**Title:** Kalman Filter Real Time Tracking Using Microprocessors and a New Language for Military Software

**Personal Author(s):** Jose Alberto Fernandes Ferreira

**Abstract:**
A sequential Extended Kalman filter routine, implemented in the "C" language, is developed for an embedded computer application. The design takes into account the real time constraints imposed by the sampling time of the data. Filter measurements consist of four (4) transit times generated by torpedo instrumentation in a TEST RANGE facility, and they are nonlinear functions of the coordinates of the torpedo. Memory, speed efficiency, and portability are emphasized in the software design.

The program was tested, using simulated trajectories, in an IBM-PC and in a CIE 680/30 microcomputers. Limitations in handling small floating-point numbers and precision issues in the CIE 680/30 microcomputers were encountered. The program was found to be robust and capable of providing accurate tracking results.

**Subject Terms:** Kalman Filtering; Torpedo Tracking

ACKNOWLEDGEMENT

I am deeply indebted to my wife, Anne, for her love, patience and understanding during the preparation of this work. I would also like to thank Professor Hal Titus for his professional guidance. I would also like to express my gratitude to Professor Alex Gerba, Mr. Robert Limes and Mr. Albert Wong for their help and suggestions.
I. INTRODUCTION

The problems of torpedo tracking have been studied, at the Naval Postgraduate School, by several researchers, who have implemented simulations that would allow analysis of tracking algorithm performance using the Extended Kalman Filter [1]. However, those studies have been limited to simulations done on large mainframe computers, without trying to adapt them to the real time processing system at the torpedo range.

The objective here is to develop a version of the Extended Kalman Filter, adapted to the constraints of real-time processing, by generating a program in the C language. Also it is designed to run in the microcomputer C.I.E 680/30, currently utilized at the Naval Torpedo Station, Washington.

The presentation herein tries to follow as much as possible the chronological order, describing the problems in the order of appearance and the way they were solved.
II. PROBLEM DEFINITION

A. RANGE TRACKING GEOMETRY

Sets of hydrophone arrays are distributed in line along the extension of the test range. Each individual array consists of four independent elements, placed at a distance "d" apart, on the vertices of a cube, thus defining an orthogonal coordinate system in which the measurement of the transit times are made. Figure 1, shows the geometry.

Four transit times, $T_c$, $T_x$, $T_y$, $T_z$, corresponding to the four hydrophones in the array are measured and the positional information is computed from the measured transit times. The torpedos are equipped with sonar transmitters which are synchronized with a master clock, allowing new data every 1.31 seconds, with a range accuracy between 3 to 30 feet.

When multiple arrays are used, the signal from the closest hydrophone is defined as the basis for the time measurements and for the range calculations. If the computer time were not critical, an 18 hydrophone signal should be processed.
Figure 1: Geometry of a tracking array.
B. GENERAL EXTENDED KALMAN FILTER EQUATIONS

A summary of the filter and associated equations is given in this section, following the order and the conventions in [1].

1. Observation Equations

For the three-dimensional problem, in which the z-position is considered invariant, a state space consisting of the three positions, $X$, $Y$ and $Z$, and the two velocities, $V_x$ and $V_y$ define the torpedo motion. Thus, the discrete linear estimation and the nonlinear observation equations are given by

\[
X(k+1) = \Xi \cdot X(k) + r \cdot W(k) \tag{2.1}
\]

\[
Z(k) = h(X(k),k) + V(k) \tag{2.2}
\]

where: $\Xi$ and $r$ are constant matrices;

$h$ is a nonlinear function of the state $X$;

$W(k)$ is the plant excitation noise;

$V(k)$ is the measurement noise.

The plant noise and the measurement noise are assumed Gaussian distributed with zero mean, and uncorrelated.

The last assumption implies that

\[
E[W(k) \cdot W^T(j)] = Q'(k) \delta_{kj}
\]

\[
E[V(k) \cdot V^T(j)] = R(k) \delta_{kj}
\]
where: \( \xi = 1, \text{ for } k = j \);
\( \xi = 0, \text{ for } k \neq j \);

2. Linearized Equations

Linearization of the observation equation is obtained by using the Taylor Series to expand about the prediction of the trajectory for the interval.

\[
\bar{Z}(k) = H(k) \cdot \hat{X}(k) + \gamma(k)
\]  
(2.3a)

where: 
\[
H(k) = \frac{\partial h}{\partial X} \bigg| X(k) = \hat{X}(k/k-1)
\]  
(2.3b)

\( \hat{X}(k/k-1) \) is the estimated value (predicted) at time \( k \), given the measurements until time \( k-1 \).

3. State Error Vector

\[
\tilde{X}(k) = \hat{X}(k) - X(k)
\]

4. Predicted State Error Vector

\[
\tilde{X}(k/k-1) = \hat{X}(k/k-1) - X(k)
\]

5. Covariance of State Error

\[
P(k) = E[\tilde{X}(k/k) \cdot \tilde{X}^T(k/k)]
\]

6. Predicted Covariance

\[
P(k/k-1) = E[\tilde{X}(k/k-1) \cdot \tilde{X}^T(k/k-1)]
\]

7. State Excitation Matrix

\[
Q(k) = R(k) \cdot E[W(k) \cdot W^T(k)] \cdot R(k)
\]

8. Measurement Noise Covariance Matrix

\[
R(k) = E[\gamma(k) \cdot \gamma^T(k)]
\]
9. Kalman Filter Equations

\[ P(k+1/k) = \Phi P(k/k) \Phi^T + Q(k) \]  
\[ Q(k) = P(k/k-1) H^T(k) [H(k) P(k/k-1) H^T(k) + R(k)]^{-1} \]  
\[ P(k) = [I - Q(k)] P(k/k-1) \]  
\[ \hat{X}(k+1/k) = \Phi \hat{X}(k/k) \]  
\[ \hat{Z}(k/k-1) = h(\hat{X}(k/k-1), k) \]  
\[ \hat{X}(k/k) = \hat{X}(k/k-1) + Q(k) [Z(k) - \hat{Z}(k/k-1)] \]

C. APPLIED EQUATIONS [1]

In order to apply the Extended Kalman filter to the torpedo tracking problem it is necessary to define the state vector and the matrices \( H, \Phi, R, W, Q, \) and \( R. \)

1. Transit Times

\[ T_c(k) = \frac{1}{vel} \left[ (x+d/2)^2 + (y+d/2)^2 + (z+d/2)^2 \right]^{1/2} + v(k) \]  
\[ T_x(k) = \frac{1}{vel} \left[ (x-d/2)^2 + (y+d/2)^2 + (z+d/2)^2 \right]^{1/2} + v(k) \]  
\[ T_y(k) = \frac{1}{vel} \left[ (x+d/2)^2 + (y-d/2)^2 + (z+d/2)^2 \right]^{1/2} + v(k) \]  
\[ T_z(k) = \frac{1}{vel} \left[ (x+d/2)^2 + (y+d/2)^2 + (z-d/2)^2 \right]^{1/2} + v(k) \]

where: \( d=30 \) feet, is the distance between two hydrophones in a given array; 
\( vel=4860 \) ft/sec, is the average sound speed at Dabob Bay.

These equations must be linearized to apply Kalman
Filter Theory. The linearization is done, in this case, about the predicted trajectory, which is being generated by the filter algorithm.

The values of transit times are corrupted by noise, \( v(k) \), which is assumed Gaussian with zero mean. The positions \( x, y, \) and \( z \) are all functions of the time interval.

2. State Equations

The plant state equations are defined by

\[
\begin{bmatrix}
x(k+1) \\
x_x(k+1) \\
y(k+1) \\
x_y(k+1) \\
z(k+1)
\end{bmatrix} = \begin{bmatrix}
x(k)+TV_x(k)+g_1 \\
x_x(k)+g_2 \\
y(k)+TV_y(k)+g_3 \\
x_y(k)+g_4 \\
z(k)+g_5
\end{bmatrix}
\]  

(2.9)

where: \( x(k), y(k) \) and \( z(k) \) are the position coordinates at time \( t(k) \);
\( x_x(k) \) and \( x_y(k) \) are the \( x \) and \( y \) components of the velocity;
the depth \( z(k) \) is maintained constant and any velocity in \( z \) is assumed random, Gaussian, uncorrelated and with zero mean;
\( T \) is the sampling interval \( T=1.31 \text{sec} \);
\( g_1, g_2, g_3 \) and \( g_4 \) are excitation terms, included to take into account random variations in speed \( (V_{yt}) \),
heading \( \gamma_{t} \), and depth \( \gamma_{z} \), which are assumed to be independent, zero mean, rates of change.

