This report includes the documentation and source listing of an user friendly interactive computer program that (1) solves simultaneous linear equations, (2) calculates the eigensystems of a square real matrix, and (3) finds the roots of a real polynomial. It is written in PASCAL MT+, the DRI implementation of Pascal, under the CPM86 operating system for the IBM PC. With the use of nested menus and keyboard filtering, the program requires no learning on the user's part. It channels the user in the right direction. Input matrices are entered from the keyboard while the answers maybe outputted to...
20. ABSTRACT (Continuation)

the screen and/or printer. The documentation along with the source listing describe how to develop a large, user friendly program through the use of modular techniques such as overlays.
Introduction to Linear Algebra Calculator

This program solves the two major problems of linear algebra: (1) the determination of the eigenvalues and eigenvectors of a square matrix "A" and (2) the solution of simultaneous equations "A X = B" for an n by n invertible matrix "A" and any n by m matrix "B". One must use the built-in matrix editor to enter the matrices "A" and "B". A program, based on eigenvalues of a companion matrix, to calculate the roots of a polynomial with real coefficients is also included. The source code of the mathematical routines and I/O routines could be used to build a more elaborate matrix calculator that might include disk I/O, a more flexible editor, addition and multiplication of matrices, and a matrix expression evaluator. This program does not have these capabilities.

The hardware configuration necessary to run this program is an IBM PC with 128K of RAM memory and one double-sided drive. It is written in Pascal MT+ and thus the source code could be compiled with any MT+ compiler after making a few modifications to the system I/O routines. Depending upon what floating point library is linked in with the compiled code, the program may be run with an 8087 chip or an 8088 chip.

To run the program one may do any one of the following: (1) if the machine is off, insert the program diskette in drive A and
turn the power on; CPM-86 will be loaded and the program, called MATRIX, will be executed; (2) if the machine is on, insert the diskette in drive A and do a warm boot by pressing "Ctrl-Alt-Del" simultaneously; CPM-86 will be loaded and the program will be executed; or (3) if CPM-86 has been loaded, insert the diskette in drive A, make the CPM prompt say A>, and key in MATRIX followed by carriage return. There are obviously other possibilities. The program and all its overlays could be transferred to RAM disk M and executed from there with M also the default drive. One must always have the program and its overlays on the default drive because the program looks for its overlays on the default drive.

Brief instructions on how to use the program will now be given. When the program is executed, the main menu is displayed. By pressing "G", one can view some very brief instructions. They are intended for somebody who has never run the program before or who does not like to read documentation. Before doing any matrix work, one must press "F" to bring up the matrix editor and displayer. The menus are self-explanatory and channel the user in the desired directions. To do matrix work one must enter a matrix "A" but the entering of "B" is only necessary for solving "AX = B". Only one matrix "A" and one matrix "B" may be stored at a time. To enter a new matrix after one has already been created one must answer "Y" to the erase prompt.

When matrices "A" and "B" are first created, they are initialized at all zeros. The user then edits the matrix in increasing column order. Each column will be displayed for
editing. If one answers "Y" to the column correct prompt, then the next column will be displayed for editing. If one answers "N", the cursor will be positioned at the entry in the first row of that column. If one wants to change that entry, he enters a new number followed by return. If one simply enters return, the entry is not changed and the cursor is positioned at the next row. After the entire column has been edited, the column is redisplayed with the same prompt. To edit column 4, one is forced to first view and answer "Y" to the first three column correct prompts. A compromise on flexibility and editing speed for user friendliness and less programming has been made here.

Once "A" has been entered, one may return to the outer menu to calculate the inverse, determinant, eigenvalues, and eigenvectors. If "B" has been entered also, one can press "C" to solve a linear system "A X = B". One can solve for the roots of a polynomial by pressing "A". One enters the coefficients of the polynomial within this segment of the program, not in the editor.

