DESIGN AND IMPLEMENTATION OF DATA BASE MANAGEMENT SYSTEM FOR THE ORGANIZATION STRUCTURE OF THE EGYPTIAN ARMED FORCES

THESIS

Presented to the Faculty of the School of Engineering of the Air Force Institute of Technology Air University In Partial Fulfillment of the Requirements for the Degree of Master of Science in Computer Systems

Lt. Colonel, Egyptian Army

December 1986

Approved for public release; distribution unlimited.
Preface

The purpose of this study is two fold. The first purpose is to design a data base management system model for the organization structure of the Egyptian Armed Force as a part of the integrated information system. The second purpose is to implement that model as an applicable system ready to serve in the Egyptian Armed Force.

I would like to acknowledge the support and encouragement that I received from my thesis advisor Dr. Henry Potoczny and from the committee members, Dr. Thomas Hartrum, Lt. Col. Richard Gross and Maj. John Stibravy.

Finally, I would like to thank my wife, Nagwa, and the rest of my family, for their constant understanding, support, and encouragement without which I could not have finished this work.

Abstract

The organization structure system is a part of the integrated information system of the Egyptian Armed Forces. It manipulates the units organization data (department, unit level, type, balance, armament, personnel, plan(s), percentage of completeness, location and position in the armed force tree). An initial survey for the problem is done. The design of the system is done through the E-R model and the functional dependency is defined. We choose the relational data base model for its advantages like data independence and simple data manipulation, over the other two DBMS models (hierarchical and network models). The system is designed in ten relations and the implementation is done through ingress using C programming language with equal (embedded ingress in C). We present several examples of queries that the system can support. An algorithm for collecting the units commanded by a particular unit is presented. The implementation includes the data definition of the ten relations in ingress. The data base editing program is presented which consists of 23 modules. This program is able to perform the addition, modification, deletion, and retrieval of units data keeping the data base in consistent state. The problems of recovery, concurrency, security and data integrity are also discussed.
I. Introduction

Background

In Egypt it's highly recommended that a national integrated information system be built. The Information System Department did a lot of work in the analysis and the design phase of the integrated information system. Building the integrated information system for the Egyptian Armed Forces is very essential. This integrated system will support the dynamic decision making process in all military areas. There is a lot of work done in the area of investigation and analysis of the integrated information system. There are many applications implemented as file system projects, but there's no application designed in data base management system yet.

Problem

The purpose of this thesis effort is to design and implement a data base management system for the organization structure of the Egyptian Armed Forces as a subsystem of the integrated information system. Keeping in consideration data base integrity and system interfaces to other systems/subsystems.
Scope

The scope of this effort was limited to the design and implementation of a prototype data base management system for the organization structure of the Egyptian Armed Forces. This newly designed system is able to answer any query related to the organization structure data. An Editing Program for the unit data is implemented.

Approach

The approach for this project follows:

1. General study of the Egyptian Armed Forces structure.
2. Description of the integrated information system.
3. Design of entity relationship model for the new designed system.
4. Choice of data base management system model.
5. Design of logical data base.
6. Physical data base representation.
7. Design and implementation of the editing program.
8. Discussion about the system related problems (recovery, concurrency, security, integrity, and system interfaces).
II. An Overview of the Egyptian Armed Force

Introduction

The Egyptian Armed Force formation consists of six main entities:

1. Arms and Equipments
2. Manpower
3. Unit Formation
4. Supply
5. Facilities
6. Transportation

Actually no single entity can stand by itself.

To get the system to work, we must assign the suitable arms and equipment with a well trained manpower to a suitable, well organized unit, and secure supplies, facilities, and transportation. That lets a single unit work in reasonable efficiency. But our goal is to let the whole armed force work in harmony with high efficiency and effectiveness in both war and peace time.

No doubt, the only way to reach the required degree of efficiency of the armed force that is equipped with a modern arms and equipment is through an integrated information system.

Developing a computerized national information system in Egypt is under investigation. The Egyptian Armed Force is
the leader in that field. The Ministry of Defense (MOD) is always eager to help other ministries build their own computerized information system.

Before attempting to design the computer system we will make a brief description of the Egyptian Armed Force from the point of view of the six main entities mentioned above.

Description of Egyptian Armed Forces

The Egyptian Armed Forces consists of five main branches:

1. Army
2. Navy
3. Air Force
4. Air Defense
5. Border Guard

Actually each branch may operate independently and has its own command. In the Army, each field army, or military area, has its own command and its own budget, but it is not completely independent. For example, logistic support is centralized for the whole armed force; also, personnel supplies with draftees is centralized (it is permitted to let the enlisted person join the branch of his choice).

The description of the Egyptian Armed Force will focus on the six main entities:
1. Arms and Equipment
2. Manpower
3. Unit Formation
4. Supply
5. Facilities
6. Transportation

Arms and Equipment (A & E)

The Egyptian Armed Force has a wide variety of arms and equipment that maybe classified into four main categories:

1. U.S. A & E
2. Eastern A & E
3. European A & E
4. Egyptian A & E

The different sources of A & E create difficulties in classification and codification processes for the arms and equipment (complete set and parts). Several studies were done on the existing inventory systems, supply systems, and technical support system.

The studies yield a decision taken by the Egyptian Ministry of Defense (MOD) to use the NATO system of classification and codification for complete arms and equipment and parts as the primary base of the new Egyptian computerized inventory system (as a subsystem of the logistic support system). To show the variety of A & E, the following are the types of arms used by the Egyptian armor and artillery as estimated in the Air Force Magazine,
December 1984.

Main Fighting Tanks
T-54, T-55, T-62, AM-60(M-60 A3), PT-76

Armored Fighting Vehicles
BRDM-1, BRDM-2, Scout ARS, BMP-1, PMP-600P,Compat
Vehicles, OT-62, Walid, FAhd, BTR-40, BTR-50, BTR-60, BTR-152
armor carriers, M 113 A2 armored carrier.

Artillery
Guns: 85 mm, M-1955, SU100-100 mm, D-30, 122 mm,
M-46-130 mm, SU-152, S-23, 180 mm.
Howitzers: M-1938 122 mm, M-1943 192 mm.
Mortars: 120 mm, 160 mm, 240 mm.
Multi-Rocket Launchers
122 mm, 132 mm, 140 mm, 240 mm.

Surface to Surface Missiles
Frog-7, Scud-D

Anti-Tank
Recoiless Launchers: 57 mm, 76 mm, 100 mm, 82 mm,
Bl1-107 mm

Guided Weapons
Sagger, Snapper, Swatter, Milan, Beeswing,
Swingfire, TOW

Air Defense
Self Propelled Aircraft Guns: ZS U-23-4, ZS U-57-Z
Surface to Air Missile: SA-6, SA-7, SA-9, Carstal,
Skyguard (6:122)
From these arms, we can find the eastern arms like the T-62 tank, the U.S. arms like the M-60 tank, the European arms like Crotal Air Defense System, and the Egyptian arms like Walid armored vehicle.

For all the A & E, we need a classification that can meet the requirements of the new designed system. This will be discussed later.

**Manpower**

The manpower may be divided into three main categories:

a. **Professionals:**
   That includes active duty officers, non commissioned officers, and civilians who are working for the Armed Forces.

b. **Draftees:**
   The draftees are men recruited to serve in the armed forces a mandatory service for a certain period of time. Four years for education below high school, three years for high school graduates and one year for education higher than high school. That is three years' average. The draftees recruited as soldiers, except for the draftees who have education higher than high school, may be recruited as officers. In this case, they must stay two years in the service.
c. **Reserve:**

All draftees must stay in the reserve service a certain period of time. The reserve man may be reassigned to the same unit he was serving in, or to another unit. The reserve is mobilized periodically for training.

Another classification of manpower which is mainly used for planning and for unit establishment tables is:

- **a. Officer:**
  
  This includes all types of officers whatever their ranks, specializations, type of service.

- **b. Secretary:**
  
  This includes all military personnel who are working in jobs like clerk, administration, finance, typing, document handling, librarians, bookkeeping, etc.

- **c. Commissions:**
  
  This includes all military personnel whose jobs are to operate an arm or equipment except for driving and technical maintenance, and also includes military drill personnel.

- **d. Driver:**
  
  This includes all types of drivers: truck drivers, tank drivers, clerk drivers, bulldozer drivers, etc.

- **e. Technician:**
  
  This includes all military personnel whose work is in technical maintenance, technical inspection, and also personnel who work in technical training jobs.
f. **Craftees:**

This includes all craft jobs like tailors, carpenters, painters, operators, etc.

**Unit Formation.**

There are different types of units in the Egyptian Armed Forces. The classification of the unit types is done according to the main mission and level of command. The unit name and class does not necessarily reflect its level of command. For example, one company may be commanded directly by a field army command, another is related to battalion then brigade, then division, then to a field army command. The following is a brief description of the unit main types:

**Ministry of Defense (MOD).**

This is the highest command level in the Egyptian Armed Forces and it commands all other units.

**Main Branches.**

There are five main branches (army, navy, air force, air defense, and border guards). Each branch has a single command. Except for the army, there is a single command for each field army or military area. The main branch is commanded directly by the MOD.

**Field Armies and Military Areas.**

Each field army or military area is a complete formation of army units. (There may be some Air Defense
units included in the formation established for a certain mission(s)). A field army or military area is commanded directly by the MOD.

Authorities.

Each authority is completely responsible for a main mission(s) in the armed forces. For example, the training authority is responsible for planning and follow-up of all types of training in the armed forces starting from primary military drill to the specialized training and graduate programs needed. The logistic authority is completely responsible for all logistic affairs for all armed forces. The authorities are commanded directly by MOD.

