LIGHT SCATTERING BY ROUGH SURFACES FULL WAVE SOLUTIONS

1. Introduction

1.1 Objectives, Motivation and Background for this Work

Scattering of electromagnetic waves in media consisting of random distributions of particles such as atmospheric aerosols, smoke and dust has been investigated extensively using the equation of transfer (Chandrasekhar 1950, Ishimaru 1978). The main difficulties in setting up the equation of transfer lie in the determination of the elements of the $4 \times 4$ phase (scattering) matrix and the extinction cross sections for the individual particles. Most of the work has been done for particles of idealized shapes such as spheres and cylinders (Ruck et al. 1970).

In many physical problems of interest however, the individual scatterers are of irregular shapes such as flakes, spheres and cylinders with random rough surfaces (Scheurman 1980, Bahar and Fitzwater 1983, Bahar and Chakrabarti 1985).

In this work the results derived for particles with idealized shapes (spheres) are modified to account for the random surface roughness of the particles. To this end the full wave approach (Bahar 1981) is used to determine the rough surface contributions to the like and cross polarized scattering cross sections (Bahar and Chakrabarti 1985), and the elements of the phase (scattering) matrix are given in terms of a weighted sum of the Mie solutions and the diffuse scattering terms due to the particle surface roughness. The extinction cross sections are determined through a judicious use of the forward scattering theorem (Born and Wolf 1964) and the very perceptive observation that for large scatterers compared to a wavelength the forward scattered "shadow forming wave is the same for all surfaces which have the same shadowline" (Morse and Feshbach 1953).
Linearly polarized waves are assumed to be incident upon a parallel layer consisting of a random distribution of irregular shaped particles. Particles with different complex dielectric coefficients and different surface roughness are considered. The rough surface height is characterized by its surface height spectral density functions (the Fourier transforms of the non-Gaussian surface height autocorrelation functions). Thus particles with a large range of roughness scales are considered. Special attention is given to determining the effects of varying the mean square height and slope of the particles.

Both single scatter (first order) and multiple scatter results are presented for smooth particles and for particles with rough surfaces. Layers with different optical thicknesses are considered and the results are presented for the forward and backward scattered incoherent diffuse scattering intensities as well as the co-polarized and cross polarized intensities. The degree of polarization of the reflected and transmitted intensities are also determined. The Gaussian quadrature technique is used to discretize the equation of transfer and the matrix characteristic value technique is used to account for multiple scattering (Ishimaru and Cheung 1980). This work is particularly relevant to problems of obscuration by aerosols.

1.2 Principal Elements of the Full Wave Approach

As indicated in Section 1.1, the full wave solutions for the scattered like and cross polarized intensities are determined using the full wave approach which accounts for the specular point (physical optics) scattering and diffuse scattering in a self-consistent manner. Unlike the small perturbation method (Rice 1951, Ruck et al. 1970, Kiehl et al. 1980), the full wave approach is not restricted to surfaces with small roughness.
parameters \( \beta = 4k_o^2<h^2> \) (where \(<h^2>\) is the mean square height and \(k_o\) is the free space wavenumber of the incident electromagnetic wave). The principal elements of the full wave approach (Bahar 1982) are:

(a) The electromagnetic fields are expressed in terms of complete expansions of vertically and horizontally polarized waves. These include the radiation fields, the lateral waves and the surface waves.

(b) Exact boundary conditions are imposed at the irregular surface.

(c) Using the orthogonal properties of the basis functions appearing in the complete expansions of the fields, Maxwell's equations are integrated over the transverse plane. Green's theorems are used to avoid term-by-term differentiation of the field expansions.

(d) Maxwell's equations for the electromagnetic fields are converted into coupled first order ordinary differential equations for the forward and backward traveling wave amplitudes which are only functions of the variable \(x\). (In view of the integration in the transverse plane \((y,z)\), the telegraphists' equations are only functions of \(x\)). The coupled equations for the wave amplitudes are referred to the generalized telegraphists' equations.

(e) A variable coordinate system that conforms with the local features of the irregular boundary is introduced and the resulting solutions for the scattered fields are shown to be invariant to coordinate transformations.

(f) Closed form second order iterative solutions for the radiation fields are obtained from the telegraphists' equations on neglecting multiple scattering from the rough surface. These second order iterative solutions account for wave scattering in arbitrary directions.

