A NOTE ON SECOND ORDER EFFECTS IN A SEMIPARAMETRIC CONTEXT

We consider a heteroscedastic linear regression model with normally distributed errors in which the variances depend on an exogenous variable. Suppose that the variance function can be parameterized as \( \psi(z_i, \theta) \) with \( \theta \) unknown. If \( \theta \) is any root-N consistent estimate of \( \theta \) based on squared residuals, it is well known that the resulting generalized (weighted) least squares estimate with estimated weights has the same limit distribution as \( \theta \) were known. The covariance of this estimate can be expanded to terms of order \( N^{-2} \). If the variance function is unknown but smooth, the problem is adaptable, i.e., one can estimate the variance function nonparametrically in such a way that the resulting generalized least squares estimate has the same first order normal limit distribution as if the variance function were completely specified. In a special case, we compute an expansion for the co-variance in this semiparametric context, and find that the rate of convergence is slower for this estimate than for its parametric counterpart. More importantly, we find that there is an effect due to how well one estimates the variance function. We use a kernel regression
A NOTE ON SECOND ORDER EFFECTS

His research was supported by the Deutsche Forschungsgemeinschaft, Sonderforschungsbereich 303.
We consider a heteroscedastic linear regression model with normally distributed errors in which the variances depend on an exogenous variable. Suppose that the variance function can be parameterized as $\psi(z, \theta)$ with $\theta$ unknown. If $\hat{\theta}$ is any root-$N$ consistent estimate of $\theta$ based on squared residuals, it is well known that the resulting generalized (weighted) least squares estimate with estimated weights has the same limit distribution as if $\theta$ were known. The covariance of this estimate can be expanded to terms of order $N^{-2}$. If the variance function is unknown but smooth, the problem is adaptable, i.e., one can estimate the variance function nonparametrically in such a way that the resulting generalized least squares estimate has the same first order normal limit distribution as if the variance function were completely specified. In a special case we compute an expansion for the covariance in this semiparametric context, and find that the rate of convergence is slower for this estimate than for its parametric counterpart. More importantly, we find that there is an effect due to how well one estimates the variance function. We use a kernel regression estimator and find that the optimal bandwidth in our problem is of the usual order, but that the constant depends on the variance function as well as the particular linear combination being estimated.
SECTION 1: Introduction

We consider a heteroscedastic linear regression model with normally distributed errors and replication:

\[ y_{ij} = x_i^t \beta + \sigma_i \eta_{ij} \quad (i = 1, \ldots, N; j = 1, 2); \]

\[ \sigma_i^2 = \psi(z_i, \theta); \]

\[ E(\eta_{ij}) = 0; \quad \text{Variance}(\eta_{ij}) = 2. \]

In this model, the regression parameter is \( \beta \), and the variance function is \( \psi \). The \( \{z_i\} \) are scalars, possibly a component of the \( p \)-dimensional vectors \( \{x_i\} \). Throughout, we will assume that the \( \{x_i, z_i\} \) are independent and identically distributed random variables mutually independent of the \( \{\eta_{ij}\} \). The errors \( \{\eta_{ij}\} \) are assumed to be independent normally distributed random variables. The reason that the variance of \( \eta_{ij} \) equals 2 will become clear later.

Let \( \hat{\theta} \) be the mle of \( \theta \). The mle \( \hat{\beta}_w \) of \( \beta \) is a generalized least squares estimate, i.e., weighted least squares with the estimated weights \( 1/\psi(z_i, \hat{\theta}) \). Let

\[ S_N = N^{-1} \sum_{i=1}^{N} x_i x_i^t / \psi(z_i, \theta) \rightarrow S \text{ (positive definite)}, \]

then it is well known that \( \hat{\beta}_w \) is asymptotically normally distributed with mean \( \beta \) and covariance \( S^{-1}/N \), i.e., with \( \Rightarrow \) denoting convergence in distribution.

\[ N^{1/2}(\hat{\beta}_w - \beta) \Rightarrow \text{Normal}(0, S^{-1}). \]

The limit distribution (1.3) is the same as if \( \theta \) were known, so that (1.3) expresses a parametric adaptation result.