Centralized Departments.

Each centralized department represents a branch of service for the military personnel and commanded directly by MOD. Infantry departments, armor departments, signal corps departments, are examples of the centralized departments. Each specialized department is responsible for supplying the armed force units and formations with personnel. For example, the armor department is responsible for supplying the armed force units and formation with armor personnel according to each unit establishment table and percentage of completeness (this will be discussed later).

Each centralized department is responsible for supporting. reviewing, and inspecting of the unit of the
same branch of service. For example, the infantry department is responsible for completeness of all personnel in all infantry units. That means it should know the requirements of each unit from each branch of service to reach the required efficiency. In other words, the infantry department should know types and quantities of personnel needed from the infantry department and from other departments to complete an infantry unit according to its establishment table and percentage of completeness. Some specialized departments are completely responsible to supply arms and equipment related to the same branch of service, some are not.

For example, the armor department is responsible for supply, technical support, training personnel, and inspection of all armor equipment in armor units and also other units. On the other hand, the infantry department is not responsible for technical support of infantry weapons.

A good example of showing how the centralized departments cooperate to support one formation is a mechanized infantry brigade.

The infantry department is the sponsor of the mechanized infantry brigade and should help it get its needs from other departments. For example, the infantry department provides it with personnel only. The armor department provides it with armor carriers, technical
equipment, and parts needed for its operation. The armor department is also providing it with armor drivers and with technical support personnel. The brigade also contains a tank battalion (armor unit). The fuel department provides the brigade with the needed fuel and oil and also personnel needed for handling and storing that fuel. The engineering department provides the brigade with engineering equipment and personnel. The air defense command provides the brigade with complete air defense battalion (only personnel). The arms and ammunition department provides the brigade with all needed types of arms and ammunition and related equipment, and also provides it with personnel needed for handling and technical maintenance of arms and ammunitions. Also, other departments like the signal corp, chemical, artillery, electronic warfare, food, clothing, etc. provide the brigade with different needs. From the above example, we can recognize that there are many departments that are responsible for providing each army unit with its needs. To keep the units and the formations free from contacting all departments, there is a sponsor department for each unit and formation that should do what is necessary to let the unit or the formation reach the required degree of completeness.

Non Centralized Departments.

The non centralized departments are not commanded directly by the MOD and/or do not represent a branch of service. Some examples of these follow.
The clothing department represents a branch of service but is commanded by the logistic authority. The information systems department is commanded by MOD but does not represent a branch of service. The recruiting department is commanded directly by organization and management authority and does not represent a branch of service. A non centralized department maybe a sponsor of a certain type of unit.

Formation Units.

In the army, formation units start from the field army, division, brigade, battalion, company, platoon, and team. In the air force it starts from air base, air brigade, air port, and squadron.

Other types of units such as workshop, depot, store, weather station, etc., should be considered also.

Supply.

There are three main types of supplies:

- Arms and equipment supplies.
- Personnel supplies.
- Consumer material supplies.

**Arms and Equipment Supplies.**

Arms and equipment supply is done in both peace and war time for several reasons:
- New unit establishment.
- Replacement of damaged or destroyed equipment.
- Replacement plan by another type of arm/equipment.
- Completion of units.

**Personnel Supplies.**

As the units do not have to be completed 100% during peace time, personnel supply with the needed specialization of personnel will function during peace time for different reasons:

- New established unit.
- Military service termination.
- Change of percentage of recompletion of the unit.
- Declaration of general mobilization.
- Recompletion of units during war.

The personnel supply is done during war with reserve or with active duty personnel (if available).

**Consumer Material Supplies.**

This type of supply includes all types of materials needed for the unit to fulfill its mission successfully. That includes ammunition, food, clothes, fuel and lubricant, medical supply, parts, and other needed materials.

**Facilities.**

This includes planning, maintenance and inspection for
all needed facilities to the armed force units. Some civilian constructions and facilities may be mobilized during war time according to facilities' mobilization plan. For example, some civilian hospitals may be dedicated to the military, some civilian factories and workshops maybe dedicated to the military also.

Transportation.

This includes transportation of material, personnel, and supplies to and from military units during peace and war time. This may be done by the unit and formation transportation means or by other means according to the transportation plan.
III. The Integrated Information System

The integrated information system of the Egyptian Armed Forces consists of two main systems as described in Figure 1.
- Logistic Support Systems
- Command and Control System

Logistic Support Systems

The term logistic is used in both military and industrial fields. From the military point of view Webster defines logistic as:

The procurement, maintenance, and transportation of military material, facilities, and personnel. (1:4)

A United States Air Force technical report defines logistic as:

The science of planning and carrying out the movement and maintenance of forces. In its most comprehensive sense, logistics pertains to those aspects of military operations which deal with:

a) design and development, acquisition, storage, movement, distribution, maintenance, evacuation, and disposition of material,

b) movement, evacuation, and hospitalization of personnel,

c) acquisition or construction, maintenance, operation and disposition of facilities,

d) acquisition or furnishing of services. (1:4)
Figure 1. Integrated Information System for the Egyptian Armed Forces
In that sense, the logistic support system should include the elements of planning, acquisition, maintenance, test and support equipment, supply support, transportation and handling, personnel management, and all needed management and technical data. The main purpose of the logistic supply system is to supply personnel, material, facilities and technical support to the armed force units and formations at the right time with the right quantity.

The management of the organization structure of the armed force is one of the most important activities in the logistic support system. That is the maintenance and support of the organization structure of the armed force according to the national defense plan and available defense budget.

The integrated logistic support system will contain four main systems:

- Personnel Systems
- Organization Structure System
- Material Support System
- Finance System

**Personnel Management System.**

The personnel system should manage the information about the following:
- Officers
- Enlisted Personnel
- Draftees
- Reserve
- Civilians

There is not a big difference between the design and the needed information for both officers and enlisted sub-system, because both are professionals and usually spend most of their productive life in the military service. Both sub-systems should keep track of all necessary information needed for promotion plan, reassignment plan, training plan, and retirement plan besides necessary personnel records.

The recruiting sub-system is not so simple. It should keep track of the personal information during three phases of the person's life:

- Before military service as a civilian
- During military service as a draftee
- After military service as a reserve

**Before Military Service.**

Every Egyptian male must have an ID card at the age of 16 years old by the law. The personnel data are transferred from the civil recording offices to the recruiting department which maintain that record and amends it if necessary according to education and health records. This data will be processed to prepare the recruiting plan according to the armed force's needs.
During the Military Service.

The system should be able to select personnel to certain jobs in certain departments according to the needs of the armed force units. The training plan for the draftees should be done for each department. Because there is a different training period needed for each type of personnel specification, the system should be able to keep track of that information and prepare the assignment plan, then follow up the execution of this plan.

The system should keep track of the personnel records during the military service (promotion, new assignment, punishments, etc.). The military service termination plan should be prepared according to the regulation stated by the law.

After the Military Service.

Every draftee must stay a certain period of time in the reserve according to the law, except some special cases stated by the law. The person should know the newly assigned unit in the reserve service (usually it will be the same unit) and how to reach it.

The mobilization may be done for training purposes or for war. The system should be able to keep track of all reserve information and prepare mobilization plan for both peace and war time and also follow-up its execution.
The civilian sub-system is a typical personnel system. It should keep track of personnel records, prepare reassignment, promotion, and retirement plans. The system also should estimate the real needs from the civilian specifications.

Management of the Organization Structure of the Egyptian Armed Forces

Establishment of a military unit is done through an organized process according to the real needs of the armed force to fulfill the national defense plan, putting in consideration the availability of the following:

1. Arms and Equipments
2. Manpower
3. Facilities
4. Supply
5. Budget

The unit is considered to be established as soon as its organization instruction is issued. The organization instruction is regarded as the "birth certificate" of the unit. A copy is sent to main branches and departments.

Each organization instruction has a unique serial number. Any units may be established by the same organization instruction. Any change in the unit establishment data must be done through another organization instruction.
The organization instruction specifies the sponsor department and lists the departments responsible for supplying the newly established unit with personnel, arms, equipment, and facilities.

Each department mentioned in the organization instruction must assign the necessary personnel, arms, equipment, and/or facilities by the due dates stated in the instructions. The organization instruction should contain the following information:

1. General description of the unit
2. Description of the unit internal structure
3. Description of logistic support
4. Full description of personnel needed for the unit establishment according to the unit internal structure (this is summarized in the organization table).
5. Full description of arms and equipments needed for the unit established according to the unit internal structure (summarized in the armament table).
6. Timetable for establishment phases.

The following unit data must be stated in the organization instruction:

1. Unit name - unique name to identify the unit.
2. Main branch - army, navy, air force, air defense, or border guard.
3. Sponsor department - armor, signal corp, artillery, etc.
4. Unit level - division, brigade, battalion, etc.
5. Unit type - This attribute (with department and unit level) identifies the unit type. For example, if (3) and (4) describe an infantry battalion, (5) will describe the infantry battalion as mechanized infantry battalion or airborn infantry battalion or other type of infantry battalion.

6. Unit number - this number is a unique number with respect to each unit type to differentiate between different units of the same type.

7. Percentage of Completeness - According to the primary mission of the unit, the percentage of completeness of personnel may be identified to be less than or equal to 100%. The unit may be completed by mobilization for training reasons or for war reasons. New units are established according to the available arms and equipment. For tactical reasons, arms and equipment should be completed even if the completeness of personnel is less than 100%.

