Evaluation of Multi-Level Support Structure Requirements for New Weapon Systems

Master's Thesis

Date of Report: September 1987

Page Count: 302

This thesis presents a computer program, CAESAR, for IBM XT/AT or compatible computers to compute the logistics demands of a new system in terms of manpower and supply.

CAESAR, (Computer Aided Evaluation of Supply and Support on All Repair Levels), uses inputs such as weapon system distribution, system characteristic data and major unit data to provide conclusions about the logistics behavior of failing weapon systems.

The modeling of system behavior with CAESAR has several advantages over the empirical approach. It can be utilized at any major unit level, and it can be used to simulate repair part consumption of weapon systems prior to their introduction into the Armed Forces.
19. Abstract (continued)

CAESAR is not an optimizer. Instead, it is an evaluator to be used to assist decision making. It facilitates the examination of various logistics trade-offs. Thus, it can be a valuable tool for managers responsible for introducing new equipment and for defining the accompanying support network.

I. THE PROBLEM

With the number of new systems that are introduced to replace outdated or worn-out equipment and with increasing monetary constraints, it is of paramount interest to know the logistics requirements of the new systems well in advance of actual deployment. Of specific interest are manpower requirements on the different maintenance levels and the stock requirements for spare parts at the different supply levels.

This study attempts to provide the decision maker with an array of options from which he can pick the one that looks favorable both as a reasonable compromise between combat readiness and budget constraints and as an acceptable choice for the units in the field.

Obviously, it would be beyond such a study to guarantee optimal solutions for all kinds of different situations. This thesis will not consider initial introduction of weapon systems or surge conditions brought about by increased usage of the equipment. Thus, the problem we consider involves the "sizing" of the logistics network for routine operations.

For this "steady state" case the output will suggest necessary, required, or otherwise pertinent
data to plan the successful build-up of an efficient logistics network.

The output of CAESAR yields the following information:

1. the number of hours spent on all the jobs,
2. the manpower required to accomplish these jobs on the different levels,
3. the numbers of repair parts for all the jobs,
4. recommended supply stocks to cover the demand.

Further, the consumption behavior with suggested stock levels will be analyzed.

Failing systems are modelled as customers of a queuing network. This network extends through several maintenance levels. Sensitivity analysis is done in terms of manpower requirements. The sensitivity analysis considers, if possible, at least a 10 per cent bandwidth on both sides of an initial computed value. All possible combinations of strengths on all repair levels within these bands are computed. This gives the decision maker the opportunity to compare different scenarios and to consider different trade-offs.

Figure 1.1 demonstrates the simplified structure within the supporting organizations and the interactions among the user in the field and the supporting organizations. Assume the user, depicted by the tank, faces a failure of one of his weapon systems.
He will notify his organizational maintenance unit and after a delay, due to administrative and transpor-
tational times, the system will undergo repair by either changing the component that failed or by repairing this component. After another delay the system will be returned to the user and will be operational again. If the component was replaced, it will enter the next level repair cycle at the direct / general support unit, where the subcomponent will be replaced or repaired. The operational component is returned to the organizational maintenance unit. If further repair is necessary, the subcomponent is shipped to the depot / industry level where it is finally repaired. It will then be shipped back to the direct / general maintenance unit to wait for the next exchange cycle.

Usually, the components and subcomponents can be used again after repair. Only parts have to be provided through the supply chain. The model will not simulate total loss of components or subcomponents but it will provide a number of available components and subcomponents on the respective maintenance levels for direct exchange.
The structures of the underlying maintenance and supply organizations are described in more detail in Chapter C.2. and C.3.

Figure 1.1 Support Structure
II. THE THEORY

A. DEFINITIONS

The following definitions are provided to make clear the terminology used in this thesis. Refer to Figure 2.1 for a graphical depiction of a weapon system.[Ref. 1]

System is the entity of all replaceable or repairable components, subcomponents and parts that make up the working piece of equipment.

Component is the first split-up level of replaceable or repairable items within a system.

Subcomponent is any item below the component level which is still repairable.

Parts are non-repairable items within a system, component or subcomponent.

Refer to Figure 2.3 for a graphical depiction of the underlying maintenance organization.

Organizational Maintenance (Org Mn) is the first repair level. It is usually performed at the battalion level.

Direct Support/General Support (DS/GS) is the next level above Org Mn. This is performed at the brigade, division or corps level for the respective supported units.
Depot Maintenance is the highest level of maintenance. It is usually performed by the military depot organization or a civilian contractor.

![Diagram of a Weapon System Structure](image)

**Figure 2.1** Tree - Structure of a Weapon System

Assignments of repair jobs to one of the repair levels is done on the basis of their need for expertise, special tools, amount of hours necessary for repair or severity of damage.

It may be possible that one level will be skipped or that work at a lower level is performed in connection with work on a higher level. This aspect will be disregarded in this study.
Refer to Figure 2.4 for a graphical depiction of the structure of the underlying supply organization.

Direct Supply Organization (DSO) is the supply unit which is responsible for the support of specific customers within the major unit.

Back-up Supply Organization (BSO) is a supply unit which can support another supply unit on its supply level.

Initial Demand Generator (IDG) is the customer of a DSO who demands service from the DSO.

Intermediate Supply Organization (ISO) is any supply unit in the supply channel that both accepts inputs of spares and passes on output of spares to other ISOs or IDGs.

End Supply Organization (ESO) is the facility where all orders that cannot immediately be filled or orders of restocks for ISO are centralized. It does not move physical items; it coordinates and routes the orders.

Mean Time Between Failures (MTBF) is the expected value of the interarrival time of failures for a working system. In this thesis equipment lifetimes are assumed to be exponentially distributed.

Mean time To Repair (MTTR) is the expected value of the time required to repair a failed equipment.
B. ASSUMPTIONS

1. Independence of Systems

Systems in any specific major unit are assumed to be independent of each other.

2. No Non-lethal Failures

Each item is assumed equally vital for the operation of the system. A failure in any part will lead to a failure for the complete system.

3. Unlimited Storage Capabilities

It is assumed that supply units can store any suggested number of spare parts. For the first simulation, unlimited supplies are assumed. Later, limited numbers of spares are considered.

4. Hierarchical Logistical Structure

The underlying logistical system is assumed to be strictly hierarchical. There is no horizontal substitution for maintenance nor vertical substitution for supplies between different major units in the model.

C. THE LOGISTICS STRUCTURE

1. System Lay-out Dependencies

The physical configuration of any new system depends on many different parameters. Cornerstones for
the design are the tradeoffs due to budget and the
operability and system availability in the field.

These connections between the various aspects
are displayed in Figure 2.2. If enough resources
(budget) are available, then the quantity of components
for a new system can be optimized, and where possible,
the idea of modular system layout can be realized. The
number of servers can be tailored to satisfy maximum
demand. All these means lead to a reduction in system
repair time. This and the ability to subsidize higher
quality material, which increases the time until a
failure occurs, yields less stress upon the logistics
organization. The resulting increase in system
availability is clearly in favor of the user in the
field. In reality, however, different users formulate
priorities for acquisitions which demand resources.
These demands have to be met as well as possible. Thus
tradeoffs between optimality and feasibility have to be
made.
Figure 2.2 System Interdependencies
2. **Underlying Maintenance Organization**

As stated earlier, the maintenance structure is assumed strictly hierarchical. Each level serves specified jobs for specific customers. An exchange of capability cannot regularly be performed between different maintenance units. Figure 2.3 shows this assumed structure.

![Diagram of Maintenance Structure](image)

**Figure 2.3 Schematic Maintenance Structure**
In the example depicted in Figure 2.3 it is assumed that units (customers) C1 to C8 perform their own organizational maintenance. In case of a failure that requires direct support, the destination of the item depends on the type of customer and his supporting unit.

C1 is supported directly (direct support, DS) by the corps unit. C2, C3, C4 and C6, C7 are units which are supported by their respective brigades. C5 and C8 are supported by their divisional units.

In case of an overload of work at the DS level, the divisional units can back up the brigade units, and the corps can back up the divisions (general support, GS). However, this is only possible within certain limitations. The model does not allow general support.

3. Underlying Supply System

The structure assumed for the supply system is similar to the maintenance system. In this structure it will be distinguished between Direct Supply Organization (DSO), which is directly responsible for its customers and back-up Supply Organization (BSO), which is, within limits, capable of supplying customers of BSO units, if they are not immediately able to serve their customers. The initial demand generator (IDG) is the customer for the supply system, which is usually the maintenance unit.
Figure 2.4 shows a typical structure for a supply network.

Figure 2.4 Schematic Structure of the Supply System
The Supply Command supports all supply units on corps, division and brigade levels in a parallel structure. Since the customers on these levels are all similarly structured, i.e. have the same equipment, type and density, a horizontal back-up (BSO) on the same level is possible.

Vertical substitution would be ineffective because customers at different levels have dissimilar equipment.

The Supply Command works as an end supply organization (ESO) since its job is to provide the intermediate supply organizations (ISO) with the needed items. The customers, the IDGs, are not shown in Figure 2.4.

4. Cooperation within the Logistics Network

A user reports a failure of a system to his own Org Mn activity. At the same time, the user becomes an IDG for the supply network since a replacement component or part must be provided. If there is stock available at the Org Mn level, and if maintenance capability is also available, the customer is notified that the equipment will be worked on. If there are no spares on hand, the ISO will get spares for the IDG either from the ESO or the BSO.

After successful repair and delivery the system will be operational and functional and the first repair
cycle (see Figure 1.1) is complete. The Org Mn unit becomes the customer for the DS unit with the broken component. This DS unit as the IDG will approach its supply unit to obtain the necessary items until the second repair cycle is completed. From here the same procedure continues at the depot level with its supply channel where the final broken item will be exchanged or repaired, if required. On either level the repair has been finished when the level 9 (non-repairable) item has been reached.

Should Org Mn not have enough manpower available then repairs might be passed on to the GS level. GS level is the division for brigade units or the corps for the divisional units.

Although the time for immediate repair and return of the system to its normal duty is of particular interest, it is further important to consider the whole chain of repairs. These repairs have an impact on the availability of spares under the assumption of limited supplies in the evaluation later in the program package.

Replacements have to be ordered for the parts, since these do not get back into circulation like components or subcomponents, which after repair regain their place on the shelves of the maintenance units. This inventory policy can be on a one-by-one basis,
regularly according to fixed time intervals or upon reaching a minimum number of stocked items.

In this study, the restocking policy will be the \((s,S)\) method. It will be explained in detail later. The number of restocked spare parts depends on the length of the chosen time interval and the demand within this interval.