Typical torpedo maneuvering parameters are

\[
\begin{align*}
\dot{\gamma}_{t} &= 22^\circ/\text{sec}; & \sigma_{\dot{\gamma}_{t}}^2 &= \text{E}[\gamma_{\dot{\gamma}_{t}}^2] \\
\dot{\gamma}_{z} &= 36 \text{ ft/sec}^2; & \sigma_{\dot{\gamma}_{z}}^2 &= \text{E}[\gamma_{\dot{\gamma}_{z}}^2] \\
\dot{\gamma}_{2} &= 1 \text{ ft/sec}; & \sigma_{\dot{\gamma}_{2}}^2 &= \text{E}[\gamma_{\dot{\gamma}_{2}}^2]
\end{align*}
\]

In state form:

\[
X(k+1) = \Xi X(k) + \nu W(k)
\]  
(2.10)

\[
\Xi = \begin{bmatrix}
1 & T & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & T & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]

\[
\nu = \begin{bmatrix}
T^2/2 & 0 & 0 \\
T & 0 & 0 \\
0 & T^2/2 & 0 \\
0 & T & 0 \\
0 & 0 & T
\end{bmatrix}
\]  
(2.11)

\[
\sigma_{X}^2 = \left(\frac{\nu}{\nu_{t}}\right) \sigma_{\dot{\gamma}_{t}}^2 + \nu_{y}^2 \sigma_{\dot{\gamma}_{2}}^2
\]  
(2.12a)
\[ s_{y}^{2} = (v_{y}/v_{t}) s_{t}^{2} + v_{y}^{2} s_{b}^{2} \]  
\[ s_{x}^{2} = v_{x} v_{y} [s_{t}^{2} - s_{b}^{2}] \]  
\[ \mathbf{q} \text{ is a symmetric matrix given by} \]
\[
\mathbf{q} = \begin{bmatrix}
q_0 & q_1 & q_2 & q_3 & q_4 \\
q_5 & q_6 & q_7 & q_8 & q_9 \\
q_{10} & q_{11} & q_{12} & q_{13} & q_{14} \\
q_{15} & q_{16} & q_{17} & q_{18} & q_{19} \\
q_{20} & q_{21} & q_{22} & q_{23} & q_{24}
\end{bmatrix}
\]
\[ \text{where: } q_0 = (T^2/2) s_{x}^{2}; \quad q_1 = (T^3/2) s_{x}^{2}; \quad q_2 = (T^2/2) s_{x}^{2}; \]
\[ q_3 = (T^3/2) s_{x}^{2}; \quad q_4 = 0; \quad q_6 = T^2 s_{x}^{2}; \]
\[ q_7 = (T^3/2) s_{x}^{2}; \quad q_8 = T^2 s_{x}^{2}; \quad q_9 = 0; \]
\[ q_{12} = (T^2/2) s_{y}^{2}; \quad q_{13} = (T^3/2) s_{y}^{2}; \quad q_{14} = 0; \]
\[ q_{18} = T^2 s_{y}^{2}; \quad q_{19} = 0; \quad q_{24} = T^2 s_{z}^{2}; \]
\[ \mathbf{Z}(k) = [T_c(k) \quad T_x(k) \quad T_y(k) \quad T_z(k)]^T \]
\[ \mathbf{R}(k) = \begin{bmatrix}
0 & 0 & 0 & 0 \\
0 & s_{T_x}^2 & 0 & 0 \\
0 & 0 & s_{T_y}^2 & 0 \\
0 & 0 & 0 & s_{T_z}^2
\end{bmatrix} \]
Typically \( e_T^2 = e_c^2 + e_x^2 + e_y^2 + e_z^2 = 10^{-10} \text{ sec.} \)

\[
H(k) = \begin{bmatrix}
h_0 & h_1 & h_2 & h_3 & h_4 \\
h_5 & h_6 & h_7 & h_8 & h_9 \\
h_{10} & h_{11} & h_{12} & h_{13} & h_{14} \\
h_{15} & h_{16} & h_{17} & h_{18} & h_{19} \\
h_{20} & h_{21} & h_{22} & h_{23} & h_{24}
\end{bmatrix}
\]

where:

- \( h_0 = (x'(k) + d/2)/\text{DEN}_1 \)
- \( h_1 = 0 \)
- \( h_2 = (y'(k) + d/2)/\text{DEN}_1 \)
- \( h_3 = 0 \)
- \( h_4 = (z'(k) + d/2)/\text{DEN}_1 \)
- \( h_5 = (x'(k) - d/2)/\text{DEN}_2 \)
- \( h_6 = 0 \)
- \( h_7 = (y'(k) + d/2)/\text{DEN}_2 \)
- \( h_8 = 0 \)
- \( h_9 = (z'(k) + d/2)/\text{DEN}_2 \)
- \( h_{10} = (x'(k) + d/2)/\text{DEN}_3 \)
- \( h_{11} = 0 \)
- \( h_{12} = (y'(k) - d/2)/\text{DEN}_3 \)
- \( h_{13} = 0 \)
- \( h_{14} = (z'(k) + d/2)/\text{DEN}_3 \)
- \( h_{15} = (x'(k) + d/2)/\text{DEN}_4 \)
- \( h_{16} = 0 \)
- \( h_{17} = (y'(k) + d/2)/\text{DEN}_4 \)
- \( h_{18} = 0 \)
- \( h_{19} = (z'(k) - d/2)/\text{DEN}_4 \)

and

- \( \text{DEN}_1 = [(x'(k) + d/2)^2 + (y'(k) + d/2)^2 + (z'(k) + d/2)^2]^{1/2} \)
- \( \text{DEN}_2 = [(x'(k) - d/2)^2 + (y'(k) + d/2)^2 + (z'(k) + d/2)^2]^{1/2} \)
- \( \text{DEN}_3 = [(x'(k) + d/2)^2 + (y'(k) - d/2)^2 + (z'(k) + d/2)^2]^{1/2} \)
- \( \text{DEN}_4 = [(x'(k) + d/2)^2 + (y'(k) + d/2)^2 + (z'(k) - d/2)^2]^{1/2} \)
D. THE SEQUENTIAL EXTENDED KALMAN FILTER APPROACH [1]

This approach assumes that all four transit times measurements are statistically independent of each other. In this way one can process the transit times sequentially and independently. The result of each computation step is used immediately, as soon as it is obtained. Thus more accurate estimates of the filter states are obtained.

This procedure also circumvents the matrix inversion when determining the filter gain, and allows one to disregard any particular time measurement that was found invalid, and not the total four times for a time slot (T=1.31sec).

Erroneous transit times are detected by implementing a three sigma gate using the covariance of the measurement noise (R) and the covariance of the estimation error (P(k/k)). For i=1 to 4,

\[
gate(i) = 3\sqrt{\frac{\text{P}_{j_{\text{maximum}}}}{4860} + R_{11}}.
\]

It can also be used to minimize position errors during high dynamic maneuvers, by repeating the calculations for the same time interval until the transit time residual error falls below a preset value.
III. THE IMPLEMENTATION PROBLEMS

A. THE HARDWARE AND THE SOFTWARE PROBLEMS

Since the objective is to use the developed software for torpedo tracking at the NAVTORPSTA, in Keyport, Washington, there was no other choice but to implement the program to run on the C.I.E. 680/30 microcomputer, and to implement it in the C language.

Two problems immediately arose.

First, there was only badly written and incomplete documentation. The manual was found difficult to read and to understand. In addition, there was no information about the computer hardware.

Secondly, poor software was available. The CIE 680/30 is a Unix based machine, designed for business applications, working with the Regulus operating system. As far as known, there is no software available (specifically written for the CIE) on the market.

As a result of these problems, there was no full-screen editor available for the C.I.E machine, no communications program, and no built in graphics capability (although the first screen that appears after booting the system shows the message "CIE GRAPHICS SYSTEM #7").
B. THE FAST APPROACH

In order to be able to write a reasonably long and complex program, in a reasonable time, debug it and make it work, it would be necessary to have a good compiler, a good full screen editor and good documentation on software and hardware.

It was then decided to make use of the known software and hardware information available for the IBM-PC microcomputer. It was not difficult to find Public Domain Programs able to communicate with Unix based machines, to emulate the VT-100 terminals, and to transfer files. Also it was not difficult to find a powerful easy to use full-screen editor for the IBM-PC.

The program was then written, trying to keep the C code the most standard possible, using the Lattice C compiler. It was executed first in the IBM-Pc, then transferred (source code) to the C.I.E using a public domain program (SIMTERM). It was then adapted, making minor changes, and recompiled on the C.I.E to generate the executable code.

C. ODDS AND EVENS OF C

The C language is not very high level but it is a very powerful language, allowing bit operations, low level read and write, system calls and easy interfaces with machine language. The general mathematical expressions can be kept
the same way as in Fortran, but some new operations, functions and expressions are also used.

Incrementing a variable:
"i=i+1;" can be "i++" or "++i", depending if you first use the variable (++i) and increment it or vice versa (i++).

Incrementing i by j: "i+=j;"

Do loop, testing the counting variable after using it:
"for (i=0;i<imax;i++)"

Blocks are delimited by "{ }";

Every program, subprogram, functions or procedures are seen as FUNCTIONS in C, including the main program. This is indicated by the calling statements as in:

main() .... for the main program that is not passing any arguments;
plot(x,y) .... for a routine that passes X and Y vectors for plotting, and so on;

C uses passing by value approach. So the value of the variable "x" is copied in and used inside a function. Arrays are equivalent to pointers and thus they can return new values from functions.

There are automatic, local, global and external variables. There are character, integer, long integer, string, floating point (double and single precision), string, and enumeration data types. Short integers have standard size. Double precision floating point allows one to
represent numbers in the range \( \pm 10^{\pm 9} \) in the IBM-PC (Lattice C compiler) and in the range \( 10^{\pm 9} \) in the CIE. There are IF, IF THEN ELSE, WHILE, DO..WHILE, and CASE statements.

There are no input and output statements as in Fortran or other languages. Input-output is done by standard functions, which must be carefully used.

Header files and "#include" statements are used to hide from the user definitions of parameters that are machine dependent or contain environment-specific information. "#define" statements are used to define constants and macros and to hide machine dependent code segments.

Reference [4] is the definition manual of the language. The other references for the C language were used primarily to look over the example programs, and functions.
IV. THE REAL-TIME KALMAN FILTER PROGRAM IN C

A. THE INITIAL APPROACH

The first idea was the simple translation of the program described in reference [1] to the C language, without worrying about specific problems that would arise when trying, later on, in a more realistic approach, to simulate as close as possible the actual running conditions.

The initial program had a structure similar to the Fortran program in [1], that is, a main program, the actual Kalman Filter, and several functions to calculate the trajectory, to add, transpose and multiply matrices and to multiply two vectors. All the floating point operations were done in double precision and the matrices were defined as two dimensional arrays.