8. This attribute describes the unit's main mission from the point of view of armed force general balance. It may be one of the following six types:

   a. Command and control (e.g.) signal corp units.

   b. Fighter (e.g.) infantry or tank battalion

   c. Fighting assistance (e.g.) engineering battalion.

   d. Logistic (e.g.) transportation battalion.

   e. Technical (e.g.) armor field workshop.

   f. Training (e.g.) artillery school.

9. Location - The organizational instruction must identify the primary unit location. Egypt is divided into six main military location areas.

10. Command Unit - Each unit must be commanded by only one unit (except the MO - that is regarded as the root of the armed forces structure tree).
11. Commanded Sub Unit(s) - The organization structure should state other units commanded by the established unit (if any).

12. Defense Plan - This attribute defines which defense plan this unit has a mission. The unit may be assigned to more than one plan.

13. Personnel Table - This table summarizes the required personnel for different departments according to the five main specifications. Figure 2 illustrates an example of a personnel table.

14. Armament Table - This table specifies the required arms and equipment needed for the unit (types and quantities). The department that is to supply that type of equipment may not be stated.

The armed force instructions define which departments supply which arms/equipment. In some cases, the department may be stated to eliminate ambiguity if necessary. Figure 3 illustrates an example of an armament table. Notice that only the main arms and equipment are listed in the table.

If the newly established unit has the same organization as an existing unit, the organization instruction refers the organization instruction number of the existing unit and both organization and armament table may not be repeated.

**User Hints from the Organization Structure Information System.**

1. Keep track of the 14 attributes mentioned in the organization instruction for each unit.

2. Define the relations between the different types of units.

3. Create the hierarchical information model for the armed force units.

**Figure 3. Armament Table for a Mechanized Infantry Battalion (Example)**
4. Be able to answer queries like:

a. Describe the organization tree for the 10th Armor Division and total number of personnel for each unit in the tree and for the division.

b. Identify the types and number of personnel needed from the signal corp department to supply the units sponsored by the armor department.

c. Identify the personnel requirement to the fifth field army by type and number from the specialized departments.

d. How many Howitzer 160 mm or 240 mm should exist in the west location?

e. What armor unit exists in Central location to support plan A?

5. Identify and secure the interface between the system and the other systems (personnel, finance, and material support) and with command and control system.

Material Support System

This system should perform the procuring, maintaining, and securing of the following:

1. Complete Arms and Equipment
2. Spare Parts
3. Daily Consumed Material (food, fuel, clothes, medical support, etc.).
4. Ammunition
5. Facilities
6. Transportation
7. Other Military Material

This system deals with a wide variety of military
material. But fortunately, most of it is related. For example, one of the system's main jobs is related to the military arms and equipments. The operation of A & E needs ammunition and fuel, the technical support of A & E needs parts and lubricants and both of them need transportation, so most of the data related to the A & E is still in the same system. On the other hand, the system still needs some information from the organization structure system about unit structure, location, and armament table for each unit.

Another type of information needed from the command and control system is the operational mission for units to be able to secure suitable amounts of ammunitions, fuel, transportation, food, and water, procurement and maintenance of the material. This needs complete interaction with the finance system.

Finance System

No one can ignore the impact of the financial matter on all segments of the armed forces. Armament, personnel, supply, and facilities are examples of those segments that are highly affected by financial decisions.

The function of the finance system is defined by Herbert T. Sprouls as:

Finance engages in two primary types of functions for top management: recording, monitoring, and controlling of financial consequences of past and current operations, and securing funds to meet current and future needs.
To accomplish the first set of functions, the finance system needs well-defined interface with material support, personnel, organization structure and command and control systems. The second set of functions needs interfacing with outside institutions (e.g., Ministry of Treasury, Ministry of National Planning, etc.). Discussion of the finance system is out of the scope of this project.

Command and Control System

To describe the system of Command and Control (C^2), note Dr. Robert E. Conley's definition:

Command and Control (C2) is a process of resource allocation (management) by a knowledgeable, recognized point of authority to accomplish a given objective. (3:16)

This definition describes the C^2 system as the process by which the military objective(s) may be accomplished with available resources. Actually, the definition is applicable for military and other management areas and the authority may not be a human. The C^2 system cannot increase the resource capability but it allows to all the resource at an appropriate time and in the idealization of the C^2 system results in C^3. "Command, control, communication and intelligence" system given a scope of information that should be collected and processed through the system. Two categories of information should be
manipulated by the system; our own forces and the opposing forces. Types of information and functions of the C² system are described by the official definition of command and control in the Joint Chief of Staff (JCS) Dictionary as:

The exercise of authority and direction by a properly designated commander over assigned forces in the accomplishment of his mission. Command and Control functions are performed through an arrangement of personnel, equipment, communication, facilities, and procedures which are employed by a commander in planning, directing, coordinating, and controlling forces and operations in the accomplishment of his mission. (3:26)

The components of the C² system are defined by J. S. Lawson as:

1. Sensors
2. Communications
3. Data Processing
4. Information Management
5. Decision Aids
6. Forces to Command
7. A Commander (3:62)

A basic model of C² process is described in Figure 4 (3:66).
Scope of the Project

From the previous discussion about the Egyptian armed forces integrated information system, we can conclude that the first step should be the design of the organization structure system. All of the systems included in the integrated information system need information about the organization structure of the units and formations and/or information related to the organization table and/or armament table for units.
The organization structure system may be designed and implemented by itself because the original source of data is the Organization Instruction for units. The percentage of completeness, location, and defense plan may be changed by operational instruction. Later, this may be done through the interface with the command and control system. For those reasons, the scope of the project will be the design of the organization structure information system using a data base management system. The implementation will be done as time permits. The designed model should define and manipulate the following data which is described earlier in this paper.

1. Organization Instruction Number
2. Unit Name
3. Main Branch
4. Sponsor Department
5. Unit Level
6. Unit Type
7. Unit Number
8. Percentage of Completeness
9. Balance Type
10. Location
11. Command Unit
12. Commanded Sub-Unit(s)
13. Defense Plan
14. Organization Table
15. Armament Table

The thesis work will cover the following areas:
- Definition of the System E-R Model
- Definition of the System F-D Model
- Choice of DBMS Model
- Normalization (if necessary)
- Design of Conceptual Data
- Implementation (as possible)
- System Recovery and Concurrency
- System Security and Integrity
- System Interfaces

This thesis work will cover the current information about the organizational structure of several Egyptian military organizations. The information is needed for planning and management of the armed forces organization structure. The implementation of this project keeps the consistency and correctness of data over all of the armed forces organization.
IV. Design of Entity Relationship Model

The E-R model is one of the most useful tools to summarize the designed data base information that may be represented as three different types:

Entity

The term "entity" is widely used in data base circles to mean any distinguishable object that is to be represented in the data base.

(2:10)

A group of similar entities may form an entity set. The entity will be represented by rectangles.

Attribute

Entities have properties called attributes, which associate a value from a domain of values for that attribute with each entity in an entity set.

(8:6)

The attributes' definition for each entity is an important step in data base design. If an attribute or a set of attributes whose values uniquely identify each entity in an entity set is called a key attribute(s), the attributes will be represented by circles (or ovals) and the key attribute will be marked by an asterisk.

Relationship

A relationship among entity sets is simply an ordered list of entity sets. A particular entity set may appear more than once on the list. If there is a relationship REL among entity sets $E_1$, $E_2$, ..., $E_k$, then it is presumed
that a set of \( k \) tuples named REL exists. We call such a set a relationship set. Each \( k \)-tuple \((e_1, e_2, ..., e_k)\) in set REL implies that 
\( e_1, e_2, ..., e_k \), where \( e_1 \) is in set \( E_1 \), 
\( e_2 \) is in set \( E_2 \), and so on, stand in 
relationship REL to each other as a group. (8:7)

The relationship will be represented by diamonds.

Entity Types

Figure 5 illustrates the designed E-R model for the system. The newly established unit may follow one of the existing models (as described in the last section), or it may be established by a new unit model. For example, all M60-43 tank battalions have the same structure (i.e., they follow the same unit model). Five entity types are defined; the first one is "Unit-Model" which represents a prescribed structure of units that may be followed by a newly established unit; the second one is "Unit" which represents an existing real unit. Two entity types "Person" and "Armament" describe both personnel and armaments assigned to the predefined unit-model. The last entity type is "Plan" which describes assigned plan for unit (See Figure 5).

Attribute Types

**Unit Model Attributes.**

There are three attributes (udep, level, type) that uniquely identify the unit-model and another three attributes.

- **udep** - unit sponsor department number. It is a 2-digit integer number ranging from 1 to 99.
Figure 5. E-R Model for Organization Structure Data Base.
*Level - Unit level (division, brigade, battalion, etc.). It is a 2-digit integer number ranging from 00 to 99 (level 00 represents MOD only).

*Type - Unit type. If the unit is infantry battalion, this attribute describes its type (mechanized, air born, amphibious, etc.). It is a 2-digit integer number ranging from 00 to 99. (Type 00 means that this unit has only one type, e.g. MOD, Infantry Department.)

Uname - Unit name like "mechanized infantry brigade". Unit name may identify the unit model and it is regarded as candidate key (a relation's attribute that uniquely identifies all relation's attributes is called a candidate key). We must add unit number (the key attribute of unit entity) to Uname to be "Mechanized Infantry brigade Number 115". It is represented by a string of 30 characters.

Balance - It represents the unit balance type (command & control): fighting, fighting assistance, logistic, technical, and training. It is represented by an integer number ranging from 1 - 6.

