ABSTRACT

The estimation of time delay and Doppler difference of a signal arriving at two physically separated sensors is investigated in this thesis. Usually, modified cross power spectrum coupled with Doppler compensation is used to detect a common, passive signal received at two separated sensors. Another successful approach uses the cross coherence to achieve this goal. This thesis modifies these two techniques to model the Doppler difference via an autoregressive (AR) technique. Analytical results are derived and experimentally verified via a computer simulation. Performance at high and low signal to noise ratios (SNRs) is examined.

ACKNOWLEDGEMENT

I wish to gratefully express my appreciation to my thesis advisor, Professor Ralph Hippenstiel, for his invaluable efforts and patience in assisting me through my research. I also want to thank my wife Young Hi who made studying easier and our stay in Monterey very pleasant.
I. INTRODUCTION

This thesis investigates the use of autoregressive (AR) models for estimating the Doppler difference and differential time delay by processing of a narrow band signal emitted from a moving source and received at two physically separated sensors. If the signal is received at two different geographical positions even in the presence of uncorrelated noise, then, depending on the signal strength and duration, it is possible to estimate the differential time delay.

Because the source is moving, the signals that are received at the sensors may have different frequencies due to the Doppler effect. To obtain accurate differential time delay estimation, Doppler difference compensation is usually required.

This compensation can be implemented by using frequency shifting of the narrow band components of the received signal. This frequency shift can be obtained using a Fourier transform. In this thesis we use an AR model to detect the frequency shift. Using this Doppler compensation, an estimate of differential time delay can be obtained. Estimating the delay and Doppler using an AR model can be interpreted as a form of a narrow band coherence procedure, provided the estimations are properly normalized.

This thesis is arranged in six chapters and six appendices. Because the estimation of the time delay and Doppler is intimately related to the coherence between two transformed complex signals, an extensive investigation of coherence is given in Chapter II. In Chapter III, AR models, advantages of AR modeling, and AR model order selection are presented. Chapter IV is devoted to the analysis and the processing of noisy signals to estimate the differential time delay and the Doppler difference. To estimate the differential time delay, two approaches are pursued. AR model performance, Doppler estimation and two types of time delay estimation are examined in Chapter V. In the last chapter some general conclusions of the work carried out in this thesis are presented, and some suggestions for future investigations are given. Computer simulation programs are included in Appendices E and F.
II. COHERENCE

A. DEFINITION

The coefficient of coherence between two wide sense stationary random processes is the normalized cross power spectral density function defined by Wiener [Ref. 1: p. 12] as

\[ \gamma_{xy}(f) = \frac{G_{xy}(f)}{\sqrt{G_{xx}(f)G_{yy}(f)}} \]  \hspace{1cm} (2.1)

where \( f \) denotes the frequency (Hz).
\( G_{xy}(f) \) is the cross power spectrum between \( x(t) \) and \( y(t) \).
\( G_{xx}(f) \) denotes the auto power spectrum of \( x(t) \), and
\( G_{yy}(f) \) denotes the auto power spectrum of \( y(t) \).

Despite some confusion in the literature, Wiener intended for the coefficient of coherence to be complex. This is apparent since he discusses both the modulus and the argument of the coefficient of coherence.

B. PROPERTY OF THE COHERENCE FUNCTION

The power spectral density matrix \( Q(f) \) is positive semi definite. Therefore, for two random processes \( x \) and \( y \), we see that

\[ \text{det} [Q(f)] = \text{det} \begin{bmatrix} G_{xx}(f) & G_{xy}(f) \\ G_{yx}(f) & G_{yy}(f) \end{bmatrix} \geq 0 \]  \hspace{1cm} (2.2)

For real processes we have \( G_{y}(f) = G_{x}^*(f) \) and thus

\[ G_{xx}(f)G_{yy}(f) - |G_{xy}(f)|^2 \geq 0 \]  \hspace{1cm} (2.3)

where * denotes the conjugate of a complex number. And

\[ G_{xx}(f)G_{yy}(f) \geq |G_{xy}|^2 \]  \hspace{1cm} (2.4)