The initial approach failed in many aspects.

It did not have enough speed, producing, on the average, one estimate every 22 sec, in an IBM-PC without math-coprocessor (8087), running at 5 MHz. The same program generated a new estimate every 5 sec in an IBM-PC with an 8087 chip. It did not have the main frame graphics capability, readily available and, finally, due to the way the C language passes parameters to the subroutines, the matrix routines worked correctly only if matrices were defined as square matrices.
B. OPTIMIZATION OF EXECUTION TIME

Although the C.I.E microcomputer runs a Motorola 68000 cpu at 8 MHz, and the IBM-PC runs at 5 MHz, executing the same program in both machines showed a difference of 10% to 20% in execution time. In this way, optimizing the execution in the IBM-PC (with 8087) would be a valid approach since it would allow a safety margin, and would require almost the same effort.

Optimization of execution time led to:

1. Transforming all the matrices from bidimensional to unidimensional arrays (or vectors). That saved memory space, and forced the access to the elements to conform with the way these are stored (C stores array elements by rows), thus speeding up retrieving when needed.

2. Eliminating functions, actually by having everything in the main program.

3. Eliminating all the unnecessary operations. That involved restructuring the program to avoid loops when possible and reasonable, avoiding multiplying by zero, avoiding adding zeros, and avoiding repeating calculations when the result was known to be constant.

4. Avoiding double precision where possible, and when improvement of the execution time could be achieved without compromising the results. The Lattice C compiler, in the IBM-PC, is defined for precision (all the floating point...
calculations are done in double precision). Then, if single precision is desired, you lose in both, precision and speed. The CIE machine calculations uses the Motorola "Fast Floating Point", a format which is not compatible with the IEEE format. The IEEE floating point values lose some precision due to the fact that the calculations use the fast floating point routines and a translation to and from the FFP format [10]. So, the FFP format was used, in the CIE.

5. Writing single precision routines to avoid calling standard mathematical routines, which are all double precision, in C.

6. Reproducing more closely the way the final program would have to work, when in the real time application.

7. Testing the program for several values and parameters, to determine bounds that would allow results of good precision without increasing the execution time. It was found, for example, that the results are highly sensitive to the way the columns of the matrix H are calculated, thus, requiring calculation of H using double precision.

8. Measuring execution time of tasks inside the program.

9. Developing software tools to allow for interactive execution and checking of correctness of the results.
V. TESTING

A. CHECKING THE TRAJECTORY-FOLLOWING PERFORMANCE

The trajectory following performance was verified for the following trajectories:

1. Straight line parallel to the array axis, and y-coordinate = 0.0, single array tracking;
2. Straight line parallel to the array axis and y-coordinate = 2121.0, single array tracking;
3. Straight line, 45° inclination relatively to the array axis, single array;
4. Straight line parallel to the array axis, long run, multiple array tracking;
5. Straight line and circular maneuver, short run, slow turn (10.0dg/sec, 1/4-G), single array tracking;
6. Straight line and circular maneuver, long run, slow turn (10.0dg/sec, 1/4-G), multiple array tracking;
7. Straight line and circular maneuver, short run, fast turn (20dg/sec, 1-G), single array tracking, adaptive maneuver implemented with 4 iterations allowed;
8. Straight line and circular maneuver, long run, fast turn (20 dg/sec, 1-G), multiple array tracking, adaptive maneuver implemented with 4 iterations allowed;
TABLE 1, and TABLE 2 summarize the results in terms of maximum absolute error for the IBM and the CIE microcomputers, respectively. For the single array cases, only the region inside a 3000 feet radius around the center of the array being used is considered in determining the errors.

The corresponding plots can be found in the following pages. The plots were obtained with the value $10^{-10}$ for the elements in the diagonal of the matrix $R$ (the Error Covariance Matrix) for the IBM-PC microcomputer and with the value $10^{-8}$ for the CIE. The plots are numbered sequentially and contain headings to identify and relate them to the Table 1 and Table 2. The actual time is obtained by multiplying the time scale by the length of the time slot, 1.31 seconds.

B. CHECKING THE EXECUTION TIME REQUIREMENT

The execution time in the IBM-PC, was verified by checking the printouts containing the values of the internal computer time for a cycle. Later, an "waiting loop" was introduced to generate an interval of 1.31 sec between each data input (that is, reading files TRJ.DAT and ZIC.DAT).

Since the "reading internal time" was not incorporated in the CIE program version (CIEKR1), and since that proved to be a faster machine, the time requirement was just checked against a chronometer for 150 iterations.

Figure 89. CIE - Error in torpedo depth during a straight run through multiple arrays. Initial conditions are: \( x=34000 \) ft, \( y=6050 \) ft, \( V_x=-84.4 \) ft/s, \( V_y=0 \) ft/s.
VI. COMMENTS AND CONCLUSIONS

There are slightly different versions of the program, for the IBM-PC and for the CIE microcomputer. However, the Sequential Extended Kalman Filter program presented have many common characteristics. The execution time per cycle, in both machines, is less than the sample interval for the data. The program is written in the "C" programming language, and it is meant to be reasonably portable. Double precision calculations are widely used, and allowed in many cases to bound errors without repeating the calculations for the same time interval.

Calculations are performed using an adaptive $Q$ matrix. That is, the matrix $Q$ is recalculated each iteration, instead of using a constant value. The trajectory simulation routine was implemented using geometrical approach. The tangential speed is assumed constant during the whole run.

The Kalman Filter can track through single and multiple arrays. The algorithm always uses the coordinates of the closest array in the calculations, for the multiple array case. There is essentially, in either CIEKR1 and KR, only a main program without subroutine calls. The bidimensional matrices were transformed and are used as vectors. Most loops were eliminated to keep the execution time within the required limits.
The CIE version can also run in the IBM-PC but the IBM-PC version runs only in the IBM since it calls assembly language routines to generate graphic output. The IBM version is slower than the CIE version and the IBM-PC microcomputer must run with its 8087 math coprocessor chip to satisfy the speed requirements. Both machines were configured with hard disks, and the data files were read from and written to the hard disks. Both, the IBM-PC and the CIE versions, will run on the IBM-AT.

There is almost no documentation or software available for the CIE microcomputer. The lack of documentation, the lack of a good compiler, a full-screen editor, and the lack of graphics capability were major problems in using the CIE.

The improvement in the execution time was more noticeable in the CIE than in the IBM. This is probably due to the presence of the math coprocessor chip, 8087, and (or) due to a better compiler, in the IBM-PC. The use of the "-f" ("fast floating point format") option, when compiling code on the CIE, seemed to help both, the speed of execution and the precision of the results.

The programs were tested for torpedo speeds from 20 knots (33.8 ft/s) to 55 knots (92.8 ft/s) and turn rates of up to 20 dg/sec, or maneuvers of up to 1-G. The magnitude of the position errors for linear trajectories were maintained less than 10 ft in either computer. The CIE could not track any of the circular maneuvers (run numbers 6, 7 and 8 in
Table 2). In the IBM-PC, keeping the maneuver within the tracking radius of a single array (± 3000 ft around the array center), the magnitude of position errors were maintained less or equal to 7 feet for an 1-G maneuver and less or equal to 22 feet for the multiple array case.

The high error obtained for the circular maneuvers in either the single or multiple array case reflects the algorithm inability to follow fast turn circular trajectories. In [1] such high errors were reduced to values comparable to the errors found in the straight runs, by adding the adaptive Q matrix to PKK to produce PKKMI and repeating the calculations for the same time interval. This was called "adaptive maneuver". The "adaptive maneuver" as implemented (see segment 2, in the algorithm, in Appendix A) was found effective for the IBM-PC when the value $10^{-10}$ was used for the diagonal elements of the matrix R. However, to keep the execution time per cycle within 1.31 sec, the number of adaptive maneuvers performed had to be limited. Almost no improvement in reducing tracking errors was achieved when the value used was $10^{-8}$. For the later case a great deal of degradation in the execution time was observed and the time interval was exceeded even when just one more iteration (optimum maneuver) was executed. The procedure did not work on the CIE, which could not handle numbers less than $10^{-7}$ reliably. The "adaptive maneuver" feature was
utilized only for the runs 7 and 8 (only 4 iterations were allowed) and have produced, for the 1-G maneuvers, results which are comparable to the results for the 1/4-G maneuvers. The single array cases showed smaller errors, meaning probably that the technique used to switch arrays can be improved.

An interesting point is the behavior of the curves for the diagonal terms of the matrix PKK. The curves PKK_X vs TIME_SLOT, PKK_Y vs TIME_SLOT and PKK_Z vs TIME_SLOT, which are the mean square errors should grow proportionally to the square of the position errors. These are depicted in the curves X_ERR vs TIME_SLOT, Y_ERR vs TIME_SLOT, and Z_ERR vs TIME_SLOT. When such does not happen it means that the filter model used is not a correct description of the process. When the value of the diagonal elements of the matrix \( R \) were \( 10^{-6} \), only the qualitative behavior of the mean square errors agreed with the expected. When \( 10^{-10} \) was used, the quantitative behavior of the mean square errors were about the expected.

Additional tests should be performed using trajectories generated from actual torpedo runs on the Dabob test range. As a future step, there is the need to adapt the program to provide it with the correct interface formats to access the real data, before running it in the real-time conditions on the range.
APPENDIX A

PROGRAM DESCRIPTION

A. OVERVIEW

There are at this moment, three versions of the Extended Kalman Filter program. In either case the simulated trajectory must be first computed and the hydrophones array times, corresponding to the simulated positions, are stored in a file in order to be read in. All three programs write the files XKK.DAT, PKK.DAT, and XDIFF.DAT to the disk.

To avoid delays due to data writing and retrieving from disk drives, the data files can be written to and read from an electronic drive built in the RAM memory. There is also a utility program — PLOT.C — which allows fast graphic analysis after the run.

