An investigation of the hydraulic flight control system of a Boeing CH-47 Chinook helicopter utilizing artificial intelligence techniques will be undertaken. Specifically, a knowledge based expert system will employ situation-action rules (production rules) to diagnose a failure and subsequently iden-
tify specific device(s) which caused that failure. Moreover, because the behavior of the system is directly responsive to the goals the system is attempting to achieve, the expert system's inference engine performs a backward-chaining process via a goal-driven control strategy. This strategy involves finding rules that demonstrate the hypothesis and then verifying the facts that enable the rule to work. The List Processing Language (LISP) is used to facilitate data processing and symbolic logic expression manipulation.

ABSTRACT

An investigation of the hydraulic flight control system of a Boeing CH-47 Chinook helicopter utilizing artificial intelligence techniques will be undertaken. Specifically, a knowledge based expert system will employ situation-action rules (production rules) to diagnose a failure and subsequently identify specific device(s) which caused that failure. Moreover, because the behavior of the system is directly responsive to the goals the system is attempting to achieve, the expert system's inference engine performs a backward-chaining process via a goal-driven control strategy. This strategy involves finding rules that demonstrate the hypothesis and then verifying the facts that enable the rule to work. The List Processing Language (LISP) is used to facilitate data processing and symbolic logic expression manipulation.
ACKNOWLEDGMENTS

Many thanks to Dave Handleman for his assistance throughout the term. He is the author of the expert system's inference engine. Thanks also go to Professor Robert Stengel for his guidance. Above all, I would like to thank my parents for their constant encouragement and help throughout my four years at Princeton.

GENERAL BACKGROUND

The CH-47 Chinook twin-rotor helicopter is an exceedingly complex flying machine. See FIGURE 1. As in any complicated apparatus, failures must be detected immediately and implementation of corrective procedures must be performed quickly, especially when human life is at stake. The project's present goal is to provide an interactive system which can detect failures and propose possible diagnostics for the flight control hydraulic system. Aspects of Artificial Intelligence (AI) relating to expert systems are implemented. The AI field is relatively new with regard to implementation of expert systems for failure diagnosis of complicated systems. Hence, this research should prove not only interesting because of its "cutting edge" nature in the AI field, but also useful in its practical applications for efficient and effective failure detection and diagnosis.
EVOLUTION OF ARTIFICIAL INTELLIGENCE

Al originated in the 1950's through the efforts of several computer scientists investigating new methodologies to solve old problems through symbolic programs. Results in automated deduction and problem-solving produced great enthusiasm. During the last two decades, Al researchers have recognized the value of domain specific knowledge as a basis for solving significant problems [1]. However, at the same time, researchers also have realized that generic problem-solving strategies by themselves cannot solve the world's most challenging problems. To solve a problem in the field of engineering, finance, or medicine, for example, machine problem-solvers found it necessary to understand human problem-solvers way of thinking about a particular subject. The computer offers many advantages over the human mind -- such as speed and consistency -- but it lacks the ability to compensate for ignorance [1].

In short, Al researchers concluded that high IQ does not necessarily make a person an expert, but specialized knowledge does. For a fast and consistent symbol processor to perform as effectively as a human expert, the machine must possess the specialized knowledge and reasoning capabilities that is inherent in a human expert. This need evolved into the field of knowledge engineering and resulted in the growth of expert systems.
ROLE OF EXPERT SYSTEMS

Expert systems are intelligent computer applications that use data, a knowledge base, and a control mechanism to solve problems of sufficient difficulty in which significant human expertise is necessary for solution. These systems use AI problem-solving and knowledge representation techniques to combine human expert knowledge concerning a problem area with human expert methods of conceptualizing and reasoning about that problem area [2]. Therefore, such a system can achieve the human expert’s level of performance in a specialized problem area. The factual knowledge domain possessed by the expert system is real, but the knowledge for diagnosis is artificially generated. The high-level knowledge base and its associated control mechanism are essentially the expert’s knowledge and reasoning capabilities coded via a high-level programming language.

Expert systems cannot replace the human being, but they can provide substantial support. Two types of expert systems are available: diagnostic and pedagogic. The first type is application oriented and its goal is to assist the user to resolve specific problems in particular fields. The pedagogic type of expert systems is concerned with how specific knowledge or information should be taught. The expert system developed in this case is of the diagnostic type.
KNOWLEDGE BASE

Knowledge bases are different from data bases in several ways. A knowledge base is an unstructured set of facts. Paths by which facts are related are determined "on the fly" as needed to solve particular problems. The bulk of the information in the knowledge base is inferred from a few basic facts. A data base incorporates a predetermined structure of facts. The relationships between data items in the data base are designed in advance. All information is stored explicitly.