Main Branch - The main branch which the unit model belongs to (army, navy, air force, air defense, border guard). Its domain is the set of values (AR, NA, AF, AD, BG).

Person Attributes.

Person entity represents the organization table as described in Figure 2. There are two key attributes and another attribute.

*Pdep - Person department number. It is the specialized department responsible for supplying the unit with the defined type of personnel. It is a 2-digit number ranging from 01 - 99. The same attribute value as Udep.
*Specialization - It is defined as the person specialization and it is one out of six specializations (officer, secretary, commission, driver, technician, or crafter). Its domain value is the set (off, Sec, Com, Dri, Tec, Cra).

#P - It is the attribute of the relationship assigned personnel and it is the number of personnel from the predefined Pdep and specialization. It is an integer number ranging from 0 - 999.

Armament Attributes.

Armament entity represents the armament table as described in Figure 3. There are two key attributes and another one.

*Adep - Armament department number. It is the specialized department responsible for supplying the unit with the defined type of arms or equipment. It is a 2-digit number ranging from 01 - 99. (the same attribute domain as Udep.)

*name - Arm or equipment name. It is represented by 30 Character String.

#A - It is the attribute of the relationship assign A & E and it represents the number of arms or equipments predefined by both Adep and name. It is an integer number ranging from 0 - 999. (The same attribute value as #P.)

Unit Attributes.

There is only one key attribute (U#). This attribute does not uniquely identify a unit. Unit is identified by unit-model keys (udep, level, type) and U#.

*U# - unit number. This attribute defines the unit number for an existing (or new established) unit which has a unit model existing in the entity set Unit-Model.
If the unit model can represent only one unit (e.g.) unit model of MOD or logistic authority, the unit number will be zero. Otherwise, the unit number will be greater than zero. Units of different unit model may have the same U#. U# is represented by an integer ranging from 0 - 999.

Percentage - percentage of completeness of the unit from personnel (in peace time). It is an integer ranging from 0 - 100. (As a matter of fact there is no zero percentage of completeness as it means no personnel in this unit but it may be considered for special cases of reserve units where the whole unit is stored.)

Location - The geographical location of the unit. Egypt is divided into six military locations (A, B, C, D, E, F). Its domain value is the set (A, B, C, D, E, F).

Instruction # - The organization instruction number that establishes the unit. It is represented by an integer number ranging from 1 to 99999.

Plan Attribute.

Plan - The defense plan(s) with which the unit has a mission with. The unit may be assigned to more than one defense plan and more than one unit may have the same plan (min). Its domain value is the set of Alphabet (A, B, C, ..., Z).

Relationships

First, relationship "established" between Unit-Model and Unit represents that each unit is established within a unit model. As many units may have the same model, the relationship is a one to many relationship. Second and third relationships "assign personnel" and "assign E"
represent the relationship between unit model and personnel and armaments assigned to that unit model consequently. Both relationships are many to many (more than one occurrence of the first entity may be assigned to one occurrence of the second entity, and more than one occurrence of the second entity may be assigned to one occurrence of the first entity). Different personnel from different departments and different specializations may be assigned to the same unit-model, and personnel from the same department and from the same specialization may be assigned to different unit models.

The fourth relationship "command" represents the hierarchical relationship between units. The command unit (which is unit) commands a set of units and each unit (except which represent the rest of the tree) is commanded by only one unit. Therefore, all units (except the root) are involved in this relationship. The other option to represent the "command" relationship is to consider the command units. From this point of view we can see that all units have commanded units except "leaf-units". The number of units involved in the second option of the relationship is much fewer than first option; therefore, we will choose the second option. The last relationship is assigns-to describes which unit is assigned to which plan(s). This relationship is a many to many relationship.
Function Dependency

The entity Unit-Model has three key attributes (udep, level, and type). These three key attributes define uname and balance as described in Figure 6.a. The other attribute "main branch" can be defined by udep only.

The relationship "assign personnel" is a many to many relationship between unit-model and personalities; #P can be defined by means of the key attributes of both entities (udep, level, type, Pdep, and specialization) as described in Figure 6.b.

A similar functional dependency exists between Unit-Model and armament entities; #A can be defined by means of the key attributes of both entities (udep, level, type, Adep, and name) as described in Figure 6.c. The unit attributes percentage, location, and instruction #, are defined by Unit Model's key attributes Udep, level, and type and Unit's key attribute U# (see Figure 6.d).

The last relationship "command" describes the command unit for each unit. Therefore, the command unit key attributes cdep, clevel, ctype, and cu# (c stands for command unit just to eliminate ambiguity) are defined by unit attributes udep, level, type, and U# (see Figure 6.e).

V. Design of Data Base

Choice of DBMS Model

The process of choosing a DBMS Model for implementation needs to compare the feature of the three main DBMS models; hierarchical, network, and relational models which will be represented by DL/1, IDMS, and SQL, respectively. This comparison will be done through a framework for the evaluation of data model which is described by Vasta (9:219-226). Figure 7 summarizes this framework of evaluation (9:220).

General Considerations.

Data Building Blocks.

It is the smallest unit of data. It is defined as a field in DL/1, data item in IDMS, and attribute in SQL. The data item unit is a segment in DL/1, and a Record in IDMS. The relational model has an advantage over the two other models; it offers two units of data transfer. SQL permits transfer of one tuple at a time, and when data is operated upon through an on-line terminal in SQL, the units of data transfer is a table (8:221).

Representation of Logical Data Structure.

The logical data structure of the design model as described by E-R diagram (Figure 5) represents two one to many relationships and three one to many relationships.

</table>

Figure 7. Framework for the Evaluation of Data Model (9:220)
The logical data structure may be represented as a network. The network structure cannot be represented directly by DL/I. Data is represented as if it were duplicated. Data are reproduced in two different segments in a tree structure then logical pointers are used to eliminate redundancy. Network model represents many to many relationships by creating a record type which contain intersection data for records involved in the many to many relationship. The intersection record is a member in each of two sets in which the related records are owners (8:221). Relational model also creates an intersection relation including primary keys of the relations involved in the many-to-many relationship.

Data Independence.

DL/I allows logical sequencing of segments and permits secondary indices. While this provides great flexibility to the application program, it causes sequence dependency and also path dependency since the desired segments is obtained through a specific path. IDMS is also subject to the same sequence and path dependency.

In relational model, pointers are not used and the relationship is kept through the tables' attributes. In a relational model, columns and rows may be presented in any order (i.e., there is no specific sequence that must be followed). Therefore, the relational model is free from both sequence and path dependency.
Navigator.

Navigation is done in both hierarchical and network models through specific paths. In a hierarchical model, it is done through the traversal of the tree structure and in a network model, through the traversal of owner and member sets. In both models, the navigator must know the current location in the data base and the direction of the desired data item. Therefore, a highly trained programmer is needed.

Because of the data independence in the relational model, there is no specific path to follow, and the data is obtained by defining the value of the attributes within relations. It is not necessary to keep track of the current data base position, or to describe how to find the data. Therefore, there is no need for a highly trained programmer. The end user with little training can manipulate data.

Performance.

In a hierarchical model, the specific paths which are defined by pointers permit rapid retrieval of desired data. The same situation is also in a network model. On the other hand, "neither IDMS nor DL/I is well suited to an unstructured environment where data relationships can be changed while the user is accessing the data base" (8:223).
The relational model needs greater space than both the hierarchical and network models. SQL is more powerful as it performs operations on many tuples within a single query. Where DL/I and IDMS operate on one record or segment at a time and may require many commands to accomplish one SQL command.

Security.

In a DBMS, security is defined on the level of the subschema. In both DL/I and IDMS, the subschema definition is translated before execution. In SQL, the definition of the subschema may be modified at any time. (8:224)

SQL has additional security tools; that is "Grant and Revoke" mechanism and "view" mechanism. The view mechanism allows the data to be conceptually divided up in such a way to that some data may be hidden from unauthorized users. The Grant and Revoke mechanism or the authorization subsystem lets the authorized user grant rights to any other user(s) but not exceeding his own rights, and also Revoke granting rights to the user he granted and any other user that granted user rights (2:441-443).

Modification of the Data Structure.

Since both hierarchical and network models are data dependent and the data are linked together in such a way that it is needed to follow a certain path to retrieve a specific segment, modification of data structure needs a
working copy of the data base(s) to be made, a new
definition of the data structure, and then recreate the data
base in the new structure from the working copy. While the
restructuring is occurring, programs may not access or
modify the existing data (9:224). In case of relational
model, the DBMS is data independent, so the data structure
may be modified at any time while the system is running and
without recreation of the data base.

Comparison of Models.

From the above discussion and considering the shape of
the data base that is defined by the E-R model described in
Figure 5, we can summarize our data base features as:

1. There are two one-to-many relationships and
   three many to many relationships.

2. There must be an algorithm to create the
   formation hierarchical relation (the relation
   that contains the set of units which are commanded
   by a particular unit) from the command relation
   (the relation that defined the subunits (if exist)
   for each unit).

3. We should consider that the data base
   will have many interfaces to other systems
   (see Figure 1) and the homogenous aspects of
   DBMS for the armed force integrated system.

From the above features of the data base we will exclude
the hierarchical model from our consideration for the
following main reasons:

1. There are many to many relationships.
2. Hierarchical model cannot represent a network directly; instead, it's decomposed into many tree structures that may cause data redundancy.

Now the comparison will be done between the network model and the relational model.

**Network Model.**

Advantages:

1. Simple representation of network
2. Rapid Response

Disadvantages:

1. Data dependent
2. Needs experienced programmer
3. Modification of data structure needs to redefine structure and related new structure.