A simplification of an argument of Rothenberg (1984) shows that \( \hat{\beta}_w \) is
symmetrically distributed about $\beta$ with a covariance expansion

\begin{equation}
(1.4) \quad \text{Covariance} \left[ N^{1/2}(\hat{\beta}_w - \beta) \right] = S^{-1} + N^{-1} A_w + o(N^{-1}).
\end{equation}

where $A_w$ is a positive definite matrix. Such second order covariance expansions when the variances depend on the mean and/or the errors are not normally distributed have been investigated by Carroll, Wu & Ruppert (1987).

Suppose that instead of a parametric model, the form of the variance function is not known a priori, so that we can write

\begin{equation}
(1.5) \quad \sigma_i^2 = \psi(z_i) = 1 / g(z_i), \psi \text{ unknown}.
\end{equation}

Now the unknown parameters are $(\beta, \psi)$, so we are in a semiparametric context, see Bickel (1982) and Begun, et al. (1983). It is easy to show that the semiparametric information bound here is the same as if $\psi$ were known. Carroll (1982), Robinson (1986) and Carroll, Ruppert & Stefanski (1987) have constructed adaptive estimates as follows. By smoothing techniques such as kernel or nearest neighbor regression, they form an estimate $\hat{\psi}$ of $\psi$, and then construct the generalized least squares estimate $\hat{\beta}_g$ of $\beta$ with the estimated weights $1/\hat{\psi}(z_i)$. These estimates have the same limit distribution as if $\psi$ were known, i.e.,

\[ N^{1/2}(\hat{\beta}_g - \beta) \Rightarrow \text{Normal}(0,S^{-1}) \] .

If $\hat{\psi}$ is chosen appropriately, $\hat{\beta}_g$ is symmetrically distributed about $\beta$. In this paper, we pick a particular estimate $\hat{\psi}$ based on kernel regression techniques and compute an analogue to the covariance expansion (1.4), namely

\[ \text{Covariance} \left[ N^{1/2}(\hat{\beta}_g - \beta) \right] = S^{-1} + N^{-4/5} A_g + o(N^{-1}). \]
There are two major conclusions. The first is that the second order covariance expansion converges at a slower rate for the semiparametric model (1.1) than it does for the parametric model (1.1). Of more general interest is that the optimal bandwidth for estimating any linear combination of the regression parameter $\beta$ is still of the usual order, but it depends not only on the variance function but also on the particular linear combination being estimated.

In a sense the context we are working in is narrow, but there are some general implications to our results. In the semiparametric context, there is some concern that much larger sample sizes than usual will be needed to achieve approximate normality than is true in a parametric model. Hsieh & Manski (1987) state "It is sometimes asserted that satisfactory nonparametric estimation of score functions requires very large samples; hence, adaptive estimates should perform poorly in moderate size samples".

Our results indicate that semiparametric adaptive estimates should indeed converge more slowly than do parametric estimates, which is not too surprising a result but is at least worth nailing down. With considerable fine tuning of their estimate of the nonparametric part of their model, Hsieh & Manski are able to do fairly well in their two-sample problem. It is clear from their simulations that how well one estimates the nonparametric part of their semiparametric model can affect the small sample properties of the parametric estimator. Our results are a theoretical complement to their simulations. How well one estimates the semiparametric nuisance function $\psi$ can affect the small sample performance of the parametric estimates.
The key to our construction is that replication in a normally distributed context allows us to do weighted least squares with estimated weights which are distributed independently of the "data". Let

\[ \epsilon_1 = (\eta_{11} + \eta_{12})/2 ; \quad \delta_1 = \epsilon_1 \psi^{1/2}(z_1) ; \]

\[ \epsilon_{i*} = (y_{11} - y_{12})/2 = \psi^{1/2}(z_1) (\eta_{11} - \eta_{12})/2 . \]