(g) The full wave solutions are compared with earlier geometric optics physical optics and perturbation solutions. The suitability of the two-scale model is shown to be limited.
2. Outline of this Research

(i) Evaluate the like and cross polarized scattering cross sections for particles of irregular shape. The particles are characterized by their complex permittivities (unperturbed) sizes, rough surface height spectral density functions--(or autocorrelation functions). The full wave approach (see Section 1.2), is used to account for specular point and diffuse scattering in a self-consistent manner.

(ii) Evaluate the extinction cross sections and the albedos for the irregular particles of finite conductivity.

(iii) Solve the transfer equation for the incoherent specific intensities (modified Stokes parameters), and the co-polarized and cross polarized intensities for linearly polarized waves at optical and infrared frequencies incident upon a layer of randomly distributed particles. Compare the results for smooth and rough particles. Present both single scatter and multiple scatter results.

(iv) Evaluate the degree of polarization of the reflected and transmitted intensities.

(v) Document computer programs for inclusion in the final report.
3. **Formulation of the Problem**

The transfer equation for the diffuse specific intensities (Stokes parameters) can be written as follows in matrix notation (Chandrasekhar 1950, Ishimaru 1978)

\[
\mu \frac{d[I]}{dt} = -[I] + \int [S][I^\prime]d\mu d\phi + [I_\perp]
\]

in which \(\tau\) is the optical distance in the \(z\) direction (normal to the plane of a horizontal layer consisting of a random distribution of particles (see Fig. 1))

\[
\tau = z\sigma_t \equiv z \int \sigma_t h(D)dD
\]

where \(D\) is the diameter of the unperturbed spherical particle, \(n(D)\) is the particle size distribution and \(\sigma_t\) is the extinction coefficient (total cross section). The symbol \(z[\cdot]\) denotes integration over the size distribution. Since the unperturbed particle is assumed here to be a sphere of diameter \(D\) and the surface roughness is assumed to be homogeneous and isotropic, diffuse scattering vanishes in the forward direction (Bahar and Chakrabarti 1985) and the extinction matrix for the rough sphere can be represented by a scalar quantity (Ishimaru and Cheung 1980).

The \((4 \times 1)\) column matrices \([I]\) and \([I^\prime]\) are the incoherent diffuse specific intensity matrices (Stokes parameters) for waves scattered by particles in the direction \(\theta = \cos^{-1}\mu\) and \(\phi\) and for waves incident in the direction \(\theta' = \cos^{-1}\mu'\) and \(\phi'\) respectively. The elements of the matrix \([I]\) are the modified Stokes parameters

\[
[I] = \begin{bmatrix}
[I_1] \\
[I_2] \\
U \\
V
\end{bmatrix} = \begin{bmatrix}
\langle E_1 E_1^* \rangle \\
\langle E_2 E_2^* \rangle \\
2 \text{Re}\langle E_1 E_2^* \rangle \\
2 \text{Im}\langle E_1 E_2^* \rangle
\end{bmatrix}
\]

in which the symbol \(\langle \cdot \rangle\) denotes the statistical average and the symbol \(^*\) denotes the complex conjugate. An \(\exp(i\omega t)\) suppressed time dependent
excitation is assumed. The vertically and horizontally polarized components of the electric field are $E_1$ and $E_2$ respectively. The $(4 \times 4)$ scattering (phase) matrix $S$ in the fixed reference coordinate system (see Fig. 1) is expressed in terms of the scattering matrix $S'$ in the scattering plane (which contains the wave normals $n^i$ and $n^f$ in the direction of the incident and scattered waves) through the following transformation

$$[S] = \mathscr{L}(-\pi + \alpha)[S'][\mathscr{L}(\alpha')]$$  \hspace{1cm} (4)

in which $[S']$ is the weighted sum of two matrices

$$[S'] = |\chi(\vec{v} \cdot \vec{a}_r)|^2[S_{\text{Mie}}] + [S_D]$$  \hspace{1cm} (5)

In (4) $\mathscr{L}$ is a $4 \times 4$ transformation matrix that represents the specific intensities relative to the reference plane of incidence to the intensities relative to the scattering plane and back from the scattering plane to the reference plane of scatter (Chandrasekhar 1950, Ishimaru 1978). The matrix $[S_{\text{Mie}}]$ in (5) is the phase matrix for the unperturbed spheres based on the Mie solution (Ruck et al. 1970, Ishimaru 1978). Furthermore, in (5) $\chi(\vec{v} \cdot \vec{a}_r)$ is the particle random rough surface height characteristic function

$$\chi(\vec{v} \cdot \vec{a}_r) = \exp(i \vec{v} \cdot \vec{a}_r h)$$  \hspace{1cm} (6)

in which $h$ is the rough surface height measured in the direction $\vec{a}_r$, the unit vector in the radial direction (normal to the surface of the unperturbed sphere) and

$$\vec{v} = k_o (n^f - n^i)$$  \hspace{1cm} (7)