**Relational Model.**

Advantages:

1. The data transfer unit may be a tuple or a whole table.
2. Data independent.
3. Simple data manipulation, that end user with little training can manipulate the data.
4. Additional security tools (view, Grant-Revoke).
5. Easy modification of data structure.
Disadvantages:
1. Needs greater space.
2. Slower response.

Choice Considerations.

From the above discussion and from the advantages and disadvantages of network and relational model, consider the following:

1. The designed data base will have interfaces to other systems that most likely to use rational models.
2. "Networks are complex and the structure is complex. This increase in complexity compared with relational system does not lead to any corresponding increase in functionality" (2:574).
3. To keep the integrated system as a homogenous system, we should use the same DBMS model.
4. Ability to have relational model for the Egyptian VAX systems.

From the above, the chosen data base model is the relational model and the implementation will be done within DBMS on a VAX 780 (SSC system).

Design of Logical Data

In a relational data base model, the data base is arranged into two dimension tables (relations). Each occurrence of data (row) is called a tuple. A tuple consists of one or more properties called attributes. Each
attribute can take on a specific set of values over a period of time. All the values that an attribute can take on are called the domain of the attribute. (9:198-199).

Retrieving the E-R model described in Figure 5, we will start defining the database relations as a relation for each entity and for each attribute. The second step is to use a computer normalization tool to normalize any non-normalized relation to third normal form (if any).

**Direct Relations Definition.**

The direct relations definition for the database described by the E-R diagram (Figure 5) will be described below. The relation name will precede the relation. The "*" preceding an attribute represents it as a key attribute:

1. Unit Model
   * dep
   * level
   * type
   name
   balance
   main branch

2. Person
   * p
   * specialization

53
3. Armament
   * Adep
   * name

4. Assign Personnel
   * dep
   * level
   * type
   * Pdep
   * specialization
   # P

5. Assign - A & E
   * dep
   * level
   * type
   * Adep
   * name
   # A

6. Unit
   * dep
   * level
   * type
   * U#
   Percentage
   Location
   Instruction #
7. Plan
   * dep
   * level
   * type
   * U#
   * Plan

8. Command
   * c dep
   * c level
   * c type
   * c U#
   * dep
   * level
   * type
   * U#

Normalization.

The purpose of normalization is to design data structures in such a manner as to eliminate the need to redesign them when new applications are added. By storing data in the third normal form, structures designed today can be integrated with new applications in the future with little, if any, redesign effort.

Using a CAD normalization tool which is running on LSI-11 System "A" by Mallory (1), we found that the two relations that need further normalization. The first relation Unit-Model is normalized as the following two relations:
1. **Unit-Model.**
   * dep
   * level
   * type
   name
   balance

2. **Department.**
   * dep
   main branch

The plan relation is normalized to the following two relations:

1. **PLAN.**
   * dep
   * level
   * type
   * U
   * plan

2. **PLANID.**
   * id

**Data Definition**

The data base of the organization structure of the Egyptian armed forces after the normalization step will be presented in ten relations. Referring to the attributes description presented previously and using ingres notations, the data base will be defined as the following set of relations:
1. **Unit Model**

<table>
<thead>
<tr>

</table>
The new data base "OMADB" (OMADB stands for Organization and Management Authority Data Base) is created under UNIX operating system using ingress. OMADB consists of the ten relations UNITMODEL, DEPARTMENT, PERSON, ARMAMENT, ASSIGNP, ASSIGNA, UNIT, PLAN, PLANID, and COMMAND. Ingres data definition of the relations is presented in Appendix A.
VI. Data Manipulation

The data manipulation will be done through Ingres Data Manipulation Language (DML). Ingres uses English-like commands to manipulate data within relations. Each relation represents a table which is identified by name. Each row represents a tuple, each column represents an attribute of the relation which is identified by name. Ingres provides two sets of commands; the data definition commands that let the user define the needed information (ask questions), and data manipulation commands for insertion, updating, and deleting data. The user need not be aware of whether he uses base table or view to retrieve the required information (views represent the visible data for the user and it will be discussed later in Chapter VII). To represent data manipulation, let us start building the physical data base for the hypothetical formation presented in Figure 8.

Physical Data Base Representation

Figure 8 presents a hypothetical formation of units which consists of:

1. MOD which presents the root of the tree.
2. Three specialized departments: infantry, armor, and signal corp departments.
Figure 8. Unit Formation of OMADB Data Base

unit code dep/level/type/num

*
3. Two infantry brigades number 100 and 200  
   (both brigades have the same unit model).
4. Four infantry battalions number 10, 11, 20,  
   and 21 (the four battalions have the same  
   unit model).
5. Two tank battalions number 100 and 200  
   (both battalions have the same unit model).

**Description of Physical Data Base.**

All departments and MOD are located in Location A.  
Infantry brigade 100 and its subunits are located in  
Location B. Infantry Brigade 200 and its subunits are  
located in Location C.

All departments and MOD have balance Code 1. All other  
units (in the sample data) have balance Code 2. All units  
have main branch "AR" (army). Percentage of completeness  
for MOD is 100%, for departments is 70%, for brigade 100 and  
it's subunits is 90%, and for brigade 200 and its subunits is  
85%.

MOD is in plans A, B, and C. All departments are in  
plan A. Infantry brigade 100 in plans B, C. Infantry  
brigade 200 in Plan B except tank battalion 200 which is in  
plans B and C. Appendix I represents the personnel and  
armament tables for the sample units as described in the  
organization instructions. Representation of physical data  
of OMKAD in the ten relations is presented in Appendix B.

64
Retrieval of Data

Retrieval of data in our model is done through the ingress data manipulation language that has the advantages of relational algebra in dealing with relations. Ingres deals with data as a set of data items (tuples) compared with the traditional methods of data manipulation that deal with each data item separately (record by record or segment by segment). In the particular case when ingress is looking for a particular tuple, it deals with it as if it's a set of data items consisting of one tuple. This new dimension in data manipulation which was introduced by relational algebra let the user write his query in more abstract form and make it easier for the inexperienced user to deal with the relational data base management system. This concept implies that dealing with data in sequential order (or in any other order) has no meaning. The reason for arranging the tuples in a particular relation is either to reduce the access time or a required output format. In the next section we will introduce some examples of questions that our system can support.

Examples of System Queries.

Ingres data manipulation language (DML) may be done interactively or imbedded in other languages like C.

The following are some examples of queries that are necessary for the management of the organization structure.
of the Egyptian armed forces. These queries may be im-
bedded in other languages or simply as interactive queries.

a. How many infantry battalions exist in location b?

Ingres DML:

*range of u is unit
*retrieve into temp (u.num)
*where u.dep = "10" and u.level = "06"
*and u.type = "03" and u.location = "b"
*\g
*range of t is temp
*retrieve (number = count (tnum))
*\g

Result

<table>
<thead>
<tr>
<th>number</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>

b. How many officers exist in a tank battalion?

Ingres DML:

*range of p is assignp
*retrieve into temp (p.num)
*where p.dep = "11" and p.level = "06"
*and p.type = "07" and p.spec = "off"
*\g
*range of t is temp
*retrieve (numP = sum (t.num))

\*\|\g

Result

\begin{tabular}{|c|}
\hline
numP  \\
24  \\
\hline
\end{tabular}

c. Write the unit name and unit number of units located in location C?

Ingres DML:

\*range of m is unitmodel
\*range of u is unit
\*retrieve (m.name, u.num)
\*where u.dep = m.dep and u.level = m.level
\*and u.type = m.type and u.location = "C"
\*\|\g

Results

\begin{tabular}{|l|}
\hline
Name       & Num  \\
\hline
Infantry Brigade  & 200  \\
Infantry Battalion & 020  \\
Infantry Battalion & 021  \\
Tank Battalion    & 200  \\
\hline
\end{tabular}

\d. How many technicians does the signal corp department supply to the armed forces?
Ingres DML:

*range of a is assignp
*range of u is unit
*retrieve into temp (a.dep, a.level, a.type, u.num, nump = a.num)
*where a.dep = u.dep and a.level = u.level
*and a.type = u.type, and a.spec = "tec"
*and a.pdep = "16"
*/g
*range of t is temp
*retrieve (tech = sum (t.nump))
*/g

Result:

<table>
<thead>
<tr>
<th>tech</th>
</tr>
</thead>
<tbody>
<tr>
<td>22</td>
</tr>
</tbody>
</table>

d. Write the unit's name and number for the units which are located in location C and in plan C?

Ingres DML:

*range of u is unit
*range of m is unitmodel
*range of p in plan
*retrieve into temp (u.dep, u.level, u.type, u.num, m.name)
*where u.dep = m.dep and u.level = m.level
*and u.type = m.type and u.location = "c"
*\g
*range of t is temp
*retrieve (t.name, t.num)
*where t.dep = p.dep and t.level = P.level
*and t.type = P.type and t.num = P.num
*and P.plan = "c"
*\g

Result

<table>
<thead>
<tr>
<th>Name</th>
<th>Num</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tank battalion</td>
<td>200</td>
</tr>
</tbody>
</table>

The above queries are examples of useful output that may be done by the end user with little training. Let us try to answer other types of questions. For example, how many drivers exist in the formation commanded by the infantry brigade 100?

