geq 1 \) members in each category \( i \). Let \( M = m_1 + \cdots + m_t \) and let \( N \leq m_i \), all \( i \). Then

\[
P(X_{N+1} \in \text{category } i|n) = \frac{m_i - n_i}{M - N} = \left(\frac{m_i}{M - N}\right) + \left(\frac{1}{N - M}\right)n_i.
\]

Thus \( a_i = m_i/(M-N) \) and \( b = (N-M)^{-1} < 0 \). Note that \( k_i = -m_i \); thus \( k_i \) (and hence \( K \)) is independent of \( N \), although \( a_i, A, \) and \( b \) are not. The next lemma states that this is always the case if, as here, the \( X_i \) are exchangeable and \( b \neq 0 \).

Let \( a_i^{(N)}, b^{(N)}, k_i^{(N)} \), and \( f_i(n_i, N) \) denote the dependence of \( a_i, b, k_i, \) and \( f_i(n_i) \) on \( N \). Thus, if (2.1) and (2.2) are satisfied for a fixed \( N \geq 1 \), then there exist \( a_i^{(N)} \) and \( b^{(N)} \) such that for all \( i \),

\[
f_i(n_i, N) = a_i^{(N)} + b^{(N)} n_i.
\]

Note that \( b^{(N)} = 0 \) if and only if \( \{X_1, \ldots, X_N\} \) and \( X_{N+1} \) are independent.
Lemma 2.2: Let $X_1, X_2, \ldots, X_{N+1}, X_{N+2}$ be an exchangeable sequence of $t$-valued random variables, $N \geq 1$ and $t \geq 2$, satisfying (2.1) and (2.3) for both $N+1$ and $N+2$.

(i) If $b^{(N)} \cdot b^{(N+1)} = 0$, then $b^{(N)} = b^{(N+1)} = 0$.

(ii) If $b^{(N)} \cdot b^{(N+1)} \neq 0$, then $b^{(N)} \cdot b^{(N+1)} > 0$
and $k_i^{(N)} = k_i^{(N+1)}$, all $i$.

Proof: (i) Choose and fix two distinct indices $i \neq j$. Let $a_i = a_i^{(N)}$, $a_i' = a_i^{(N+1)}$, $b = b^{(N)}$, $b' = b^{(N+1)}$, etc. Suppose $b = 0$. It follows from exchangeability that for any partition $n$ of $N$,

$$\begin{align*}
P(X_{N+1} = i, X_{N+2} = j | n) &= P(X_{N+2} = j, X_{N+1} = i | n) \\
\text{hence} \quad (a_i)(a'_j + b' n_i) &= (a_j)(a'_i + b n_j) .
\end{align*}$$

First taking $n$ in (2.10) with $n_i = 0$, $n_j = N$, then with $n_i = N$, $n_j = 0$ and subtracting, we obtain $a_i b' N = -a_j b' N$,
hence $b' = 0$ (since $a_i, a_j > 0$). Similarly, if $b' = 0$ then $b = 0$.

(ii) Suppose $b \cdot b' \neq 0$. Then it follows from (2.9) that for any partition $n$ of $N$,

$$\begin{align*}
(\frac{n_i + k_i}{N+K})(\frac{n_i' + k_i'}{N+K'}) &= (\frac{n_j + k_j}{N+K})(\frac{n_j' + k_j'}{N+K'}),
\end{align*}$$

hence
(2.12) \[ k_1n_j + k'_j n_{1} + k_1k'_j = k'_1n_j + k_1n_{1} + k'_1k_j. \]

Letting \( n_i = 0, n_j = N \) in (2.12), then \( n_i = N, n_j = 0 \) and subtracting, we obtain \( k_1 + k_j = k'_1 + k'_j \); since \( i \) and \( j \) were arbitrary, this implies \( K = K' \) and, if \( t > 2 \), \( k_1 = k'_1 \) for all \( i \). Since \( a_i, a'_i > 0 \), clearly \( b \) and \( b' \) must have the same sign.