In this work the rough surface height probability density function $p(h)$ and joint probability function $p(h, h')$ are assumed to be Gaussian, thus

$$|\chi|^2 = \exp(-\vec{v} \cdot \vec{a}_r <h^2>)$$  \hspace{1cm} (8)

and the rough surface height joint characteristic function is
\[ x_2 = \exp[i \mathbf{v} \cdot \mathbf{a}_r \mathbf{h} \mathbf{h}'] = \exp(\mathbf{v} \cdot \mathbf{a}_r <\mathbf{h} \mathbf{h}'>)|x|^2 \]  

Thus in (5) the coefficient \(|x|^2\) accounts for the degradation of the scattering by the smooth sphere (primarily specular point for spheres with large \(k_D\)) due to surface roughness. The diffuse scattering contribution to the phase matrix \([S']\) due to surface roughness is

\[
[S'_D] = \begin{bmatrix}
[S'_{11}] & [S'_{12}] & 0 & 0 \\
[S'_{12}] & [S'_{22}] & 0 & 0 \\
0 & 0 & [S'_{33}] & [S'_{34}] \\
0 & 0 & [S'_{43}] & [S'_{44}] 
\end{bmatrix}
\]

where

\[
[S'_{ij}] = \frac{A_y}{4\pi \rho[\sigma_t]} \rho[\langle O^i_j \rangle] \text{ for } i,j=1,2
\]

in which \(A_y = \pi D^2/4\) is the cross sectional area of the unperturbed particle and \(\langle O^i_j \rangle\) in (11) is the like \((i=j)\) or cross \((i\neq j)\) cross polarized normalized scattering cross section (Bahar and Chakrabarti 1985). The first and second superscripts \(i,j\) denote the polarization \((V\text{ vertical, } H\text{ horizontal})\) of the scattered and incident fields respectively

\[
\langle O^i_j \rangle = \frac{2\pi}{\int_0^{\pi} \int_0^{\pi} |x_{D}^{i,j}|^2 P_2 Q \sin y dy dy/\pi^2
\]

in which

\[
Q = \int_{-\infty}^{\infty} (x_2 (\mathbf{v} \cdot \mathbf{a}_r) - |x(\mathbf{v} \cdot \mathbf{a}_r)|^2) \exp(i \mathbf{v} \cdot \mathbf{r}_d) dx_d dz_d
\]

The surface height autocorrelation function \(<\mathbf{h} \mathbf{h}'>\) and therefore the joint characteristic function \(x_2\) (9) are only functions of distance \(r_d = (x_d^2 + z_d^2)^{\frac{1}{2}}\) measured along the surface of the unperturbed sphere since the random rough surface is assumed to be isotropic and homogeneous. Furthermore,

\[
[S'_{11}] = A_y \rho[\text{Re}[\langle O^1_{22} \rangle_D + \langle O^2_{12} \rangle_D]/4\pi \rho[\sigma_t]
\]

for \(i=3\) (upper sign) and \(i=4\) (lower sign). For \(i\neq j\)

\[
[S'_{ij}] = A_y \rho[\text{Im}[\pm \langle O^1_{22} \rangle_D + \langle O^2_{21} \rangle_D]/4\pi \rho[\sigma_t]
\]
where the upper sign is used for \( i = 4, j = 3 \) and the lower sign is used for \( i = 3, j = 4 \). In (14) and (15)

\[
|_{k}^{i}k^{j} \rangle = \int_{\sigma_{k}} \int_{\sigma_{l}} 2^{i}D_{k}^{i}D_{l}^{j} P_{2} Q \sin \gamma \gamma \delta / \pi^{2}
\]

In (12) and (16) \( P_{2} \) is the shadow function (Sancer 1969). It is the probability that a point on the surface is both illuminated and visible given the slope of the surface at that point. The scattering coefficients \( D_{i}^{j} \) are functions of \( \vec{n}_{i}, \vec{n}_{j} \) and \( \vec{n} \) the normal to the unperturbed surface of the particle as well as the electromagnetic parameters of the material of the particle \( \varepsilon, \mu \) (Bahar 1981). Since \( D_{i}^{i} \) and \( D_{i}^{j} \) (\( i \neq j \)) are symmetric and antisymmetric respectively with respect to the azimuth angle, \( \delta \), of the particle, the remaining eight terms of \( [S]_{p} \) vanish.