Note that the sequence \( \{\epsilon_{i*}\} \) is observable. Because the \( \{\eta_{ij}\} \) are normally distributed, the sequences \( \{\delta_1\} \) and \( \{\epsilon_{i*}\} \) are mutually independent and identically distributed standard normal random variables. Also, the \( \{\epsilon_i\} \) are distributed independently of the \( \{\epsilon_{i*}\} \). Since

\[ E(\epsilon_{i*}^2) = \psi(z_1) , \]

it is plausible to base estimates of the weights on the \( \{\epsilon_{i*}^2\} \). Of course, this will not be the most efficient way to estimate the variance function \( \psi \), but will still allow us to estimate \( \beta \) efficiently to first order. We first write the results in terms of \( g(z) = 1/\psi(z) \), see (1.5). Let \( \hat{g}_N \) be an estimate of \( g \) which is based solely on the \( \{\epsilon_{i*}^2\} \). Make the following definitions:

\[ \hat{y}_N(z) = \hat{g}_N(z) - g(z) ; \]

\[ S_N = N^{-1} \sum_{i=1}^{N} x_i \epsilon_{i*} \hat{g}(z_1) ; \quad \hat{S}_N = N^{-1} \sum_{i=1}^{N} x_i \epsilon_{i*} \hat{g}(z_1) ; \]

\[ R_N = N^{-1/2} \sum_{i=1}^{N} x_i \delta_1 \hat{g}(z_1) ; \quad \hat{R}_N = N^{-1/2} \sum_{i=1}^{N} x_i \delta_1 \hat{g}(z_1) ; \]

\[ M_N = \hat{S}_N - S_N ; \quad Q_N = \hat{R}_N - R_N . \]
LEMMA 1: For any $N$, 
\[ \text{Cov} \left[ N^{1/2}(\hat{\beta}_g - \beta) \right] = S_N^{-1} + E\left[ T_N T_N^t \right] \]

PROOF OF LEMMA 1: Note that 
\[ T_N = N^{1/2}(\hat{\beta}_g - \hat{\beta}_w) : E\{T_N\} = 0. \]

the latter following easily since $\hat{\beta}_N$ is independent of the $\{\delta_i\}$. Since the distribution of $T_N$ does not depend on $\beta$ and $\hat{\beta}_w$ is a complete sufficient statistic for $\beta$, by Basu's Lemma $T_N$ is independent of $\hat{\beta}_w$. This means that 
\[ \text{Cov} \left[ N^{1/2}(\hat{\beta}_g - \beta) \right] = \text{Cov} \left[ N^{1/2}(\hat{\beta}_w - \beta) \right] + \text{Cov} \left[ T_N \right] \]
\[ = S_N^{-1} + E\left[ T_N T_N^t \right]. \]

Because $T_N T_N^t$ is positive (semi) definite, Lemma 1 implies that estimating weights by our method results in an inflation in variance. Define 
\[ C_N = T_N T_N^t - (Q_N - M_N R_N) (Q_N - M_N R_N)^t \]

We show in the appendix that under reasonable regularity conditions, $C_N = O_p(N^{-1})$. Thus, it is not too implausible to assume that 
\[ N E\left[ C_N \right] \rightarrow 0 \quad \text{as} \quad N \rightarrow \infty. \]

THEOREM 1: Assume (2.1). Then 
\[ \text{Cov} \left[ N^{1/2}(\hat{\beta}_g - \beta) \right] \]
\begin{align*}
= S_N^{-1} + S_N^{-1} \left[ E\{ Q_N Q_N^t \} - E\{ M_N S_N^{-1} M_N^t \} \right] S_N^{-1} + o(N^{-1}).
\end{align*}

The proof is in the appendix.

The translation from \( \hat{g}_N(z) - g(z) \) in the definition of \( Q_N \) and \( M_N \) is to note that

\begin{equation}
(2.3) \quad \hat{g}_N(z) - g(z) \equiv - \left[ \hat{\psi}_N(z) - \psi(z) \right] / \psi^2(z).
\end{equation}

We will ignore the error in (2.3) by subsuming it under "additional regularity conditions". Define

\begin{align*}
\nu_1 &= x_1 x_1^t \psi(z_1); \\
A_N &= N^{-1} \sum_{i=1}^N \nu_1 \left[ \hat{\psi}_N(z) - \psi(z) \right]^2 / \psi^4(z); \\
B_N &= N^{-1} \sum_{i=1}^N x_1 x_1^t \left[ \hat{\psi}_N(z) - \psi(z) \right] / \psi^2(z).
\end{align*}