Suppose \( t = 2 \) (so that \( i = 1, j = 2 \), say, and \( K = k_1 + k_2 \)).

Taking \( n_i = 0, n_j = N \) in (2.12), we obtain \( k_1(N + k'_2) = k'_1(N + k_2) \), hence

\[ k_1(N + K - k'_2) = k'_1(N + K - k_2), \]

from which it follows (since \( N + K = b^{-1} \neq 0 \)) that \( k_1 = k'_1 \); hence \( k_2 = k'_2 \).

Together, Lemmas 2.1 and 2.2 immediately imply

**THEOREM 2.1:** Let \( X_1, X_2, \ldots, X_N \) \((N \geq 1)\) be an exchangeable sequence of \( t \)-valued random variables such that for every \( N < N_0 \), (i) (2.1) holds,

(ii) (2.2) holds if \( t > 2 \) or (2.3) holds if \( t = 2 \). If the \( \{X_j\} \) are not independent \((= b^{(1)} \neq 0)\), then there exist constants \( k_i \neq 0 \), either all positive or all negative, such that \( N + \Sigma k_i \neq 0 \) and

(2.13) \[ P(X_{N+1} = i | a) = \frac{n_i + k_i}{N + \Sigma k_i}. \]

for every \( N < N_0 \), partition \( \pi \) of \( N \), and \( i \in \pi \).

**COROLLARY 2.1:** If \( X_1, X_2, X_3, \ldots \) is an infinitely exchangeable sequence which for every \( N \geq 1 \), satisfies both (i) (2.1), and (ii) either (2.2), if \( t > 2 \) or (2.3), if \( t = 2 \), then \( b^{(1)} > 0 \).
Proof. Suppose $b^{(1)} < 0$. But then $N+K = 1/b^{(N)} < 0$ for all $N$, which is clearly impossible.

**COROLLARY 2.2:** For all $N \leq N_0$, under the conditions of Theorem 2.1,

$$P\{X_i = i_1, X_2 = i_2, \ldots, X_N = i_N \} = \frac{\prod_{i=1}^{n-1} \prod_{j=0}^{N-1} (j+k)}{\prod_{i=1}^{t} \Gamma(N+K) \Gamma(k_i)}$$

(2.14)

Proof. It follows from the product rule for conditional probabilities that it suffices to prove $P\{X_1 = i\} = k_i/K$ for all $i \in \mathbb{I}$. But

$$P\{X_1 = i, X_2 = j\} = (a_j^{(1)} + b^{(1)} \delta_j(i))P\{X_1 = i\}$$

(2.15)

where $\delta_j(i)$ is the indicator function of $\{i=j\}$. Summing over $i$ in (2.15) gives $P\{X_2 = j\} = a_j^{(1)} + b^{(1)} P\{X_1 = j\}$, hence by exchangeability $P\{X_1 = j\} = a_j^{(1)} / (1-b^{(1)}) = k_i / K$, since $a_j^{(1)} = k_i b^{(1)}$, $1-b^{(1)} = A^{(1)}$ (cf. (2.6)), and $K = A^{(1)} / b^{(1)}$.

It follows from Corollary 2.2 that $(k_i : i \in \mathbb{I})$ uniquely determines $P = \xi(X_1, X_2, \ldots, X_{N_0})$. Conversely, for every summable sequence of constants $(k_i)$, all of the same sign, there exists a maximal sequence of $\mathbb{I}$-valued random variables $X_1, X_2, \ldots, X_{N_0}$ ($N_0 \leq \infty$) such that (2.1) and (2.13) hold. The length of this sequence is determined by $N^*$, the largest value of $N$ such that
\[ p_{i,N} = \frac{n_i + k_i}{N + K} \]

determines a positive probability measure on \( t \), i.e., \( N_0 = N^* + 1 \), where

(i) if \( k_i > 0 \), all \( i \), and \( \sum k_i < \infty \), then \( N^* = \infty \), or

(ii) if \( k_i < 0 \), all \( i \), and \( \sum |k_i| < \infty \), then

\[ N^* = \max\{N \geq 0: N + k_i < 0, \text{ all } i\} \].