The most prevalent technique used in organizing knowledge bases is to form production rules, which become connected to one another by if-then statements that build rule networks. Rules in the knowledge base represent both facts and heuristics -- facts being discrete pieces of information that are generally accepted and heuristics being rules of thumb that characterize expert-level decision making in the problem area. Both facts and heuristics are generated throughout the session directly resulting from system inferences and user intervention.

INFERENCE ENGINE

The expert system's control structure or inference engine makes decisions concerning the use of the system's knowledge by organizing and controlling the steps needed to solve current problems. The control mechanism is actually a collection of procedures or strategies whose function is to solve problems. Two search techniques generally employed are backtracking and graph-searching. Backtracking uses pro-
cedures which explore one path as far as possible. If the path search reaches a dead end or determines that a goal can be reached, the procedure then backtracks to previous states and chooses another path in a different direction. The goal is to search all paths and determine the outcome of such searches. The procedures are written recursively to avoid redundancy and complexity of code [3]. Graph-searching explores several paths simultaneously while maintaining concurrently the status of several states of the system. Either some paths may be explored faster or a breadth first search may be employed in which all paths are searched at the same speed.

A common but powerful problem-solving mode of rule based systems involves the chaining together of if-then rules to form a line of reasoning. Subsets of the search techniques mentioned previously are available: forward and backward chaining. Forward chaining employs knowledge base rules on some initial state or condition of the data and continually applies rules to new conditions until the desired goal is attained.

This project implements the technique of backtracking while employing a backward-chaining search which has had proven success in systems for diagnosis and planning. In backward chaining, the conclusion is assumed but the path to it is not, as in the case of goals and hypotheses. These rules work from goals to subgoals by using the action side of rules to deduce the condition of rules. Specifically, the control mechanism scans the rule base to find those rules whose consequent actions can achieve the desired goal. Each of these rules is tried in suc-
cession. If the antecedent side of the rule correlates to the existing conditions in the working memory (coined by J. McDermott in "R1: An Expert in Computer Systems Domain") [4], then the rule is fired and the subgoal is achieved. However, if an unmatched antecedent is encountered, that antecedent becomes a new subgoal, and the same procedure is applied recursively. If no rules establish that subgoal, the system prompts the user for additional information.

Without the appropriate heuristics for guidance, backward-chaining will encounter problems in handling conjunctive subgoals [2]. In general, this requires finding a case where all interacting subgoals are satisfied, a search that in the worst case could result in an overload of information. Thus, in addition to appropriate heuristics, suitable inferences and architectures must be found for each type of problem area in order to achieve an efficient and effective expert system.

As an example, the following illustration concisely depicts the basic structure of a knowledge based system [4].

\[ H = \text{hypothesis} \]
\[ P = \text{proof} \]

SAMPLE TREE

*FIGURE 2*
Backward-chaining initially analyzes the truthfulness of H1 by determining the values of H2, H3, where P1's value is known. To determine the value of H2, the system must look at the value of H4. To conclude H4, the system must look at P2's and P3's values. Finally, to determine the value of H3, the system must inspect P4 and P5. In other words, the system determines the value of the premise by first concluding the value of the associated action. The associated action then becomes the premise of another node further down the tree, and the process repeats until all hypotheses are determined by the values of their proofs. The present system incorporates many judgmental and empirical rules according to which the evidence supports a conclusion or hypothesis. As a final note, rules are neither implemented as subroutines nor embodied in any other part of the program code. The program uses rules as input to produce an internal representation which provides the expert system with expert knowledge specific to the task domain. The program itself is an interpreter and general reasoning mechanism. This important fact distinguishes the knowledge base from the inference engine.

Thus, the inference engine's primary functions are to accept and process problem queries from users to arrive at a solution while also allowing updates to the knowledge base. The following figure is taken from the ELSIE A. EXPERT SYSTEM developed by David Handleman, a graduate student at Princeton University. The diagram illustrates the inference engine's logic flow. "Determine Value Of <param>" and "Test <rule>" are user initiated function calls which execute the failure diagnosis. The backward-chaining search technique is employed.

ROTORCRAFT MAINTENANCE EXPERT SYSTEM

In the commercial and industrial sector, many companies have undertaken the development of AI types of systems for equipment maintenance [5]. The growing operational complexities of helicopters require an increased need for highly competent technicians to maintain the various systems in use. Maintenance tasks have become so complicated that few technicians capable of assessing malfunctioning equipment are available; consequently, there is an increased need for expert systems in the diagnosis/maintenance field to assist less-skilled workers. Furthermore, the time even high-skilled workers need to investigate problems by referencing maintenance manuals can be saved by the use of an expert system.