Two possible I/O problems are the following: (1) real numbers are not filtered for underflow or overflow when inputted; they have to be entered in the interval \([1.0 \ E-307, \ 1.0 \ E+307]\); and (2) the printer must be on-line (or must be put on-line when the CPM-86 error message is displayed) if a hardcopy is desired. If one cannot get the printer on line after a hardcopy was requested, CPM-86 exits the user back to a system prompt and the entered matrices "A" and "B" are lost.
An example matrix "A" to key in is: column 1 is the vector (1,3,6), column 2 is the vector (-3,-5,-6), and column 3 is the vector (3,3,4). Let $X$ and $r$ (not variables in the Program Matrix) stand for the associated eigenvector and eigenvalue in the equation "AX=rX". The eigenvalues of "A" are 4, -2, -2 and the associated eigenvalues are respectively (1,1,2), (-1,1,2) and (1,3,2). It should be noted that eigenvectors returned by the calculator will differ by scalar multiples from those above. Also, keep in mind instead of (-1,1,2) and (1,3,2) which are associated with the eigenvalue -2, we could have another pair of eigenvectors such as (0,4,4) and (2,2,0) which are in the same eigenspace as the first pair. The inverse of the matrix "A" is the matrix whose columns are: (1) .125(-1,3,6), (2) .125(-3,-7,-6), and (3) .125(3,3,2). This matrix has 16 as its determinant. The polynomial $x^3 - 6x^2 + 11x - 6$ would be entered as the vector (1,-6,11,-6). It has roots 1,2,3.

Description of CRT and keyboard utilities

The utility programs in Module CRTLIB are for cursor control and filtered input of characters, integers, and real numbers. This section should be read concurrently with the source listing of Module CRTLIB. These routines are based upon two CPM-86 BIOS calls, which are implemented in the Procedure Bioscall. Bioscall has two input parameters: (1) FUNC, a variable of type CPHOPERATION and (2) OCII, an integer variable. Bioscall, as presented here, only responds to two inputs, CONIN and CONOUT, of
type CPMOPERATION.

In the following, terminal character refers to a character that is being sent to the monitor to effect a cursor control. To send a terminal character to the CRT interface (monitor), one calls Bioscall with input parameters FUNC equal to CONOUT and OCH equal to the ASCII number of the terminal character. The value of the variable BDOSVAL (integer global to Module CRTLIB) is not used explicitly; here it is used only to call Procedure @BDOS86. To read a character from the keyboard, one calls Bioscall with input parameters FUNC equal to CONIN and OCH equal to any dummy integer. The global variable BDOSVAL is set equal to the ASCII number of the keyboard character pressed. The number 50 in @BDOS86(50, ADDR(DESCRIPT[1])) is the BDOS function number for a BIOS call. The five consecutive bytes allocated by DESCRIP'T are used for passing information in the @BDOS86 call. For example, "DESCRIPT[1]:=4" is the Pascal line for console display while "DESCRIPT[1]:=3" is the line for keyboard input. The Pascal MT+ manual gives a brief description of the MT+ utility @BDOS86 while the CPM-86 manual gives a detailed discussion of BDOS calls in its Appendix D. The Procedure Bioscall presented here is a Pascal implementation combining @BDOS86 with the BDOS calls (for function number 50) of CPM-86.

One could expand Procedure Bioscall to include all the parameters in CPMOPERATION by combining the ideas in Bioscall with Appendix D of the CPM-86 manual. One does not need to use Bioscall to write an alpha-numeric character to the screen; Write or Writeln can be used for this. Most of the routines in Module
CRTLIB either call Bioscall or another routine which calls Bioscall. Function Getchar is the only procedure that calls Bioscall with the CONIN parameter.

In order to use the utilities in Module CRTLIB one must call Procedure Crtinit at the beginning of the main program. Crtinit initializes the arrays CRTINFO and PREFIXED so that their values can be used by the utilities in Module CRTLIB.