Thus, if \( K < 0 \), \( N^* = \lfloor \min\{|k_i|: i \in t\} \rfloor \), where \( \lfloor \cdot \rfloor \) denotes the integer part of a number. Hence, if \( N_0 > 1 \), then \( t < \infty \) (since \( \sum |k_i| < \infty \) implies \( k_i \to 0 \)).
3. Complements and Extensions.

3.1. The Symmetric Dirichlet. Johnson considered the special case where

(i) \( f_i \) is independent of \( i \), i.e., for each \( N \), there exists a single function \( f \) such that

\[
P(X_{N+1} = i|\mathbf{n}) = f(n_i, N) \quad \text{for all } i;
\]

(ii) \( b \) is positive.

Under these conditions \( t < \infty \), \( a_i \equiv a \), \( k_1 \equiv k > 0 \), \( P(X_1 = i) = \frac{1}{t} \),

\[
P(X_{N+1} = i|\mathbf{n}) = \frac{n_i + k}{N + k},
\]

and \( X_1, \ldots, X_N \) can be extended to an infinitely exchangeable sequence, whose mixing measure \( dF \) in the de Finetti representation is the symmetric Dirichlet distribution with parameter \( k \).

3.2. Alternate approaches. Let \( \Delta_t \) be the probability simplex \\
{\{p_i \geq 0, i = 1, \ldots, t: \sum p_i = 1\}}. Doksum (1974, Corollary 2.1) states in the present setting that a probability measure \( dF \) on \( \Delta_t \) has a posterior distribution \( dF(p_i|X_1, \ldots, X_N) \), which depends on the sample only through the values of \( n_i \) and \( N \), if and only if \( dF \) is Dirichlet or

(i) \( dF \) is degenerate at a point (i.e., \( X_1, X_2, \ldots \) is independent);

(ii) \( dF \) concentrates on a random point (i.e., \( dF \) is supported on the extreme points \( \{\delta_i(j): i = 1, \ldots, t\} \) of \( \Delta_t \), so that (2.1) would not hold);

(iii) \( dF \) concentrates on two nonrandom points (i.e., \( t = 2 \) or can be taken to be so).
This is a slightly weaker result than Johnson's, which only makes the corresponding assumption about the posterior expectations of the $P_i$.

Diaconis and Ylvisaker (1979, pp. 279-280) prove (using Ericson's theorem (1969, p. 323)) that the beta family is the unique one allowing linear posterior expectation of success in exchangeable binomial sampling, i.e., $t = 2$ and $\{X_n\}$ infinitely exchangeable, and remark that their method may be extended to similarly characterize the Dirichlet priors in multinomial sampling. Ericson's results can even be applied in the finitely exchangeable case and permit the derivation of alternate expressions for the coefficients $a_i$ and $b$ of (2.3).

3.3. When is Johnson's postulate inadequate? In practical applications Johnson's sufficientness postulate, like exchangeability, may or may not be an adequate description of our state of knowledge. Johnson himself did not view his postulate as universally applicable:

the postulate adopted in a controversial kind of theorem cannot be generalized to cover all sorts of working problems; so it is the logician's business, having once formulated a specific postulate, to indicate very carefully the factual and epistemic conditions under which it has practical value.

[Johnson (1932, pp. 418-419)].