The direct translation from (2.2) is

\begin{equation}
(2.4) \quad \text{Cov} \left[ N^{1/2} (\hat{\beta}_g - \beta) \right] \\
= S_N^{-1} + S_N^{-1} \left[ E\{ A_N \} - E\{ B_N S_N^{-1} B_N^t \} \right] S_N^{-1} + o(N^{-1}).
\end{equation}

In the next section we compute (2.4) in a special case.
SECTION 3: An Example

The purpose of this section is to get an explicit expression for the covariance expansion (2.4) in a special case. The major question is whether the second term on the right hand side is of order $O(N^{-1})$ as it would be in the parametric case. We use a kernel regression estimator. Let $K(\cdot)$ be a symmetric density with bounded support and let $f(\cdot)$ be the marginal density of the $\{z_i\}$. Let $b = b_N \rightarrow 0$ be the bandwidth and define

$$K_b(u) = b^{-1} K(u/b) ;$$
$$[K] = \int u^2 K(u) \, du .$$

The estimator we will use is a leave-one-out type estimator, which Robinson (1986) has also found to be convenient analytically:

$$\hat{\psi}_N(z_i) = \frac{N}{\sum_{j \neq i}^N \epsilon_j^2} K_b(z_j - z_i) / \sum_{j \neq i}^N K_b(z_j - z_i).$$

We will also need the following:

(3.1) \hspace{1cm} N b_N^6 \rightarrow 0 .
(3.2) \hspace{1cm} \int v K^2(v) \, dv = 0 .
(3.3) If $\psi_j$ is the jth derivative of $\psi$ and $f_1$ is the first derivative of $f$, then

$$c_1(v) = (1/2) d(v) [K], \text{ where}$$
$$d(v) = \psi_2(v) + 2f_1(v)\psi_1(v)/f(v).$$

Define the following terms:

$$c_K^{(1)} = \int K^2(v) \, dv ; \quad \mu_4(v) = E \left[ (\epsilon_j^2 - \psi(v))^2 \mid z=v \right]$$
\[ c_2(v) = c_k^{(1)} \mu_4(v) / f(v) \]

\[
d_1 = S_N^{-1} E \left[ x^t c_2(z) \psi(z) S_N^{-1} \right] ;
\]

\[
d_2 = S_N^{-1} E \left[ x^t c_1(z) \psi(z) S_N^{-1} \right] ;
\]

\[
\tau = S_N^{-1} E \left[ x^t c_1(z) \psi(z) S_N^{-1} \right] ;
\]

\[
S = E \left[ x^t / \psi(z) \right] \quad \text{(see (1.2))}
\]

\[
d_3 = d_2 - \tau \tau^t \geq 0 \quad \text{(by Cauchy Schwarz)}.
\]

**THEOREM 2**: Assume (2.4). Then, for estimating any linear combination \( a^t \beta \),

\[
\text{(3.4) } \quad \text{Cov} \left[ N^{1/2} \left( a^t \hat{\beta} - a^t \beta \right) \right]
\]

\[
= a^t \left[ S^{-1} + (N b_N)^{-1} d_1 + b_N^{-4} d_3 \right] a + o(b_N^{-4} + (N b_N)^{-1}).
\]

From (3.4), the optimal bandwidth is \( c N^{-1/5} \), where

\[
\text{(3.5) } \quad c = \left[ q a^t d_1 a \right]^{1/5} / \left[ 4 a^t d_3 a \right]^{1/5}.
\]

Note how the optimal bandwidth depends on the design and which linear combination you are interested in estimating.

**Remark**: Assume the result of Lemma 1, we could generalize (3.4) and (3.5) somewhat by allowing the \( z_i \) to be q-vectors. The changes needed are these:

\[
K_b(u) = b^{-q} K(u/b) ; \quad [K] = \int uu^t K(u) du ;
\]

\[
c_1(v) = (1/2) \text{trace}(d(v) [K]), \quad \text{where}
\]

\[
d(v) = \psi_2(v) + (\psi_1(v)f_1(v)^t + f_1(v)\psi_1(v)^t)/f(v).
\]

The optimal bandwidth is \( c N^{-1/(4+q)} \) and (3.4) and (3.5) become

\[
\text{(3.4')} \quad \text{Cov} \left[ N^{1/2} \left( a^t \hat{\beta} - a^t \beta \right) \right]
\]
\[ a^t \left[ s^{-1} + (Nb_N^q)^{-1}d_1 + b_N^4 d_3 \right] a + o(b_N^4 + (Nb_N^q)^{-1}). \]

\[ c = \left[ q a^t d_1 a \right]^{1/(4+q)} \left/ \left[ 4 a^t d_3 a \right]^{1/(4+q)} \right. \]

REFERENCES

APPENDIX A
Without loss of generality, we may set $S_N = I$.