To answer this query, we first must know what units are existing in this formation. The command relation can give us the set of units that is commanded directly by the infantry brigade 100 (i.e.) one level of the formation hierarchy. Unfortunately, we do not know how many levels we should travel. For that reason the query should have a recursive feature. Unfortunately, neither ingress DML nor equal (embedded ingress in c language) allows recursive construction. From the above information and to let our
system answer any type of query (about the data in the ten relations), we need an algorithm to collect the units that belong to a particular formation or, in other words, get the nodes of the subtree that belong to a specified node in the armed force tree. This algorithm will be introduced in the next section.

Collect Formation Unit Algorithm.

For the reason of keeping the set of units that is under the command of a particular unit, we create a new relation in the system, the relation formation (dep, level, type, num). This relation is a working relation to keep the unit collection of the required formation (the output of the algorithm). Then we can do our queries about that formation.

The algorithm of collecting the units under the command of a specified unit is:

1. Get the command unit code - unit code is (dep/level/type/number).
2. Create the temporary relation parent (dep, level, type, num).
3. Create the temporary relation sons (dep, level, type, num).
4. Delete the controls of the relation formation (if any).
5. Append to parent the control unit - unit here means unit code.
6. Append to sons the units that are commanded directly by any unit(s) which exist in parent (using command relation).

7. Append to formation all units in parent.

8. Delete the contents of parent.

9. If the number of units in sons < 1, go to Step 13 or else continue.

10. Append to parent all units in sons.

11. Delete the contents of sons.

13. Destroy sons, destroy parent.

(See Figure 9)

This algorithm is established as the computer program "tree" (see Appendix C).

To get the set of units that is commanded by a specified unit, from UNIX, type "tree". The program tree will start running and it will let you enter the command unit data (dep, lev, tpye, num) as the program requests. The program will check the existence of the command unit. If the unit does not exist, or if the input format is not correct, the program will ask you to re-enter the command unit data again or to quit (by typing 'Q'). If the entered data are correct, the program will start execution and the output will be stored in the related formation. If the entered
Start

Get Command Unit Code

Create PARENT relation
Create SONS relation
Delete FORMATION relation

Append to PARENT command unit (code)

Append to SONS all units commanded
directly by any unit(s) in PARENT

Append to formation all units in PARENT

Delete PARENT

Are units in sons < 1

Yes

no

Append to PARENT all units in SONS

Delete SONS

Destroy SONS
Destroy PARENT

End

Figure 9. Call Formation Units Algorithm
command unit is a leaf unit (command no unit), the relation formation will contain this unit only and the program will let you know by an appropriate message.

The program (TREE) is done in C language with embedded ingres. It consists of a main body (main) and 3 functions (get-unit-model, check unit, and Ctree) as shown in the structure chart described in Figure 10. TREE program is presented in Appendix C, and a copy of the output results is presented in Appendix D.

The answer to the query described in the previous section (how many drivers exist in the infantry brigade 100) will be presented in Appendix E using tree program.

![Structure Chart of Tree Program](image)

**Figure 10. The Structure Chart of Tree Program**

**Updating of Data**

The problem of data updating in our system should be treated carefully. The designed system consists of 10
relations and an update in assigned relation may violate the integrity of the data base. For example, if we are trying to delete a unit, deleting the unit from unit relation is not enough. It should also be deleted from any occurrence in plan relation tuples and also from the occurrence in the command relation as a commanded unit. Another violation of the consistency of data will happen if we delete a unit which exists in the command relation or a command unit. If we only do this, we will leave its subunit be commanded by a non-existing unit. In this case, we should either delete all the units commanded by this unit or quit according to the user request.

The updating of the program "OMAED" which is presented in Appendix G is designed to perform the three main updating functions (insertion, deletion, and modification) in a certain algorithm so that it keeps the data integrity over the whole system. The ability of retrieving unit data is added to the program to let the user retrieve unit data according to his request. The program is designed in menu driven fashion to make it easy to use. The program is designed in main body and 22 functions that count 23 modules. The structure chart of OMAED program is shown in Figure 11.

**Insertion.**

To insert a new unit into the data base, the program
Figure 11. The Structure Chart of OMAED Program
will check the format of the unit code first before calling ingress, then it checks if the unit exists. The system does not allow the existence of the same unit twice. If these checks are passed, the program will check if the new unit has an existing unit model. If not, it will ask the user to enter the new unit model data and it gives the user the chance to quit. After insuring that the unit model exists (or correctly entered by the user), the program will ask the user to enter the unit data (unit number, percentage, location, plan(s), instruction number, and command unit). The system will make an appropriate check for each entered piece of data. For example, the command unit should be an existing unit, plan should exist in planid relation.

After insertion of the data, the program returns to the menu, and the user can retrieve the entered data using "r" option.

**Modification.**

To modify existing unit data, the program will check first the existence of the unit in the data base, then it will show another menu to select one of the following modification options:

- modify unit percentage
- modify unit location
- modify unit plan
- modify command unit
- modify instruction number
For every selection, the program will ask the user to enter the new data, then it makes an appropriate check on it. For example, modification of plan will be done through two operations, either to assign the unit to a new plan or to delete a previous assignment for plan. To do that, there should be two types of checks, one to insure that the new plan exists, the other check is to insure that we will not try to delete a plan which the unit is not assigned to. Modification of command unit will insure that the new command unit exists.

Deletion.

To delete an existing unit, the program will start a check to see if the unit exists. If so, the program will give the user a chance to quit by asking "Are you sure?" At this step, the program cannot delete the unit before doing another operation. The program will be called "Ctree" module to collect the unit(s) which are commanded by the unit in question into the relation "formation". If there is any other unit in the relation formation rather than the unit in question, the program will ask the user again if he wants to delete all subunits. At this step, the user has another chance to quit. If not, the program will delete the unit and all its subunit(s), if any. Deletion is done in such a way as to keep the integrity of data base. That will be discussed in Chapter VIII.
VII. Recovery, Concurrency and Security

Recovery

In our system, the problem of recovery may arise due to the transaction processing. The transaction is a logical unit of work. When executing the data base editing program EDOMADB, one transaction that seems to the user as one operation may be a sequence of several operations. For example, deleting a unit looks like a single transaction, but actually it affects three relations. One tuple must be deleted from unit relation, another tuple must be deleted from command relation, and all the occurrences of this unit in plan relation must be deleted. A similar situation is done when inserting a new unit. A system crash might occur between two operations, or the program itself might, for any reason, terminate between the two. In this case, the program has no means to detect in which stage the failure is done. The recovery should be done on the system level.

A system that supports transaction processing should provide a guarantee that if the transaction executes some updates and then a failure occurs (for whatever reason) before the transaction reaches its normal termination, then those updates will be undone. Thus the transaction either executes in its entirety or is totally canceled (2:414).
The COMMIT and ROLLBACK operations are the key to providing the system recovery. The COMMIT operation indicates to the system that a successful logical unit of work is completed and the data base is in a consistent state. The ROLLBACK operation tells the system that something has gone wrong and a transaction is unsuccessfully terminated. In this case, the data base might be in an inconsistent state, so this logical unit of work should be undone or rolled back. COMMIT and ROLLBACK (and program initiation) represent a synchronization point for the system and at this synchronization point all updates made by the program since the previous synchronization point are committed (COMMIT) or undone (ROLLBACK).

Note carefully that COMMIT or ROLLBACK terminate the transaction not the program. In general, a single program execution will consist of a sequence of several transactions, running one after the other, with each COMMIT or ROLLBACK operation terminating one transaction and starting the next. (2:416)

Another type of failure is possible. It is the media failure (such as a disk head crash). In this case, the disk has been physically destroyed. Recovery from such failure needs to reload the back-up copy of the data base and uses the log (either manual or in the computer) to redo all transactions that have been done since the previous archive operation for the back-up copy.

Back-up copies should be done frequently and the
data base state reached logged. For example, use the organization instruction number reached or date of last update.

Concurrency

The concurrency problem may arise when the system allows more than one user to update the data base concurrently. In our particular system, concurrency problems may also arise when more than one user is trying to ask questions about the unit formation. In this case, the working relation FORMATION is used to contain the formation units. The sequence of operations is that the program deletes the previous contents of the relation FORMATION, then starts appending to it the unit of the formation under question. After finishing, the required query will be done upon the relation FORMATION. If another user is trying to ask questions about another formation unit, and just after the first user finishes collecting his formation units into the relation FORMATION, second user is trying to delete the relation formation to use it in his query. If he succeeds, the first user will receive false results.

Fortunately, deleting the relation FORMATION is a kind of update and we will return to the problems of concurrent update. There are three concurrency problems:

The Lost Update Problem.

The lost update problem will appear when, for example.
there are two instructions. The first one is to add 3 guns to Unit X, and the second one is to add 4 guns to the same unit. User A is trying to add 3 guns and user B is trying to add 4 guns concurrently. User A reads the number of guns of Unit X in his buffer as 10. Then user B reads the number of guns of Unit X in his buffer as 10. User A adds 3 to 10 and writes the number of guns as 13. User B adds 4 to 10 and writes the number of guns as 14. Finally, Unit X got 14 guns instead of 17.

The Uncommitted Dependency Problem.

The uncommitted dependency problem occurs when a transaction reads updated data from another transaction which is not committed yet and might rollback. For example, in the previous example, if user A adds 3 guns to Unit X but does not commit yet, and user B reads Unit X data as 13 guns, user A rolls back, then user B adds 4 guns to Unit X and writes the sum as 17 guns instead of 14.

The Inconsistent Analysis Problem.