A linearly polarized wave is assumed to be normally incident upon a parallel layer (of optical thickness \( \tau_{0} \)), containing a random distribution of irregular shaped particles. Thus, the incident Stokes matrix at \( z = 0 \) (see Fig. 1) is

\[
[I_{inc}] = \begin{bmatrix}
1 \\
0 \\
0 \\
0
\end{bmatrix}
\]

in which \( \delta(\cdot) \) is the Dirac delta function. Thus, the reduced incident intensity is

\[
[I_{ri}] = [I_{inc}] \exp(-\tau)
\]

The \((4 \times 1)\) excitation matrix \( [I_{i}] \) in (1) is

\[
[I_{i}] = \int [S][I_{ri}] d\mu d\phi' = [F] \exp(-\tau)
\]

in which \( [F] \) can be expressed as

\[
[F] = [S][I_{o}] \begin{bmatrix}
\mu' = 1 \\
\phi' = 0
\end{bmatrix}
\]

\[
\begin{bmatrix}
[F]_{a} \\
[F]_{b}
\end{bmatrix} \cos 2\phi + [F]_{a} \sin 2\phi
\]

and the matrix \( [I_{o}] \) is defined in (17). The solution of the equation of
transfer (1) for the incoherent specific intensity matrix [I] can be expanded in a Fourier Series (Cheung and Ishimaru 1982). In view of the excitation (20), only the azimuthally independent term (m=0) and the \( \cos 2\phi \) and \( \sin 2\phi \) terms (m=2) are non-vanishing. Thus, the transfer equation (1) together with the associated boundary conditions

\[
[I] = 0, \quad \text{for } 0 \leq \mu \leq 1 \text{ at } \tau = 0
\]

and

\[
[I] = 0, \quad \text{for } 0 \geq \mu \geq -1 \text{ at } \tau = \tau_0
\]

are solved for the specific incoherent diffuse scattering intensities using the Gaussian quadrature method (to discretize the angles \( \theta = \cos^{-1}\mu \)) and the matrix characteristic value technique (Ishimaru 1978).

The only remaining parameter that needs to be evaluated to solve the equation of transfer (1) is the extinction coefficient (total cross section) \( \sigma_t \). The "forward scattering theorem" (Born and Wolf 1964) relates the total cross section to the imaginary part of the scattering (complex) amplitude in the forward direction \( f_{iI}(n_f, n_i) \) (Ishimaru 1978). Thus, for a spherical particle, the normalized total cross section (per unit cross sectional area of the sphere of radius a) is

\[
\sigma_t = \frac{\lambda}{k_o a^2} \, \text{Im}[f_{iI}(n_f, n_i)] \quad i=1,2
\]

For particles with irregular shape and particles with random rough surfaces, it is very difficult to determine the scattering amplitude \( f_{iI} \). When the surface roughness of the particle is small, such that the roughness parameter \( \beta = 4k_o^2 \langle n^2 \rangle \ll 1 \), perturbation theory can be used to determine the diffuse scattering contribution (Rice 1951, Ruck et al. 1970). In this case \( (\beta \ll 1) \) \( \sigma_t \) can be approximated by its unperturbed value since the diffuse scattering contribution \( [s_D] \) for large particles vanishes in the forward direction and the shadow boundary is practically the same as that.
of the unperturbed particle. However, for the small perturbation case, the effects of particle surface roughness upon the specific intensities is almost negligible. Since in this work particles with very rough surfaces $1 < \beta < 40$ are considered, small perturbation theory cannot be used to determine the scattering amplitudes $f_{11}$, and the effects of surface roughness upon the specific intensities is not negligible. To facilitate the solution to the problem when $\beta$ is large, judicious use is made of the scattering theorem and the perceptive observation that for large scatterers (physical dimensions large compared to wavelength) the forward scatter "shadow forming wave is the same for all surfaces which have the same shadow line" (Morse and Feshbach 1953). Thus, the albedos $A$ for the particles with random rough surfaces are evaluated as follows

$$A = \frac{\sigma_s}{\sigma_t} = \frac{\sigma_s}{\sigma_{to}} \frac{\sigma_{to}}{\sigma_t} = \frac{\sigma_s}{\sigma_{to}} \left[ \frac{\sigma_{to}}{\sigma_t \cdot P.C.} \right]$$