D. THE COMPUTATIONAL FORMULAE

The simulation consists of two parts. First, in an idealized run, planning figures will be computed assuming unlimited resources of both manpower and spare parts. Thus waiting times in the system are considered to be zero. In the second run the planning figures of the idealized run are used and the actual queuing behavior with limited servers and spare parts is analyzed. In this run the waiting times are greater than zero. The major computational formulas used in the simulation are presented in the following paragraphs.

1. Random Number Generation

The basis for all the random numbers used in CAESAR are the uniform(0,1) random numbers [Ref. 2].

a. Uniform Random Number

To transform the uniform\((0,1)\) random number to a uniform\((LL,UL)\) number the following algorithm is used:

24
U(UL,UL) = LL + (UL-LL) * U(0,1).

where
LL = mean - SQRT[ 3 * (std.dev.)^2 ]
UL = mean + SQRT[ 3 * (std.dev.)^2 ]

b. Exponential Random Number

To transform the uniform(0,1) random number to an exponential random number the following algorithm is used [Ref. 3]:

EXP = - ( 1/lambda ) * ln [ U(0,1) ]

with
EXP ....... exp. distributed random variable
lambda .. parameter for exp. distr. variable
ln ........ natural logarithm
U(0,1) .. uniform(0,1) random number.

where
Lambda = 1/mean

b. Gamma Random Number

A gamma (Erlang) random number with n degrees of freedom is generated from the following algorithm [Ref. 3]:

GAMMA = - ( 1/lambda ) * ln [ prod[ U(0,1) ] ]

with
GAMMA .... Gamma distributed random variable
lambda .. parameter for Gamma distr. variable
n .......... degrees of freedom
ln ........ natural logarithm
U(0,1) .. uniform(0,1) random number
prod[ ] .... product from 1 to n of U(0,1).

where
lambda = mean / ( std.dev.)^2
n = ( mean / std.dev.)^2
d. Normal Random Number

To obtain a normally distributed random number a Box–Mueller algorithm is used [Ref. 3]:

\[ N_1 = \sqrt{\text{SRT}(-2 \times \ln[U_1(0,1)])} \times \cos[2\pi \times U_2(0,1)] \]
\[ N_2 = \sqrt{\text{SRT}(-2 \times \ln[U_1(0,1)])} \times \sin[2\pi \times U_2(0,1)]. \]

with
\[ N_1, N_2 \] the normally distributed r.n.
\[ \text{SRT}() \] square root of the argument ()
\[ \ln \] natural logarithm
\[ \pi \] \(3.141592654\)
\[ \cos() \] trigonometric cosine function
\[ \sin() \] trigonometric sine function.

This algorithm produces two independent normally\((0,1)\) distributed random numbers. To use one of them randomly, another Monte Carlo trial is performed. A \(U(0,1)\) random number is drawn, and depending on that outcome either \(N_1\) or \(N_2\) is chosen.

The norm\((0,1)\) random numbers are converted to norm\((\text{mu}, \text{sigma})\) numbers as follows:

\[ N(\text{mu}, \text{sigma}) = \text{mu} + N(0,1) \times \text{sigma} \]

with
\[ \text{mu} \] desired mean of the norm. distr. r.n.
\[ \text{sigma} \] standard deviation of the r.n.

e. Lognormal Random Number

For the lognormal distribution the following computation is made [Ref. 4]:

26
\[ L(\mu, \sigma) = \exp[N(\mu_n, \sigma_n)] \]

with
- \( L[] \) .... desired lognormal random number
- \( N[] \) .... a normally distributed random number
- \( \mu \) .... desired mean of the lognormal r.n.
- \( \mu_n \) .... mean of the normal random number
- \( \sigma \) .... std.dev. of the lognormal r.n.
- \( \sigma_n \) .... the std.dev. of the normal r.n.

where
- \( \mu = \exp(\mu_n + 1/2 \sigma_n^2) \)
- \( \sigma = \sqrt{\exp(2 \mu + 2 \sigma_n^2) - \exp(2 \mu + \sigma_n^2)} \)
- \( \mu_n = 2 \log(\mu) - 1/2 \log(\mu^2 + \sigma^2) \)
- \( \sigma_n = \sqrt{\log(\sigma^2 + \mu^2) - 2 \log(\mu)} \)

2. System Mean Time Between Failure (MTBF System)

Suppose a system is made up of \( n \) components. Let \( \Lambda_i \) be the failure rate for component \( i \). Let \( T \) be the time to failure for the system. Let \( T_i \) be the time to failure of component \( i \).

Then, the probability of the lifetime of component \( i \) being greater than \( t \) is

\[ P(T_i > t) = e^{\Lambda_i * t} \quad \text{for all } i. \]

For the system lifetime \( T \) the following holds:

\[ P(T > t) = P(\min(T_1, T_2, \ldots, T_k) > t) \]
\[ = P(T_1 > t, T_2 > t, \ldots, T_k > t) \]
\[ = e^{\Lambda_1 * t} e^{\Lambda_2 * t} \cdots e^{\Lambda_k * t} \]
\[ = e^{(\Lambda_1 + \Lambda_2 + \ldots + \Lambda_k) * t} \]

27
Thus the system time to failure is exponential with parameter $\Lambda_1 + \Lambda_2 + \ldots + \Lambda_n$. The mean time to failure for the system is

$$\frac{1}{\Lambda_1 + \ldots + \Lambda_n} = \frac{1}{MTBF_1} + \ldots + \frac{1}{MTBF_n}$$

Let us now determine the probability, that a system failure is due to component $i$. Let us consider the case in which the system has only two components. The probability, that the first system failure is due to component $1$ is given by $P(T_1 < T_2)$.

Conditioning we get [Ref. 5]:

$$P(T_1 < T_2) = \int_0^\infty P(T_1 < T_2 | T_2 = t) \cdot \Lambda_2 \cdot e^{-\Lambda_2 t} \, dt - \int_0^\infty P(T_1 < t) \cdot \Lambda_2 \cdot e^{-\Lambda_2 t} \, dt - \int_0^\infty (1 - e^{-\Lambda_1 t}) \cdot \Lambda_2 \cdot e^{-\Lambda_2 t} \, dt - \int_0^\infty \Lambda_2 \cdot e^{-\Lambda_2 t} \, dt - \Lambda_2 \cdot \int_0^\infty (\Lambda_1 + \Lambda_2) t \, dt$$

$$= 1 - \frac{\Lambda_2}{\Lambda_1 + \Lambda_2} - \frac{\Lambda_1}{\Lambda_1 + \Lambda_2}$$
Because of the loss of memory property of the exponential the probability of any system failure being due to component 1 is the same,

\[ \frac{\text{Lambda}_1}{\text{Lambda}_1 + \text{Lambda}_2} \]

This can be extended to the general case of n components in a straightforward manner. The probability that the failure is due to component i is:

\[ P(X_i < X_k) = \frac{\text{Lambda}_i}{\text{Sum}(\text{Lambda}_k)} \]

\[ = \frac{1/\text{MTBF}_1}{\text{Sum}(1/\text{MTBF}_k)} \]

for \( i = 1, 2, \ldots, n \)

\( k = 1, 2, \ldots, i-1, i+1, \ldots n. \)

Example:

Suppose, a system consists of three parts \( X_1, X_2 \) and \( X_3 \). The respective mean times to failure (MTTF) are:

\[ \text{MTTF}_1 = 1000 \text{ hrs} \]
\[ \text{MTTF}_2 = 500 \text{ hrs} \]
\[ \text{MTTF}_3 = 500 \text{ hrs}. \]

Then the expected MTTF for the system is

\[ \text{MTTF}_{\text{System}} = \frac{1}{\frac{1}{1000} + \frac{1}{500} + \frac{1}{500}} \]

\[ = \frac{1}{5/1000} \]

\[ = \frac{1}{0.005} \]

\[ = 200 \text{ hrs}. \]
The probability the failure is caused by item 2 is

\[ P(X_2 < X_1, X_3) = \frac{\Lambda_2}{\Lambda_1 + \Lambda_2 + \Lambda_3} \]

\[ = \frac{1/500}{5/1000} \]

\[ = 0.40 \]

If a component \( j \) fails it is due to failure of one of its subcomponents. In the same way computed as above, the MTBF for the component depends on the MTBFs of its subcomponents.

\[ \text{MTBF}_{\text{comp.}} = \frac{1}{\sum \left( \frac{1}{\text{MTBF}_{\text{subc.}}} \right)} \]

and the conditional probability of a component failure being the result of subcomponent \( j \) is

\[ P(\text{comp.} i \text{ fails} | \text{subcomp.} j \text{ fails}) = \frac{1/\text{MTBF}_j}{\sum (1/\text{MTBF}_i)} \]

This continues until the part level has been reached.

3. **Total System Downtime**

The time it takes to repair the system and get it back into service consists of several individual steps. First, the failure has to be reported to the next level maintenance facility. This facility will fill out a work order and inspect the system for damage. This time period will be called "administrative time delay" (TA).
Furthermore the system has to be shipped to the facility and back. The time for one-way transportation will be called "transportational time delay" (TT). Both delays are regarded as random variables. Then the system enters the repair queue and waits for an available server. This time will be called waiting time (WT). When a server is available the system enters repair. The repair time is RT.

The total system downtime will be:

\[ \text{DOWNTIME}_{\text{System}} = \text{TA}_{\text{Orig Mn}} + (2 \times \text{TT}_{\text{Orig Mn}}) + \text{RT}_{\text{Comp}} + \text{WT} \]

Similarly, the downtime for a component will be:

\[ \text{DOWNTIME}_{\text{Comp.}} = \text{TA}_{\text{DS/GS}} + (2 \times \text{TT}_{\text{DS/GS}}) + \text{RT}_{\text{Subcomp.}} + \text{WT} \]

and the downtime for a subcomponent:

\[ \text{DOWNTIME}_{\text{Subc.}} = \text{TA} + 2 \times \text{TT} + \text{RT} + \text{WT} \]

(indices depend on the next level maintenance facility).

The following variables have to be known:

- TA
- TT
- RT

for each maintenance level.

For the idealized run, the WT's are assumed to be zero.

4. The Queuing System

In reality a system cannot expect to be served as soon as it fails and is inspected. A server at the maintenance facility has to be available and all needed
spare parts must be available. Otherwise, the customer has to wait for the next available server or for the arrival of the necessary parts.

Service times are assumed to be independent of each other, and are distributed according to a user specified distribution. The service policy is FCFS\textsuperscript{1}. The number of servers at a repair facility is \(k\). The customer will always be served by the next available server.

If a spare part is not immediately available, the customer has to wait even to get into the server queue. These waiting times have to be accounted for. Therefore the total downtime of the system is:

\[
DOWNTIME_{Sys} = WT_{parts} + WT_{labor} + TA_{Org Mn} + (2 \times TT_{Org Mn}) + RT_{Sys}
\]

with

\[
WT_{parts} \quad \text{.... waiting time for spare parts}
\]

\[
WT_{labor} \quad \text{.... waiting time for service}
\]

5. Failure Generation

The system lifetime is computed from all the component lifetimes (MTBF). The lifetimes of the components are assumed to be exponentially distributed.