Suppose Unit Y has 10 officers, 10 secretaries, and 20 technicians. The sum is 40 persons. User A is asking about the sum of personnel in Unit A, he reads 10 officers, and 10 secretaries. Then user B is trying to make an update in Unit Y. He deletes 5 secretaries and adds 5 technicians (the sum should stay at 40). Then user A reads the number of technicians as 25 and adds the sum as 45 instead of 40.
**Locking.**

A way of solving the concurrency problem is through a locking mechanism. The basic idea of locking is when a transaction needs an access on an item in the data base, it acquires a lock on that object. The effect of the lock is to prevent other transactions from accessing that object before its commitment accessing and thus it prevents other transactions from changing it or from getting false data (in case of update then rollback).

There are two types of locks, exclusive locks (x locks) and shared locks (s locks). X lock is requested when the transaction will update the data base. S lock is requested when the transaction will only retrieve the data. Many transactions of s lock may access the same data item. But only one transaction can access the data item if x lock is requested (i.e., x lock can not share any type of lock). A disadvantage of the locking mechanism is the probability of the deadlock. This problem should be handled by the system having the ability to detect the deadlock and decide what to do to recover from it. The whole concurrency problem will be handled on the system level and we should insure that the system is able to solve this problem.
Security

Security is to protect the data base against both undesired modification or destruction of data and against unauthorized reading of data (7:355).

General Considerations.

There are some aspects to the security problem that should be considered:

- Legal and social aspects. For example, if the user asking about the unit data has the right to do so.
- Physical Control. For example, are the computer, the terminal rooms, and the magnetic media locked and/or guarded?
- Policy question. For example, what is the policy of accessing, i.e., who should be allowed to access what?
- Operational problem. For example, how are the passwords that are used kept secret?
- Hardware control. For example, does the CPU provide any security feature, such as storage protection keys?
- Operating system security. For example, does the underlying operating system erase the contents of storage and data when it is finished?

(2:238).
**View Mechanism.**

The view mechanism is an efficient way for security purposes. We can create a view to a user and the user will access the view as if it is a real relation. There are three ways for making a view. First, a user may see the view as a projection of the original relation. For example, the transportation department needs only to know which unit is in which location to manage the transportation plan, so there is no reason to let its user see unit percentage of completion or instruction number. Other relations may not be seen by the user. For example, relations unit model, persons and armament may be hidden from the user of the food department.

The second type of a view allows the user to see a particular selection of the relation. For example, the armor department can see only the units that are supplied by armor personnel. There is no reason to let the armor department user see the organization of the navy units.

The third type is a combination of projection and selection of data in the particular view.

**GRANT and REVOKE Mechanism.**

The view mechanism allows the data base to be conceptually divided up into pieces in various ways so that sensitive information can be hidden from unauthorized users. However, it does not allow for the specification of the operations that authorized users may execute against those pieces. (2:441).
GRANT and REVOKE mechanism or the authorization subsystem can do that. The system administrator has full rights to the database. According to the organization policy, he can GRANT a user rights to access certain pieces of the database in a certain way. Some users will have the rights to retrieve the data only, others may have the rights to update but not to delete. Other users may have rights for full access to a certain view.

Any authorized user who has certain rights to access the database can GRANT rights (not exceeding his own rights) to another user. The second user may again GRANT rights (not exceeding his own rights) to a third user. The first user can REVOKE the right he or she granted to the second user, and this operation REVOKEs automatically the rights of the third user. The system should keep track of the authorization subsystem and the system administrator should check that the authorization subsystem is running according to the organization policy.
VIII. Data Base Integrity and System Interfaces

Data Base Integrity

In any designed data base management system, there should be facilities to protect the data base from both incorrect data (for example, the unit percentage of completeness must be between 0 and 100) and inconsistent data (for example when inserting a new unit, the command unit must be an existing unit). These two problems refer to the integrity problem. Integrity means protecting the data base against the misuse by the authorized users.

Integrity Rules.

There are two integrity rules for the relational model as mentioned by C. J. Date (2):

1. Entity Integrity

No attribute participating in the primary key of a base relation is allowed to accept null values.

2. Referential Integrity

If base relation R2 includes a foreign key FK reaching the primary key PK of some base relation R1, then every value of FK in R2 must either (a) be equal to the value of PK in some tuple of R1 or (b) be wholly null (i.e., each attribute value participating in that FK value must be null). R1 and R2 are not necessarily distinct (2:252).
DESIGN AND IMPLEMENTATION OF DATA BASE MANAGEMENT SYSTEM FOR THE ORGANIZATION. (U) AIR FORCE INST OF TECH WRIGHT-PATTERSON AFB OH SCHOOL OF ENGI. G A ELSHARAWY UNCLASSIFIED DEC 86 AFIT/GCS/ENG/86J-4
The second integrity rule is handled in the application program level.

**Integrity in OMADB.**

Since OMADB consists of 10 relations and or updates in one relation, other relations may be affected. The designed update program EDOMADB observed and handled the second integrity rule carefully.

**Inserting a New Unit.**

When inserting a new unit, the program starts checking the entered unit code format before calling the data base. If the syntax is correct, the program checks if there is any existing unit in the data base has the entered code. Simply the system cannot allow two units to have the same code. To keep the consistency between UNIT relation and UNITMODEL relation, the program checks if the new unit has an existing unit model. If not, the user has to insert the required unit model before updating UNIT relation. The program asks the user to enter the new unit model data. Three relations (UNITMODEL, ASSIGNP, and ASSIGNA) will be updated to insert the new unit model. To keep the correctness of the unit model itself, the personnel data (person department and specialization) will be checked if such departments provide such specialization or not. The relation that keeps this information is the relation PERSON.
If the department and specialization are consistent, the data will be accepted and a new tuple will be added to the relation ASSIGNP. A similar test is done when entering the unit armament table. The relation armament holds the information about which department supplies which arms or equipment, and the program checks the entered armament data against this relation. If the program insures that the unit model of the new unit exists, it asks the user to enter the unit data to start modifying the unit data which is stored in the relations UNIT, PLAN, and COMMAND. An appropriate test is done on each unit data entered by the user. The unit percentage of completeness must be between 0 and 100. The unit location must be one of the six locations a, b, c, d, e, or f. The unit plan must be identified by PLANID relating to the command unit must be an existing unit. At this point, the system can respond that the new unit is inserted and the data base is in a consistent state.

Adding an Existing Unit Data.

When amending a unit, the program checks the existence of such a unit. The amended module displays a menu to the user for selecting an attribute to be amended. A similar check as is done in case of inserting a new unit data, is done on the amending data. Because the unit-plan relationship is many to many, each tuple in PLAN relation has the information about one plan for one unit. For this
reason, amending unit plan is done through the insert/delete operation. The program prevents the user from adding a plan which the unit has, and from deleting a non-existing plan. Modification is done attribute by attribute and the user has the chance to re-amend the same attribute if he or she needs. After the modification of each attribute, the database will be in a consistent state.

**Deletion of Unit(s).**

When the user asks the program to delete a unit, the program checks the existence of the unit first, then it starts checking if this unit has another subunit(s). This check is done by calling the CTREE module that uses COMMAND relation as the source of data and FORMATION relation as the destination of the result and other two temporary relations SONS, and PARENT. After execution of CTREE module, FORMATION relation contains the deleted unit and its subunits if any. The program checks if formation relation contains more than one unit and asks the user if he or she wants to delete all subunits or not. The program is not allowed to delete a unit and leaving its subunit(s) created by a non-existing unit. If the user answer is "yes", the program deletes any occurrence of the unit(s) that exist in the relation FORMATION from the three relations UNIT, PLAN, and COMMAND. At this point, the database is in consistent state.
**System Interfaces**

Recalling Figure 1 which describes the integrated information system for the Egyptian Armed Forces, we will observe that the organization structure system has interfaces to other systems. We will discuss these interfaces as two types of activities, data needed from other systems, and data needed for other systems.

**Data Needed From Other System.**

The ten relations that our system consists of are not basic system relations. Some of these relations may be a view of a relation created and manipulated by another system. One reason for the integrated information system is to keep the data integrity over all organizations in the armed force and consequently in all information system. The ARMAMENT relation, which could be a view of another relation, which contains more information about armament in the material support system.

ARMAMENT relation (or view) may give us an answer of a question that the organization structure alone is not able to answer. What armaments exist in department X (or in the armed forces) that is not used by any unit. The answer of this query gives us the most recent types of armament that is not yet used by any unit, and also gives us the obsolete type that is out of service and the department did not get rid of yet. A different question may arise, and that is
whether the material support system allows the organization structure system to retrieve this information. If not, how will a new unit that will use a new type of weapons be inserted to the data base without the conflict of the non-existance of the new type of weapons in ARMAMENT relation? Again, the view system should be studied carefully. Similarly, PERSON relation may be a view of another relation in the Personnel System, and PLANID relation may be a view of another relation in Command and Control System. For that reason, editing of the relations PERSON, ARMAMENT, and PLAN is not mentioned in the EDOMADB program. To let the system work, and until establishing the interfaces to other systems, editing of the mentioned three relations will be done by separate programs and we will let that be done by users representing Personnel Material Support, and Command and Control Systems.

Unit percentage of completeness, location, and plan are amended by operational instruction. The unit is created with these three attributes by our system. Amending these attributes should be done through the command and control system (or its representative user for the time being) and it should have the right to amend percentage and location in UNIT relation (only amend, not delete or insert) and should have full access to PLAN relation.
Data Needed for Other Systems.