1. The CIE1.C Program

This was the first program to run in the CIE microcomputer. It reads "clean" (without noise) trajectory data from the file TRAJ.DAT and writes 3 columns, corresponding to the coordinates x, y, and z, to the disk. The code to generate Gaussian noise is contained in the main program.

CIE1.C generates 3 data files, XKK.DAT, PKK.DAT, and XDIFF.DAT, containing filtered data to be post-processed. XKK.DAT, contains 4 columns, corresponding to the time slot and the filter estimates, X(k/k), for the coordinates x, y,
and $z$ in that order. PKK.DAT contains 4 columns with the corresponding values of the time slot and the error covariance matrix for the coordinates $x$, $y$, and $z$, in that order. XDIFF.DAT contains 4 columns with the corresponding values of the time slot and the errors for the coordinates, $x$, $y$, and $z$, in that order.

2. The CIEKR1.C Program

This program runs in the CIE and provides input and output similar to the KR.C. It is able to simulate only straight line trajectories, due to the lack of an "arc tan" function in the CIE's C Compiler, and at present does not access the computer internal clock.

3. The KR.C Program

This program includes a set of assembly language routines for interfacing with the keyboard, display, and output ports of the IBM-PC/AT. It also includes a plotting routine, written in C, which calls the assembly routines to generate the frame, to print updated values, and to draw the estimated trajectory. Another assembly language routine was added to allow access to the internal clock in the IBM-PC.

See references [7] and [8] and Appendix C for details.

The Kalman Filter section of KR.C needs the files TRJ.DAT and ZIC.DAT, generated by the trajectory simulation routine, for inputs.

The trajectory simulation generates transit times data already corrupted with noise. That involves inclusion
of the noise generation routine with the "clean" trajectory. The clean trajectory can be either a straight line or a circular curve.

The trajectory simulation routine creates the files TRJ.DAT, ZIC.DAT, TRJ.INP, and PARAM.DAT.

The TRJ.DAT contains the data for the clean trajectory, corresponding to the time slot, and the x, y and z coordinates. ZIC.DAT contains the noise corrupted transit times. TRJ.INP and PARAM.DAT contain information to be used by PLOT.C program in order to identify and relate the trajectory data and the parameters used in the Kalman Filter to the graphic outputs.

B. DETAILED DISCUSSION

Since the programs evolved one from the other, only the last one, KR.C, will be discussed in more detail. The routine that generates the trajectory and the tools developed to facilitate the objective analysis of results will also be briefly described.

1. The Kalman Filter Program - KR.C

The algorithm for the program KR.C is provided as Appendix B and the actual program implementation is shown in the Appendix E.

The capability of tracking through multiple arrays is implemented by simply defining switching points along a coordinate axis, and comparing the estimated x-position against switching values. The coordinates of the tracking
array are then changed in order to always keep the closest array tracking the torpedo. Figure 90 shows the coordinate system for the multiple array tracking, the location of the switching points and the hydrophone location matrix.

Tests performed using a straight line trajectory and keeping the Q matrix constant showed no improvement over the case where the adaptive Q is used.

2. The Trajectory Simulation Routine - TRAJEC

This routine was developed as an independent simulation program, to generate trajectories, where circular and linear segments can be combined to produce a desired path.

Given the initial x,y,z, positions and the initial speeds and assuming that the vertical speed is zero, this routine generates noisy data to represent the "raw" data as it would come from the hydrophones. TRAJEC finds the position of a point in a circle after a time interval $T$, given the tangential speed of the point, and given the desired turn rate or given the centrifugal acceleration. It is assumed that the tangential speed is constant during the maneuver. Either the turn rate or the centrifugal acceleration can be used to determine the radius.

Figure 91 represents the geometry of the problem. The straight line shown is tangent to circle. A point is initially moving on the line and at the time $t_0$ it is

Figure 90
Figure 91: The circular trajectory problem.
subjected to centrifugal force which makes it turn. The point then describes a circular movement generating a circle of radius $R$, and at the time $t_0 + T$ will be at the position $X, Y$. Assume $V_y$ and $V_x$ known speeds, $m = V_y / V_x$ is then the slope of the line tangent to the circle that passes at the point $x_0, y_0$ and has center at $a, b$. The angular coefficient of the line perpendicular to the circle and passing at the point $x_0, y_0$ is

$$\frac{x_0 - a}{y_0 - b} = -\frac{1}{m}, \text{ so}$$

$$x_0 - a = m \cdot (y_0 - b)$$

and $$R^2 = (x - a)^2 + (y - b)^2$$

is valid for any point on the circle.

At $x_0, y_0 \rightarrow R^2 = (x_0 - a)^2 + (y_0 - b)^2$

$$R^2 = (m^2 - 1) \cdot (y_0 - b)^2$$

$$y_0 - b = \pm R / \sqrt{1 + m^2}$$

or $$b = y_0 + R / \sqrt{1 + m^2}$$

and $$a = x_0 + m \cdot (y_0 - b)$$

For any point on the circle

$$x - a = R \cos \theta$$

$$y - b = R \sin \theta$$

From the Figure 91
\[ \alpha = \tan^{-1} m \]
\[ \theta_0 = \pi / 2 - \alpha \]
\[ \theta = \theta_0 + \omega \Delta t \]

Given \( V_x \), \( V_y \), \( V_t = \sqrt{V_x^2 + V_y^2} \)

Given \( \omega \) \( R = V_t / \omega \)

Given the central acceleration, \( g \) \( \omega = g / V_t \)

At the end of the interval, the position will be \( x \), \( y \) and the speeds will be given by

\[ V_x = -V_t \sin \theta \]
\[ V_y = V_t \cos \theta \]

These equations, when implemented, generate the true trajectory.

The routine also computes the measurement noise times. The Gaussian noise is generated by computing the linear approximation of the inverse of the normal curve [9]. The input comes from a sequence of uniformly distributed numbers generated by the equation below

\[ r(I + 1) = r(i) * 317 \mod(1) \]

The resultant sequence is zero mean and is scaled to obtain the desired variance.

3. The Plotting Routine - PLOT

The plotting routine is contained in the file PLOT.C (IBM-PC), and was written as an independent module to be
linked with BIOSIO.OBJ, and reads data from the files XKK.DAT, PKK.DAT, XDIFF.DAT, TRJ.INP, and TRJ.DAT.

That is a menu driven program, which provides fourteen (14) different options and was designed to simplify the analysis of data generated in a torpedo run. The plots have their titles already chosen. The scales reflect the maximum and minimum values. A reference number and a label for SINGLE or MULTIPLE array cases is printed on the plot for reference. Linear interpolation is used to interconnect the sample data points. An optional plot, where the data points are simply plotted, is also available. This last option would allow the time to be associated to each point on the curve.

In an attempt to provide the CIE machine with similar capabilities, an ANSI driver was also defined and tested successfully in the IBM. However, that provides a very limited graphics capability, allowing only 80 columns by 25 rows of resolution against the 640 by 200 in the IBM, in graphics mode. The file KR1.C makes use of the defined driver to produce the graphics presentation of the estimated trajectory.

For UNIX systems, like the CIE, one might want to consider the "termcap" database of hundreds of encoded descriptions for terminal control. However, except in unusual circumstances, C’s standard-library I/O functions
provide excellent portability and a wide range of display features [6].

4. BIOSIO.ASM and BIOSIO.OBJ

These files contain the assembly language code (public domain) and the object code (IBM-PC) to interface the C programs with the keyboard, display, output ports and to access an absolute memory location.

5. DOSTIME.ASM and DOSTIME.OBJ

These files contain the assembly language code and the object code, respectively, that allow access to the internal clock (IBM-PC).

6. The SIMTERM program

This is a public domain program written by Jim & Eric Holtman that allows one to emulate an HP-like terminal to a UNIX system. It is a self contained module that allows one to connect the IBM-PC to the CIE microcomputer, directly by using the RS-232 output on the IBM and one of four (4) output ports on the CIE.

7. The KALMAN.H header file

It contains the definitions of the program constants, initial values of parameters, and the definition of the ANSI terminal driver, which can be used in the future to generate rough plots on most of the nongraphic terminals.

APPENDIX C

SETTING UP FOR EXECUTION

A. USER’S NEEDS

This section describes the actual hardware and software utilized to produce the results in Appendix H.

HARDWARE

The following describes the hardware utilized and the way to interconnect the IBM-PC and the CIE microcomputer.

IBM-PC: 2 floppy disk drives, 10 megabytes hard disk, graphic board, graphic color display, serial port (RS-232), 8087 math coprocessor chip and Epson parallel printer;

CIE 680/30: 20 megabytes hard disk, 4 serial output ports, Amdek monitor and keyboard.

The computers were interconnected by cable, from the IBM RS-232 output port to one of the 4 ports on the CIE.

SOFTWARE

The files and/or programs utilized are:

1. SIMTERM - communications program (in the IBM). Allows transferring files between the IBM and the CIE.

2. CIE.BAT - batch file (IBM). Executes the necessary sequence to interconnect the IBM and the CIE. Needs SIMTERM.

3. KR.EXE - executable file that contains the program to simulate the torpedo trajectory and the Kalman filter program (IBM). The trajectory routine is executed directly from the KR.C program as a menu option and it generates the
data files "trj.dat", and "zic.dat". Then the trajectory and
time information from the files, "trj.dat" and "zic.dat", is
used by the Kalman filter algorithm to produce estimates. It
generates the files "xkk.dat", "pkk.dat", "xdiff.dat",
"trj.inp" and "param.dat". At the end of the run, a total of
7 files would be generated.