For purposes of saving memory and to be able to capture the feature that other components of a failed system do not fail while the system is shutdown, we generate system failures in accordance with the system

\textsuperscript{1}FCFS = First Come First Served

32
failure distribution. Given the system failed, we then determine the component which failed by a uniform draw. In the same way, subcomponent failures and part failures are determined by the Monte Carlo method of drawing uniformly distributed random numbers and comparing these to a table of cumulative probabilities, which has previously been generated.

Example:
Let the system consist of three items with failure rates

\[ \Lambda_1 = \frac{1}{1000} \text{ hrs} \]
\[ \Lambda_2 = \frac{1}{500} \text{ hrs} \]
\[ \Lambda_3 = \frac{1}{500} \text{ hrs} . \]

Then the probability of a system failure due to item 1 is 0.2, due to item 2 is 0.4 and due to item 3 is 0.4.

The cumulative table would look like this

\[
\begin{array}{ccc}
0.00000 & \ldots & 0.20000 & \text{item 1} \\
0.20001 & \ldots & 0.60000 & \text{item 2} \\
0.60001 & \ldots & 1.00000 & \text{item 3}.
\end{array}
\]

Now a uniform(0,1) random number is drawn. Suppose this number was 0.6775. Thus the failing item would be item 3, because 0.6775 lies between 0.60001 and 1.0000, the range for item 3.

Using the same procedure would lead from the failing component to the failing subcomponent and finally the part, that caused the system to fail.
6. **Restocking Policy**

Since the program QBEHAVE analyses the behavior of the spare part stock levels, a restocking policy has to be defined.

We considered three common restocking policies:

- **Restock on a one-for-one basis.**

Whenever an item is consumed, a substitute is immediately ordered and after a processing and shipping delay it fills the empty spot in the warehouse. Problems may be caused by shortcomings due to limited stocks and delays in the shipment.

- **Restock after fixed time periods.**

After given time intervals a fixed number of items is shipped to replace the consumed items. Surpluses are possible with this method.

- **Restock at the critical inventory level.**

This method is widely used. It combines the advantages of being able to satisfy most of the demand with the stock on hand with the smaller number of restocking transactions. Whenever the stock level reaches the refill level, the difference between this refill level and the stock maximum is ordered and shipped after delays. The problem is to keep the minimum level high enough to avoid stockout and low enough not to generate too large a holding cost.

In this simulation the third method, restocking at the critical lower levels, is used. This method is also known as the (s,S) - method, where s denotes the lower and S the upper limit.

S is taken to be the average demand during the four week planning period computed by program ESTIMATE. The value s is computed so as to satisfy a specified stockout risk.
The stockout risk factor \( r \) is the probability of running out of stock while the replacement is ordered and shipped to the consuming facility. This delay for generating the order and for receiving it is called leadtime.

With exponential times to failure the distribution of the number of failures during a leadtime \( L \) is POISSON with parameter \((\Lambda \times L)\). We therefore compute the stock level \( s \) by finding the smallest \( s \) such that

\[
P[X_1 > s] \leq r,
\]
where \( X_1 \) is POISSON\((\Lambda \times L)\).

To find \( s \) from this, compute

\[
P[X_1 \leq s] = 1 - r
\]

For \( s=0 \): probability \( p(0) = \exp(-\Lambda \times L) \)

\[
s=1: \quad p(1) = \frac{(\Lambda \times L)}{1} \times p(0)
\]

\[
s=2: \quad p(2) = \frac{(\Lambda \times L)}{2} \times p(1)
\]

Compute \( p(k) \) recursively until the sum of the cumulative probabilities

\[
p(0)+p(1)+p(2)+\ldots+p(k) \geq 1-r.
\]

The value for \( s \) is then \( k \).
E.g. $\Lambda_1 = 1/30$, $L = 5$, $r = 0.10$

$k = 0$: $p(0) = \exp(-\Lambda_1 \times L) = \exp(-5/30) = 0.8465$

$k = 1$: $p(1) = \frac{\Lambda_1 \times L}{1} \times p(0)$

$= \frac{0.1667}{1} \times 0.8465 = 0.1411$

$[p(0) + p(1) = 0.9875] > [1 - r = 1 - 0.1 = 0.9]$

That implies $s = 1$. 

III. THE REALIZATION

A. DETERMINATION OF THE OUTPUT DATA

Before the simulation could be realized, the decision variables for the desired output data had to be determined. It seemed to be reasonable that the needed data would consist at least of information about:

- the number of maintenance personnel on each level of maintenance
- the number of spare parts to be provided for each supply level
- the use of the provided capabilities in terms of manpower and spare parts
- the total expected cost for the system.

These data should be based on a planning period. This period should not be too short, because that would unnecessarily extend the duration of program runs, and not too long, because the resulting data would be unreal. A period of four weeks seemed to be adequate for planning purposes.

B. STANDARDIZATION OF THE INPUT DATA

Due to the large volume, the input data are stored in files. To improve access times, the data are written
into random access files with linked lists used to navigate through the files.

This program is written for military use; knowledge about the military organization of major units is assumed. Appendix C displays all used tactical signs used in this thesis.

1. **Major Unit Structural Data**

To be able to extract the distribution of the system in question out of the desired major unit (brigade, division and/or corps), the structure of these major units has to be known and standardized. The program TACMIX gives the user the interface to enter the required data. Once the program is loaded, the user is prompted to choose among four options:

- Create New Organization (1)
- View Existing Organization (2)
- Modify Existing Organization (3)
- Terminate Program (9)

If the user chooses option (1) he will see a screen with tactical signs of the following major unit types:

- Corps
- Armored Division
- Mechanized Infantry Division
- Infantry Division
- Airborne Division
- Air Assault Division
- Mountaineer Division
- Armored Brigade
- Mechanized Infantry Brigade

---

2 see Appendix A.1.
After the decision for one major unit type, all unit types, regiments, battalions, companies, which may be possible under this major unit will be displayed. The user chooses the units, their number and creates the structure of the major unit. The newly created file will overwrite any existing file for this major unit.

Selection of option (2) will display the contents of the chosen unit type file in graphical form: the tactical signs for the units in the major unit and the number of each of these units.

Selection of option (3) will also display the contents of the major unit file. In addition, it allows the user to implement modifications into the file. The new file overwrites the previous one.

For each of the above major units there exists a file in the program package in accordance with reference 1.

2. Distribution of Systems

Next, the user calls the program INMILDAT for entry of the number of the systems into the military structure. The program displays all types of units from regiment to company and prompts for the number of...
systems in the respective unit. Another prompt will have the user check the correctness of the entry. After all units have been displayed the program will ask for reserve in either percentage or absolute numbers. Program ESTIMATE will use this number to find the total number of systems within a corps. ESTIMAT will give the amount of systems in the major units below the corps level and also the reserve if one exists.

At the end of the program INMILDAT it will prompt the user to enter a data file name for the data just created and write the data sequentially into this file. If no name is entered the default file name "DISTRIBN" will be used.

3. System Structural Data

Before the user can enter the system data, they have to be available in the format necessary for these inputs.

The following information will be entered:

**Item Type** - to be able to answer this prompt, the system must be broken down such that the structure is similar to the one shown in Figure 1. A part, a non-repairable item, will always require a 9, even if it is directly under the system level 1, a component will always be a 2, and the subcomponents have to be classified from 3 to 8 depending on their level within the system.

**National Stock Number** - this is the NATO standardized stock number in the format:

AAAA-BB-CCC-DDDD.

\[3\text{see Appendix A.3.}\]
All the groups of letters stand for numbers. In this program it will be assumed that the country code (BB) is the same throughout the system. If the country code is omitted, the stock number can be written as: AAAADDDD.CCC

and can be used as a unique item file name.

Item Description - this is the name of the item

How many of these Items - this is not the overall total but rather the number within the next level item. If subcomponent A appears x times in the system but y times in component B, then enter y here.

Unit Price in US Dollars - self-explanatory

MTBF\(^4\) (assumed) in Days - this information should be provided by the manufacturer of the item. If there are no data available, an estimate of this number is necessary. Fractions of hours can be entered.

Replacement Level - this is the maintenance level where the failed item is replaced.

Repair Level - this is the maintenance level where the replaced item will be repaired.

MTTR\(^5\) in hours - enter here the repair time provided by the manufacturer. If no data are available, enter an estimate based on similar items.

After entering all data, a summary of these data will be displayed. The user has to acknowledge the correctness of the input. If they are correct the user will be asked if there are more items to be entered.

When the last item has been entered, they will be written onto the disk into a random access file with its transformed stock number name in the case of the

\(^4\)MTBF = Mean Time Between Failures

\(^5\)MTTR = Mean Time To Repair
system. In all other cases the name will be the transformed stock number of the next higher level item.

C. PERFORM IDEALIZED EVALUATION RUN

1. Macro - Flowchart Program ESTIMATE

The basic structure and sequence of computations of the program ESTIMATE starts with an initialization part including reading default data and string variables from the memory and prompting the user for additional information necessary for the simulation (see Figure 2.5). It computes the system lifetime from the component data and requires the choice of major unit, for which the simulation will be run. Finally, a failure time is drawn for each of the systems in the major unit using the system lifetime. These failure times are sorted.

The sequence of steps depicted in Figure 2.6 is repeated for as many times as failures have to be generated. For the next failing system the failing component, subcomponent(s) and part are determined by the randomization procedure described in Chapter II. A repair time is drawn from the selected distribution and the total downtime for the system (ignoring any queuing waiting times) is computed. For this system the time to the next failure $T$ is then determined and merged with the failure times of the other systems.
Once all the failures have been simulated and stored in the data files, the output is generated for each maintenance level. Some additional statistical data about the simulation are provided on the last output page (see Figure 2.7).

Figure 2.5 Initialization Phase of Program ESTIMATE
Figure 2.6 Simulation Core of Program ESTIMATE
Figure 2.7 Output of Program ESTIMATE
2. Detailed Look at Program ESTIMATE

ESTIMATE takes the data in the item files and the military structure files and computes planning figures for the desired output information. Since the amount of data is so huge, the data are kept in auxiliary random access files during the program run. This allows rapid access to the data without cluttering the computer's memory.

In the introductory phase of the program, default values and strings are read into variables. Old auxiliary files are deleted and the random number generator is seeded with the DOS day/time group to achieve real randomness. The user then enters the number of failures to be generated.