Function Getchar, using Bioscall, performs the task of reading a character from the keyboard. The input to Getchar is a variable set of characters, called OKSET in Getchar's declaration. When Bioscall is called by Getchar to get a character from the keyboard, Getchar then checks to see if the character represented by BDOSVAL is in OKSET. If it is, this character becomes the value of the Function Getchar and is used in the procedure calling Getchar; if it is not, a beep is sounded and the process is repeated until a character in OKSET is finally entered. This version of Getchar automatically changes lower case to upper case. An example of Getchar being used with OKSETs that are dynamically changing can be seen in Procedure Getreal.

Procedure Crt is the main routine that calls Procedure Bioscall with the CONOUT parameter. Depending on the boolean value given by an element in the array PREFIXED, the leading character, ESC, is sent to the monitor and then the actual terminal character is sent to the monitor. For example, suppose we want to clear the screen. One uses the variable ERASEOS of type CRTCOMMAND as the parameter input to Procedure Crt. Using
ERASEOS as the index variable, Crt sends the leadin character ESC to the monitor since PREFIXED[ERASEOS] is true and then sends the character 'J', which is CRTINFO[ERASEOS]. It should be noted that in the above, the ASCII numbers of the various characters are actually inputted to Bioscall in Procedure Crt.

One can control background colors by using the type COLOR, the arrays COLORINFO, CRTINFO, and PREFIXED along with the Procedures Initcolor, Altcolor, and Paint. One then needs to write a procedure similar to Altcolor to change foreground colors. These would be the fundamental library routines for using colors.

Procedure Gotoxy(X,Y:INTEGER), which also calls Bioscall with input parameter CONOUT, places the cursor at vertical line number X and horizontal line number Y. The other cursor control routines are fairly obvious in view of the above discussion.

Procedure Intread is used to read an integer between -32768 and +32767. The characters are filtered, put into a string, checked for the proper range, and then converted to an integer. Intread requires an integer to be entered; one cannot simply enter carriage return. Procedures Getreal and Value are used together to read a real number. Some explanation is required on the use of Getreal. In the procedure calling Getreal, we have a string variable, SREEL, initialized at '', an empty string of length zero but still a string. Procedure Getreal reads and dynamically filters a string of characters and if this string is of length greater than zero, this string is returned to the
calling procedure by Getreal and SREEL is set equal to it. If Getreal only reads a carriage return, then SREEL remains only an empty string and Procedure Value is not called. If SREEL has length greater than zero, Procedure Value calculates the real number corresponding to SREEL. Getreal and Value are used to edit a real number that already exists, either through initialization or calculation. By pressing carriage return, one can leave an existing real number as is. This use eliminates a computer crash caused by keying in only a carriage return when the usual READ or READLN wants an actual number. Procedure Value was taken from The Byte Book of Pascal while Procedure Powrten is from the Pascal Users Manual by Jensen and Wirth.

Data and Overlay Description

This program illustrates the use of module overlays, an ordinary module, matrix types and external variables. This description explains the manner in which the program was implemented, and therefore it should be used as a guide to understanding the structure of the code. Modules are separately compiled groups of procedures. There are two types: (1) an overlay module and (2) an ordinary module which must be linked with an overlay module or main program. The Module CRTLIB is separately compiled and linked in with the main program. CRTLIB's subroutines essentially become a part of the main program (sometimes called the root overlay) and always are resident in RAM memory. Since the utilities in CRTLIB are continually being
called, it would not be practical to make CRTLIB an overlay module and thus force a lot of disk accesses. If a module overlay (including the main program) uses a procedure in Module CRTLIB, then the "calling" overlay must declare the procedure as an external procedure in the calling overlay's declaration heading just below the variable declarations.