(24)

In (24) $\sigma_s$, the normalized scattering cross sections for the finitely conducting particles, are given by

$$\sigma_s = \frac{1}{\pi a} \int |x|^2 |\chi|^2 |s_M^s| d\Omega + \frac{1}{4\pi} \int \langle \sigma \rangle d\Omega$$

$$\equiv \sigma_{s1} + \sigma_{s2}$$

(25)

in which $\chi$ is the rough surface characteristic function $\sigma_M$ is the Mie solution for the smooth (unperturbed) sphere (Ruck et al. 1970, Ishimaru 1978) and $d\Omega$ is the elementary solid angle. Thus integrate with respect to the azimuth angle to get (in the notation used by Ishimaru, 1978)

$$\sigma_{s1} = (k_o a)^{-2} \int |x|^2 [|s_1(\theta)|^2 + |s_2(\theta)|^2] \sin \theta d\theta$$

(26)

The full wave approach is used to obtain the diffuse contribution $\sigma_{s2}$ to the scattering cross section. Thus

$$\sigma_{s2} = 0.25 \int \langle \sigma^V_D + \sigma^H_D + \sigma^{HV}_D + \sigma^{HH}_D \rangle \sin \theta d\theta$$

(27)

in which $\langle \sigma_{PQ} \rangle$ are the like and cross polarized diffuse differential
scattering cross sections per unit solid angle (Bahar and Fitzwater 1983, Bahar and Chakrabarti 1985). Furthermore, in (24), $\sigma_{to}$ is the total cross section for the smooth particle. On approximating $(\sigma_{to}/\sigma_{t})$ by its corresponding, perfectly conducting value $(\sigma_{to}/\sigma_{t})_{P.C.}$ use is made of the forward scattering theorem and the fact that for $k_o a >> 1$, the forward scatter, shadow-forming wave is the same for all surfaces which have the same shadow line. Since for perfectly conducting particles

$$(\sigma_{t})_{P.C.} = (\sigma_{t})_{P.C.}$$  \hspace{1cm} (28)

where $(\sigma_{s})_{P.C.}$ is the normalized scattering cross section for the perfectly conducting particle with the same rough surface as the one under consideration. Thus $(\sigma_{s})_{P.C.}$ is evaluated using (25) for the corresponding perfectly conducting particle and the expression for the albedo is given by

$$A = [\sigma_{s}/\sigma_{to}]/[\sigma_{s}/\sigma_{to}]_{P.C.} = A_1/A_2 .$$  \hspace{1cm} (29)

Two limiting cases for the above expression are of particular interest. As the conductivity of the particle increases to infinity $A_1 \rightarrow A_2$ and $A \rightarrow 1$. As the surface roughness becomes very small $\beta \rightarrow 0$, $A_2 \rightarrow 1$, (since $(\sigma_{s})_{P.C.} + (\sigma_{t})_{P.C.} + (\sigma_{to})_{P.C.}$) and $A \rightarrow A_1 = \sigma_{s}/\sigma_{to}$, Thus as expected $A \rightarrow 1$ for perfectly conducting particles and $A \rightarrow A_1$ its corresponding unperturbed value for $\beta \rightarrow 0$. The value of the extinction coefficient $\sigma_t$ is obtained from the relationship $\sigma_t = \sigma_s/A$. 
4. Summary of Results and Conclusions

4.1 Illustrative Examples

For the illustrative examples presented in this section, the random rough surface height \( h \) (measured normal to the surface of the unperturbed spherical surface of the particle of radius \( a \)) is characterized by its surface height spectral density function \( W(k_x, k_z) \). Since the random rough surface is assumed to be isotropic and homogeneous, the spectral density function is expressed as a function of \( k_T^2 = (k_x^2 + k_z^2)^2 \)

\[
W(k_T) = W(k_x, k_z) = \frac{1}{\pi^2} \int_{-\infty}^{\infty} <hh'> \exp(ik_x x_d + ik_z z_d) dx_d dz_d
\]

\[
= \frac{2}{\pi} \int_{0}^{\infty} <hh'> \frac{J_0(k_T r_d)}{r_d} dr_d .
\]

(29)