Jeffreys (1939, §3.23) briefly discusses when such conditions may hold. Good (1953, p. 241; 1965, pp. 26-27) remarks that the use of Johnson's postulate fails to take advantage of information contained in the "frequencies of frequencies" (often useful in sampling of species problems), and elsewhere (Good, 1967) advocates mixtures of symmetric Dirichlets as frequently providing more satisfactory initial distributions in practice.
3.4. **Partition exchangeability.** If the cylinder sets \( \{X_1=i_1, \ldots, X_N=i_N\} \) are identified with the functions \( g: \{1, \ldots, N\} \rightarrow \{1, \ldots, t\} \), then the exchangeable probability measures \( \mathcal{P} \) are precisely those \( \mathcal{P} \) such that

\[
\mathcal{P}(g \cdot \pi) = \mathcal{P}(g)
\]

for all \( g \) and all permutations \( \pi \) of \( \{1,2,\ldots,N\} \). Equivalently, the exchangeable \( \mathcal{P}'s \) are those such that the frequencies \( n \) are sufficient statistics with \( \mathcal{P}(\cdot|n) \) uniform.

The rationale for exchangeability is the assumption that the index set \( \mathcal{N} \) conveys no information other than serving to distinguish one element of a sample from another. In the situation envisaged by Johnson, Carnap (see Section 4 below), and others, a similar state of knowledge obtains *via-a-vis* the index set \( \mathcal{T} \) (think of the categories as colors). Then it would be reasonable to require of \( \mathcal{P} \) that

\[
\mathcal{P}(\pi_2 \cdot g \cdot \pi_1) = \mathcal{P}(g)
\]

for all functions \( g: \mathcal{N} \rightarrow \mathcal{T} \), and permutations \( \pi_1 \) of \( \mathcal{N} \), \( \pi_2 \) of \( \mathcal{T} \). Call such \( \mathcal{P}'s \) *partition-exchangeable*. The motivation for the name is the following. Let \( a(n) = \{a_r: 0 \leq r \leq N\} \) denote the frequencies of the frequencies \( n \), i.e., \( a_r = \delta(n_i = r) \). Then \( \mathcal{P} \) is partition-exchangeable if and only if the \( a_r \) are sufficient with \( \mathcal{P}(\cdot|a(n)) \) uniform, i.e., \( \mathcal{P}(a_1) = \mathcal{P}(a_2) \) whenever \( a(n(a_1)) = a(n(a_2)) \). The set of partition-exchangeable probabilities is a convex set containing the symmetric Dirichlets. From this perspective the frequencies of frequencies emerge
as maximally informative statistics and the mixtures of symmetric Dirichlets as partition-exchangeable.

It would be of interest to have extensions of Johnson's results to "representative functions" of the functional form \( f = f(n_1, a(n)) \); for partial results in this direction (\( f = f(n_1, a_0) \)), see Hintikka and Niiniluoto (1976), Kuipers (1978). It would also be of interest to have Johnson type results for Markov exchangeable and other classes of partially exchangeable sequences of random variables; cf. Diaconis and Freedman (1980) for the definition and further references; Niiniluoto (1980) for an initial attempt.
4. **Historical Note.** Johnson's results appear to have attracted little interest during his lifetime. C.D. Broad, in his review of Johnson's *Logic* (vol. 3, 1924), while favorable in his overall assessment of the book, was highly critical of the appendix on "education" (in which Johnson introduced the concept of exchangeability and characterized the multinomial generalization of the Bayes-Laplace prior!): "About the Appendix all I can do is, with the utmost respect to Mr. Johnson, to parody Mr. Hobbes's remark about the treatises of Milton and Salmasius: 'Very good mathematics; I have rarely seen better. And very bad probability; I have rarely seen worse.'" [Broad (1924; p. 379); see generally pp. 377-379.] Other than this, two of the few references to Johnson's work on the multinomial, prior to Good (1965), are passing comments in Harold Jeffreys's *Theory of Probability* (1939, §3.23), and Good (1953, pp. 238-241). This general neglect is all the more surprising, inasmuch as Johnson could count among his students Keynes, Ramsey, and Dorothy Wrinch (one of Jeffreys's collaborators). 7