The bottleneck in the field lies in the knowledge acquisition interface which is the most critical facet of building expert systems [6]. The problem domain's human expert must communicate with the "programmer" to collectively encode the expert system's knowledge base. The average maintenance technician must understand the dialogue employed in the expert system. All terms should be understandable and as natural as possible. The natural language interface is critical; hence, coupled with the inference procedure, the user interface provides the intelligence capability. The capacity to remember must occur while diagnosing specific problems. Answers to diagnostic questions and production rules accessed from the knowledge base must be remembered. The inherent recursive capabilities of LISP allow this to be effectively accomplished.
The expert system's organizational maintenance structure incorporates the operational checks of the rotorcraft system by isolating failures, adjustments, removals, and replacements of line item units all in accordance with maintenance and operational manual specifications. These manuals include general helicopter information, ground operations, environmental conditions, and extensive troubleshooting procedures. See Ref. 8 and 9. The CH-47 Chinook helicopter undergoes routine maintenance checks which necessarily require human manual tasks. The current manual procedures are quite arduous. This project investigates one feature of the manual procedure: the diagnosis of helicopter malfunctions relating to the flight control hydraulic system. This report provides design considerations for use of the expert system and illustrates the requirements for such an automated diagnostic system. The model is developed in LISP on the IBM Personal Computer XT to demonstrate the feasibility for full-scale maintenance expert systems.

LISP - THE LANGUAGE

Originated in 1958, LISP has built-in language functions to provide the string processing capabilities desired for AI programming. The language has since become the primary artificial intelligence programming language. Symbolic manipulation is required for computers to appear intelligent. LISP's functions are to recognize specific symbolic expressions, break down old expressions and assemble new expressions. The following diagram is excerpted from Winston and Horn's book LISP. See Ref. 7.

Floating

Point

LISP STRUCTURE

FIGURE 4

The above diagram's thrust is to define both data and executable statements (functions). The atom is the smallest accessible element. A list is one atom or a list of atoms. A symbol is a user-created item or an available function. Executable statements are of a mathematical format in which the function call is represented as a list. The first element of the list is the function name while all other elements in the list are function arguments. The arguments also can be calls to other functions or, in a recursive process, to itself. The LISP function call is embedded in parentheses, which are used to indicate the function structure. Within LISP, there are approximately seventeen "primitively" defined categories of functions, in which a total of 83 LISP functions are defined.

INITIAL ASSUMPTIONS

The present knowledge base assumes a closed world rule space. In other words, the knowledge base assumes by default that the only causal effects which result in device failures are those that are coded in
the parameters and rules. Of course, the rules are only as comprehensive as the source from which they were derived. Operation and maintenance manuals have been used as primary sources of information here. There are certain cases in the knowledge base when no rules can be used to determine the value of a particular parameter. Instead, the user is asked to provide the value of the unknown parameter. As more knowledge is accumulated about the system, the knowledge engineer can refine and perfect the knowledge base, eventually obviating any unnecessary user intervention. The present system derives its credibility from the accuracy and "expertness" of the aforementioned manuals.

DESCRIPTION OF FLIGHT CONTROL SYSTEM OPERATION

The flight control hydraulic system consists of two separate and independent systems [8]. Specifically, the two systems are parallel in operation, hydraulically separated, and electronically integrated [9]. The system provides boost to the pilot for flight control movements. The normal operating pressure is between 2500 and 3200 pounds per square inch (psi). Any pressure below 2500 psi is characterized by the system as abnormally low, and pressure above 3200 psi is considered abnormally high. Each system has its own hydraulic tank, pump, plumbing installations, and the concomitant valves, filters, and fittings. The flight control systems are labeled No.1 and No.2, and the HYDRAULIC BOOST switch on the control panel in the cockpit allows the pilot to alternate between systems when one system fails. Furthermore, each system provides hydraulic pressure to operate the forward
and aft pivoting and swiveling dual-actuating cylinders, the Stability Augmentation System (SAS), dual extensible link actuating cylinders, and dual stick boost actuating cylinders. The expert system's qualitative reasoning can be applied separately and independently to either flight control system. The expert system arbitrarily treats all data as referring to Flight Control System No. 1. Any references to the other system are, by default, Flight Control System No. 2.

FIGURE 5 is a schematic flow of the working fluid through the system. Its purpose is to provide the user with a general idea of the flight control system's operation methodology. FIGURE 6 and FIGURE 7 provide the flight control hydraulic system layout, as diagrammed in Ref. 9.
HYDRAULIC FLIGHT CONTROL SYSTEM OPERATION
FIGURE 5
FLIGHT CONTROL HYDRAULIC SYSTEM (1/2)

FIGURE 6
DISCUSSION OF PARAMETERS AND RULES

The knowledge base rule tree has essentially four major levels as illustrated in the following figure.

\[ \text{FAILURE DETECTION} \Rightarrow \text{ISOLATION OF SPECIFIC COMPONENT MALFUNCTIONS} \]

\[ \text{MALFUNCTION DETERMINATION} \]

\[ \text{SYMPTOMS} \]

\[ \text{USER SUPPLIED INFORMATION} \]