In (29) \( J_0(k_T r_d) \) is the Bessel function of the first kind and \( <hh'> \) is the rough surface height autocorrelation function which is only a function of distance \( r_d = (x_d^2 + z_d^2)^{1/2} \) measured along the surface of the unperturbed particle. In view of the Fourier transform relationship between \( W(k_T) \) and \( <hh'> \)

\[
<hh'> = \int_{-\infty}^{\infty} W(k_x, k_z) \frac{1}{4} \exp(-ik_x x_d - ik_z z_d) dk_x dk_z
\]

\[
= \frac{\pi}{2} \int_{0}^{\infty} W(k_T) J_0(k_T r_d) k_T r_d dk_T .
\]

(30)

The following explicit expressions are assumed in this work for the surface height spectral density function

\[
W(k_T) = \frac{2 \gamma}{\pi} \left[ \frac{k_T}{k_T^2 + k_m^2} \right]^n , \quad k_T > 0
\]

(31)

in which the exponent is \( n = 6 \) case (a) and \( n = 8 \) case (b). The value of \( W(k_T) \) is maximum for \( k_T = k_m \) (the dominant roughness scale)

\[
W(k_m) = 2\gamma k_m^n
\]

(32)

For \( n = 8 \) the scales of roughness are more tightly bound around \( k_m \) than for \( n = 6 \). The mean square height \( <h^2> \) and mean square slope \( <\zeta_s^2> \) of the
rough surface are related to $k_m$ and the constant $C$. Thus
\begin{equation}
<h^2> = \frac{\pi}{2} \int_0^\infty W(k_T^2) k_T^2 dk_T = \begin{cases} 
C/210 k_m^6, & n = 8 \\
C/40 k_m^4, & n = 6 
\end{cases}
\tag{33}
\end{equation}
and
\begin{equation}
<\sigma_s^2> = \frac{\pi}{2} \int_0^\infty W(k_T^2) k_T^4 dk_T = \begin{cases} 
C/84 k_m^4, & n = 8 \\
C/10 k_m^2, & n = 6 
\end{cases}
\tag{34}
\end{equation}
and the surface height correlation distance $r_c$ (where $<hh'> = \exp(-1)$ is
\begin{equation}
r_c = 2(<h^2>/<\sigma_s^2>)^{1/2} = \begin{cases} 
1.265/k_m, & n = 8 \\
1/k_m, & n = 6 
\end{cases}
\tag{35}
\end{equation}
The autocorrelation functions corresponding to the rough surface height spectral density functions (31) can be written in closed form. Thus for $n = 8$
\begin{equation}
R(\xi) = \left[ 1 - \frac{3\xi^2}{8} + \frac{3\xi^4}{32} + \frac{\xi^6}{3072} \right] \xi K_1(\xi) \\
+ \left[ \frac{1}{2} - \frac{\xi^2}{4} - \frac{\xi^4}{96} \right] \xi^2 K_0(\xi)
\tag{36a}
\end{equation}
and for $n = 6$
\begin{equation}
R(\xi) = \left[ 1 - \frac{3\xi^2}{8} - \frac{\xi^4}{96} \right] \xi K_1(\xi) \\
+ \left[ \frac{1}{2} + \frac{3}{16} \xi^2 \right] \xi^2 K_0(\xi)
\tag{36b}
\end{equation}
in which $K_0$ and $K_1$ are the modified Bessel functions of the second kind or order zero and one respectively (Abramowitz and Stegun 1964) and the dimensionless argument $\xi$ is
\begin{equation}
\xi = \frac{k_m r_d}{m}
\tag{37}
\end{equation}
The wavelength of the optical excitation is
\begin{equation}
\lambda = 0.555 \mu
\tag{38}
\end{equation}
and the diameter of the unperturbed sphere is
\begin{equation}
D = 10 \lambda
\tag{39}
\end{equation}
The particles are assumed to be made of (i) aluminum for which the relative dielectric coefficient is (Ehrenreich 1965)
(40a)
\[ \epsilon_r = -40-i12 \]
and (ii) a dissipative dielectric with

(40b)
\[ \epsilon_r = 1.5-i8 \]

Two sets of data for each case \( n = 6 \) and \( n = 8 \) and each dielectric material are presented graphically in this work. In the first set

\[ k_D = 4; \]
thus the correlation length \( r_c \) is fixed (35) while both the mean square height and slope vary. The maximum value of \( \langle \sigma_s^2 \rangle \) is 0.101 corresponding to \( \beta_m = 4k_o^2 <h^2> = 40 \) for \( n = 8 \) and \( \beta_m = 25 \) for \( n = 6 \).