**Lemma A.1**: Assume that

(A.1) $\| M_N \|^3 = o_p(N^{-1})$.

(A.2) $\| Q_N \| \overset{p}{\to} 0$.

(A.3) $\| M_N M_N^T Q_N \| = o_p(N^{-1})$.

Then,

$$T_N T_N^t = (Q_N - M_N R_N)(Q_N - M_N R_N)^t + o_p(N^{-1}).$$

**Proof of Lemma A.1**: We have that

$$S_N^{-1} - S_N^{-1} = -M_N + M_N M_N + o_p(\| M_N \|^3).$$

Thus,

$$T_N = S_N^{-1} R_N - S_N^{-1} R_N = (S_N^{-1} - S_N^{-1}) R_N + S_N^{-1} (R_N - R_N)$$

$$= (S_N^{-1} - S_N^{-1}) R_N + (S_N^{-1} - S_N^{-1}) Q_N + S_N^{-1} Q_N$$

$$= \left[ -M_N + M_N M_N \right] R_N + \left[ -M_N + M_N M_N \right] Q_N + S_N^{-1} Q_N + o_p(N^{-1})$$

$$= S_N^{-1} Q_N - M_N R_N + M_N M_N R_N - M_N Q_N + o_p(N^{-1})$$

the last following from (A.1) - (A.3). From (A.1) - (A.3), we have

$$T_N T_N^t = S_N^{-1} Q_N Q_N^t S_N^{-1} - M_N R_N Q_N^t S_N^{-1}$$

$$- \left[ M_N R_N Q_N^t S_N^{-1} \right]^t + M_N R_N R_N^t M_N + o_p(N^{-1}).$$

Since $S_N = I$, the proof is complete.
**LEMMA A.2** : Define
\[ v_i = x_i x_i^t / g(z_i) = x_i x_i^t \psi(z_i). \]

Then,
\[ E[ Q_N Q_N^t ] = N^{-1} \sum_{i=1}^{N} E[ v_i (\hat{g}_N(z_i) - g(z_i))^2 ] . \]

**PROOF OF LEMMA A.2** : Since
\[ Q_N Q_N^t = N^{-1} \sum_{i=1}^{N} \sum_{j=1}^{N} \delta_{i,j} x_i x_i^t (\hat{g}_N(z_i) - g(z_i)) (\hat{g}_N(z_j) - g(z_j)) , \]

and since \( \hat{g}_N \) and the \( \{ \delta_{i,j} \} \) are independent, we find that
\[ E[ Q_N Q_N^t | g, \{ x_i, z_i \} ] = N^{-1} \sum_{i=1}^{N} v_i (\hat{g}_N(z_i) - g(z_i))^2 . \]

This completes the proof.

**LEMMA A.3** : We have that
\[ E\left[ (Q_N - M_N R_N) (Q_N - M_N R_N)^t \right] = E[ Q_N Q_N^t ] - E[ M_N M_N^t ] . \]

**PROOF OF LEMMA A.3** : Exploiting the independence of \( \hat{g}_N \) and the \( \{ \delta_{i,j} \} \), as well as remembering that \( S_N = I \), we see that
\[ E\left[ M_N R_N R_N^t M_N^t \right] = E[ M_N M_N^t ] . \]

It thus suffices to show that
\[ E\left[ M_N R_N Q_N^t | \hat{g}_N, \{ x_i, z_i \} \right] = M_N M_N^t . \]
This is routine.

**PROOF OF THEOREM 1**: The proof follows from the previous Lemmas.

**APPENDIX B**

Our calculations rely on the following result due to Collomb (1977, 1981).