4. PLOT.EXE - executable file that contains the plotting
routine (IBM). Allows posterior graphic analysis of the
results. Uses the information contained in the files
"xkk.dat", "pkk.dat","xdiff.dat","trj.dat" and "trj.inp".

5. KAL.BAT - batch file (IBM). Executes the necessary
sequence to run KR.EXE and PLOT.EXE.

6. KALMAN.H - header file (IBM and CIE). Contains
definitions used by CIEKR1.C, KR.EXE, PLOT.EXE, TR.EXE.

7. a.out - executable file generated from compilation of
CIEKR1.C on the CIE machine.

B. PROGRAMMER'S NEEDS

It is highly recommended to have a good full-screen text
editor, and the source code files included in the directory
of the IBM-PC. Source code files have extension ".C". A good
C compiler (IBM) is also recommended.

The software required is:

1. LATTICE C or MICROSOFT C compiler;
2. FULL SCREEN EDITOR;
3. SIMTERM - terminal emulation / communication program:
4. SOURCE files: TR.C, KR.C, PLOT.C;
5. HEADER files: KALMAN.H, MATH.H, STDIO.H;
6. ASSEMBLY LANGUAGE ROUTINES: BIOSIO.ASM, DOSTIME.ASM;
7. IBM MACRO ASSEMBLER;
8. MICROSOFT LINKER.

Using the Lattice C compiler requires the files LC1.EXE, LC2.EXE, LCS.LIB, LCMS.LIB, CS.OBJ, MATH.H, STDIO.H to be present. The assembly language routines must first be transformed into object files by using the Macro Assembler. The file TR.C must also be compiled using LC1 and then LC2 to generate the TR.OBJ file. These are all linked to the file KR.OBJ to produce the executable file KR.EXE.
APPENDIX D

COMPILING, EXECUTING, TRANSFERRING FILES, AND PLOTTING

A. RUNNING THE PROGRAM ON THE IBM-PC

This will assume one is running the Kalman Filter program on the IBM PC/AT with a hard disk drive defined as drive "c". The system prompt is "c>", and the required files are in the subdirectory named "KALMAN".

If you are not in drive "c", change to the correct drive typing "c:" and hit "RETURN". The system will then answer with the prompt "c>". Type "cd kalman" to access the directory KALMAN.

1. Compiling KR.C

This will assume you are running the Lattice C compiler. Type "ce kr" to compile the file KR.C, using the batch file "CE.BAT". The files KALMAN.H, DOSTIME.OBJ, TR.OBJ, BIOSSID.OBJ, LINK.EXE, CE.BAT, and KR.C need to be in the same directory.

The Appendix E contains a listing of the file CE.BAT.

2. Executing KR.EXE and PLOT.EXE

Type "KAL", in drive "c", to execute the batch file KAL.BAT. The required sequence of commands is initiated and can be interrupted by pressing "CTRL-BREAK" ("CTRL" and "BREAK" keys at the same time). The Appendix E contains a listing of the file KAL.BAT.
The first file to be executed is GRAPHICS. It allows dumping IBM-PC graphic screen to the printer.

Next the file KR.EXE, containing the trajectory routine and the Kalman Filter program, is executed. Menus give the indication for data input, to run the trajectory routine, and to run the Kalman Filter. One normally defines the parameters first (option # 3), then run the trajectory routine (option # 1), and then run the Kalman Filter (option # 2).

After the run, the plotting routine ("Plot") is called to produce the graphic output. Up to fourteen different plots can be generated by making the desired selection from the menu. The output to the printer is obtained by pressing "SHIFT-PRTSC" ("Shift" and "PrtSc" at the same time).

If a plot ends abnormally, for instance by the use of CTRL-BREAK, the screen is left in the graphics 640 by 200 mode, then the command "mode bw80" will set the display mode to Black and White with 80 characters per line.

B. RUNNING THE PROGRAM ON THE CIE

Turn on the system with the floppy disk drive open. This will force the system to boot and accept the internal hard disk drive as the current drive. Turn on the terminal display and when the cursor appears, press "ENTER". Follow the prompts for date and time input.
After booting, the screen will show the message "CIE GRAPHICS SYSTEM # 7" at the top, and "login : " at the bottom. At this moment one should have the SIMTERM diskette in drive A (the one at the left) on the IBM-PC. If the logged drive is not A, one should type "a:" and press "ENTER" to change to drive A. In drive A, one should type "cie" and "RETURN" (ENTER). The batch file CIE.BAT will send the correct command line to connect the IBM and the CIE. Make sure the cable connection is already done.

The message "connection established" will then appear on the screen. Press "ENTER" to get "login:". Log in using the account "jose", and press "ENTER" for the password. The system prompt is "%". Change directory using "cd work". One is then ready to transfer files or to execute a program in the CIE machine.

1. Transferring Files from the IBM to the CIE

To transfer a file use the redirection capability of the Unix system and the command "cat".

Type "cat > filename.ext" and press "ENTER", at the system prompt ("%"). The cursor will stop at the beginning of the next line. "ALT-D" will dump a file to the communication line. One will be prompted for the filename.

If, for instance one wishes to transfer the file "kalman.h", which is in drive c: (IBM), to the CIE, given it the name "kalman.h", the following sequence should be performed, starting at the prompt "%" : Type "cat >
the name "kalman.h", the following sequence should be
performed, starting at the prompt "%": Type "cat >
kalman.h"; press "ALT-D"; type "c:\kalman.h" , when asked for
the IBM filename, and press "ENTER" to start the
transmission.

At the end of the transmission the computer bell
will ring, signaling buffer overflow. One should wait until
no more new lines are being written. Press "CTRL-D" to close
the file in the CIE. The prompt "%" will reappear on the
screen.

The new file (kalman.h) will have to be edited on
the CIE to remove the inserted empty lines:

Type "ed kalman.h" and the editor will show the
number of lines in the file. Then, type "g/^$/d" and press
"ENTER". The number of lines in the file will be reduced to
the half. This will not affect the blank lines originally
in the program, just the ones inserted by the process of
transmission.

Type "w" to write the modified program version to the
disk, and "q" (quit) to leave the editor.

2. Compiling on the CIE

Type the command line "cc -f -v -L -7 ciekri.c" to
generate the executable file "a.out".

where: "cc" invokes the C compiler;
"-f" option , informs the compiler to use "fast
floating point format";
"-v" option ...  
"-L" option instructs the compiler to generate pointers to allow long jumps, for a code+data greater than 32 kbytes;  
"-7" option instructs the compiler to use the Unix version 7 standard library.

3. Executing CIEKRI

Type "a.out" to start execution and then follow the menus for inputs. Since the CIEKRI.C program does not generate circular trajectories, the files containing the trajectory data (TRJ.DAT) and transit time data (ZIC.DAT) will have to be transferred from the IBM to the CIE, in order to run the Kalman Filter for the circular trajectory. Be sure to input the same data that were used to generate the circular trajectory on the IBM, and then select option #1 (Run Kalman). For straight line trajectories, just follow the menus.

4. Plotting the Results

Since there is no graphics capability built in the CIE, the only way to obtain plots is to transfer the files XKK.DAT, PKK.DAT and XDIFF.DAT, obtained on the CIE, back to the IBM and then use the routine PLOT to generate the desired graphic output. The procedure is described below:

"ALT-C", during the SIMTERM session, will open a capture file. One will be asked the name of the capture, or log file. The drive name should be specified.
For instance, assume one wants to transfer the file XKK.DAT from the CIE to the IBM in order to use it later to generate plots. Since, the routine PLOT reads specific files, be sure to erase the old file XKK.DAT, in the IBM, before copying the file XKK.DAT from the CIE, because the same name will be used.

Type "list -n xkk.dat", at the prompt "%", without pressing "ENTER". Pressing "ALT-C", will start the capture mode. Then one will be asked the name of the log file. Type "c:xkk.dat", and press "ENTER", to open the file on drive C. The command line "list -n ... " will reappear. Press "ENTER" to start the transfer and the capture. Press "ALT-C" at the end of the file listing, to close the log file.

After doing similar procedure for the files XDIFF.DAT and PKK.DAT, leave the account on the CIE by typing "logout".

Leave the SIMTERM program and drop the line, pressing "ALT-F2". One will be back to drive A on the IBM.

Type "c:", to change logged drive to C.

One may use his preferred text editor to eliminate the undesired lines in the files XKK.DAT, XDIFF.DAT, and PKK.DAT. The files should contain only four columns of numbers, except for the first row, which is blank. Then one can use the routine PLOT to obtain the desired plots, by typing "PLOT =8000", and following the menu options.
APPENDIX E

KR.C PROGRAM LISTING - IBM-PC VERSION

This Appendix contains a listing of the Extended Kalman Filter program implemented in the IBM-PC microcomputer, as well as the listings of the Trajectory Simulation routine and the header file "kalman.h", which are used by the main program KR.C. The other header files declared at the beginning of the main program are standard files contained in the C compilers.

APPENDIX I

SIMTERM - PROGRAM DOCUMENTATION

This Appendix contains the listing of the file "readme" found in the PC-SIG LIBRARY (Public Domain Library), disk number 362.
SIMTERM Instructions

1. Introduction

Feel free to make copies of this program. There is no restriction on the distribution as long as the copyright notices are left on the source and that there is no charge for the distribution. This program is made available to users of IBM-PCs (and compatibles since I really like the COMPAQ/PLUS). No guarantees are made or implied. If you have any questions or suggestions, please give me a call and I will try to answer them. A recent acquisition of an interrupt driven communication driver from the University of British Columbia Computer Center has enabled me to remove the requirement that you have the IBM Async Communications Support package which included a driver I used to use. This version of SIMTERM is therefore self-contained and requires no other software to run. Have fun using it and **HAPPY COMPUTING**.