KNOWLEDGE BASE LEVELS

\text{FIGURE 8}

The controller uses the backward-chaining technique beginning from the top level down to determine the various parameters involved in the analysis. More critical than determining whether a failure is detected is deducing the specific devices which failed during the session. The inference engine hypothesizes the failure of a particular device, such as the pressure transmitter or the pressure filter. The inference engine, after internalizing the knowledge base by separating the antecedent and action side of all rules and developing a master list of parameter rule relationships, scans down this list, which has the device failure in question in its action clause. In order to prove the action, the engine must prove the antecedent. This becomes the new subgoal; hence, it is
the motivation behind the use of a backward-chaining search. The search scans all rules using a left-to-right ordering preference. For instance, in the top level tree in Appendix D, Rule 001 is fired before Rule 002. Hence, the absolute position of a rule in the master rule list is irrelevant; its relative position to related rules however is crucial to the expert system's efficiency and to its search speed. Primary rules are fired before secondary rules so that conclusions can be deduced more quickly. Instances where rules are not found to be applicable to a particular parameter determination may occur, and the system prompts the user for the necessary information. These should not be interpreted as holes in the knowledge base per se. In most cases, the nature of the data requested by the system has to be asked (e.g., the pressure value). In a real life situation, the maintenance technician would read the pressure value from a pressure gage.

The reader must keep in mind that the present knowledge base serves only to demonstrate the feasibility of a full-scale expert system. The knowledge incorporated only touches on the most general aspects of the flight control system while analyzing five devices in depth (pressure filter 114HS120-13 and 14, pressure filter 114HS120-15 and -16, pressure reducing valves 26C26602, pressure reducing valve 3A011, and flight control pump). The five devices are analyzed as in depth as any maintenance procedure will require. Specifically, for each device, the knowledge delves into the status of the component parts which comprise that device. In a full-scale expert system, there may be hundreds, even thousands, of such devices.
The expert system that has been developed is presently suited only for use in a laboratory environment. The system is heavily dependent on user interaction and to achieve any significant results, the user should be familiar with the general operation of the flight control hydraulic system. Such knowledge is required even of the maintenance technician who will eventually be called upon to operate this type of software package.

The results are promising. A knowledge base with 155 parameters and 258 rules has been incorporated. The system requires the user to respond generally in either the affirmative or the negative, with occasional responses of not applicable. The system interned this knowledge in order to generate more questions and eventually determine the specific devices which have malfunctioned as well as the concomitant corrective procedures.

The system provides responses which are realistic and in some instances border on the obvious. For example, if the pressure pump breaks down, then the system will inform the user to replace the pump. However, this simplicity should not be construed as a weakness; in fact, simplicity is the system's major strength. The structure of the knowledge base is such that additional rules can be added easily without changing the structure of the knowledge base. Thus, the knowledge base can be expanded indefinitely. Disk storage space is the only limitation.

A critical process in the development of an expert system is the transferral of expert knowledge from the maintenance manuals to a
high level programming language. The following illustration is taken from actual knowledge in the knowledge base. The source of the information comes from the August 16, 1978 issue of the *Aviation Unit and Aviation Intermediate Maintenance Manual*, published by the Army. See Ref. 8.
Pressure Filters 114HS120-13(17500) and -14(17510) Troubleshooting

MALFUNCTION
TEST OR INSPECTION
CORRECTIVE ACTIONS

Leak around pressure differential indicator.

STEP 1. Inspect for damaged sliding sleeve (40).
Replace spool assembly (43).

Numbers in parenthesis refer to component number in Figure 9.

ENGLISH TRANSCRIBED RULES

Rule AAA: If the pressure filters 114HS120-13 and -14 are not malfunctioning, then there is no leak around the pressure differential indicator.

(Notice that there is no rule which states that if the pressure filters are malfunctioning then there is a leak. Not enough information is available to make such a strong statement.)

Rule BBB: If there are leaks around the pressure differential indicator, then sliding sleeve (40) is damaged.

(Notice that such a strong statement is valid because the information does not suggest otherwise. Such a strong statement was determined independently of the user manual)

Rule CCC: If the sliding sleeve (40) is damaged, then replace spool assembly (43).
CONCLUSIONS

This two-semester independent work's goal has been to develop a prototype knowledge based maintenance expert system. The results are threefold.

First, the source (Ref. 8 and 9) of the knowledge base has proved reliable and extremely useful in providing factual and heuristic rules. Operation and maintenance manuals were used; specifically, troubleshooting procedures were extensively implemented. In many instances, these procedures were directly transferred into if-then rules.

Second, LISP was found to be the ideal language to use in failure diagnostics. Its capabilities in list processing and parameter associations form the crux of the analysis. Also, LISP's capabilities in backward chaining prove instrumental in the project's ultimate success.