**PROPOSITION B**: Let $K$ be a symmetric $q$-dimensional density. Let $(X,Y) \in \mathbb{R}^{q+1}$, where $X$ is a $q$-vector. Define $m(x) = E[y \mid X=x]$ and let $f(x)$ be the marginal density of $X$. Assume that $m(x)$ and $f(x)$ are four times continuously differentiable. Define

$$K_b(u) = b^{-q}K(u/b)$$

$$\hat{m}_b(u) = \sum_{i=1}^{N} Y_i K_b(x-X_i) / \sum_{i=1}^{N} K_b(x-X_i)$$

$$v(x) = E[(Y - m(x))^2 \mid X=x]$$

$$[K] = \int u u^t K(u) \, du$$

$$b(x) = (1/2)m_2(x) + (1/2)[m_1(x)f_1^t(x) + f_1(x)m_1^t(x)]/f(x).$$

Then, as $b \to 0$,

$$E\{m_b(x) - m(x)\} = b^2 \text{trace}(b(x) [K]) + O(b^4);$$

$$\text{Var}(m_b(x)) = (Nb^q)^{-1} v(x) \int k^2(u) \, du / f(x) + O(N^{-1}b^{-q+2}).$$

**LEMMA B.1**: Under regularity conditions (Proposition B) on $\psi$ and $K$,

\begin{equation}
(B.1) \quad s(z_1) = E\left[ \psi_N(z_1) \mid z_1 \right]
\end{equation}

$$= \psi(z_1) + b_N^2 c_1(z_1) + O_p(b_N^4).$$

**PROOF OF LEMMA B.1**: Immediate from Proposition B.
LEMMA B.2: If \( s(z_i) \) is defined in (B.1), we have

\[
E\left[ \left( \hat{\psi}_N(z_i) - s(z_i) \right)^2 \right| z_i \right]
= c_2(z_i)/(Nb_N^q) + O_p(b_N^{-2q}) + O_p\left(b_N^{-1}b_N^{-2(q-2)}\right).
\]

PROOF OF LEMMA B.2: From Proposition B with \( Y = e^{2i\pi k} \), \( X = z_i \), \( m(x) = \psi(x) \).

LEMMA B.3: We have

\[
E\left[ \left( \hat{\psi}_N(z_i) - \psi(z_i) \right)^2 \right| z_i \right]
= c_2(z_i)/(Nb_N^q) + b_n^4 c_1^2(z_i) + O_p\left(b_N^6 + N^{-1}b_N^{-2(q-2)}\right).
\]

PROOF OF LEMMA B.3: The expansion in question is

\[
E\left[ \left( \hat{\psi}_N(z_i) - s(z_i) \right)^2 \right| z_i \right] + \left[ s(z_i) - \psi(z_i) \right]^2
= c_2(z_i)/(Nb_N^q) + b_n^4 c_1^2(z_i) + O_p\left(b_N^6 + N^{-1}b_N^{-2(q-2)}\right). \quad \Box
\]

Now assume without loss that \( S_N = I \). Define

\[
W_i = x_i x_i^t / \psi^3(z_i) ; D_i = \psi(z_i) W_i .
\]

LEMMA B.4: As \( N \to \infty \),

\[
(B.2)
E\left[ N^{-1} \sum_{i=1}^{N} W_i \left( \hat{\psi}_N(z_i) - \psi(z_i) \right)^2 \right] = c_1/(Nb_N^q) + b_n^4 d_2 + O(b_N^6 + N^{-1}b_N^{-2(q-2)}).
\]
PROOF OF LEMMA B.4: Apply Lemma B.3 after conditioning on $(x_i, z_i)$. \( \Box \)

Lemma B.4 gives us the form of \( E(A_N) \) in (2.4), and in order to complete the calculation we note that \( B_N = B_{N1} + B_{N2} \), where

\[
B_{N1} = N^{-1} \sum_{i=1}^{N} D_i \left[ \hat{\psi}_N(z_i) - s(z_i) \right]
\]

\[
B_{N2} = N^{-1} \sum_{i=1}^{N} D_i \left[ \psi(z_i) - s(z_i) \right].
\]

It is easy to see by conditioning that

\[
E(B_{N1} B_{N2}) = 0.
\]