The data storage of the program will now be explained. The controlling data allocation declarations are (1) the TYPE DOMAIN1=1..20, (2) the CONST MAXDEG=20, (3) the CONST MAXDEGP1=21, and (4) the TYPE DOMRPl=1..MAXDEGP1. MAXDEG, MAXDEGP1 (MAXDEG PLUS 1), and DOMRPl are used to solve for roots of a polynomial. DOMAIN1 is the maximum dimension of a matrix entered as input data. MAXDEG should be set to be less than or equal to the value of the DOMAIN1 upper bound since the polynomial root finding technique uses an n by n matrix to solve an n degree polynomial equation. In this program, the coefficients of a polynomial are not stored in a global variable (for the main program) and there is not much I/O to go with the polynomial routine. It is included as a side benefit to illustrate the use of the eigenvalue procedures as subroutines to another procedure. Variables that are referred to as global are declared in the main program and then declared external in the overlays that use them. The matrix "A" whose square dimension is IONDIM is stored in the upper left-hand corner of the global variable IOTA and the matrix "B" whose dimension is ROWDIMB by IOM is stored in the upper left-hand corner of the global variable IOTB. IOTA, IOTB, IONDIM, ROWDIMB, and IOM are declared in the
root overlay (Program Matrix) and referenced in the appropriate overlays by declaring them as external variables. The global matrix "XX" is used to store the solution to "AX=B" and is referenced as external in Module Overlay20 (whose source code is AXEQSB.SRC). The global vectors TEVR, TEVI store the real and imaginary components of the eigenvalues and are referenced as external in Module Overlay24 (EIGENVEC.SRC). The global matrix TVEC, referenced as external in Module Overlay24, is used to store the eigenvectors of the matrix "A". Communication of data between the root overlay (Program Matrix) and the overlay modules #3, #19, #20, #24 is accomplished by initially declaring the above mentioned variables in the main program and by declaring them external in the necessary overlay modules. The Types of matrices and vectors must be declared in the root overlay and redeclared in the overlay modules. When using dimensions less than the maximum allocated in the Types, all data will be stored in the upper left-hand corner of matrices or beginning components of a vector. Intermediate results produced by Module Overlay1 (LINSYS.SRC), Module Overlay5 (EIGENHQQR.SRC), and Module Overlay6 (EIGENBAL.SRC) are passed as parameters in the procedure calls.

The root overlay (Program Matrix) calls directly six main procedures located in six overlays. They are (1) Procedure Matrixio, located in Module Overlay3, which is the editor for matrix input, (2) Procedure Help, located in Module Overlay23, which is a brief set of instructions on how to run the program, (3) Procedure Ttrdet, located in Module Overlay19, which calculates the determinant of the matrix stored in variable IOTA,
Procedure Ttsaxb, located in Module Overlay20, which solves "AX=B" for "A" stored in the variable IOTA and "B" stored in the variable IOTB or "B" is the identity matrix (used to calculate the inverse of "A"). (5) Procedure Ttrnaa, located in Module Overlay24, which calculates eigenvectors and eigenvalues of the matrix stored in IOTA, and (6) Procedure Ttrpqr, located in Module Overlay21, which calculates the roots of a polynomial with real coefficients. These six procedures which are located in module overlays must be declared external in the root overlay heading. After the word "External", the overlay number to which the procedure belongs must appear in square brackets.

Other external procedures used within these overlays do not have to be declared within the root overlay; they are declared as external procedures with the appropriate overlay numbers within the overlay that calls them. For example, Procedure Ttrdet, located in Overlay Module19, calls Procedure Rlud, located in Overlay Module1. Therefore, Procedure Rlud must be declared external in the heading of Module Overlay19. Module Overlay3 uses procedures located in the Module CRTLIB (not an overlay module), and therefore these called procedures must be declared as external in the heading of Module Overlay3. These external procedures from Module CRTLIB do not have overlay numbers.

Module Overlay3 (IOMATRIX.SRC) is the module responsible for keyboard input of matrices and printer output of matrices. The maximum size of the matrix is set in the TYPE DOMAIN1 = 1..20. If one wanted only matrices of dimension 10 or less, one would set TYPE DOMAIN1 = 1..10. One must change these type declarations for
all the overlays that use them. It should be noted that the editing programs are based upon editing a column of a matrix that fits onto one screen display. If one wanted to enter a column of dimension larger than twenty, the column display and editing routines would have to be modified a little. On the other hand it is not practical to enter a matrix larger than 10 by 10, let alone 20 by 20. Large matrices should be generated by a program or read from a disk file. For example, Module Polyroot generates a 20 by 20 matrix when one requests the root of \( X^{20} = 1 \).