In the second set the mean square slope \( \langle \sigma_s^2 \rangle \) is set equal to 0.101 while both the mean square height \( <h^2> \) and \( k_m \) (and thus \( r_c \)) vary.

In Tables I through VI the value of the scattering cross sections \( \sigma_s \), \( \sigma_{s1} \) and \( \sigma_s \) (24) as well as \( A_1, A_2 \) the albedo \( A \) (28) and the extinction coefficient \( \sigma_t \) are listed for different values of the roughness parameter \( \beta = h_0^2 <h^2> \). In Tables I and II the relative dielectric coefficient is \( \epsilon_r = -40-i12 \) and for Tables III through VI \( \epsilon_r = 1.5-i8 \). Tables I through IV are for \( n = 8 \) while V and VI are for \( n = 6 \). In Tables I, III and V \( k_D = 4 \) and \( \langle \sigma_s^2 \rangle \) varies while in Tables II, IV and VI \( \langle \sigma_s^2 \rangle = 0.101 \) and \( k_m \) (and the correlation distance \( r_c \)) varies.

In Fig. 2 the scattering cross sections \( \sigma_s, \sigma_{s1} \) and \( \sigma_{s2} \) are plotted as functions of \( \beta (0 < \beta < \beta_m) \) and in Fig. 3 the albedo \( A \) and the extinction cross section \( \sigma_t \) are plotted as functions of \( \beta \) for the case given in Table I. Similarly, Figs. 4 and 5 correspond to the case given in Table II, Figs. 6 and 7 correspond to the case given in Table III and Figs. 8 and 9 correspond to the case given in Table IV.

It is interesting to note that while \( \sigma_s \) the scattering cross section is primarily dependent on the roughness parameter \( \beta \), the absorption cross section \( \sigma_a = \sigma_t - \sigma_s \) depends both upon \( \beta \) and the mean square slope \( <\sigma_s^2> \). Thus for particles with the same roughness parameter \( \beta \), the
absorption cross section $\sigma_a$ increases (and the albedo decreases) as the mean square slope increases. In the next set of 24 plots, the (differential) like and cross polarized normalized diffuse scattering cross sections $<\sigma_P^D>_{D}$ are plotted as functions of the angle $\theta$ between the incident and scattered wave normals $\hat{n}^i$ and $\hat{n}^f$ respectively. In Figures 10 through 18 the surface height spectral density function $W$ is given by (31) with $n = 8$. The constant parameter for the different curves is $\beta = 4k_o^2 <\gamma^2>$. In this set of curves $k_mD = 4$ thus the correlation length $r_c$ is constant while the mean square slope $<\sigma_s^2>$ is different for different values of $\beta$. The relative dielectric coefficient, for Figures 10, 11 and 12 is $\varepsilon_r = 4.00-1.00$ for Figures 13, 14 and 15 it is $\varepsilon_r = 1.5-1.0$, and for Figures 16, 17 and 18 the particle is assumed to be perfectly conducting ($|\varepsilon_r| \to \infty$). In Figures 19 through 27 $n = 8$ however the mean square slope is constant, $<\sigma_s^2> = 0.101$ thus for different values of the roughness parameter $\beta$ the correlation distance $r_c$ is different. In Figures 28 through 33 $<\sigma_P^D>_D$ is given for $n = 6$ and $\varepsilon = 1.5-1.0$. For Figures 28, 29 and 30, $k_mD = 4$ while the mean square height and mean square slope are parameters and for Figures 31, 32 and 33 $<\sigma_s^2> = 0.101$ while the mean square height and correlation distance $r_c$ are parameters.

In order to facilitate comparison between the different data for the case $n = 8$, the data corresponding to $\beta = 4.00$ is common to the set $k_mD = 4$ and the set $<\sigma_s^2> = 0.101$. Similarly, for the case $n = 6$, the data corresponding to $\beta = 25$ is common to the set $k_mD = 4$ and the set $<\sigma_s^2> = 0.101$.