The user also has to enter the distributions for administrative and transportation delay times. The first input screen\(^6\) requires the entry of the maintenance level after which the type of distribution and its parameters must be entered.

Choices for the distributions and parameters are:

- **Uniform**
  - Parameters: lower, upper limit
- **Normal**
  - Parameters: mean, standard deviation
- **Exponential**
  - Parameter: mean
- **Gamma**
  - Parameters: mean, degrees of freedom
- **Lognormal**
  - Parameters: mean, standard deviation
- **Fixed**
  - Parameter: mean.

---

\(^6\)see Appendix C.4.
If the user is uncertain about the parameter choice, default values are provided for each distribution. Both, the distributions and the parameters for each maintenance level are printed\textsuperscript{7}.

After input of the system stock number, the program computes the overall system failure rate $\lambda_{\text{system}}$ from all the individual failure rates of the components, subcomponents and parts.

The next step is to find the distribution of the systems in the corps. The program takes the entries in the system distribution file created with the program INMILDAT and compares them with the military structure data created by the program TACMIX. The output will be a list of the major units in the corps with the respective number of systems\textsuperscript{8}. This list will be displayed on the screen and printed together with the user’s choice of major unit within the corps.

The program will compute one individual failure time for each of the systems in the major unit. The program will generate an exponentially distributed random number with parameter $\lambda_{\text{system}}$ for each system and then order these failure times.

After having obtained all failure times the program will determine which component caused each

\textsuperscript{7}see Appendix B.1.a.

\textsuperscript{8}see Appendix B.1.b.
failure. It does this as described in chapter II. The same procedure is used to determine the failed subcomponent and part. As soon as the failed part is determined, all information (times, costs, etc.) about the chain of failed items within the system up to this part have been stored in auxiliary files.

Starting from the time of failure (FTIME), the program computes an idealized repair cycle for this system. It assumes that there are unlimited resources in spare parts and manpower available.

The time at which the system is operational again and back at its location, is computed as follows:

$$UPTIME = FTIME + 2 \times TT + TA + MTTR$$

with FTIME ... time system fails
TT ....... transportation delay time
TA ....... administrative delay time
MTTR .... mean time to repair.

The program will always serve the next failing system until the desired number of failures have occurred.

3. Output Program ESTIMATE

The output of the idealized run performed in the program ESTIMATE consists of information about the
manpower requirements for each maintenance level and the spare part stocking levels\(^9\).

The output consists of at least six pages. The first two pages provide data about manpower requirements and the consumed spare parts. The last page gives additional information about the simulation itself and the costs involved for the systems.

Page 1 of the output gives the number of failures, a listing of the distributions and parameters for the transportation and administrative delay times and the repair time distribution. These data were entered by the user in the initialization phase of ESTIMATE.

Page 2 of the output gives the distribution of the systems within the major units of the corps. It also provides information about the number of systems on reserve and the total number of systems in the corps.

Pages 3 to 5 give the summaries for manpower and spare part consumption for the three maintenance levels. The header shows the number of simulation replications. Next is a list of consumed items on each respective level. Provided are the national stock numbers, the item descriptions and the total number of units consumed.

\(^9\)see Appendix A.4
The manpower data show the total number of manhours spent on the given number of simulations. This total time is converted to an average time within a four week planning period. Based on this number the average number of repairmen for this level is shown.

Page 6 gives additional information about the simulation. It lists the total time for the simulation in weeks and the number of four week periods.

It also provides system data. The average system downtime and the average system availability during the simulation are provided.

For the costs of the new systems the output shows the average maintenance cost per system (only parts are consumed), the initial acquisition costs for introducing the new system plus one four week spare part package into the given major unit and finally the cost for an additional average four week supply of spare parts.

D. RERUN THE SIMULATION WITH QUEUING

1. Macro - Flowchart Program QBEHAVE

The data processing in the program QBEHAVE starts with a reading of parameters generated in program ESTIMATE. Then, for each system, the first failure time is read. Taking transportation and administrative delays into account, the times of the
actual arrival at the maintenance facility are computed and sorted. Then the program simulates the repair at the Org Mn level by checking the availability of servers.

To keep track of the times the servers are busy, the program uses two pointers for each server. One for the earliest time the server starts service (intime) and the second for the earliest time at which the server will be available (outtime). As soon as a customer (weapon system) enters the queuing system (entertime), the next available outtime is found. If the outtime is less or equal the entertime, the customer is immediately served. Otherwise the difference between the minimum of the outtimes and the entertime is the waiting time for this customer. The outtime pointer for the selected server is set to the value (intime + repair time). Thus an entering customer always gets to see the first available server and the time at which service will be complete is determined when each customer arrives. Levels DS/GS and Depot are handled in the same way. The stock levels for each spare part at all levels are computed and printed.

This simulation is run with the numbers of servers equal to the numbers suggested by the program ESTIMATE or for each of these numbers within +/- 10%.
of that figure (unless not feasible, i.e. number $\leq 0$
or percentage busy $< 10\%$).

Figure 2.8 shows the initialization and the first repair level (Org Mn) within the sensitivity
analysis loop.

![Diagram]

**Figure 2.8 Repair Level OrgMn in Program QBEHAVE**
Figure 2.9 shows the other two repair levels (DS/GS and Depot) within the sensitivity analysis loop.

Figure 2.9 Repair Levels DS/GS and Depot in QBEHAVE
Figure 2.10 shows the computation of spare part consumption within the sensitivity analysis loop.

Figure 2.10 Spare Part Consumption in QBEHAVE
2. Detailed Look at Program QBEHAVE

QBEHAVE gives a more realistic view of the behavior of the systems in terms of downtimes than does the program ESTIMATE, which provides the data for QBEHAVE. QBEHAVE takes the ordered failure times of the systems and adds to these numbers one half of the administrative delay time, assuming that this delay occurs equally at the beginning and at the end of processing a workorder. One transportational delay time is also added. The ordered numbers are used to determine the entry time for the system into service. The customer with the earliest failure does not necessarily have to be the first one to be served. It might take him longer to get to the server or the administrative delay might be longer.

The service policy is FCFS. The algorithm checks for the next available server and if a server is free, the customer entry time plus the MTTR result in the customer departure time. To this time the remaining half of the administrative delay and another transportational delay time is added to obtain the time the customer is operational again. The time the customer leaves the server is also used as the failure time of the customer for the next level of maintenance, where the replaced item itself will now be repaired.
These computations continue until the part level is reached and no further repairs will be performed.

The calculations on the next level can only be performed after the previous level is completely computed, since the times the customer leaves the previous level have to be converted to arrival times at the next level. They then have to be sorted to obtain the proper sequence of service.

3. Output Program QBEHAVE

The output of QBEHAVE offers information about the manpower requirements for each of the maintenance levels and the spare part consumption\(^{10}\). Because this phase of the simulation is not an idealized run such as was the case with the program ESTIMATE, queuing waiting time data are also available.

The number of output pages is always a multiple of two. A set of output for each combination of servers consists of two consecutive pages - one for the manpower and the other for the spare part data. The total number of output pages depends on the program mode. If the sensitivity analysis is to be performed, then the number of pages depends on the number of different cases considered in the sensitivity analysis. For this mode the first set shows the data for the

\(^{10}\)see Appendix A.5
combination of smallest server numbers on all repair levels. The next set usually shows the results for an increased number of servers on the Org Mn level unless the upper limit is reached or the percentage of time server 1 is busy is less than 10 per cent.

When all possible numbers of servers on the Org Mn have been tried, the number of servers on the DS/GS level is increased, the number of servers on the Org Mn level is reset to its lowest value and the computations start over again.

After all possible combinations of servers on Org Mn level and DS/GS level have been accounted for, then the number of servers on the Depot level is increased. The program terminates when all combinations of server numbers on all three levels have been tried. For each combination the spare part consumption is collected through all three levels and printed. The results are shown on the second page of the output set. Each combination of server numbers produces one set of output.

The first page of each output set shows the statistics for the maintenance queues on the various levels. On the Org Mn level the number of customers (systems in the major unit) and the number of simulations are provided. For the other levels these numbers do not change.
The output then shows the number of servers available for each maintenance level. The total number of delays, the total waiting time and the maximum number of customers waiting are provided. Also provided are the average waiting times per customer, (given the customer waited), and the expected average waiting for any customer entering the queuing system. Also shown is the percentage of time each server was busy. Finally, statistics about the simulation, like total elapsed time and the number of four week periods are given.

The second page offers a summary of stock behavior for all consumed items, repairable or not. Initial and final stock levels within the simulation period are shown. The last column shows the minimum stock number, where negative values represent stockouts.
IV. LIMITATIONS

To keep the size of the different programs and the amount of generated and accessed data manageable, a few limitations were built into the programs.

The number of iterations (trials) is restricted to 1000. Numbers close to 1000 cause excessive execution time for the program. The number of systems handled is restricted to 500. The total number of different components, subcomponents, and parts is limited to 1000. The number of each individual part is not restricted. If a larger number of items is required, then the system has to be divided, and the simulation has to be run for the different parts of the system. These partial results can then be added together to obtain the numbers for the system as a whole. The number of items under any other higher level item is limited to 99. The item price must not be greater than $99999.99 (of course, one can express costs in tens, hundreds, and thousands of dollars to avoid this problem.

The maximum number of repairmen on each of the three maintenance levels is restricted to 50. It would be unreasonable to assign more people to one system.

The systems are strictly structured as serial systems.
V. **SUMMARY AND CONCLUSIONS**

The output of the program ESTIMATE yields the average numbers of repairmen per maintenance level for a four week period and the total number of spare parts for the whole simulation. Although these numbers are computed assuming no queuing they are useful for planning figures. The values are input to QBEHAVE which simulates more realistic behavior.

For a quick overview of the expected requirements and to obtain ballpark figures a run of ESTIMATE will likely yield reasonable numbers. For a more detailed view the user has to run QBEHAVE and select a suitable solution out of the array offered. When interpreting the output of QBEHAVE, the user should not only take the waiting times for the customers into consideration, but also observe the proportion of time the various servers are busy. Changes on a lower level directly influence the behavior on the higher levels. These must be taken into account when raising the number of repairmen.

CAESAR is capable of generating valuable predictions for both the maintenance and the supply organization by bringing a multitude of aspects into the consideration of the responsible manager.
CAESAR presents a broad spectrum of options for the deployment of manpower and supplies within the hierarchical logistics structure. CAESAR will not make the decisions for the manager. But CAESAR will make the decision process easier and the alternatives more transparent.
APPENDIX A

SAMPLE RUN

In all sample runs of CAESAR's programs the following conventions are used:

- a message from the computer will always be denoted in lower and upper case letters with an (M) at the beginning of the message,
- an input for the computer will always be denoted in upper case letters with an (I) at the beginning of the input,
- <enter> means to press the ENTER key after typing the input
- any comments will be denoted (C).