Within this module, Procedure Getcolumn and Procedure Getpolcof are the work horses. Respectively, they take the column of a matrix or the coefficients of a polynomial and display them on the screen for editing. These two routines use the cursor control utilities and Procedures Intread, Getreal, and Value to edit existing columns. Procedure Matrixio is the editing procedure which calls the Procedures Edit and Display. Edit displays menus, initializes matrices, and calls the above mentioned procedures to edit existing matrices. Procedure Display, which is somewhat redundant, gives a faster display than Procedure Edit. Procedure Hardcopy is used to printout the matrices "A", "B", inverses, determinants, matrix equation solutions, eigenvectors, and eigenvalues.

Module Overlay24 (EIGENVEC.SRC), Module Overlay6 (EIGENBAL.SRC), and Module Overlay5 (EIGENHQR.SRC) are the overlays which calculate eigenvectors and their corresponding eigenvalues. Procedure Trnnaa takes the global matrix IOTA
containing the matrix \(A\) and its dimension, \(IOWDIM\), and calls the Procedure Rnaa. Procedure Rnaa is the procedure which calls the Procedures Balance, Elnihes, Eltran, Hqr2, and Balbak, which together calculate the eigenvalues and eigenvectors. The eigenvalues are returned to Ttrnaa in the global arrays TEVR and TEVI. TEVR[1] and TEVI[1] give the real and imaginary parts of the eigenvalue \#1. The eigenvectors are returned in the matrix TVEC in a not so obvious way. They are returned in an order corresponding to the eigenvalues in TEVR and TEVI. The manner in which TVEC returns the eigenvectors needs to be illustrated by an example. Let TEVR[1]=1 and TEVI[1]=2; the eigenvalue is 1+2i. Then TEVR[2]=1 and TEVI[2]=-2 since eigenvalues and eigenvectors of real matrices occur in conjugate pairs. Now the two eigenvectors that correspond to these eigenvalues are conjugates. TVEC in its first column will have the real part of eigenvector \#1 and in its second column it will have the imaginary part of eigenvector \#1. Eigenvector \#2 will just be the conjugate of this eigenvector. If the eigenvalue is pure real, then the eigenvector is pure real and only one column is necessary. In the case of a matrix with repeated eigenvalues without a full set of eigenvectors, the eigenvectors will be repeated in the matrix TVEC (probably numerically slightly different). These eigenvector subroutines are Pascal translations by the author of EISPACK eigenvector routines in Fortran.

Module Overlay21 (POLYROOT.SRC) also uses the eigenvalue subroutines to solve for the roots of a polynomial with real coefficients. It makes the integer \(l\) the leading coefficient of a
polynomial of degree n and enters the other n coefficients into the first row of an n by n matrix with 1's on the subdiagonal; this matrix is called the companion matrix and the eigenvalues of it are the roots of the polynomial. Procedure Tttrpqr does the preliminaries and Procedure Rppqr calls the sequence of eigenvalue subroutines to find the eigenvalues which are returned in the variables TWR and TWI. Procedure Balbak is not used since the eigenvectors are not needed. POLYROOT.SRC illustrates the use of these subroutines in a real problem and it also serves as a test of the correctness of the eigenvalue codes.

Module Overlay20 (AXEQSB.SRC) and Module Overlay1 (LINSYS.SRC) are the overlays which solve systems "AX=B" as well as find the inverse of the matrix "A" (B will be the identity matrix in this case). Again the "A" matrix is in IOTA and the "B" matrix is in IOTB. Procedure RLUD does an L-U decomposition on the matrix in the variable SA (the constant matrix B tags along) and Procedure Rfbs does the back substitution to solve the system. In the case where "B" has more than one column, Rfbs is called IOM times to solve the equations. Procedures Rlud and Rfbs are Pascal translations by the author of a Sandia Labs matrix equation solver; it is very successful with matrices "A" that are almost singular (no inverse).