Furthermore, \( G_{x}(f) \) and \( G_{y}(f) \) are nonnegative, real functions of frequency. When \( G_{x}(f) \) and \( G_{y}(f) \) are strictly positive definite (i.e., \( G_{x}(f)G_{y}(f) > 0 \)), Eq. (2.4) can be divided by \( G_{x}(f)G_{y}(f) \) without changing the sense of the inequality.
This provides as an upper bound

$$|\hat{y}_{xy}(f)| \leq 1 \quad \forall f$$

and since the magnitude of any complex number is greater than or equal to zero, we have the lower bound

$$0 \leq |\hat{y}_{xy}(f)| \leq 1$$

The magnitude of the coherence function is always between zero and one. It is zero if the processes $x(t)$ and $y(t)$ are uncorrelated and it is equal to unity if there exists a linear relationship between $x(t)$ and $y(t)$. In order to define the coherence it is necessary that the numerator and denominator of Eq. (2.1) are not simultaneously equal to zero. Coherence is not defined if either auto spectra is zero.

C. COHERENCE ESTIMATION

If $X(f_i)$ denotes the Fast Fourier Transform (FFT) of the $l$th segment of $x(n)$ at frequency $f_i$, then the spectral density estimates are given by [Ref. 2: p. 22]

$$\hat{G}_{xx}(f_k) = a \sum_{i=1}^{N} |X_i(f_k)|^2$$

$$\hat{G}_{xy}(f_k) = a \sum_{i=1}^{N} X_i(f_k)Y_i^*(f_k)$$

$$\hat{G}_{yy}(f_k) = a \sum_{i=1}^{N} |Y_i(f_k)|^2$$

where $a = \frac{1}{NT_0}$.

$N$ = number of segments,
$T$ = segment length, and
$f_0$ = sampling frequency.

Finally the coherence estimation is
D. COHERENCE OF NARROW BAND SIGNALS WITH DIFFERENTIAL TIME DELAY AND DIFFERENTIAL DOPPLER

The output of the band pass filters (BPF1 and BPF2) in Figure 1 are denoted by \( X(f_k) \) and \( Y(f_k) \) respectively. Each term represents the Fourier transform of the corresponding time series evaluated at frequency \( f_k \) and time \( l \). For narrow band signals a Doppler shift corresponds to a frequency shift. If a signal arrives at the two sensors having a differential Doppler shift as well as a differential time delay, then we see that a frequency compensation and time delay compensation by the appropriate values tend to line up the signals in frequency and time. This is accomplished by using an additional Fourier transform in channel-1 of the processor and a time delay in channel-2 of the processor. Mathematically, this can be expressed as

\[
\hat{\gamma}(f_k) = \frac{\hat{G}_{xy}(f_k)}{\sqrt{G_{xx}(f_k)G_{yy}(f_k)}} \sqrt{\sum_{l=1}^{N} X(f_k)Y_l^*(f_k)} \frac{1}{\sqrt{\sum_{l=1}^{N} |X_l(f_k)|^2 \sum_{l=1}^{N} |Y_l(f_k)|^2}}
\]

Comparing this with Eq. (2.10), we see that we generalized the coherence concept. We also note that the implementation resembles a correlator, where one of the signals is frequency compensated and the time delay corresponds to the delay operation of the correlator.
If the Figure 1 is redrawn as in Figure 2, then it can be interpreted as an IIT implementation as shown in Figure 3.

Figure 1. Coherence estimation block diagram.

Figure 2. Coherence estimation block diagram (reinterpretation).
Figure 3. Coherence estimation block diagram using the FFT.

But this FFT has a poor resolution. To obtain a better resolution, an AR model is desirable. This approach is shown in Figure 4.

Figure 4. Coherence estimation block diagram using an AR model.

Figure 1 and Figure 4 represent two different schemes to compute the coherence function. Differential time delay and Doppler difference can be estimated by using AR models in the modeling of the coherence function.
III. AUTOREGRESSIVE (AR) MODELS

A. AR MODELING

If the following difference equation is satisfied, the resulting structure is called an AR model of order $p$. [Ref. 3: p. 177]

$$x(n) = - \sum_{k=1}^{p} a_k x(n - k) + u(n)$$  \hspace{1cm} (3.1)

where $x(n) =$ the signal at instant $n$, 
$u(n) =$ the white noise driver, and 
$a_i =$ the $k$th coefficient of the AR model.