1. Program TACMIX

TACMIX is the graphic interface for CAESAR to provide the input of major unit structures. The program will present all units and major units with their respective tactical signs. If the number of units of any type is greater than 1, then an index outside the lower right corner of the symbol will indicate this number.

If you intend to create or modify a major unit, and you want to keep the old data, make a copy of the data file for this major unit. To do this you enter from DOS

C> COPY OLDNAME NEWNAME <enter>

using the old and the new name for the data file.

E.g. to copy BRIG16 into a back up file called BR16 you enter
C> COPY BRIG16 BR16 <enter>.

There will be a new file named BR16 containing the same data as BRIG16. Now you can modify BRIG16 in any way you like.

To retrieve the data after you are done, simply copy the contents of BR16 back into BRIG16, typing

C> COPY BR16 BRIG16 <enter>.

To start TACMIX, type at the DOS prompt:

C> TACMIX <enter>

(M)

<table>
<thead>
<tr>
<th>Program TACMIX</th>

</tr>
</tbody>
</table>

Enter Number of Choice :

(C) Let us create a new organization for major unit 11.
(1) 1 <enter>
(M)

Enter major unit code number:

(I) 11 <enter>

(M)

Enter unit code number (ENTER for next frame):

(C) We will only browse through the tactical signs.

(I) <enter>
Let us use option 2 (view existing organization) to take a close look at major unit 14.
(I) 2 <enter>

(M)

1 2 3 4 5
6 11 12 13 14
15 16 17 19

Enter major unit code number:

(I) 14 <enter>

(M)

14
3 117 131 132 133

134

Press any key

(I) <enter>
(C) This brings you back to the menu screen.

(M)

Program TACMIX

Options:

- Create New Organization ........ (1)
- View Existing Organization .... (2)
- Modify Existing Organization .. (3)
- Terminate Program ................. (9)

Enter Number of Choice:

(C) Let us use option 3 (modify existing organization) and modify major unit 12.

(I) 3 <enter>

(M)
(I) 12 <enter>

(M)

(I) y

(C) change the number of units type 51 from 2 to 3

(M) Which Modification? (0-erase, 1-change number of units, 2-add a unit)

(I) 1

(M) Which Unit Number?

(I) 51 <enter>

(M) Enter new number of units

(I) 3 <enter>
(I) n

(C) Now we are back in the main menu

(C) Let us change the number back to 2

(M)

- Create New Organization ........(1)
- View Existing Organization ....(2)
- Modify Existing Organization ..(3)
- Terminate Program ...............(9)

Enter Number of Choice:

(I) 3 〈enter〉
enter major unit code number:

(I) 12 <enter>

(M)

Any Modifications?

(I) y
(M) Which Modification ....
(I) 1 <enter>
(M) Which Unit Number ?
(I) 51 <enter>
(M) Enter new number of units
(I) 2 <enter>
(M)

(C) We are now in the main menu. Let us abort the program.
(I) 9 <enter>

This input brings us back to DOS.
2. **Program INMILDAT**

INMILDAT is the graphical interface for CAESAR to provide the input of the distribution of the new systems within the corps. The program will represent all units and major units with their respective standardized tactical signs. Below each tactical sign is displayed the name of the unit.

To start INMILDAT type from the DOS prompt:

(I) `C>INMILDAT <enter>`

(M)

![Diagram of Anti Aircraft Defence Regiment]

(I) 30 <enter>

(C) The program will successively display all unit types and ask for the number of systems in this unit until it reaches the last stored unit image:
(M)

To save data, name file.  
Default file name is DISTRBM

To accept default press ENTER or enter file name

(C) no systems in this unit type
(I) <enter>

(M)

(C) enter a name of your choice
(I) TESTFILE <enter>
(C) That is the end of INMILDAT

74
3. **Program INSYSDAT**

INSYSDAT is the interface for CAESAR to enter the relevant data about the new systems.

To start the program type from the DOS prompt:

(C) Let us enter a component called TEST ITEM for the system with the stock number 1234-12-999-0000.

(I) C>INSYSDAT <enter>

(M) Item Type (1=System, 2=Component, 3..8=Subcomponent, 9=Part)

(I) 2 <enter>

(M) National Stock Number:

(I) 1234-12-140-0000 <enter>

(M) Belongs to what item (next level stock number):

(I) 1234-12-999-0000 <enter>

(M) National Stock Number: 1234-12-140-0000

Item Description:

(I) Test Item <enter>

(M) How many of these Items:

(I) 5 <enter>

(M) Unit Price in US Dollars :$

(I) 253.98 <enter>

(M) MTBF (assumed) in Days:

(I) 120 <enter>

(M) Replacement Level (2=Org MN, 3=DS/GS, 4=Depot):

(C) assume replacement on ORG MN level

(I) 2<enter>
(M) Repair Level (0-no, 2-Org MN, 3-DS/GS, 4-Depot):
(C) assume repair on DS/GS level
(I) 3 <enter>
(M) MTTR (Repair/Replace) in Hours:
(C) fractions are possible; (e.g. for 200 minutes enter 3.3)
(I) 3.3 <enter>

(M)

**********  Entries correct? (y/n)  **********
(I) y <enter>
(M) another entry?
(C) For this sample run another entry is not necessary.
(I) n <enter>

This input brings us back to DOS.

4. Program ESTIMATE

ESTIMATE is the first of two simulation programs in CAESAR to compute the requirements of the system's
logistics support organization. To start ESTIMATE type from the DOS prompt:

(I) C>ESTIMATE <enter>.

(M) Enter total number of failures to simulate (<=1000):

(C) let us chose 50 for this sample run

(I) 50 <enter>

(M) adjust paper in printer

(M) press a key to continue

(C) make sure you start with a new page on your printer

(C) and the printer is switched on and online.

(I) <enter>

(M)

Enter desired value for the standard deviation of the delay distributions in per cent of the mean

the default value is 10 per cent

to accept press ENTER; else type percentage

(C) to use the default value of 10 % press ENTER key

(I) <enter>
Enter required information about the transportation times (one way):

- on the user / org maint. level (1)
- on the DS / GS level (2)
- on the Depot / Industry level (3)
- no more entries (9)

(C) enter for level Org Mn
(I) 1 <enter>

transportation times (one way)

Enter desired distribution for the time delays:

uniform (1)
normal (2)
exponential (3)
Gamma (4)
lognormal (5)
fixed (6)

default distribution is NORMAL

to accept default press ENTER else type number

(C) accept normal distribution as default
(I) <enter>
transportation times (one way)

On the user / org maint. level, enter for the normal distribution

the average (mean) value in hours
the default value is: 3

to accept default press ENTER else type value

(C) accept default
(I) <enter>
(C) back to the transportation delay level menu

Enter required information about the transportation times (one way):

- on the user / org maint. level (1)
- on the DS / GS level (2)
- on the Depot / Industry level (3)

- no more entries (9)

(C) for DS/GS level
(I) 2 <ENTER>
(C) now the same prompts as for the Org Mn level
(M) ... distribution ...
(I) <enter>
(M) ... default value ...
(I) <enter>
(C) back to the transportation delay menu
(C) for Depot level enter
(I) 3 <enter>
(C) now the same prompts as for the Org Mn level
(M) ... distribution ...
(I) <enter>
(M) ... default value ...
(I) <enter>
(C) back to the transportation delay menu
(C) no more entries here
(I) 9 <enter>
(M)

Enter required information about the admin time delays:
- on the user / org maint. level (1)
- on the DS / GS level (2)
- on the Depot / Industry level (3)
- no more entries (9)
(C) for the Org Mn level enter
(I) 1 <enter>
(M)

**admin time delays**

Enter desired distribution for the time delays:

- uniform (1)
- normal (2)
- exponential (3)
- Gamma (4)
- lognormal (5)
- fixed (6)

default distribution is NORMAL
to accept default press ENTER else type number

(C) let us change this distribution to exponential
(I) 3 <enter>
(M)

**admin time delays**

On the user/org maint. level, enter for the exponential distribution

the average (mean) value in hours
the default value is: 4

to accept default press ENTER else type value

81
(C) accept default value and press
(I) <enter>
(C) now do the same for the other two levels
(M) Enter required ...
(I) 2 <enter>
(M) ... distribution ...
(I) 3 <enter>
(M) ... default value ...
(I) <enter>
(M) Enter required ...
(I) 3 <enter>
(M) ... distribution ...
(I) 3 <enter>
(M) ... default value ...
(I) <enter>
(M) Enter required ...
(C) you are finished with this part
(I) 9 <enter>
(C) you now choose the repair time distribution
Enter desired distribution for the repair time:

- uniform (1)
- normal (2)
- exponential (3)
- Gamma (4)
- lognormal (5)
- fixed (6)

The default distribution is LOGNORMAL.
To accept press ENTER, else type number.

(C) use default distribution lognormal
(I) <enter>

Enter desired value for the standard deviation.
The default value is 10 per cent of the mean.

To accept press ENTER, else type percentage.

(C) accept default value
(I) <enter>
(M) Enter number of workhours per day
(C) for an average of 9 hours per day
(I) 9 <enter>

(M) Enter number of workdays per week
(C) for an average of 5 days per week
(I) 5 <enter>

(M) Enter system stock number (e.g. 1234-12-123-1234)
(C) use the CAESAR sample file
(I) 1234-12-100-0000 <enter>

(M) Compute Lambda for overall system
(M)

System Dislocation within Major Units

Input filename for system distribution file
Default filename is DISTAIN

To accept default press ENTER or enter name

(C) use the default filename
(I) <enter>
(M)

Enter choice:

(C) the number of failures is 50. Therefore pick a major unit with less than 50 systems.

(I) 3 <enter>

(C) this was the last input for ESTIMATE.

(C) ESTIMATE generates various messages.

(C) Display when the MTBFs are drawn:

(M) Failure Time Generation

(C) The next message is updated for each simulation

(M) .. th Iteration for Simulation

(C) within each simulation this message is displayed:

(M) Subroutine Summation of consumed Items

(C) the last message will be:

85
Elapsed Time for 50 Simulations: xxx Weeks

PROGRAM END

The program has terminated correctly. We are back in the DOS environment.

The following six pages demonstrate the output of ESTIMATE with the data we just entered:

- parameters for delay distributions
- distribution of system within the corps
- summary of items and manhours on Org Mn level
- summary of items and manhours on DS/GS level
- summary of items and manhours on Depot level
- additional statistics
Number of Failures to be generated: 50

Average rounded number of mainten. personal: 1 repairman
Additional Statistics

total elapsed time for 50 simulations : 12.19 weeks

total number of 4 week periods for 50 simulations : 3.05

average system down time : 3.05 Days

average system availability : 95.00 per cent

average maintenance cost per system : $40.90

initial system cost for MOUNT BRIG : $40766.00
(systems and spare parts for 4 weeks)

cost of additional 4 week supplies : $402.63
5. **Program QBEHAVE**

QBEHAVE is the second of the two simulation programs in CAESAR that compute the logistics requirements for new systems. QBEHAVE sends results to the printer. Thus it is necessary to switch the printer on and align the paper.