LEMMA B.5: As \( N \to \infty \),

\[
E\left( B_{N2} B_{N2}^t \right) = b_N^4 \tau \tau^t + o(N^{-1}b_N^q + b_n^4).
\]

PROOF OF LEMMA B.5: Let \( c_* = E(B_{N2}) \). Now,

\[
c_* = b_N^2 \tau + o(b_n^4)
\]

By (3.1) and (B.1),

\[
E(B_{N2} B_{N2}^t) = E\left[ [B_{N2} - c_*] [B_{N2} - c_*]^t \right] + c_* c_*^t
\]

\[
= c_* c_*^t + o(N^{-1}) = b_N^4 \tau \tau^t + o(N^{-1}b_N^q + b_n^4). \quad \Box
\]
It is the calculation of the second moment matrix for $B_{N_1}$ that causes the most difficulties. Write $D(z_1) = D_1$.

**Lemma B.6**: As $N \to \infty$,

$$E\{ B_{N_1} B_{N_1}^t \} = N^{-1} E \left[ \mu_4(z) D(z) D(z)^t \right]$$

$$- N^{-1} E \left[ D(z) \psi(z) \right] E \left[ D(z) \psi(z) \right]^t + o(N^{-1}) = 0(N^{-1}).$$

**Proof of Lemma B.6**: $B_{N_1}$ is the average of mean zero but not independent random variables. By Lemma B.2, we have

$$E\{ B_{N_1} B_{N_1}^t \} = N^{-2} \sum_{i=1}^{N} \sum_{j \neq i}^{N} E \left[ D_i D_j \xi_i \xi_j \right] + o(N^{-1}),$$

where $\xi_i = \psi_N(z_1) - s(z_1)$.

By a direct calculation,

$$E\{ \xi_i \xi_j \mid z_i, z_j \} =$$

$$= (N-1)^{-2} \sum_{k \neq i}^{N} \sum_{m \neq j}^{N} E \left[ \kappa_N(i,k) - s(z_1) \right] \left[ \kappa_N(j,m) - s(z_j) \right] \mid z_i, z_k],$$

where $\kappa_N(i,k) = e_{kx}^2 K((z_k-z_i)/b_N) \cdot \left( b_N f_{Z}(z_i) \right)$.

$$s(z_1) = E \left[ \kappa_N(i,k) \mid z_1 \right].$$

If $(i,j,k,m)$ are all distinct, the expectation is zero. There is only one case that $(k=j) \neq (i=m)$, and its contribution is of order $N^{-2}$, which is too small to matter. There are $(N-2)$ terms in which $k=m \neq i, k=m \neq j, i \neq j$. Thus, (B.3) is

$$N^{-1} \int \left[ \mu_4(v) K((v-z_1)/b_N) K((v-z_j)/b_N) f_{Z}(v) \right]$$

$$\times \left[ b_N^2 f_{Z}(z_1) f_{Z}(z_j) \right]^{-1} dv - N^{-1} \psi(z_1) \psi(z_j) + o_p(N^{-1})$$
= N^{-1} \left[ H_N(z_i, z_j) - \psi(z_i)\psi(z_j) \right] + o_p(N^{-1}).

We thus see that

\[ E\left( B_{N_1}^* B_{N_1} \right) = N^{-1} E\left[ D(z_i) D(z_j) \{ H_N(z_i, z_j) - \psi(z_i)\psi(z_j) \} \right] + o(N^{-1}). \]

To complete the proof we have to show that

(B.4) \quad E\left[ D(z_i) D(z_j) H_N(z_i, z_j) \right] = o(1).

Taking into account the form of \( H_N \), we find that (B.4) equals

\[
\int \int \int b_N^{-2} D(z_i) D(z_j) \mu_4(v) K((v-z_i)) K((v-z_j))^2 f_Z(v) \, dv \, dz_i \, dz_j
\]

\[
= \int \int \int \mu_4(v) K(w_i) K(w_j) D(v + b_N w_i) D(v + b_N w_j) f_Z(v) \, dw_i \, dw_j \, dv
\]

\[
= \int \mu_4(v) D(v) f_Z(v) \, dv + o(b_N^2),
\]

completing the proof.

\[ \square \]