For the case $<\sigma_s^2>$ constant the diffuse scattering terms merge for $\beta > 5$ except for scattering in the near forward direction where the parameter $\beta$ (and $r_c$) has a very significant effect on $<\sigma_P^D>_D$. For the
case \( k_{mD} = 4 \ (r_c = \text{const}) \), the parameter \( \beta \) (and \( \langle \sigma_s^2 \rangle \)) has an effect on the diffuse scattering cross section \( \sigma_{sD}^{PQ} \) for all \( \theta \). The main differences are in the backscattered (\( \theta = 0 \)) and the forward scattered (\( \theta = 180^\circ \)) directions. The effects of particle conductivity (absorption) on the scattering cross sections are also evident from the plots in these figures. The level of the diffuse scattering terms decreases as the absorption of the particle increases. The differences between the results for cases \( n = 8 \) and \( n = 6 \) are most significant for scattering in the forward direction.

Note in particular that there is a significant like polarized backscatter enhancement due to the surface roughness of the particle. The cross polarized diffuse cross sections have sharp nulls in the backscatter direction. This is due to the symmetry of the particle and the fact that the particle surface roughness is assumed to be isotropic.

In the last set of figures, solutions of the transfer equation (1) are presented for a parallel layer consisting of a random distribution of particles with rough surfaces. The incident wave is linearly polarized and normally incident upon the layer of optical thickness \( \tau_0 \). The special cases considered in detail are for particles with very rough surfaces \( \beta = 40, \ k_{mD} = 4, \ \langle \sigma_s^2 \rangle = 0.101, \ n = 8, \ \lambda = 0.555 \mu \). Both aluminum particles \( \varepsilon_r = -40-112 \) and dissipative dielectric particles \( \varepsilon_r = 1.5-18 \) are considered.

In Figures 34 and 35 the transmitted diffuse incoherent specific intensities \( I_1 \) (copolarized) and \( I_2 \) (cross polarized) are plotted as functions of \( \theta \) \( (0 < \theta < 90^\circ) \) and in Figures 36 and 37 the reflected diffuse specific intensities are plotted as functions of \( \theta \) \( (90^\circ < \theta < 180^\circ) \). The optical thickness of the layer is \( \tau_0 = 2 \) and the relative dielectric coefficient is \( \varepsilon_r = -40-112 \). Single scatter and multiple scatter results are shown for both (except for single scatter cross polarized intensity...
for the smooth particles). Similarly, in Figures 38 through 41, the
copolarized and cross polarized transmitted and reflected specific
intensities are plotted as functions of $\theta$ for $\tau_o = 2$ and $\epsilon_r = 1.5-18$.
In Figures 42 through 47 the copolarized incoherent specific intensity
$I_x$ (scattered electric field parallel to incident electric field) and cross
polarized incoherent specific intensity $I_y$ (scattered electric field
perpendicular to incident electric field) (Ishimaru 1978) are plotted as
functions of the azimuth angle $\phi$. The optical thickness $\tau_o = 2$ and
$\epsilon_r = -40-112$. In Figures 42 and 43, $I_x$ and $I_y$ are plotted for $\theta = 9.7^\circ$.
Similarly in Figures 44 and 45, $I_x$ and $I_y$ are plotted for $\theta = 170.3^\circ$, and
in Figures 46 and 47 $I_x$ and $I_y$ are plotted for $\theta = 175.8^\circ$. Here, too, both
the single scatter and multiple scatter results are given for both the
smooth and the rough particles.

In Figures 48 through 50, the degree of polarization $m$ (Ishimaru 1978)
is plotted as a function of the azimuth angle $\phi$. The optical thickness
is $\tau_o = 2$ and the relative dielectric coefficient is $\epsilon_r = -40-112$. In
Figure 48 $\theta = 4.2^\circ$ and $9.7^\circ$, in Figure 49 $\theta = 15.3^\circ$ and $20.8^\circ$ and in
Figure 50 $\theta = 170.3^\circ$ and $\theta = 175.8^\circ$.

1.2 Computer Data and Programs

The tapes contain all the computer programs needed in this work as well
as the computed data for the following 12 cases. Surface height spectral
density function $W(31)$ with $n=6$ and $n=8$. Complex dielectric coefficient
$\epsilon_r = -40-112, \epsilon_r = 1.5-18$ and $|\epsilon_r| = \infty$. The mean square slope $<\sigma_s^2>$ is a
constant parameter ($\beta$ and $r_c$ vary) in one set of data while the correlation
length $r_c$ is a constant parameter ($\beta$ and $<\sigma_s^2>$ vary) in the other set of
data. Data for layers of different optical thickness $\tau_o = 0.1,1,2,10$
are computed. Selected data are plotted in Figures 2 through 50.