It is ironical that in the decades after Johnson's death, Rudolph Carnap and his students would, unknowingly, reproduce much of Johnson's work. In 1945 Carnap introduced the function $c^* = P(X_{n+1} = 1 | n)$ and proved that it had to have the form (1.4) under the assumption that all "structure-descriptions" $[= partitions n]$ were a priori equally likely. 8 And just as Johnson grew uneasy with his combination postulate, so too Carnap would later introduce the family of functions $\{c_\lambda: 0 < \lambda < \infty\}$ $[=(n_1+k)/N+k, \lambda$ corresponding to our $k]$, the so-called "continuum of inductive methods" (Carnap (1952)). But while Johnson proved that (3.2) followed from the sufficientness postulate (3.1), Carnap initially assumed...
both, although his collaborator John G. Kemeny was soon after able to show their equivalence for \( t > 2 \). Subsequently Carnap generalized these results, first proving (3.2) follows from the linearity assumption (2.3) when \( t=2 \) (Carnap and Stegmuller (1959), and later, in his last and posthumously published work on the subject, dropping the equiprobability assumption (3.1) in favor of (2.2) (Carnap (1980, §19); cf. Kuipers (1978)).

For details of Johnson's life, see Broad (1931), Braithwaite (1949); for assessments of his philosophical work, Passmore (1968, pp. 135-136, 343-346), Smokler (1967), Prior (1967, p. 551). In addition to his work in philosophy, Johnson wrote several papers on economics one of which, on utility theory, is of considerable importance; all are reprinted, with brief commentary, in Baumol and Goldfeld (1968).

Acknowledgment: I am grateful to Persi Diaconis and Stephen Stigler for a number of helpful comments and references.
FOOTNOTES

1. This research was supported by Office of Naval Research Contract N00014-76-C-0475 (NR-042-267).

2. Good (1967) later shifted to the term "sufficiency" to avoid confusion with the usual statistical meaning of sufficiency.

3. The argument can be made rigorous by noting that $dF$ is uniquely determined by its moments; see, e.g., Murray (1930); Edwards (1974, 1978). Stigler (1981) traces how Bayes's argument was systematically distorted by later statisticians to fit their own foundational preconceptions.

4. Most notably by Boole, Venn, and Chrystal. Unfortunately, Fisher's account (1956, Chapter 2) of their reservations is seriously flawed; see Zabell (1982).

5. This is the major gap in Johnson's proof. If $\{X_1, X_2, \ldots\}$ is infinitely exchangeable, but not independent, the assumption that $b$ is positive is superfluous (see Corollary 2.1 above).

6. Good (1965, p. 25) suggests that Johnson was "unaware of the connection between the use of a flattening constant $k$ and the symmetrical Dirichlet distribution." However, Johnson was at least aware of the connection when $k = 1$, for he wrote of his derivation of (1.4) via the combination postulate,

...I substitute for the mathematician's use of Gamma functions and the $\alpha$-multiple integrals, a comparatively simple piece of algebra, and thus deduce a formula similar to the mathematician's, except that instead of for two, my theorem holds for $\alpha$ alternatives, primarily postulated as equiprobable. [Johnson (1932, p. 418); Johnson's $\alpha$ corresponds to our $t$.]
7. For Keynes's particular indebtedness to Johnson, see the former's *Treatise on Probability* (1921), pp. 11 (fn. 1), 68-70, 116, 124 (fn. 2), 150-144; cf. Broad (1922), pp. 72, 78-79, Passmore (1968), pp. 345-346.)

W.E. Johnson, sufficientness postulate, exchangeability, Dirichlet prior, Rudolph Carnap.

How do Bayesians justify using conjugate priors on grounds other than mathematical convenience? In the 1920's the Cambridge philosopher William Ernest Johnson in effect characterized symmetric Dirichlet priors for multinomial sampling in terms of a natural and easily assessed subjective condition. Johnson's proof can be generalized to include asymmetric Dirichlet priors and those finitely exchangeable sequences with linear posterior expectation of success. Some interesting open problems that Johnson's result raises, and its historical and philosophical background, are also discussed.