The organization structure system is able to provide the other systems useful data. For example, the command and control system needs to know information about the command relationship between units; also, other unit information is needed for the command and control system. UNIT, COMMAND, ASSIGNP, and ASSIGNA relations may be seen by command and control system. UNIT, ASSIGNP, COMMAND may be seen by Personnel Systems. UNIT, ASSIGNA, COMMAND may be seen by Material Support System. The Finance System may need information about number of units, total number of personnel for each specification and/or for each department, and may need some information about unit armaments. Interfaces between systems/subsystems should be identified to keep the overall system integrity.
IX. Conclusions and Recommendations

The integrated information system of the Egyptian Armed Force consists of two main systems, Command and Control System and the Logistic Support System. The Logistic Support System consists of four main systems, Organization Structure System, Material Support System, Personnel System, and Finance System. The integrated information system must not be designed and implemented all at the same time. A better way is to design and implement system by system and subsystem by subsystem keeping in mind the design consideration, the system (or subsystem) interfaces, and the overall data base integrity. This projects presents a design model and a methodology that may be followed in other systems and subsystems. One way of doing that is to assign the mission of the system integration to an organization (maybe information systems department). This organization designs the overall system design, determines the design considerations for each system and subsystem, and sets the required specification for each system and subsystem. Once the overall design is done, design and implementation of each system and subsystem should be assigned to an armed force organization taking into consideration the required personnel, training, and finance. To keep the integrated
information system homogeneous, the system integrator should choose the proper DBMS model that will be used in all systems and subsystems. (This project choose the relational data base model for the considerations mentioned in Chapter V). The needed software and hardware should be estimated early by information system departments for the entire integrated information system. The signal corp department may carry the mission of design and implementation of the data communication needed for the integrated system.

Four problems should be handled carefully over all the system and subsystem.

1. Recovery from failure
2. Concurrency
3. System security
4. Data integrity

Again, system/subsystem interfaces should be identified clearly and carefully.

This thesis effort contributes to building the Egyptian Armed Force integrated information system. Design and implementation of other system/subsystem in the integrated information system may follow the same methodology as used in this work.

Computer Program for Collecting Formation Units
COLLECT FORMATION'S UNITS THROUGH A ROOT

LT COL GABER A. ELISHARAWY
AFIT/EN GCS 86J

TITLE: COLLECT UNIT TREE
SOFTWARE SYSTEM: UNIX
DATE: 7 MAY 1985
VERSION: 1.0

INPUTS: none
OUTPUTS: error messages.

FUNCTION: Collect Formation's units through a root
ALGORITHM: 1 - call get_unit_code
            2 - call checkunit
            3 - call ctree function to collect the unit tree
            into the relation FORMATION

CALLED MODULES: get_unit_code(), checkunit(), ctree().
CALLING MODULES: none

AUTHOR: LT COL GABER A. ELISHARAWY
HISTORY: Version 1.0 by Lt Col Gaber A. Elsharawy

Appendix F
User Manual for the Edit Program

Introduction

This manual contains a brief introduction on how to use the edit program OMAED to edit the data base CMADB. It does not go into a lot of detail about the program design or data base features, but tries to give enough information to get a user to use the system. After reviewing this manual, the user should have enough information to deal with the editing program CMADB. The manual is divided into four sections. Each section describes an operation the program can perform (Retrieve, Del., Amend, and Insert). To get the program started, just type OMASE and hit return, the program will start by displaying: "Call Ingres", then the following menu will be displayed with a command summary:

Amending Units Data.

Command Summary.

I . . . . Insert new unit.
D . . . . Del. an existing unit.
A . . . . Amend an existing unit.
R . . . . Retrieve an existing unit.
H . . . . Help (display command summary).
E . . . . Exit to UNIX.

The program can accept the command in lower or upper
case characters. "H" command displays the command summary menu. Now you can select the required operations by entering the corresponding command. After finishing the edit, type "e" to exit to UNIX.

Retrieve Unit Data

To retrieve unit data, type "R" and hit return. The program will ask you to enter unit key (dep, level, type, num) and will check the syntax. If not correct, you will see the message "the key format should be C2, C2, C2, C3." If the unit does not exist in the data base, you will see the message "This unit does not exist." If the key is correct, the system will print on the screen the required unit data (unit name, unit location, instruction number, unit balance, percentage, number of personnel, command unit code, and unit plan(s)). The program will return after that to the command mode.

Deleting a Unit(s) From the Data Base

To delete a unit type "D", the program will ask you to enter the unit key. If the unit does not exist, the program will print "This unit does not exist." The program will ask you "Are you sure (Y/N)?" to give you a chance to quit. If you type any character rather than "Y", the program will return to the command mode. If you type "Y", the
program will delete the unit. If the unit has another subunit, the program will ask you "Do you want to delete all subunits (Y/N)." If you type "Y" the program will delete the unit and all its subunits.

Amending Unit Data

To amend unit data type "A" from the command mode, the program will display the following menu:

Modification Codes.

Modify unit percentage . . . t
Modify unit location . . . l
Modify unit plan . . . . . p
Modify command unit . . . c
Modify instruction number . . i
End of Modification . . . e

Again the program will accept both lower and upper case letters as modification codes. Select the required modification code and type it. The program will ask you to enter the new unit attribute. After entering the new value, the program will check it to ensure that it is in the permissible value domain, if it is not correct, you will receive an error message. After each amendment, the program will ask you to enter another modification code, when you finish modification type "e" or "E" to return to the command mode.
Inserting a New Unit

To insert a new unit type "i" or "I", the system will ask you to enter the new unit code. If this unit already exists, you will see the message "This unit already exists."

If the new unit has an existing unit model in the data base, the program will ask you to enter the unit data (percentage, location, instruction number, plan(s), and command unit).

Checks will be done on unit data and an error message is displayed if the check is not passed. If the unit has no unit model in the data base, the program will ask you "Do you want to insert a new unit model (Y/N)". This is a chance to quit if you mistyped the unit code. If you type "Y" the program will ask you to enter the following unit model data:

- Unit name
- Personnel data (occupation, specialty, number)
  (to end entering personnel data type "*").
- Armament data (type, unit, arm name, number)
  (to end entering armament data type "*").

Checks will be done on unit model data and an error message is displayed if the check is not passed. After entering the unit model data, the program will ask you to enter the unit data as described above, then the program will return to the normal mode.
Appendix G

Computer Program for Editing the Data Base
UPDATING OF THE EGYPTIAN ARMED FORCES

ORGANIZATION STRUCTURE DATA BASE

LT COL GABER A. EL SHARAWY

AFIT/EN GCS 85J

DATE : 7 MAY 1986
VERSION : 1.0
TITLE : EDIT G4AE
FILE NAME : G4AE.DO
SOFTWARE SYSTEM : UNIX
USE : To edit the DBMS G4AE

CONTENTS : main, menu, get_unit_code, checkunit, insert,
check_unit_model, insert_unit_model, insert_person,
check_person, insert_arm, check_arm, insert_plan,
check_planid, amend, modify_command, modify_plan,
check_plan, modify_percent, modify_location,
modify_inst, retrieve, delete, store.

FUNCTION :
1 - Display command summary
2 - Accept input command (I, D, A, R, + or -)
3 - accept unit code from the terminal
4 - Check the unit code
5 - Call a suitable module
6 - Display error message if the code is wrong or
   if the operation is inconsistent with the unit
   status (exist/not exist)
7 - After performing the operation, return to command
   mode.

*******************************************************************************/

/** / 1.0 main */
/**
DATE : 7 MAY 1986
VERSION : 1.0
FILE NUMBER : 1.0
FILE NAME : main
FUNCTION : call ingres, display command summary,
accept the user command, check it, and
 call a suitable module.
ALGORITHM : 1 - declare external variables
2 - call ingres
3 - display command summary
4 - accept the user command
5 - if the command is not correct
   display an error message and
   go to step 4
6 - if the command is D, A, R, I, +,
   or - call get unit code
   and then call check unit code.
7 - unit status = check unit code (+ / false)
3 - If the unit status is consistent with the operation, call the required module.

3 - If not print an error message.

10 - Go to step 4.

Bibliography

Lt. Col. Gaber A. Elsharawy was born on 17 December 1949 in Alexandria, Egypt. He received the degree of Bachelor of Science in Mechanical Engineering from the Military Technical College, Cairo in June 1972. He received a Diploma in Computer Science in Commercial Application from Air Shams University, Cairo, Egypt in May 1982. He received a bravery medal, first class in 1973 war. He has served in the information systems branch of the organization and management authority for four years until entering the school of Engineering, Air Force Institute of Technology, in May 1986.

**Title:** Design of Data Base Management System for the Organization Structure of the Egyptian Armed Forces

**Type of Report:** MS Thesis

**Time Covered:** FROM May 85 to Jun 86

**Date of Report:** 86 Jun 7

**Page Count:** 186

**Abstract:**

The organization structure system is a part of the integrated information system of the Egyptian Armed Forces. It manipulates the units organization data (department, unit level, type, balance, armament, personnel, plan(s), percentage of completeness, location and position in the armed force tree). An initial survey for the problem is done. The design of the system is done through the E-R model and the functional dependence is defined. We choose the relational data base model for its advantages like data independent and simple data manipulation, over the other two DBMS models (hierarchical and network models). The system is designed in ten relations and the implementation is done through ingress using C programming language with equal (embedded ingres in C). We present several examples of queries that the system can support. An algorithm for collecting the units commanded by a particular unit is presented. The implementation includes the data definition of the ten relations in ingres. The data base editing program is presented which consists of 23 modules. This program is able to perform the
19. ABSTRACT (CONT'D)

addition, modification, deletion, and retrieval of units data keeping the data base in consistent state. The problems of recovery, concurrency, security and data integrity are also discussed.