Module Overlay19 (DETERM.SRC) and Module Overlay1 (LINSYS.SRC) are used to calculate determinants. Rlud in LINSYS.SRC does an L-U decomposition of the matrix TALU (a copy of IOTA) and returns the L-U decomposition in TALU. The matrix L has ones on the diagonal and therefore the determinant of "A"
will be the determinant of "U" which is just the product of U's diagonal entries.

Layout of Overlays

Module overlays are divided into groups. Overlays #1 - #16 are in overlay group #1, overlays #17-#32 are in overlay group #2, etc. The source code of an overlay module must begin with its identification number; for example overlay module #1 is the heading, Module Overlay1. The root overlay is just the main program; here it is Program Matrix. This program does not use the most sophisticated overlay structure. In this program, overlays within the same group do not call each other and there is no heap. When compiling an overlay, one does not have to specify the address in RAM memory where the overlay will be loaded. This is done during the linking process. All the overlays within the same group must be located at the same address. This address must be larger than the length of the root overlay including any runtime library routines or ordinary modules linked with the root overlay. For example, the root overlay, Program Matrix with routines from the libraries TRANCEUD.R86, 87REALS.R86, PASLIB.R86, and Module CRTLIB useUFFCH(hex) bytes of storage. The memory allocated for overlay group #1 must be some address larger than this; here 86000H is used. In the linking instructions below, overlays #1 - #16 must be directed to begin at 86000H. Then one looks at the largest length of the compiled overlays in group #1 and adds this to 86000H. In this program, Module Overlay5 has length 42AAH. This should be verified again after all the
overlays in group #1 have been linked to the root overlay. One adds 8600H to 42AAH to obtain the length C8AAH. The address where overlays #17 - #32 begin must be larger than C8AAH. This program uses address D200H for the location of overlays in group #2. The overlay of the largest length in group #2 is Module Overlay21 with a length of 1370H. 1370H plus D200H equals E570H. Therefore, the total length of the code that must be specified in the last link command with the R switch must be greater than E570H. The value used is FC00H. The data storage required is only that from those variables declared in the main program and it is 576CH. The value 8000H is more than adequate and is declared with the D switch in the last linker command. Local variables and parameters are stored in the stack. This stack is automatically given 32K bytes of RAM. One can actually assign the stack size by using the Z switch in the last linker command. For example, "Z/300" will assign 30001 for stack memory. Note that 300 here means 3000 if or 12K bytes.

One has to make sure the total RAM allocated for data, code, stack, and heap is smaller than the RAM allocated for program execution. Otherwise, upon program execution, a "Memory not available" message will be displayed. In this program, the stack was reduced to 12K in order that the program would execute in a 128K machine. Having a stack too small is a potential problem, but by far the major source of problems is having one overlay group overwrite another. Apparently, one needs to have some memory available between the end of the largest overlay in a particular group (including the root overlay) and the beginning
of the next overlay group. For example, in this program when the addresses 7200H, B800H, and DE00H were used in place of the addresses 8600H, D200H, and FC00H the program would not execute properly. The Pascal MT+ manual should address this problem. If one experiences weird program execution, the distance between overlay groups should be increased as the first approach to solve the problem.

Computer Configuration for Pascal MT+

In doing developmental work for this program, the IBM PC was configured with two DS/DD disk drives, 512K of RAM, and the CPM-86 operating system. The RAM was partitioned into 140K for running programs (compiler, editor, linker, and the executable linear algebra routine) and 372K for a RAM disk, called the M: drive. The program SETUP.CMD, furnished with CPM-86, was used to configure the RAM drive and the cursor pad of direction arrows. Upon bootup, the RAM drive is created and the cursor pad is initialized.

A RAM disk is essential (though not required) for program development with Pascal MT+ because of the heavy disk access by the MT+ Speed Editor, Compiler, and Linker of their overlays and the program's source and object code files. If one follows the implementation techniques described in the following, the user will find MT+ not just a powerful Pascal implementation, but one that possess good development time and is not cumbersome. It should be mentioned that in many articles comparing the MT+
implementation to others, the benchmarks involving compile and link times are misleading. Pascal MT+ uses a lot of disk I/O because of its code size and this eats up a lot of time. Using a RAM disk reduces this I/O time considerably.