Finally, the feasibility for a full-scale expert system has been demonstrated by the successful testing of the present system. The proven workability of the knowledge base structure for a small-scale expert system is a great springboard from which to launch the development of a full-scale system. The troubleshooting procedures listed in Ref. 8 are crystal clear. No ambiguities were encountered in the development of the knowledge base for the present expert system. Therefore, the factual knowledge from which the knowledge was generated is of the highest integrity. Consequently, the system's artificially generated knowledge is also highly reliable.
The program and knowledge base are listed in the appendices. Specifically, Appendix A provides a user's guide and Appendix B presents a sample run. Appendix C presents and describes the list of parameters implemented in the knowledge base. Appendix D depicts the schematic representation of the knowledge base rules in a logical upward causal flow. Also, several figures of the devices (i.e. pressure reducer valve, pressure filter, etc.) are presented in an exploded view. The figures were taken from Ref. 8. Finally, Appendix E presents the actual code written in LISP. The rules' English translations are also included.
SUGGESTIONS FOR FUTURE WORK

The prototype expert system has provided keen insight into the enormous requirements (time and analysis tools) but unlimited potential for a full-scale maintenance expert system applied to failure detection and diagnosis of a Chinook CH-47 flight control hydraulic system. The present knowledge base already incorporates over two hundred fifty rules and 150 parameters, yet it concentrates on only a fraction of the flight control system.

First, for a full-scale, in-depth operational maintenance system, many more man hours must be invested in this project in order to produce such a package. Commercially available maintenance expert systems generally have required up to ten man years to produce. Given the success of the prototype system, the development of a full-scale operational system within a few years is reasonable. Thus, the author recommends such an undertaking.

Second, a different search technique should be employed for a full-scale expert system. The problem domain in such an expert system imposes requirements for execution in real time. New architectures specifically designed for performing AI based tasks for large systems should consider a parallel type of search. This type of search divides the knowledge base into logical subsections and solves each subsection concurrently using a least constraint approach. The subsection requiring the least information is solved first; subsequently, other subsystems are solved.
Finally, the present computer facilities will prove wholly inadequate for a full-scale expert system implementation. The IBM Personal Computer XT has adequate "crunching" capabilities for the present knowledge base, but an IBM Personal Computer AT would be more desirable and use of such a machine could decrease processing time by up to threefold. Furthermore, an interpretive version of IQLISP rather than a compiled version has been used because of its availability. A compiled version of LISP would no doubt increase processing efficiency.

LOOSEN LINE TO FLIGHT BOOST ACCUMULATOR due to trapped air in system
Appendix C

LIST OF PARAMETERS

Appendix C presents the list of parameters that are to be used in the present knowledge base. The basis for the rules are drawn from maintenance and operation manuals - specifically the troubleshooting procedures. There are two levels or categories of parameters. The first level of parameters indicate the general diagnosis characteristics of the flight control system. These parameters aide the user in pinpointing the devices which caused the malfunction(s). The second level or focus parameters probe deeper into the flight control system. After the first level of parameters determine the device failure, the second level of parameters are used to determine the specific component(s) which caused the malfunction in the downed device.
### LIST OF PARAMETERS

#### GENERAL PARAMETERS: (FIRST LEVEL)

- **PL** - PRESSURE INDICATION IS LOW: (LESS THAN 2500 PSI)
- **PH** - PRESSURE INDICATION IS HIGH: (GREATER THAN 3200 PSI)
- **PZ** - PRESSURE INDICATION IS ZERO
- **PFL** - PRESSURE INDICATION IS FLUCTUATING

- **P-450-550** - PRESSURE IS BETWEEN 450 AND 550 PSI AFTER APU START
- **NP-2500-3200** - NEW PRESSURE IS BETWEEN 2500 AND 3200 PSI
- **NP-EQ-P** - NEW PRESSURE IS EQUAL TO PRESSURE
- **AGP-2500-3200** - ACCUMULATOR GAGE PRESSURE IS BETWEEN 2500 AND 3200 PSI

- **HBF-1CL-ON** - HYD BOOST OFF SYSTEM 1 CAUTION LIGHT ON
- **PI-L** - PRESSURE INDICATION IS LOW
- **PI-F** - PRESSURE INDICATION IS FLUCTUATING

- **IPS** - INOPERATIVE PNEUMATIC SYSTEM

- **AGP-EQ-P** - ACCUMULATOR GAGE PRESSURE EQUAL TO COCKPIT PRESSURE INDICATION

- **AGB-26** - TEMPERATURE OF HOSE FITTING AT PUMP PRESSURE PORT IS GREATER THAN TEMPERATURE OF HOSE FITTING AT PUMP CASE DRAIN PORT BY 28 DEGREES CELSIUS