A realization of the AR model is illustrated in Figure 5.

---

Figure 5. AR filter of order $p$. 
B. ADVANTAGES OF THE AR MODEL

The motivation for parametric modeling of random processes is the ability to obtain better spectral estimates based upon the model than estimates produced by classical spectral estimation. Both the periodogram and correlation methods can be used to yield Power Spectral Density (PSD) estimates. The unavailable data or autocorrelation sequence (ACS) values outside a given window are assumed to be zero. This kind of an unrealistic assumption leads to distortions in the spectral estimate.

The advantages of the AR approach are

1. AR spectra tend to have sharp peaks, a desirable feature of high resolution spectral estimators.
2. AR parameter can be obtained as solutions to linear equations.

C. POWER SPECTRAL DENSITY

Eq. (3.1) can be rewritten as follows

\[ x(n) = -\sum_{k=1}^{p} a_k x(n - k) + u(n) \]

\[ = \sum_{k=0}^{\infty} h_k u(n - k) \quad (3.2) \]

where \( h_i \) = the causal filter impulse response.

Let us take the \( Z \)-transform of Eq(3.2).

\[ X(z) = H(z)U(z) \quad (3.3) \]

Rewriting Eq. (3.1) as

\[ \sum_{k=0}^{p} a_k x(n - k) = u(n) \quad (3.4) \]

where \( a_0 = 1 \), and taking the \( Z \)-transform gives

\[ A(z)X(z) = U(z) \quad (3.5) \]

Eq. (3.3) and Eq. (3.5) can be solved to obtain \( H(z) \)
$H(z) = \frac{1}{A(z)} \quad (3.6)$

and hence

$X(z) = \frac{U(z)}{A(z)} \quad (3.7)$

The $Z$-transform of the output sequence \( \{x(n)\} \) is related to the $Z$-transformation of the input random process \( u(n) \) by [Ref. 4: p. 56]

$$P_{xx}(z) = X(z)X^*\left( \frac{1}{z} \right) = \frac{U(z)U^*\left( \frac{1}{z} \right)}{A(z)A^*\left( \frac{1}{z} \right)} = \frac{P_{uu}(z)}{A(z)A^*\left( \frac{1}{z} \right)} \quad (3.8)$$

The AR power spectral density is obtained by substituting \( z = e^{j\omega T} \) into Eq. (3.8) and scaling it by the interval \( T \).

$$P_{AR}(f) = T\rho_\omega \frac{1}{|A(f)|^2} = T\rho_\omega \frac{1}{e_p^H(f)aH^e_p(f)} \quad (3.9)$$

where \( c_\omega = [1, e^{-j2\pi f}, ..., e^{-j2\pi Tf}]^T \)

\( a = [a_1, a_2, ..., a_p]^T \)

\( \rho_\omega = \) variance of driving sequence.

**D. BURG'S ALGORITHM**

In practice, the autocorrelation is usually not available, so one must make an AR spectral estimation based on the available data samples. The simplest procedure to obtain an AR spectral estimate from data samples would be to produce estimates of the autocorrelation sequence from the data. These autocorrelation estimates would be used in lieu of the true autocorrelation sequence in the YULE-WALKER equations to yield the AR coefficients. However better results are obtained, particularily for short data segments, by algorithms that obtain the AR model parameters directly from the data, without explicitly estimating the autocorrelation function.

The Levinson recursive solution to the YULE-WALKER equations relates the \( p \)th order AR parameters to the \( p - 1 \)th order parameters as given by [Ref. 3: p. 211]

$$a_p(n) = a_{p-1}(n) + k_p a_{p-1}^*(p - n) \quad (3.10)$$
For \( n = 1 \) to \( n = p - 1 \), the reflection coefficients \( k_r \) can be found by using the known autocorrelation function for lag 0 to \( p - 1 \). So we have

\[
\frac{- \sum_{n=0}^{p-1} a_{p-1}(n)r_{xx}(p-n)}{p_{p-1}}
\]

The recursion for the driving white noise variance is given by

\[
\rho_p = \rho_{p-1}(1 - |k_p|^2)
\]

where \( \rho_0 = r_{xx}(0) \).