This floppy contains all the software for the terminal simulator for the IBM PC. The main function of this program is to provide a reasonable terminal simulation on the IBM PC of an HP-like terminal to a UNIX(TM) system. The file 'simterm.exe' is the load module and when invoked, assumes a default of 1200 baud, 1 stop bit, no parity, and flow control (XON/XOFF). The only programs that have to be on the floppy are SIMTERM.EXE, HELP.TXT, and MENUS. If you have a VENTEL or a Hayes modem, the file BOARDS can be copied over as a starter for a list of BBSs. The BOARDS file is set up for a VENTEL autodialer. The dialing strings will have to be changed to conform for the Hayes standard.

If you have DOS 2.0, put SIMTERM.EXE, HELP.TXT, BOARDS and MENUS in a subdirectory called \simterm. That way, if you change directories during a SIMTERM session, by specifying a path for any type of file transfer, SIMTERM will be able to find its way back to these two important files. If you don't have DOS 2.0, then just IGNORE the occasional "directory not found" messages, they're harmless.

2. Command Line Parameters

Optional parameters on the command line will override the defaults as follows:

Copyright @ 1982,1984

Jim & Eric Holtman

213
SIMTERM Instructions

'–a' put the simulator into the ADM3a emulation mode for those systems which don’t support TERMCP.

'–b' Causes SIMTERM to assume you are using a monochrome display, even though you may not really have one.

'–B' will cause the transmit and receive buffers to be cleared when a BREAK (End key) is sent. This is mainly for high baud rate lines where there is still junk in the buffers that you don’t want to see.

'–cn' specifies which COMx device you want to use. The default is 1 (use COM1).

'–d' Enter direct connect mode. SIMTERM won’t wait for carrier detect. Use this option if you’re connected directly to the remote, with no modem. You can also use this option when SIMTERM seems to hang at startup, with the "Establish communications link" message. This may be case with Hayes modems if you don’t have them optioned to raise the carrier detect.

'–D' When this flag is used, SIMTERM will ignore DEL (127 Ascii) characters, and the character immediately following the DEL. We use it because we have a noisy line.

'–e' specifies that the EPSON printer does not have the GRAFTRAX option. Therefore when using 'ibmp' to route stuff to the printer, the code will simulate underlining, subscripts, and superscripts. Default is an EPSON with GRAFTRAX.

'–g' Causes SIMTERM to assume you are using a graphics display, even though you may not really have one.

'–h' SIMTERM will operate in the ‘half-duplex’ mode; i.e., it will echo the characters the user types since the host system does not.

'–in' specifies the IRQ (interrupt request level) to be

Copyright © 1982,1984 Jim & Eric Holtman
SIMTERM Instructions

used. Default is 4, but some boards (like the Quadram) use IRQ3 for COM2, so in this case SIMTERM would have to be invoked with the parameters `-c2 -i3' to set it up correctly.

`-m' Tells SIMTERM that you have a Hayes modem instead of the default VenTel modem. This will enable SIMTERM to use the directory dialing features (Alt-V)

`-M' Redefines the cursor control keys compatible with a set of UNIX-like utilities on a PRIME computer at UofVa.

`-nxxxx' if you have a Ventel or Hayes modem, this option will automatically dial the number when the simulator is started.

`-o' turns off the error messages caused by communications line; e.g., framing error and invalid parity.

`-px' specifies the parity where 'n'-none, 'o'-odd, 'e'-even, 'm'-mark, and 's'-space.

`-PFfil' Use file "file" as a script source file (see SCRIPTS below)

`-PDscr' Execute script "scr" upon start-up (see SCRIPTS below)

`-r' this causes SIMTERM to wait for the horizontal retrace when writing to the screen. If you notice 'sparkles' on your graphics monitor, invoke SIMTERM with this option and it should clear up.

`-snnnn' specifies 'nnnn' as the baud rate (e.g., -s300).

`-Sn' specifies the number of stop bits (1 or 2)

`-vxxxx' specifies the file (xxxx) to be used when the Alt-V options is invoked to dial BBS. The full path name of the file should be specified.

Copyright © 1982, 1984 Jim & Eric Holtman
SIMTERM Instructions

`-wn` set the word length to 'n'. Default is 8 (7 data + 1 parity).

`-xn` this option will turn off the XON/XOFF flow control. The program will send an XOFF when the receive buffer is almost full and then an XON when it has emptied out. It will also recognize an XOFF from the host to stop transmitting and then an XON to start again.

`-kfilename` will read in the file 'filename' to initialize the function keys. The file is of the form

```
 n=string of chars
```

where 0<=n<=9

example
```
 0=who^V
 1=who:wc^V
```

If the string is terminated with a `^V` (chr(174) -- obtained by holding down the 'Alt' key and typing 174 on the key pad), a 'carriage return' will be appended.

For example:

If you want to run at 9600 baud, even parity, without waiting for carrier detect
```
simterm -s9600 -pe -d
```

If you want to use COM2 (and it requires IRQ3) at 300 baud and run script "xyzzy" from file "scr2"
```
simterm -s300 -c2 -i3 -PFscr2 -PDxyzzy
```

If you are using a Hayes modem and want a number dialed when SIMTERM is started, use the following command line:
```
simterm -m -d -n12145551212
```

Copyright © 1982,1984 Jim & Eric Holtman
3. Program Functions (Unix specifics)

Once loaded, the program will use all available memory above the module for save space for paging through previous output. I have 256K on my system and this provides about 20 pages (~500 lines) of saved text. The TERMCAP entry for the terminal is in the file 'termcap.ibm'. This should either be added to your termcap library or the 'shell' variable TERMCAP should be set to it before trying to use any package that requires cursor addressing. The TERMCAP entry makes use of the fact that 'vi' (and 'curses') will use a special sequence to enter and leave the control mode. The simulator uses these sequences to redefine the cursor control keys so that they can be used in that mode; e.g., in 'vi' the "up arrow" will send in a "k", while the "PgDn" will send in a "^D" to scroll the display down, etc. For those of you who are running on UNIX systems that use "terminfo", there is a file "terminfo.ibm" which has the appropriate definitions.

Output to the printer can be initiated under program control with a filter similar to 'hp' which is used for HP terminals. The source file for 'ibmpr' (which is the filter that use on UNIX) is on the floppy. You should compile this UNIX and then use for controlling output to the printer. A typical use of this filter is:

    nroff -T37 file 1 ibmpr -p

The '-p' option says to route the output to the EPSON printer. The '-i' option will cause underlined text to come out in italics. The '-c' option is used to invoke the compressed mode (132 characters/line).

If those escape sequences are output, they will be displayed appropriately on the CRT and output to the printer correctly.

4. User Defined Function Keys

There are 10 user definable functions keys that will send a character sequence of up to 30 characters.
display the current contents of the keys, hold the 'Alt' key down and type '='. To change the contents, hold the 'Alt' key and type '-' and follow directions. To invoke the functions keys, hold down the 'Alt' key and type the corresponding digit (e.g., 'Alt 3'). A user can define a file with the contents of the keys and cause it to be read in with the '-k' option on the command line.

5. Upload/Download (Unix Specific)

This is used to transfer 'text' files (ones that only contain printable ASCII and tabs) between the PC and the host. To remember which way the data flow, just remember that the IBM PC looks 'up' to UNIX, while UNIX looks 'down' on the PC. To move files between the PC and UNIX, hit 'Cntl-PgUp' to transfer PC->UNIX. Answer the prompts. Hit 'Ctrl-PgDn' to move from UNIX->PC. As the transfer is taking place, a message will indicate the # of bytes transferred. When going UNIX->PC, there will be more bytes on the PC disk than on UNIX because of added 'end-of-line' and 'end-of-text' bytes. This can only be used to transfer TEXT files.

6. Upload/Download (Straight ASCII & XMODEM)

The program can be used to connect to BBSs and any other systems that support async devices. To download a file to the PC, go through the normal dialog on the BBS and then when it is waiting for you to hit return to start the transfer, press Alt-C to open the 'copy' file that will receive the data. You will be put back to the original screen where you can hit return. At the end of the data transfer, hit Alt-C to close the copy file.

To upload a file from the PC to a BBS, again go through the dialog to setup the transfer and when the BBS is ready, press Alt-D to specify the data file. This will then 'dump' the file to the comm line. At the end of the transfer, you may have to type in a control sequence to indicate that you are done. This option will request a 'delay' between characters so that you do not overrun the receiving system. Use '0' for no delay; a value of '1' is probably sufficient for most systems that can not handle the normal baud rate. Experiment.

Copyright © 1982,1984 Jim & Eric Holtman

218
SIMTERM Instructions

SIMTERM supports the XMODEM protocol for data transfer from a BBS. To invoke this option, hit Alt-R to receive with XMODEM at the point that the sender is ready. You will be prompted for the file to receive into and then the PC will initiate the transfer of data. Transmitting with XMODEM is invoked with Alt-T and prompts will follow.

7. Script files

Script files are used to allow SIMTERM to do mindless interactive login and other such sequences. A Scriptfile can be created by your favorite word processor and SIMTERM will compile it for you, and save the compiled version so you don't have to re-compile at each run. Script files read much like English, so they are both easy to understand and create.