- **BG-102** - TEMPERATURE OF HOSE FITTING AT PUMP CASE DRAIN PORT IS GREATER THAN 102 DEGREES CELSIUS

- **TC-GTE-TA** - TEMPERATURE OF RETURN LINE TUBE ASSEMBLY AT FLIGHT CONTROL MANIFOLD IS GREATER THAN OR EQUAL TO TEMPERATURE OF HOSE FITTING AT PUMP PRESSURE PORT

- **TDA-COMPONENT\_X** - TEMPERATURE DIFFERENTIAL BETWEEN INLET AND OUTLET PORT OF COMPONENT X IS ABNORMAL

- **TDA-PR\_Y** - COMPONENT Y = PRESSURE REDUCE VALVE
- **TDA-FBA** - COMPONENT X = FLIGHT BOOST ACCUMULATOR
- **TDA-FCP** - COMPONENT X = FLIGHT CONTROL PUMP
- **TDA-HT** - COMPONENT X = HYDRAULIC TANKS
- **TDA-PF** - COMPONENT X = PRESSURE FILTER
- **TDA-RF** - COMPONENT X = RETURN FILTER

- **TA-IN-SYS** - TRAPPED AIR IN SYSTEM

- **AG-F** - ACCUMULATOR GAGE FLUCTUATION
POSSIBLE DEVICE FAILURES/CORRECTIVE ACTIONS:

- EC-FCP - ELECTRIC CIRCUIT TO FLIGHT CONTROL PUMP
- SH-BO2 - SET HYDRAULIC BOOST 2 ON
- FCM - FLIGHT CONTROL MANIFOLD
- TA-AT-PT - TRAPPED AIR AT PRESSURE TRANSMITTER
- PI - PRESSURE INDICATOR
- PT1 - PRESSURE TRANSMITTER DETERMINATION INDICATED BY PRESSURE INDICATION VALUE
- PT2 - PRESSURE TRANSMITTER DETERMINATION INDICATED BY ACCUMULATOR GAGE PRESSURE INDICATION BETWEEN 2500 AND 3200 PSI
- PT3 - PRESSURE TRANSMITTER DETERMINATION INDICATED BY ACCUMULATOR GAGE FLUCTUATION
- FCP1 - FLIGHT CONTROL PUMP DETERMINATION INDICATED BY ACCUMULATOR GAGE PRESSURE
- FCP2 - FLIGHT CONTROL PUMP DETERMINATION INDICATED BY TEMPERATURE AT HOSE FITTING
- FCP3 - FLIGHT CONTROL PUMP DETERMINATION INDICATED BY TEMPERATURE DIFFERENTIAL AT INLET AND OUTLET PORT
- FCM - FLIGHT CONTROL MANIFOLD
- PRV - PRESSURE REDUCE VALVE
- FBA - FLIGHT BOOST ACCUMULATOR
- HT - HYDRAULIC TANK
- PF - PRESSURE FILTER
- RF - RETURN FILTER
- L-FS-L - LOOSEN FLEXIBLE SUPPLY LINE TO PUMP
- L-FBA-L - LOOSEN LINE TO FLIGHT BOOST ACCUMULATOR

GOAL: (FIRST LEVEL)

FAILURE-DETected - GOAL OF THE EXPERT SYSTEM: TO DETERMINE WHETHER THE FAILURE DEVICE HAS BEEN DEDUCED OR IF THERE INDEED IS A FAILURE

ALL-DEVICES-TESTED - TO DETERMINE WHETHER ALL DEVICES WERE TESTED

NOTHING-FAILED - TO DETERMINE WHETHER ANY DEVICES FAILED OR CORRECTIVE ACTIONS TAKEN

PACKING8-PF1516 - DAMAGED PACKING #8
R-PACKING8-PF1516 - REPLACE PACKING #8
CLGD-ELEMENT5-PF1516 - CLOGGED OR DIRTY ELEMENT #5
C-R-ELEMENT-PF1516 - CLEAN OR REPLACE ELEMENT
SHOVAL10-PF1516 - SHUTOFF VALVE #10 NOT PROPERLY OPENED
R-PART10-PF1516 - REPLACE DEFECTIVE PART OF SHUTOFF VALVE
LSVH-PF1516 - EXCESSIVE LEAKAGE BETWEEN SHUTOFF VALVE AND HEAD
DAM-SESURFH-PF1516 - DAMAGED SEALING SURFACE ON HEAD
R-FIL-ASSEMBLY-PF1516 - REPLACE FILTER ASSEMBLY
INDPP15-PF1516 - INDICATOR #15 DOES NOT ACTUATE AT PRESET PRESSURE
R-INDICATOR15-PF1516 - REPLACE INDICATOR #15