To start QBEHAVE, type from the DOS prompt:

(I) `C>QBEHAVE <enter>`

(M)

```

Program Mode Menu

( 0 ) ... Check Queuing Behavior without Sensitivity Analysis (faster)
( 1 ) ... Check Queuing Behavior with Sensitivity Analysis

Default Value is 0.
To accept press ENTER, else enter value :
```

(C) let us use the full computational power of CAESAR

(I) 1 <enter>
Enter sensitivity analysis bounds in per cent

The default value is 10.

To accept default press ENTER, else type value

(C) let us use the default value
(I) <enter>

Enter the stockout risk factor $r$

(0.0 < $r$ < 1.0)

The default value is 0.1.

To accept default press ENTER, else type value

(C) let us use the default value
(I) <enter>
Enter avg. shipping time for ordered items in days

The default value is 5 days.

To accept default press ENTER, else type value

(C) let us use the default value
(I) <enter>
(C) QBEHAVE starts sorting data for level Org Mn

Level Org Mn
Sort Data Entries

(C) now assign servers on Org Mn level
number of servers for level Depot : 1
number of servers for level DS/GS : 1
number of servers for level Org Mn : 2

Compute Queueing Behavior

Level Org Mn
Service Number 14

(C) assign servers on DS/GS and DEPOT level
(C) this screen looks like the one earlier, because the number of servers has not yet changed.

number of servers for level Depot : 1
number of servers for level DS/GS : 1
number of servers for level Org Mn : 2

Compute Queueing Behavior

Level DEPOT
(C) one combination of servers has been calculated. This continues until calculations with all combinations have been performed. Eventually, with two repairmen on each maintenance level, the screen looks like

```
number of servers for level Depot : 2
number of servers for level DS/6S : 2
number of servers for level Org Mn : 2

Compute Queueing Behavior

Service Number  28
```

(C) each combination of repairmen on the different levels is printed

(C) QBEHAVE starts analyzing the spare part consumption
Ordering of Part Consumption Times

(C) the final results of this process will be printed

(M) ************************
** Program End **
************************

(C) this concludes the program QBEHAVE

(C) the output contains the following information:

- number of customers
- number of failures
- number of servers for each level
- number of delays for each level
- max. queue length for each level
- total waiting time for each level
- percentages servers are busy for each level
- total elapsed time and number of 4 week periods

for the service organization and

- national stock number
- initial stock level
- final stock level
- minimum stock level

for the supply organization.

98
The following pages are the output of ORHANE's sample run with data created earlier by ESTIMATE.

Eight pages show different combinations of numbers of repairmen on the three maintenance levels. Compare the waiting times and the percentages of time the servers are busy!

The last of the output pages shows the behavior in terms of spare parts. Observe the bottleneck of insufficient stocks for item 13 in all of the combinations (the debits were only a maximum of one each). One might want to increase the stock level for this item by one.

APPENDIX B

USER'S GUIDE

The summary of CAESAR in this user's guide enables the user to use CAESAR without need of the theoretical overhead in the main part of the study.

Each program in CAESAR will be explained in detail. Inputs and outputs are clearly marked and the user can easily follow the program flow.

All programs of CAESAR were written and compiled with the program TURBO BASIC [Ref. 6].
1. Introduction

a. **Purpose of CAESAR**

The programs contained in CAESAR were written for the IBM XT/AT or compatible computers to estimate the logistics requirements for a new system in terms of manpower and supply stocks.

CAESAR, (Computer Aided Evaluation of Supply and support on All Repair levels), uses inputs like system distribution, system characteristic data and major unit data to create a scenario within any major unit that provides conclusions about the behavior of a given number of failing systems in this scenario before the system is introduced into the Armed Forces (or any other customer with similar structures).

CAESAR is strictly thought of as a decision making aid, it must not be confused with artificial intelligence. The output of CAESAR is able to explicitly suggest reasonable logistical structures and to show alternatives to the suggested solution. Thus it can be a valuable tool in the hands of a manager, responsible of introducing new equipment and the accompanying supporting network.

System requirements for CAESAR are at least 512 kByte of memory, one floppy disk drive and a harddisk. The use of extended or expanded memory and
the installation of a RAM-Disk will speed up the programs significantly.

Operating system is DOS version 2.10 or higher. A printer has to be connected for the programs ESTIMATE and QBEHAVE, otherwise the programs will generate an error message and abort.

For the following instructions the use of a harddisk as drive C is assumed.

b. How To Get Started

To be able to use the program, boot-up your computer and after getting the DOS-prompt "C>" create a sub-directory on your harddisk with the following command:

C>MD\CAESAR. (You do not have to type C> !)

Make this sub-directory your current directory:

C>CD\CAESAR.

Now insert the CAESAR I floppy disk into your A-drive. If you are not sure which drive is the A-drive consult your computer manual.

To copy the program files from the CAESAR I floppy disk to the harddisk enter the following command:

C>COPY A:*.* C:.

This command will copy all files from the floppy drive A to the sub-directory CAESAR on your
harddisk C. Repeat the above procedure for the CAESAR II and III floppy disks.

Now you are ready to enter the structural data for the major units and the new system. These data will later be used in the programs that perform the simulations.

2. Program TACMIX.EXE

a. Start TACMIX

TACMIX is the graphic interface for CAESAR to provide the input of major unit structures. The program is written and compiled in TURBOBASIC. TACMIX is found on CAESAR disk I. Familiarity with the common tactical signs is assumed (see app. C). The program will present the tactical signs of both the US and West German Armies.

To start TACMIX simply type:

C>TACMIX.

The program will respond with the main menu as shown in figure B.1.

After your choice the display of all available major unit types will appear (except for option 9). Figure B.2 shows this screen. Now you have to choose the major unit you want to work with.
Program TACMIX

Options:

- Create New Organization ........(1)
- View Existing Organization ....(2)
- Modify Existing Organization ..(3)
- Terminate Program ..............(9)

Enter Number of Choice:

Figure B.1 Main Menu Program TACMIX

Figure B.2 Major Units Display Screen
b. **Option 1: Create New Organization**

In option 1, create a new organization, the program will present several screens like the one in Figure B.2 with all possible unit types for your selected major unit.

On the bottom of the screen you will read the following message:

"enter unit code number (ENTER for next frame) : ".

If you decided you need any of the depicted unit types for your major unit, simply enter the code number below the symbol. End your input with the ENTER key. The program wants to know how many of these unit types are in the major unit you chose and displays this message on the bottom of the screen:

"enter number of these units (default=1) : ".

You can enter any number now. If you only have one of this unit type in your major unit, simply press the ENTER key and TACMX will set the number to 1.

Repeat this for all unit types on this screen that you want to include in your major unit.

When you have entered all wanted units from the current graphic screen, press the ENTER key at the unit
code number prompt to see the next available unit symbols. Take your choices as before. If you press the ENTER key at the unit code number prompt after the last screen is displayed, TACMIX will store your input in a sequential data file.

Depending on the type of major unit you chose, the file will be called "CORPS", "DIVx" or "BRIGxx", where the "x" or "xx" stand for the number of the major unit, you chose.

E.g. the contents of file "BRIG12" might look like depicted in Figure B.3.

Figure B.3 Sample Contents of a Major Unit File
Working samples for all major unit types are included on the CAESAR data disk.

c. **Option 2: View Existing Organization**

In option 2, view existing organization, the program will display the screen shown in Figure B.2. After your choice of the major unit, the program will access the major unit data file and display all of the unit types within this major unit on consecutive screens. Figure B.4 gives an example for major unit 14 (airborne brigade).

![Diagram of major unit types]

**Figure B.4 View Airborne Brigade**

If there are more than one units of a specific type, then there will be an index outside the lower right corner of the symbol, indicating the number of
these units. In Figure B.4 there are three unit types 48 and one each of the others.

To get to the next screen, simply press any key. To get back to the main menu after the last screen for your chosen major you press any key.

d. **Option 3: Modify Existing Organization**

In option 3, modify existing organization, the program will display the screen shown in Figure B.2. After your choice of the major unit, the program will access the major unit data file and display all of the unit types within this major unit on consecutive screens. Figure B.5 gives an example for major unit 12 (armored brigade).

![Figure B.5 Modify Major Unit 12](image)
For each screen you will be asked:

"Any Modifications ?".

If you respond with "n" or "N" (do not type the quotes), then the next screen will be displayed. If there is only one screen or you have already reached the last one, "n" or "N" will get you back to the main menu. If you press any other key you will be asked:

"Which Modification ? (0=erase, 1=change number of units, 2=add a unit)".

You decide now, which kind of modification to perform and enter the appropriate number. The program will prompt you:

"Which Unit Number ?",

and you enter the code number for the unit to be changed.

If you wanted to erase a unit, the screen will now be redrawn without the erased unit - the file has been modified in the meantime.

For the change of number of units you see this prompt:
"Enter new number of units".

After you entered the required number the screen will be redrawn and the modification will have been made both on the screen and in the file.

If you want to add another unit type you enter the unit code number at the:

"Which Unit Number"

prompt. Now you will be asked to

"Enter number of new units".

When you enter this number the data file will be updated and the screen will be redrawn including the new unit type and the correct number of this type outside the lower right corner of the symbol for this unit type. Since the unit code numbers are in ascending order, the unit you have added might be on a later screen.

e. **Option 9: Terminate Program**

When you are finished with the program you chose option 9, termination of the program.

Do not turn off your computer without running option 9. You might loose data if not all file are closed.
After you chose option 9, the program will get you back to the DOS prompt "C>".

3. Program INMILDAT.EXE
   a. Start INMILDAT

   INMILDAT is the graphic interface for CAESAR to provide the input of the distribution of the new systems within the corps. INMILDAT can be found on the CAESAR I disk. Familiarity with the common tactical signs is assumed\(^1\). The program will present the most commonly used tactical signs of both the US and West German Armies.

   INMILDAT will create a new data file with the unit code numbers of the selected units and the respective number of systems. If you want to keep the previous data file, make sure to select another name for the new one or rename the old one and type from the DOS prompt "C>":

   "C>RENAME DISTRIBN DISTOLD".

   This DOS command will rename the data file "DISTRIBN" into "DISTOLD". You can use any other name up to 8 characters, as long as it is not the same as one already in use. Now, when you start INMILDAT, you can use the file name "DISTRIBN" without losing any previous data.