Script Commands Available

Each of the following commands can appear in a script file. Note that each separate command must be separated by a space, tab or newline. The compiler ignores extra white-space, so you can have indenting, multiple commands per line, or whatever you want. Syntax notes: "str" in the following denotes a string constant delimited by quotes. A string can have multiple words. To get a quote character into a constant, write it as ". To get a backspace, write it as \ . Although one-word strings need not have quotes, they should, so that they are not confused with keywords (commands). Non-quoted strings generate warnings from the compiler.

name "str" --- defines an entry point for the script that you can use to identify this part, i.e., if a "name whuxlb" appears in the file, then you can start running the script by using the name "whuxlb". (See "running scripts" below) If you choose "whuxlb" from the pop-up menu later, the script will start executing at the statement immediately following the "name" statement.

send "str" --- sends the string to the remote computer, with a carriage return tacked onto the end. Some escapes can be placed into the string, as follows: an "\1" causes a one second pause when it is encountered. "\m" sends

Copyright @ 1982,1984

Jim & Eric Holtman
a carriage return. "\j" sends a line-feed. "\c" suppresses
the carriage return that is normally tacked onto the end of
a string. Remember, though, you need to type TWO backspaces
to get one, so these sequences should appear as \\l, \\m, etc
in your file.

dial "str" --- dials the string on a VenTel
dialer. Obviously, if you don't have a ventel, don't use
this command (Fake it with "send"). For example, to dial
"3395" on a Hayes, put a line like "send ATDT3395" in your
file.

say "str" --- outputs "str" onto the screen, so
that you can put tracer statements in the script.

goto "str" --- branches to str. labels to be
branched to must be followed by a colon. I.e. early in the
script you have a line "label:" all by itself. Later, you
can call "goto label" (no colon) to branch back up to the
earlier statement

gosub "str" --- like goto, but when a "return"
statement is encountered later, the program branches BACK to
the statement that follows the gosub. Gosubs may be nested.

return --- returns from a "gosub" statement

input "str" --- Prompts the user with "str",
reads one line, and sends it to the remote computer.

settime "str" --- sets the timeout value to "str"
seconds. Default is fifteen.

quit --- execution is returned to SIMTERM.
There is an understood "quit" at the end of file

The Logical Operators (IF/CASE)

Besides the COMMANDS, the script compiler
recognizes two logical operators, the if/else statement and
the case.

IF SYNTAX

Copyright @ 1982,1984 Jim & Eric Holtman
SIMTERM Instructions

if "str" stmt1 else stmt2 OR if "str" {
    stmt
    stmt

OR

if "str" stmt1 (no ELSE)

} else stmt

OR } else {
    stmt
    
}

When encountered, the program will scan the output from the remote computer until either it finds "str" or it times out. If it finds "str", stmt1 is executed, if it times out, stmt2 is executed. Execution then drops down to the next statement, unless the stmt1 or stmt2 contained a goto or gosub or quit.

stmt1 or stmt2 may be either single commands from above, or multiple commands delimited by { and } (note white space around the brackets. If the else following the if is missing, then execution falls to the next statement. Note that ifs may be nested. For example

if "str" dial "4244" else if "str2" dial "4324"

Be aware, however, that input is only scanned once, so if "str2" appears before "str" in the preceding example, both tests will fail!!

CASE SYNTAX

The case statement is like multiple simultaneous IFs. It allows you to set up a few strings to be searched for SIMULTANEOUSLY, with an action specified to be executed if and when one of the strings is found. Syntax is

case
    str1: action
    str2: action

otherwise action
caseend

Copyright @ 1982,1984 Jim & Eric Holtman
Action can be either a single statement (say, send, dial, or even an if, or another case.) or multiple statements surrounded by ( and ) (like the if clause.). For example, if you have

```plaintext
case
eric: dial "eric's #"
holtman: dial "another #"
caseend
```

and the input is "djsfhj gfgj eric holtman" then "eric's #" will be dialed and the case will quit. Note that "holtman" is not matched since a case statement executes as soon as any of the strings is found.

### Script Examples

**Call number 3395, wait for "login" prompt. If I get it, gosub to a login procedure. If I don’t then say something, then quit. The login subroutine will send my id, then prompt for my password, send it, then return.**

```plaintext
call example
name example
  dial 3395
  if "login" gosub "subr" else {
    say "3395 didn't answer"
    quit
  }
  quit

subr:
  send "id3434"
  input "Your password, sire?"
  return
```

Note that after the "return" the next statement to be executed will be "quit".

### Compiling Scripts

To use the example above, copy it out to a file called, for example, "prog". Then invoke SIMTERM with a -PFprog flag, like so: "sinterm -PFprog". This tells SIMTERM that you wish to use scripts from the file "prog". If no -PF flag appears, SIMTERM will read the file "scripts" which is where you may want to keep compiled scripts. After SIMTERM
gets running, type an Alt-L. This informs SIMTERM that you wish to use a script. It will examine the file "prog" and determine that it needs to be compiled. Tell SIMTERM what file you want to put the compiled stuff in, then sit back and watch for error messages. After it compiles, hit return and proceed to the next step. Remember the file name you used for the compiled scripts, and use it next time you run SIMTERM, so that you don’t have to recompile everything again.

Using a script

After you type Alt-L, or after the compile is finished, a menu of all "name" strings will pop up. If you’re still using the example, only one name ("example") will be there. Using the up and down arrows, make your choice, then hit the space bar. SIMTERM will then execute your script starting at that named point.

To execute a script from startup, use the -PD flag. For example, to run script "example" from the file "prog.scr", type

```
simterm -PFprog.scr -PDexample
```

8. Functions Available from the Keyboard

All these functions can be accessed from the keyboard by typing the appropriate character. If you forget the commands, Alt-H will bring up a menu for you. Just follow the menu selection process until you find the desired function. Note that the menu will tell you which key to use to activate that function in the future. I.e., the menu has Alt-L next to the script choice to remind you that you can use Alt-L instead of the menus to activate the script functions.

F1 Will ‘toggle’ the display so that usually non-displayed control characters are displayed in reverse video using the upper case letter that they are equivalent to.

F2 Will ‘print’ the line that the cursor is positioned at.
SIMTERM Instructions

F3  Send a BREAK

F8  Freezes the display above the cursor. Handy to save some data on the upper portion so you can see it as you do other commands.

F9  Turns on the row/column display at the bottom of the screen so that you know where the cursor is currently positioned.

F10 Toggles XON/XOFF. A convenient way of stopping/restarting the output to the CRT when connected to a system that honors the XON/XOFF protocol for flow control.

Alt-F1 Will terminate SIMTERM, but leave the DTR line high so OR that you can restart SIMTERM and pickup where you left Alt-255 off.

Alt-F2 Terminate SIMTERM, and drop DTR so that the modem will hang up.

Alt-F3 Toggles the DTR (data terminal ready) lead on the communications line. This is used to drop the carrier at the modem so that you can redial.

Alt-F4 Toggles the graphics-mode. This will display characters with their parity bits so that the 'graphics' characters of the PC (>127) are shown. This is used on some of the BBSs.

Alt-F5 Clears line 25 if it becomes cluttered.

Alt-F6 Display various mode settings on line 25.

Alt-F7 Resets the communications software. In some instances an interrupt might be missed and leave the system in a state where it is expecting data that will not be sent. If you suspect this, try an Alt-F7 before rebooting the software to see if it breaks you out of the situation.

Alt-C Puts SIMTERM in a 'capture' mode so that all input received over the communication line is logged to a disk file. Handy for picking up ASCII text from a

Copyright © 1982,1984 Jim & Eric Holtman
SIMTERM Instructions

system that does not support XMODEM. It will prompt you for a file name.

Alt-D Will 'dump' a ASCII file on the PC to the comm line. This is a way of 'uploading' to a system that does not support XMODEM. You can also specify a delay to prevent overruns.

Alt-E Toggles the 'vi' mode. Handy when you exit SIMTERM and then come back into it with UNIX still in 'vi'. The mode should be TRUE to have the cursor keys work for 'vi'.

Alt-F Enter the 'local' line editing mode. This allows you to make corrections to a line and then reenter it. Use the cursor control keys to move to the line, 'Ins' and 'Del' to fix up the line and then hit return to reenter the line and leave the line edit mode.

Alt-H Display a 'help' menu listing the defined function keys.

Alt-L Invoke the 'script' processor

Alt-R Receive a file using the XMODEM protocol.

Alt-T Send a file using the XMODEM protocol.

Alt-V Will display a menu that is used with the 'auto-dial' capability of the Ventel. Once in this menu, select the desired feature.

Alt-= Display the user defined function keys

Alt-- Change a user defined function key

Home Goto top of file in "vi" (unix specific)

Ins Send the current line to remote (similar to the ENTER key on an HP-2621) OR if in "vi" toggle insert mode.

Del Clear display from cursor to bottom OR if in "vi" delete a character

Copyright @ 1982,1984 Jim & Eric Holtman
SIMTERM Instructions

Arrows Move through screen memory in the specified direction
PgUp Back up one page through memory
PgDn Go down one page in memory
Ctrl+ Toggle output to printer
PrtSc

Ctrl+ Download (Unix --> IBM)
PgDn
Ctrl+ Upload (IBM --> Unix)
PgUp

9. Remote Control of SIMTERM

Certain sequences of characters, when received over the communications line, will cause SIMTERM to execute certain functions, like clearing the screen, moving characters, turning the printer on and off. In the following descriptions ESC is Escape (ASCII 27), and Ctrl-X denotes the character generated by holding down Ctrl and typing X. I.e. Ctrl-A is ASCII 1. Note: in the descriptions "ESC H F" for example means ESCAPE, capital H, capital F, with NO SPACES.