FOCUS PARAMETERS FOR PRESSURE REDUCING VALVES 26C26602, 03, 08

PRV238 - PRESSURE REDUCING VALVE 26C26602, 03, 08 ARE DAMAGED
CYCLE-SYSTEM-PRV238 - CYCLE THE AFFECTED SYSTEM LONG ENOUGH TO MOISTEN THE SEALS.
E-L-PRV238 - EXTERNAL LEAKAGE
S-L-PRV238 - STATIC LEAKAGE
PACKING2-PRV238 - DAMAGED OR INCORRECTLY INSTALLED PACKING #2
R-PACKING2-PRV238 - REPLACE PACKING #2
RET-PORT-PRV238 - RELIEF FLOW FROM RETURN PORT IS NOT WITHIN SPECIFIED LIMITS
IADJ-REL-VAL8-PRV238 - INCORRECTLY ADJUSTED RELIEF VALVE #8
A-REL-VAL8-PRV238 - ADJUST RELIEF VALVE #8
F-REL-VAL8-PRV238 - FAULTY RELIEF VALVE #8
R-REL-VAL8-PRV238 - REPLACE RELIEF VALVE #8 ASSEMBLY AS A MATCHED SET
LEAKAGE-RESEAT-PRV238 - LEAKAGE AT RESEAT EXCEEDS SPECIFIED LIMITS
SPRING13-PRV238 - FAULTY SPRING #13
R-SPRING13-PRV238 - REPLACE SPRING #13
REG-PORT-PRV238 - FLOW FROM REG PORT NOT WITHIN SPECIFIED LIMITS
REDUCER-VAL12-PRV238 - INCORRECTLY ADJUSTED REDUCER VALVE #12
A-RED-VAL12-PRV238 - ADJUST REDUCER VALVE #12
POPPET21-SLEEVE22-PRV238 - FAULTY POPPET #21 AND SLEEVE ASSEMBLY #22
R-POPPET21-SLEEVE22-PRV238 - REPLACE POPPET AND SLEEVE ASSEMBLY AS A MATCHED SET
L-RET-PORT-PRV238 - LEAKAGE FROM RET PORT EXCEEDS SPECIFIED LIMIT
PACKING1923-PRV238 - DAMAGED OR INCORRECTLY INSTALLED PACKINGS #19 AND #23
R-PACKING1923-PRV238 - REPLACE PACKINGS #19 AND #23

FOCUS PARAMETERS FOR PRESSURE REDUCING VALVE 3A011

PRV3A - PRESSURE REDUCING VALVE 3A011 IS DAMAGED
E-L-PRV3A - EXTERNAL LEAKAGE
PACKING410-PRV3A - DAMAGED PACKING #4 OR #10
R-PACKING410-PRV3A - REPLACE PACKING #4 OR #10
RING39-PRV3A - INCORRECTLY ASSEMBLED BACKUP RINGS #3 OR #9
R-RING39-PRV3A - REMOVE AND REASSEMBLE BACKUP RING #3 OR #9
EX-L-RETPORT-PRV3A - EXCESSIVE INTERNAL LEAKAGE THROUGH RETURN PORT
PACKING2123-PRV3A - DAMAGED PACKING #21 OR #23
R-PACKING2123-PRV3A - REPLACE PACKING #21 OR #23
RING20-PRV3A - INCORRECTLY ASSEMBLED BACKUP RING #20
R-RING20-PRV3A - REMOVE AND REASSEMBLE BACKUP RING #20
EX-FLOW-RETPORT-PRV3A - EXCESSIVE FLOW THRU RETURN PORT DURING LEAKAGE TEST
PLUNGER14-BARREL15-PRV3A - INTEGRAL RELIEF VALVE CRACKS DUE TO PRESSURE BUILD-UP CAUSED BY LEAKAGE THROUGH SEAT ON BARREL #15
R-PLUNGER14-BARREL15-PRV3A - REPLACE PLUNGER #14 AND BARREL #15
DASHPOT16-PRV3A - INCORRECTLY ASSEMBLED DASHPOT #16
R-DASHPOT16-PRV3A - REMOVE AND REASSEMBLE DASHPOT #16
REL-VAL-LOW-PRV3A - INTEGRAL RELIEF VALVE CRACKS LOW AT CORRECT PRESSURE SETTING
BALL-SEAT19-PRV3A - DAMAGED BALL SEAT #19
R-BALL-SEAT19-PRV3A - RESEAT OR REPLACE BALL SEAT #19
REL-VAL-HIGH-PRV3A - INTEGRAL RELIEF VALVE CRACKS HIGH AND RESEATS LOW
PUSHROD17-BARREL15-PRV3A - BINDING BETWEEN PUSHROD #17 AND BARREL #15 IS FAULTY
BUFF-CLEAN1-PRV3A - BUFF AND CLEAN PUSHROD #17 AND BARREL #15 AND CHECK FOR SMOOTH FIT
BUFF-CLEAN2-PRV3A - BUFF AND CLEAN BINDING BETWEEN VARIOUS COMPONENTS
VAL-RED-PRV3A - VALVE FAILS TO REDUCE CORRECTLY
BINDING-PRV3A - BINDING BETWEEN VARIOUS COMPONENTS FAULTY
WRONG-PACKING-PRV3A - INCORRECT ASSEMBLY OR WRONG SIZE PACKING
R-PACKING-PRV3A - REMOVE AND REASSEMBLE PACKING
VAL-SQUEALS-PRV3A - VALVE CHATTERS OR SQUEALS
C-PLUNGER14-PRV3A - CHECK FOR FREE FIT WITH PLUNGER #14 AND REASSEMBLE
PACKING12-WASHER11-PRV3A - INCORRECT ASSEMBLY OF PACKING #12 AND WASHER #11
R-PACKING12-WASHER11-PRV3A - REMOVE AND REASSEMBLE PACKING #12 AND WASHER #11
FITTINGS8-PRV3A - TIGHT FITTING #8
R-FITTINGS8-PRV3A - UNSCREW AND RETORQUE FITTING #8 TO 250 POUND-INCHES