One must configure three diskettes. Diskette #1, called the compiler diskette, must contain CPM.SYS (configured for RAM drive and optionally the cursor pad), the MT+ compiler (consisting of a CMD file and its several overlays), and three R86 files: (1) 87REALS.R86, (2) PASLIB.R86, and (3) TRANCEJD.R86. It is optional, but useful to put the utility routines such as PIP.CMD and STAT.CMD on the compiler diskette. Diskette #2, called the editor diskette, should contain the Speed Programming Editor (CMD file and its overlays), SIP.CMD (PIP.CMD renamed by the user), and STAT.CMD. Diskette #3, called the linker diskette, should contain the MT+ linker (CMD file and its overlays) and the SUBMIT.CMD file. For single stroke execution, it is convenient to rename the compiler, editor, and linker respectively M.CMD, S.CMD, and L.CMD.

The following is the start up process. Put the compiler diskette in drive A: and the editor diskette in drive B: and then turn the power on. When the "A>" prompt comes up, key in "PIP M:=B:S*.*". This will transfer the editor, SIP.CMD, and STAT.CMD to the M: drive. One can use an editor other than DRI's Speed Editor. Users of UCSD's P-Editor will find the Speed Editor acceptable when not in the P-system. After the editor is transferred to RAM drive, one removes the editor diskette from drive B: and inserts a work diskette containing source and their
compiled, R86, files.

One then presses Control-C and changes the default drive to M:. If one wants to edit an existing source file, one uses SIP.CMD on drive M: to "pip" the source file from drive B: to drive M:. While in the M: drive, one edits a Pascal source file. If one is using the Speed Editor, a word of caution is necessary. If one attempts to save a file on a drive without enough memory (including RAM drive), the old source file as well as the source file in the editor's buffer will be lost. This potentially serious problem can be avoided if one is aware of it. If the Speed Editor is used one should use its syntax scanner and variable checker to locate syntax errors and typos prior to compilation.

Once a source file has been edited it must be compiled. It is not necessary to transfer the compiler to RAM drive. One must change the default drive from M: to A:, leaving the compiler diskette in drive A: and the source file on RAM drive. Since Pascal MT+ is oriented toward modularity and modular compilation in particular, individual source files (modules and overlay modules) are relatively short. Because of this, disk I/O to drive A: to load the compiler overlays is not too frequent. With the source code being read from RAM drive and compiled code being written to RAM drive, compiles are quite timely.

To compile all the overlays and modules for the linear algebra calculator, one must do the following tasks. There are eleven source codes which must be saved on the work disk. They
are (1) MATRIX.SRC, (2) CRTLIB.SRC, (3) IOMATRIX.SRC, (4) EIGENBAL.SRC, (5) EIGENHQR.SRC, (6) MHELP.SRC, (7) LINSYS.SRC, (8) DETERM.SRC, (9) AXEJSB.SRC, (10) POLYROOT.SRC, AND (11) EIGENVEC.SRC. Each file should be transferred to RAM drive and then compiled. To compile the root overlay, MATRIX.SRC, one enters the following command: "MT+86 M:MATRIX.SRC". If one changed the name of the compiler to M.CMD, then one enters "M M:MATRIX.SRC". The compiler will compile the file and write a code file, MATRIX.R86, to RAM drive. Similarly, one compiles the other ten source code files to produce ten more R86 code files. These code files should be saved on the work diskette in drive B:. It should be emphasized that if the source code of a module or overlay module is not changed, then it does not have to be compiled.