\(^1\)see Appendix C
To start INMILDAT simply type:

C>INMILDAT.

The program will immediately respond with the first unit symbol.

b. Operate INMILDAT

The first graphic screen will show the anti-aircraft defence regiment, code number 21. Figure B.6 shows this screen.

Figure B.6 Sample INMILDAT Screen

You will be asked:

"how many systems"
If there will be some of the new systems in this unit type, enter the number of the systems. If not, press ENTER to see the next unit symbol. Once you enter a number you will be asked to verify:

"entry ok".

Any keystroke except "n" or "N" will accept the input and the program will ask:

"another entry".

Any keystroke except "n" or "N" will lead to the next available symbol until all possible symbols have been presented in the described manner.

After the last symbol you will be asked:

"do you want a reserve".

If you decide to have one, answer with "y" or "Y". The next required information is:

"in per cent or absolute (p/a)".
Now enter the appropriate letter (P or A). Should you decide for per cent, the program will ask you to:

"enter percentage (e.g.:25)".

Please enter now the value of the percentage, not the fraction of 100. Given the example, for 25% (.25) you would enter the number 25. Do not enter .25 unless you want .25%.

In the case of a reserve in absolute numbers the program will ask you to:

"enter number of systems".

After this entry you will be asked to enter a name for the data file that will contain the system distribution data:

"To save data name file. Default file name is DISTRIBN. To accept default press ENTER or enter file name".

Now you can enter the file name you prefer or use the above default file name. If you decide to use the default, simply press the ENTER key and the data
will be saved into "DISTRIBN". Otherwise they will be saved into the file you named. You can enter any name up to 8 characters.

! Do not use a name that has already been used before! The new file will overwrite the old one and all previous data will be lost!

4. Program INSYSDAT.EXE.

a. Input Format for INSYSDAT

INSYSDAT is the interface for CAESAR to enter the characteristic data about the new systems. To be able to enter the appropriate inputs you have to know the formats of these inputs. You will be asked for the following entries

(underlined entries will be explained in detail):

<table>
<thead>
<tr>
<th>Item Type</th>
<th>National Stock Number</th>
<th>Item Description</th>
<th>Number of Items</th>
<th>Price in Dollars</th>
<th>MTBF in days</th>
<th>Replacement Level</th>
<th>Repair Level</th>
<th>MTTR in hours</th>
</tr>
</thead>
</table>

**Item Type:** to find the required number you have to break up the system (see figure B.7).

The system (level 1) consists of several components (level 2). Each of these contains subcomponents (level 3) which themselves contain
subcomponents (level 4) etc. If an item cannot be split up further, then it is a part (level 9). Parts can be found on all levels except the system (level 1).

Figure B.7 shows the schematic structure of a system.

![Figure B.7 System Structure](image)

**Figure B.7 System Structure**

The above schematic requires the classification of all items, of which the system consists, in one of the levels 2 - 9. Use this classification as input for the "Item Number".

**EXAMPLE:**

Consider a car as the system. It will be coded "1". Now take the body. It is a component of the car and will be coded "2". The rear hood is a subcomponent "3" and the lock on the hood is a subcomponent "4". The opening mechanism of the lock is subcomponent "5" and consists of parts "9" like bolts, nuts, etc.
National Stock Number (NSN): this is a 13-digit number in the following format (e.g.):

1234-12-123-1234,

where the fifth and sixth digit (-12-) should be the same for all items in the system, because the program will not use these to discriminate between items. These two digits are the code for the country where the item is built. The name of the random access data file that is generated for each system, component and subcomponent is

AAAADDDDD.CCC
derived from the National Stock Number

AAAA-BB-CCC-DDDD.

Replacement Level: this is the level where the failed item is replaced at a maintenance facility. For the system it is the level where the component is replaced, for the component, where the subcomponent is replaced etc. Parts can be replaced on any level.

These are the possible levels:

- Organizational Maintenance (Org Mn) level "2"
- Direct/General Support (DS/GS) level "3"
- Depot/Industry Maintenance (Depot) level "4".

Please enter the code number for the appropriate level.

Repair Level: this is the level where the replaced item is repaired at a maintenance facility. For the system
it is the level where the component is repaired, for the component, where the subcomponent is repaired etc.

Parts can be repaired on any level.

These are the possible levels:

- No Repair level "0"
- Organizational Maintenance (Org Mn) level "2"
- Direct/General Support (DS/GS) level "3"
- Depot/Industry Maintenance (Depot) level "4".

Please enter the code number for the appropriate level.

b. **Start INSYSDAT**

To start INSYSDAT simply type at the DOS prompt:

C>INSYSDAT.

c. **Operate INSYSDAT**

For each entry you will find a sample input. To become familiar with the program, you are welcome to use these examples.

The first program prompt will ask you for:

"Item Type (1=System, 2=Component, 3...8=Subcomponent, 9=Part)".

You are required to enter the type classification code (1 to 9) as described in paragraph a.

E.g. for a component enter 2.

The next prompt will ask you for:
"National Stock Number :".

Please enter the stock number in the format described in the paragraph a (AAAA-BB-CCC-DDDD).

E.g. enter a stock number like 1234-12-140-0000.

If the item type code is 2 or greater, the program will now ask you:

"belongs to what item (next level stock number):"

You want to enter the national stock number of the next higher level item here, which in the case of a component would be the system, in the case of a level 3 subcomponent the component etc.

For the system in this example enter 1234-12-100-0000.

With this information the program is able to check if this item is already stored under the same next level item. If it is, you will see the following error message:

"input error: item already stored
press any key to continue"

and the program will start from the beginning. If the item is not yet stored the program will proceed and you will be asked to enter:

"Item Description :".
E.g. enter Test Item.
The next inputs only apply to item types 2 to 9:

"Unit Price in US Dollars : $".

Give the price for one item.
E.g. type 253.98.
Now the program will ask you for:

"How many of these Items :"

Enter the actual number of these items within the next level item. Do not enter the overall total number of this item in the complete system.
E.g. enter 5.
The next prompt will be:

"MTBF (assumed) in Days :".

Enter here either empirical data, an estimate or the proposed MTBF by the manufacturer.
E.g. type 120.
The next input will be:

"Replacement Level (2=Org Mn,3=DS/GS,4=Depot)".
Use the code number (2 to 4) for the replacement level as described in paragraph a.
E.g. enter 2 for organizational maintenance.
You will now be asked for:

"Repair Level (0=no, 2=Org Mn, 3=DS/GS, 4=Depot)"

Again use the code number (0, 2 to 4) for the repair level as described in paragraph a. For a part, repair level 0 is set by default and displayed on the screen.
E.g. enter 3 for direct/general support.
The next prompt will ask you for:

"MTTR (Repair/Replace) in Hours :"

Enter here the actually needed repair/replace times, an estimate or numbers given by the manufacturer in hours.
E.g. for 200 minutes you enter 3.3.

You now have completed the input phase. To verify your inputs the screen in Figure B.8 with a summary of your inputs will be displayed.

Figure B.8 shows the data you just entered to verify the input.
<table>
<thead>
<tr>
<th>Type</th>
<th>Component</th>

</tr>
</tbody>
</table>

Figure B.8 Summary of Inputs for INSYSDAT

If you want to accept the inputs, press "y" or "Y". If not press "n" or "N".

After accepting the data are written into random access files. This file is for item type code numbers 2 to 9 the next higher item stock number converted into a file name as described in paragraph b. For the system it is its own stock number converted into that format.
The last prompt in this sequence is:

"another entry?".
"Y" or "y" get you to the program starting point and you can enter the next set of data. Any other key will end the program.

d. **Error Messages**

**INSYSDAT** handles three different types of input errors:

- **Invalid Repair Level**
  If the repair level for any item is less than the replacement level you will see the following error message:

  "input error: repair level invalid
  press any key to continue"

The program assumes an earlier input error and starts all over again.

- **Item Already Stored**
  If an item with the same stock number has already been stored under the given next level item stock number then this message will be displayed:

  "input error: item already stored
  press any key to continue"

The program starts from the beginning.
Number Exceeds Maximum

The number of data sets in the random access files is restricted to 95 for each file to guarantee reasonable run time of the program. If the entered data set exceeds this number you will see this message:

"input error: number of items exceeds maximum
press any key to continue"

To avoid this message recheck the structure of the system. It might be possible to define another item to decrease the number of items in this specific level.

Make sure that all data files for the system, the components and the subcomponents are in the same directory. Otherwise the program is not able to search for already stored items. Furthermore the use of the data files by the programs ESTIMATE and QBEHAVE requires that they will be in the same directory as these programs.

With the input of these data the process of generating data files is complete and the data can now be evaluated.
4. Program ESTIMATE.EXE
   a. Start ESTIMATE

   ESTIMATE is one of the two major programs in CAESAR to simulate and compute logistics requirements. The other one is QBEHAVE. ESTIMATE combines the data in the major unit structur files, created by TACMIX, the data in the system distribution file, created by INMILDAT and the system data, created by INSYSDAT. From these data it simulates the new systems in the chosen major unit for a given number of failures. After ESTIMATE finishes the SAMPSIZE trials for all levels of maintenance the number of manhours and consumed parts as well as all related times will be known.

   The generation of the various times is based on the assumption that all times have known distributions whose parameters are also known. If you are not sure about the distribution or the parameters for an input, take a guess for the distribution and then use the default values. That should give reasonable results.

   For MTTR and MTBF the distributions are assumed to be exponential with the given values as means.

   ESTIMATE requires a printer for the output, otherwise DOS will generate an error message and abort.

   To start ESTIMATE simply type at the DOS prompt:

   C>ESTIMATE.
b. Operate ESTIMATE

As soon as you start ESTIMATE, it will ask you to:

"Enter total number of failures to simulate (<=1000):"

The number you enter here is the number of failures to generate. This is not the number of systems in a specific major unit. These numbers are independent of each other since the number of systems depend on the major unit type that is chosen later in the process. The number to be entered has to be at most 1000 and will be printed. The greater the number you pick, the better the prediction will be, but also the longer the runtime of the program.

After this the program will tell you to:

"adjust paper in printer
press a key to continue".

Make sure your printer is connected and online and that your paper is at the top of a new page. Press any key to proceed. The next required steps are to enter the distributions and parameters of the transportation and administrative delay times for each of the three maintenance levels.
Figure B.9 shows the screen for the selection of levels.

![Screen for Selection of Levels](image)

Enter required information about the transportation times (one way):
- on the user/org maint. level (1)
- on the DS/QS level (2)
- on the Depot/Industry level (3)
- no more entries (9)

Figure B.9 Menu for Administrative Delay Times

You have to enter data for all levels of maintenance. Do not skip any input since these data will be used later in the program. You may, however, use the default values for each distribution. So, enter a "1" for the Org Mn level and the screen will present the available distributions.