Completed April 23, 1986

For a more complete description of the parameters used above, consult Ref. 8.
Appendix D

FAILURE DIAGNOSIS RULES

The expert system uses rules and a global data base to diagnose failures. Appendix D concentrates on the diagrammatical upward causal flow of the knowledge base. The symbol $\lor$ symbolizes the OR function and the symbol $\land$ symbolizes the AND function. The value NA denotes NOT APPLICABLE. This is an alternative to the boolean values TRUE and FALSE. In addition, the inference engine should produce all possible device failures. The system should NEVER return an unknown value for a possible device failure. As an illustration of the use of the schematic diagrams, the English translation of RULE ONE is as follows: "If all devices tested is true and nothing failed is true then failure detected is false."

An in-depth example with explanation follows on the next page. The example refers to a set of corrective actions applied to defective flight control pumps.
CORRECTIVE ACTIONS: FAULTY FLIGHT CONTROL PUMP

EXPLANATION OF PREVIOUS LOGIC TREE: REPLACE THE PUMPS

The inference engine determines the value of parameter R-PUMP1-FCP (replace the pump in the flight control system due to scoring or nicks on the mating surfaces). To accomplish the feat, the engine backward chains and inquires about the value of SNMATSUR-FCP (scoring or nicks on mating surfaces). Notice that a value of NA (not applicable) or FALSE for SNMATSUR-FCP implies that one not need replace the pump due to SNMATSUR-FCP and says nothing about whether to replace the pump due to other circumstances. The use of the FALSE value for SNMATSUR-FCP is straightforward. When SNMATSUR-FCP takes on a value of NA is not quite as obvious. This value denotes that only insufficient evidence for SNMATSUR-FCP to determine whether it is TRUE or FALSE is available. Since a true value of R-PUMP1-FCP means to replace the pump solely due to scoring, nicks etc., then a NA value of SNMATSUR-FCP necessarily implies that R-PUMP1-FCP is false.

If, on the other hand, R-PUMP1-FCP were denoted as to replace the pump for some general case, then a value of NA for SNMATSUR-FCP cannot imply that R-PUMP-FCP is FALSE.

The remainder of the rules applied for this corrective procedure is straightforward. If the external leakage in the flight control pump (EL-FCP) is NOT APPLICABLE then scoring or nicks on the mating surface (SNMATSUR-FCP) is also NOT APPLICABLE. The same logic is applied when both of the parameters are false. Finally, when the flight control pump (FCP1, FCP2, FCP3) is OK, then there cannot possibly be any external leakages, hence the parameter EL-FCP must by necessity
be FALSE. Notice that no rule states that if the flight control pump has failed, then there must be an external leakage in the flight control pump. A faulty flight control pump could mean several possible failures, not exclusively external leakages.

KNOWLEDGE BASE SOURCE CODE

The following knowledge base is coded in IQLISP. As of April 25, 1986, there are 155 parameters and 258 rules. It is listed in subdirectory CLOH and under filename LOHKB.LSP.
LOADING THE EXPERT SYSTEM SHELL

(FLOAD "EXPSHELL")

(MSG 'CR "Reading Knowledge Base")

# KNOWLEDGE BASE PARAMETER GROUPS #

Christopher J. Loh
Laboratory for Control & Automation
Knowledge Base
CH-47 Flight Control Hydraulic System
Fall / Spring 1985-1986

PARAMETER GROUP PROPERTIES

- system-supplied:
  - used-by: specifies rules with this parameter in their premise
  - contained-in: specifies rules with this parameter in their action but that do not assign a value to the parameter
  - updated-by: specifies rules that conclude a value for this parameter in their action

- user-supplied:
  - trans: English translation (definition)
  - expect
  - initial-value
  - never-ask: If a parameter value is unknown, it cannot be inferred with rules, and has never-ask TRUE, then the search fails
  - prompt
  - askfirst
  - justification