The most important implementation method in MT+ code development is to automate the linking process. Without this automation, the linking process is extremely time consuming. Automatic linking is accomplished by using SUBMIT.CMD and linker input command files, called KMD files. These will now be described in detail and applied to the linear algebra calculator. Once all the overlays have been compiled one makes up a KMD file for each compiled overlay module. A KMD file is actually a text file keyed in using an editor and given the suffix KMD instead of the usual SRC suffix. The following KMD text files are needed:

(1) M:MU.KMD with the line of source:

(2) M1.KMD with the line of source:
M: MATRIX.001=M: MATRIX/O: 1, M: LINSYS, M: PASLIB/S/P: 8600/L

(3) M3.KMD with the line of source:

(4) M5.KMD with the line of source:

M:MATRIX,M:CRTLIBM:TRANCEND,M:87REALS,/C
M:PASLIB/S/D:8000/V1:8600/V2:D200/R:FCU0/2:300

These linker input command files are stored on the linker diskette. As with the editor, RAM drive will be used extensively. One transfers the compiled, R86, files from the work diskette to the M: drive. Then one transfers the three R86 library files to the M: drive: (1) 87REALS.R86, (2) PASLIB.R86, and (3) TRANCEND.R86. If one does not use the 8087 chip then FPREALS.R86 must be used in place of 87REALS.R86. At this point, one should remove the compiler diskette, and insert the linker diskette. Then one enters Control-C and makes A: the default drive. The input command files save a lot of time since the overlay module names and addresses rarely change during program development. Remember that the linker has been renamed L.CMD for keyboard simplicity. Instead of keying in: "L M:MATRIX,M:CRTLIBM:TRANCEND,M:87REALS,M:PASLIB/S/E/W" one simply enters: "L M0/F". Without the input command files option, one would have to do eleven links, keying in by hand each time all of the names and addresses in the linker input command files. Instead, one merely executes the eleven commands: (1)"L M0/F", (2)"L M1/F", (3)"L M3/F", (4)"L M5/F", (5)"L M6/F", (6)"L M23/F", (7)"L M19/F", (8)"L N20/F", (9)"L M21/F", (10)"L M24/F", (11)"L MR/F".

One can further automate the above process by using SUBMIT.CMD to do batch processing of the above eleven commands.
To do this, one must prepare a textfile, with the suffix, SUB. In the linear algebra calculator, this SUB file is called MLINK2.SUB. In this text file, each line of text will be a single command. The eleven command lines of this textfile will be the command lines of the above paragraph. It should be noted that this SUBMIT.CMD code is a very sensitive code. When the MLINK2.SUB was constructed using the Speed Editor, the batch process would not execute. If MLINK2.SUB was constructed using WORDSTAR with no editing changes, it worked fine. Also, some editing such as exchanges gave no problem while deletes did. SUBMIT.CMD seems to perform better under CCPM-86.

The following is the file configuration to do an automatic link. All R86 files including compiled source files and run-time libraries must be on drive M:. The linker diskette, in drive A:, must contain L.CMD and its overlays, SUBMIT.CMD, MLINK2.SUB, and the eleven linker input command files.

With A: as the default drive, one enters "SUBMIT MLINK2" and the linking process will be automatically executed. Once automated, the linking process is not a big hassle. Linking MT+ code is the price one pays for modular compilation. The link will be fairly fast, considering the size of the codes. The fact that the R86 files are being read from RAM drive and the final overlays are being written to RAM drive creates a tremendous savings in time. The linker will create ten overlays: (1) MATRIX.CMD, (2) MATRIX.001, (3) MATRIX.003, (4) MATRIX.005, (5) MATRIX.016, (6) MATRIX.017, (7) MATRIX.018, (8) MATRIX.013, (9) MATRIX.014, (10) MATRIX.015, (10) MATRIX.018. After they have been created, they
should be transferred to another diskette to be saved and executed as desired. It might be possible to put the linker and its overlays and the KMD files on RAM disk also if one had a larger RAM drive. It does not seem that there is a tremendous loss in time to load the linker overlays and read the command files from a diskette. If the R86 files are read from a diskette and the compiled overlays are written to a diskette, there is a tremendous loss of time. One has to keep in mind that SUBMIT.CMD is sensitive to the selection of drives that have the files that it is batch processing. It seems only experimentation tells what SUBMIT.CMD accepts; it went for the above configuration.