But the ACS is not available, hence we can not calculate the reflection coefficients. The Burg algorithm provides an estimate of the reflection coefficients which in turn are obtained through a least squares criterion.

The forward linear prediction error is given by

\[
e_p^f(n) = x(n) + \sum_{m=1}^{p} a_p^f(m)x(n - m)
\]

while the backward linear prediction error is given by

\[
e_p^b(n) = x(n - p) + \sum_{m=1}^{p} a_p^b(m)x(n + m - p)
\]

Substitution of Eq. (3.10) into Eq. (3.13) and Eq. (3.14) yields the recursive relationships

\[
e_p^f(n) = e_{p-1}^f(n) + k_p e_{p-1}^b(n - 1)
\]

\[
e_p^b(n) = e_{p-1}^b(n - 1) + k_p e_{p-1}^f(n)
\]

At each order \( p \), the arithmetic mean of the forward and backward linear prediction error power (sample prediction error variance) is given by
\[
\rho_p^b = \frac{1}{2} \left[ \frac{1}{N} \sum_{n=p+1}^{N} |e_p'(n)|^2 + \frac{1}{N} \sum_{n=p+1}^{N} |e_p^b(n)|^2 \right]
\]

(3.17)

This expression is minimized, subject to the recursion given by Eq. (3.15) and Eq. (3.16). Thus, \( \rho_p^b \) is a function of single parameter, namely the complex valued reflection coefficient \( k_p \). Setting the complex derivative of Eq. (3.17) to zero

\[
\frac{\partial \rho_p^b}{\partial \text{Re}(k_p)} + j \frac{\partial \rho_p^b}{\partial \text{Im}(k_p)} = 0
\]

(3.18)

and solving for \( k_p \) yields

\[
\hat{k}_p = \frac{-2 \sum_{n=p+1}^{N} e_p'(n)e_p^b^*(n-1)}{\sum_{n=p+1}^{N} |e_p'(n)|^2 + \sum_{n=p+1}^{N} |e_p^b(n-1)|^2}
\]

(3.19)

The estimation of the reflection coefficient represents the HARMONIC mean between the forward and backward partial correlation coefficient, where \( e_n'(n) = e_n^b(n) = x(n) \) and \( N \) = number of data points.

E. FINAL PREDICTION ERROR (FPE) CRITERION

Because the best choice of filter order is not generally known a priori, it is usually necessary in practice to postulate several model orders. FPE is a kind of criterion which was provided by Akaike [Ref. 3: p. 230]. This criterion selects the order of the AR process so that the average error variance equals the sum of the power in the unpredictable part of the process and of a quantity representing the inaccuracies in estimating the AR parameters. The FPE for an AR process is defined as

\[
FPE(p) = \hat{\rho}_p^{N/(p+1)}
\]

(3.20)
where $N$ is the number of data samples,

$p$ is order of the filter, and

$\hat{\rho}_p$ is the estimated white noise variance when using a $p$ th order filter. The order $p$ selected is the one for which the FPE is minimum.
IV. DOPPLER AND DIFFERENTIAL TIME DELAY ESTIMATION

A. DOPPLER ESTIMATION

Let $x(t)$ and $y(t)$ be the signals received by two sensors

$$x(t) = \cos(2\pi(f + \alpha_1)t)$$

$$y(t) = \cos(2\pi(f + \alpha_2)t)$$

where $f$ is the carrier frequency,

$\alpha_1$, $\alpha_2$ are Doppler shifts, and

$t$ is the time variable.