Figure B.10 shows your options for the distributions. Pick the one you want or guess at one of them. If you do not want to have a random time pick the fixed value. Your delay time for the selected level
will in this case not be generated by a random number generator but will be treated as a constant.

These are your options for the distributions:

![Figure B.10 Distributions of Delay Times](image)

Figure B.10 Distributions of Delay Times

Figure B.11 shows a screen prompting for the lower limit of a uniform distribution as an example for a screen to enter parameters for the distributions.

As soon as a distribution with its respective parameters has been entered, the program will print these. When the input is complete for all maintenance levels this information will also be available in an auxiliary data file "006".
This is a sample screen to enter parameters:

transportation times (one way)

On the tree - any plant, level, enter for the uniform distribution

the lower limit is hours
the default value is : 1

Want to accept default value - press ENTER key?

Figure B.11 Enter Parameters for Distribution

If you entered wrong data, simply pick the level again at the menu shown in Figure B.9 and enter the correct numbers. When you have entered all the transportation delay time distributions for the three levels correctly, choose option 9 to get to the screens for the administrative delay times. These screens look the same as the previous ones. Enter the data for all three levels and close the input with a "9" at the level menu (see Figure B.9). This will conclude this phase of the program.
Next enter a few additionally required data. To be able to compute the time frame ESTIMATE will ask you to:

"Enter number of workhours per day".

Give here the average number of both the system and the maintenance workhours on a workday. Then

"Enter number of workdays per week".

Again enter the average number of days here.

Now the program needs to know for which system the simulation run has to be performed. Therefore:

"Enter the System Stock Number (e.g. 1234-12-123-1234)"

You enter the national stock number for the overall system in the format given in the parentheses.

For the last part of the interaction with the user, ESTIMATE needs to know where to find the information about the system distribution within the military structure.

Figure B.12 shows the screen that asks for the name of this file.
System Dislocation within Major Units

Input filename for system distribution file
Default filename is DISTRIBUT

To accept default press ENTER or enter name

Figure B.12 Name of System Distribution File

After this entry the program takes one major unit after the other and finds in the appropriate data file all unit types within the major unit and checks them if they contain the system in question. Finally, after all units are checked, the total number for that major unit is determined. For division level there will be two numbers computed, one for the divisional units and the other one for the total number including the subordinate brigades. The same is valid for the corps, in which the number for the corps units and the total including the subordinate divisions will be computed. Finally the program will find the number for the reserve. Major units, that do not contain any of the
systems, will not be taken into account. Figure B.13 shows the menu for the major units.

Enter choice:

Figure B.13 Menu for Major Units

The number in parentheses stands for the number of systems in that particular major unit. Enter the number (1 to 10) that represents your choice.

This was the last input for ESTIMATE. Now the computation starts. ESTIMATE will display what it is just doing with messages such as:

"Compute Lambda for overall system"
"Subroutine MTBF Generation"
"xx th Iteration for Simulation
Subroutine Failure Generation"

"xx th Iteration for Simulation
Subroutine Update Data Files"

"Subroutine Summation of consumed Items",

where the xx stand for the numbers inserted by the program at execution time. The final screen with the following message is shown in Figure B.14:

"elapsed time for xxx simulations : xxx.xx weeks

PROGRAM END"

Before this message appears on the screen, the printer will have printed the consumed items and manhours for each level of maintenance and the planning figures for a four week period. Also statistical data about the elapsed time and the systems' status plus the total cost of parts will be provided.
Figure B.14 End Screen Program ESTIMATE

5. Program QBEHAVE.EXE
   a. Start QBEHAVE

   QBEHAVE is the second of the two major programs in CAESAR to simulate and compute logistics requirements. The other one is ESTIMATE. QBEHAVE recomputes the data from ESTIMATE, the idealized run. But now it simulates the failing systems as customers in a real service environment. Customers have to form a queue and will be served as soon as a server is available.

   The number of servers is determined by ESTIMATE. QBEHAVE takes this number and, if this option is chosen, computes for a given bandwidth, minimum one
server, on either side the real behavior. It is assumed, that at least one server will be assigned to each level of maintenance.

A printer is required for QBEHAVE to avoid a DOS error message.

To start QBEHAVE type at the DOS prompt:

\texttt{C\textgreater QBEHAVE.}

\textbf{b. Operate QBEHAVE}

All required data, distributions and related information will be obtained from auxiliary data files, created by ESTIMATE and the data files containing major unit, system and organizational data. The first input for QBEHAVE is the choice of either the verification of the numbers obtained from ESTIMATE or a sensitivity analysis of the numbers (see Figure B.15). QBEHAVE computes its results for the same failures as ESTIMATE, to assure the comparability of the two sets of figures.

After this choice, the user has to determine the sensitivity bounds (see Figure B.16), the stockout risk factor (see Figure B.17) and the average shipping time for ordered items (see Figure B.18) to provide the basis for the restocking computations.
Figure B.15 Program Mode Menu

(8) ... Check Queuing Behavior without Sensitivity Analysis (faster)

(1) ... Check Queuing Behavior with Sensitivity Analysis

Default Value is 0.
To accept press ENTER, else enter value :

Figure B.16 Choice of Sensitivity Bounds

Enter sensitivity analysis bounds in per cent

The default value is 10.

To accept default press ENTER, else type value
Enter the stockout risk factor $r$

$0.0 < r < 1.0$

The default value is 0.1.

To accept default press ENTER, else type value

Figure B.17 Input of the Stockout Risk Factor

Enter ave. shipping time for ordered items in days

The default value is 5 days.

To accept default press ENTER, else type value

Figure B.18 Input of the Ave. Shipping Time
QBEHAVE will always display what it is just computing. That provides the user with the program status at each time.

When the program is started, the first thing to compute is the sequence of entry data for the Org Mn queue. This sequence determines all other times for the different maintenance levels.

Figure B.19 shows the message for this step.

![Figure B.19 QBEHAVE Sort Screen Org Mn](image)

After these data have been sorted, the customers will be served in their sequence of entering level Org Mn. The time, the customers leave service will be computed and the time the systems are operational again. Furthermore, QBEHAVE keeps track of
the part consumption and will, at the end of the program run, print the supply levels.

Figure B.20 displays the screen, that is shown during these computations.

```
number of servers for level Depot : 1
number of servers for level DS/GS : 1
number of servers for level Org Mn : 2

Compute Queueing Behavior

Level Org Mn

Service Number  14
```

Figure B.20 Service on Org Mn Level

The times, the customers leave level Org Mn are the failure times for the next level, DS/GS. Transportational and administrative delay times will be added. The service enter times are computed and brought into sequence.

As before, the customers will be served and leave service. The spare parts consumption will be noted. The repaired items will go back into the supply chain as spares for the lower maintenance level.
The last step for the maintenance portion of the program are the computations for the Depot level. They are performed using the same algorithms as before. The times of failure for the customers at the Depot level are the times the customer leaves the lower level service. Transportational and administrative delay times are added.

After each sort routine, the program will display the service screen with the number of servers available on all levels and the customer being serviced. When all three levels are computed, the current combination of servers on each level is printed with:

- number of customers
- number of failures
- number of servers for each level
- number of delays for each level
- max. queue length for each level
- total waiting time for each level
- percentages servers are busy for each level
- total elapsed time and number of 4 week periods

Figure B.21 shows the screen for the sample run after all combinations of servers on all levels have been computed.
QBEHAVE will now analyze the spare part consumption. The times, when items were needed are known. ESTIMATE suggested the stock levels. QBEHAVE uses these suggestions. Refill of parts will be performed every four weeks with constant increments. All other repairable items will have the initial stock level. After repair they will be rerouted into the supply chain. There will be no attrition for these items.

Figure B.22 shows the screen, that is displayed during these computations.
Ordering of Part Consumption Times

Figure B.22 Compute Spare Part Behavior

The spare part consumption will be protocolled on the printer including:
- national stock number
- initial stock level
- final stock level
- minimum stock level.

That concludes the program QBEHAVE. The output of QBEHAVE offers an array of alternatives for server numbers as well as the trade-offs between waiting times and the server numbers. From these the decision maker can chose his preferred option. The statistic of the part consumption can guide to decisions about the respective stock levels.
The total number of output pages can be computed as:

\[(\text{total number of pages}) - \text{combinations of server numbers} + 1\]
\[- \text{(number of mutations level Org Mn)} \times \]
\[- \text{(number of mutations level DS/GS)} \times \]
\[- \text{(number of mutations level Depot)} + \]
\[- \text{(one page for spare parts)}.\]

E.g. Org Mn level \((5+/−1)\). servers: 4, 5, 6
DS/GS level \((3+/−1)\). servers: 2, 3, 4
Depot level \((1+/−1)\). servers: 1, 2 (min 1!)

Total number of pages:
\[3 \times 3 \times 2 + 1 = 19 \text{ pages}\]
APPENDIX C
TACTICAL SIGNS

Appendix C summarizes the tactical signs, used in the programs of CAESAR. This is the standard notation for unit sizes:

- xxx: corps
- xx: division
- x: brigade
- ||: regiment
- ||: battalion
- ||: company

The tactical signs are ordered with respect to unit size and the CAESAR code numbers. This order does not imply any other meaning.

The display format is as follows:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>CAESAR code number</th>
<th>Description</th>
</tr>
</thead>
</table>

Here are the most commonly used tactical signs of both the US and GE Armies [Ref. 7 and 8]:

- 0: Corps

4. Source Code Program ESTIMATE

REM program ESTIMATE                                      AUGUST 1987
REM This program simulates SAMPSIZE failures for a
REM maximum of 500 systems in a selectable major
REM unit simultaneously. It requires access to the
REM major unit data, the system distribution data and
REM the system data.
REM Output is the expected failure distribution within
REM the selected major unit in terms of consumed items,
REM used maintenance capabilities and system downtimes.
REM If the number of systems is greater than 2000,
REM the model is scaled.
REM

5. **Source Code Program QBEHAVE**

REM program QBEHAVE

AUGUST 1987

REM This program recomputes the queueing behavior with
REM the numbers computed in the program ESTIMATE.
REM Given are the four weeks planning data for stocks
REM and manpower requirements. These figures are taken
REM to establish the environment, in which the systems
REM are failing.
REM The program accesses the data in datafiles "003",
REM "005" and "006", computes the arrival times at the
REM maintenance facilities, checks for availability of
REM parts and manpower and processes the systems
REM through the server queues.
REM Output is not only the statistics for the specified
REM number of servers but also a sensitivity analysis
REM with server numbers varying and the consumption
REM behavior with the given supply stocks.
REM The results can be used to propose a structure for
REM the logistics organization needed to support the
REM new systems.