ESC A  -- move the cursor up one line
ESC B  -- move the cursor down one line
ESC C  -- move the cursor right one space
ESC D  -- move the cursor left one space
ESC E  -- take SIMTERM out of INSERT mode
ESC F  -- remotely program a function key. After the F, send a number from 1 to 9 to indicate which key to program, or a 0 to program key 10. Everything following the numeral, up to, but not including a terminating Ctrl-Z is then stored in that function key. (See User Function Keys, above)
ESC H  -- moves cursor to top left of screen (HOME)
ESC K  -- clears the rest of the line, from cursor position over

Copyright © 1982,1984 Jim & Eric Holtman
SIMTERM Instructions

ESC J       -- clears display from cursor to end of line, and all lines below the cursor.
ESC L       -- inserts a line above the cursor by rolling bottom lines down. Bottom line of text is lost.
ESC M       -- current line is deleted, lower lines scrolled up to close the gap.
ESC P 1     -- turn on printer (Like Ctrl-PrtSc). Everything that now appears onscreen will be copied to the printer.
ESC P 2     -- like P 1, but printer is put in COMPRESSED PRINT MODE.
ESC P E     -- like P 1, but printer is put in EMPHASIZED PRINT MODE.
ESC P i     -- doesn't turn printer on, just sets ITALICS mode. So, to print in ITALICS, first turn on printer (ESC P 1), then have the remote computer send this.
ESC P P     -- turn on printer, and set into PROPORTIONAL print mode.
ESC P O     -- turn off printer. Screen is no longer copied to printer.
ESC Q       -- Enter INSERT mode. All subsequent characters will be inserted before the cursor on this line.
ESC R       -- Deletes the character at current cursor position.
ESC T A     -- Cause SIMTERM to begin ADM3A simulation.
ESC T a     -- Cause SIMTERM to end ADM3A simulation.
ESC T R     -- Cause SIMTERM to set up to play ROGUE, so that arrow keys work.
ESC T r     -- Cause SIMTERM to end ROGUE playing set up.
ESC V S     -- Cause SIMTERM to set up for vi, so that arrows, Ins, Del, PgUp and PgDn do reasonable things in this Unix text editor.
ESC V s     -- End Vi mode.
ESC [xc     -- causes character 'c' to be printed x number of times, i.e. to print 27 B's, send ESC [ ESC B, since ESC has an ASCII value of 27.

Copyright © 1982,1984       Jim & Eric Holtman
SIMTERM Instructions

ESC &dB -- set screen attribute to a value that equals BOLD on the printer (Actual screen color varies from monochrome to graphics monitor.)

ESC &dB -- set attribute to correspond to UNDERLINE

ESC &dH -- set attribute to be SUPERSCRIPT

ESC &dL -- set attribute to be SUBSCRIPT

ESC &d@ -- set attribute back to normal

ESC = y x -- move cursor to position y, x: where y and x are the ASCII characters which equal the desired position plus 32. I.e. to move to position 3, 3 send ESC = # #, since the ASCII value of # (35) minus 32 is 3

ESC ^ -- request ID. SIMTERM will send back the string "IBM PC" terminated by a newline.

10. XMODEM Under UNIX

When using XMODEM with a UNIX system, the programs 'xrecv.c' and 'xtrans.c' should be uploaded and compiled on the host. These programs are setup for the System V release of UNIX and may need rework if used on other systems (e.g., Berkeley). To send a file from the PC->UNIX, type 'xrecv filename' on UNIX and when the prompt comes up to start transmission, hit Alt-T and follow the instructions.

To send a file from UNIX->PC, type 'xtrans filename' on UNIX and when the prompt comes up to set up the receive, hit Alt-R and follow the instructions.

If you are sending ASCII Text files, invoke the 'xrecv'/'xtrans' with the '-t' argument so that conversion is done between the DOS and UNIX conventions. The XMODEM protocol using the '-t' option is the safest way to transfer text files between systems since checks are made for successful transmission and any errors introduced by noisy lines will be filtered out.

Note: if the '-d' option is given to either program, the following will occur. xrecv leaves a running commentary on the connection status in "xr.err", and xtrans leaves a corresponding file called "xt.err". They
SIMTERM Instructions

are used for debugging purposes.

11. Using SIMTERM with Other Modems

SIMTERM has been tailored to work with the VENTEL or Hayes modem. If you are using it with another modem then make sure that the modem is optioned to present the 'modem ready' signal. If you want to be able to 'dial' the phone number from the keyboard, you will also have to option it to present the 'carrier detect' signal. SIMTERM will not get past its initialization code unless it see both the carrier detect and the modem ready signals.

If you are using an acoustic coupler or a 212 'dial up', then when the message 'establish communications' appears, dial up the computer and enable the 'data' (e.g., hit the DATA button on the 212 or put the receiver in the coupler).

If you are using any modem (or are directly connected), and SIMTERM seems to hang right after the "Establish communications link" message, it probably means that your modem (or local connection) is not outputting the correct RS-232 signals for SIMTERM. If the equipment's not yours, or you don't understand how to fix the problem, or you're just too lazy to bother, try invoking SIMTERM with the -d flag. I.e. say "simterm -d" instead of just "simterm". This will keep SIMTERM from looking at the state of your modem, and your problem will disappear. If it still doesn't work, you can always give us a call.

12. Compiling the Simulator

If you look at the link control file 'simterm.lnk' you will see the programs that have to be compiled or assembled. You must use the MACRO assembler (masm). The file 'struct.mac' has some macros for structured assembly code which makes it easier to write. The file 'mactest.asm' has some examples of the use of the structured macros. The 'relations' between variables or constants are the same as the conditional jumps with the 'j' removed. 'long' can be appended to the macro to cause a long jump to be generated.

'com.asm' is the interface to the Async Comm line. The file 'comm.inc' has the entry points defined.

Copyright © 1982,1984 Jim & Eric Holtman

229
SIMTERM Instructions

The file 'comm.inc' has the entry points defined. 'xxgraph.asm' has functions for cursor control and such from PASCAL programs. The file 'graph.inc' has the entry points defined.

'arglist.obj' and 'arglist.inc' provide 'argv' and 'argc' for the parameters to the PASCAL program. See 'mainSim.pas' for examples of their use. Most of the program will be self-explanatory (hopefully). Any questions, give me a call.

If you want to run SIMTERM on a PC with 128K, you will have to have access to the compiler and macro assembler. Instead of re-compiling and linking the programs in simterm.lnk, use "smterm.lnk". This will build a SIMTERM without VenTel features and without Login Scripts, but it also knocks about 50K off the '.exe' file.

13. Funny Error Conditions

Sometimes SIMTERM will appear to lockup and not accept any input from the keyboard (you will hear the bell indicating that the input buffer is full). This is usually caused by an incomplete ESCAPE sequence that has been sent to SIMTERM and it is waiting for the rest of the characters, which will probably never come from the computer. To 'break out' of this condition, depress at the same time the 'Ctrl', 'Shift', and 'Alt' keys on the left side of the keyboard. This will cause SIMTERM to terminate its 'wait state' and continue. This sometimes happens after dialing into a BBS or other system since you might get some noise of the line.

Also the transmitter may have missed an interrupt, and what you are typing is not sent. If you suspect this, hit Alt-F7.

If SIMTERM gets into a funny condition that you can not get it out of, then terminate it with 'Alt-F1' and then reinvoke it. This procedure will leave the PC attached to the system and you can pick up where you left off.

There have been problems on some systems that use PROKEY, NEWKEY, or other software that interprets the keyboard. If SIMTERM is locking up on you and you have a

Copyright @ 1982,1984
Jim & Eric Holtman
program like this loaded, reboot the system without it and try it. Whatever those programs are doing, they are not very friendly to SIMTERM.

Jim Holtman                              Eric Holtman

If you add any interesting new features to the program, please keep me informed.

I have several other public domain programs that I will be willing to trade for ones that I don't have. Drop me a note (or a floppy disk) with what you have and we can setup a trade. Changes and improvements are continually being added to the program and if you are interested in what the changes are, just drop me a note (or a floppy) for the latest information.

APPENDIX J

ASSEMBLY LANGUAGE ROUTINES - IBM-PC

This Appendix contains the listings of the file "biosio.asm" and "dostime.asm", used in the IBM-PC Kalman Filter program to generated graphic output and to evaluate execution time respectively. The "biosio.asm" is also used by the plotting routine, PLOT.C. The files "biosio.asm" and "dostime.asm" are part of the Public Domain Library and can be found in the PC-SIG library disk number 216.
**biosic.asm**

IBM-PC: Microsoft "C" under PC-DOS v2.00

MICROSOFT "C" callable 8088 assembly routines that interface directly with the basic I/O system (BIOS).

**NOTE** -- The IBM Technical Reference Manual contains a listing of the BIOS and more complete descriptions of each interrupt.

; IBM-PC 8088 assembly for interface with microsoft "C"
; under PC-DOS

; "C" callable subroutines that provide absolute pointer
; addressing.
; Pointers within an IBM-PC microsoft "C" program are
; relative to the start of the programs data segment. These
; subroutines provide a mechanism to address absolute memory
; locations.

; Supplied by microsoft - commented by L. Cuthbertson, April
; 1984

; Read an absolute memory location.
; synopsis c = readabs(loc);

239
; int c; contents of memory location
; int loc; absolute memory location in hex

INP PROC NEAR
PUSH BP
MOV BP,SP
MOV DX,[BP+4] ;GET LOCATION ADDRESS
IN AL,DX ;READ LOCATION
XOR AH,AH ;CLEAR HIGH BYTE
POP BP
RET
INP ENDP

; Write an absolute memory location.
; synopsis writeabs(loc,c);

; int loc; absolute memory location in hex
; int c; integer to write to memory location

OUTP PROC NEAR
PUSH BP
MOV BP,SP
MOV DX,[BP+4] ;GET LOCATION ADDRESS
MOV AX,[BP+6] ;GET ADDRESS OF INTEGER TO WRITE
OUT DX,AL ;WRITE TO MEMORY LOCATION
POP BP

*** dostime.asm ***

IBM-PC microsoft "C" under PC-DOS

Microsoft "C" callable 8088 assembly routine that uses a DOS function call to obtain and return the hours, minutes, seconds, and hundredths of a second as integers.

; synopsis dostime(&hour,&min,&sec,&ths);

*** no function value returned ***

int hour; 0-23 military time
int min; 0-59
int sec; 0-59
int ths; 0-99