Let $f_s$ be the sampling frequency which satisfies the Nyquist theorem. For convenience, in all derivations and simulations a sampling frequency of 64 Hz is used, together with band pass filter width of 1 Hz. We assume that $|\alpha_i| < 0.5$ ($i = 1,2$) which implies that the signals stay in the band pass filter regions of their respective band pass filters regardless of any Doppler shift. Note, these values can be modified to arbitrary sampling rates and pass band regions. The sampling rate is given by

$$f_s \geq 2f + 1 > 2(f + \alpha_i) \quad (i = 1,2)$$

(4.3)

The phase at instant $k$ and sampling time interval $T$ are given by

$$x\phi_k = \frac{2\pi(f + \alpha_1)k}{f_s}$$

$$y\phi_k = \frac{2\pi(f + \alpha_2)k}{f_s}$$

$$T = \frac{1}{f_s}$$

(4.4)

(4.5)

(4.6)

Let $x(n)$ denote the sampled analog signal $x(t)|_{mT}$ then

$$x(n + m) = \cos\{2\pi(f + \alpha_1)\frac{n}{f_s} + x\phi_m\}$$

(4.7)
\[ y(n + m) = \cos\left(2\pi(f + \alpha_2) \frac{n}{f_s} + \phi_m\right) \]  
\[ (4.8) \]

The derivations of Eq. (4.7) and Eq. (4.8) are given in Appendix A.

These signals, \( \{x(n)\} \) and \( \{y(n)\} \), are processed to detect the Doppler difference. Let BPF1 be the band pass filter centered at \( f_1 \) and BPF2 be the band pass filter centered at \( f_2 \) (where \( f_2 \) might equal \( f_1 \)). \( N \) data points are processed in the band pass filters, to generate one output. The inputs to BPF1 and BPF2 at time \( m \) are vectors \( X_m(n) \) and \( Y_m(n) \), respectively. The size of the input vector to the filter is the number of data points taken during 1 second (i.e., the number of points processed in the filter = \( N = f_1 \)). The input vectors are denoted by

\[ X_m(n) = [x(n), x(n + 1), \ldots, x(n + N - 1)] \]  
\[ (4.9) \]

\[ Y_m(n) = [y(n), y(n + 1), \ldots, y(n + N - 1)] \]  
\[ (4.10) \]

The filtering is performed using FFTs, where successive FFT outputs are generated at the input data rate. The BPF2 output is conjugated.

To avoid the complexity the following four complex constant variables are defined:

\[ A_x = \sum_{n=0}^{N-1} \cos\left(2\pi(f + \alpha_1) \frac{n}{f_s} \right) e^{-j2\pi f \frac{n}{N}} \]  
\[ (4.11) \]

\[ B_x = \sum_{n=0}^{N-1} \sin\left(2\pi(f + \alpha_1) \frac{n}{f_s} \right) e^{-j2\pi f \frac{n}{N}} \]  
\[ (4.12) \]

\[ A_y = \sum_{n=0}^{N-1} \cos\left(2\pi(f + \alpha_2) \frac{n}{f_s} \right) e^{j2\pi f \frac{n}{N}} \]  
\[ (4.13) \]

\[ B_y = \sum_{n=0}^{N-1} \sin\left(2\pi(f + \alpha_2) \frac{n}{f_s} \right) e^{j2\pi f \frac{n}{N}} \]  
\[ (4.14) \]

At instant \( m \) the complex output signal of BPF1 can be calculated as follows
\[ X_m(f) = \sum_{n=0}^{N-1} \cos\{2\pi(f + \alpha_1) \frac{n}{f_s} + x\phi_m\} e^{-j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=0}^{N-1} \left[ \cos\{2\pi(f + \alpha_1) \frac{n}{f_s}\} \cos x\phi_m - \sin\{2\pi(f + \alpha_1) \frac{n}{f_s}\} \sin x\phi_m \right] e^{-j2\pi f \frac{n}{N}} \]

\[ = \cos x\phi_m \sum_{n=0}^{N-1} \cos\{2\pi(f + \alpha_1) \frac{n}{f_s}\} e^{-j2\pi \frac{n}{N}} - \sin x\phi_m \sum_{n=0}^{N-1} \sin\{2\pi(f + \alpha_1) \frac{n}{f_s}\} e^{-j2\pi \frac{n}{N}} \]

\[ = A_x \cos x\phi_m - B_x \sin x\phi_m \]

\[ = \frac{A_x e^{j\phi_m} + e^{-j\phi_m}}{2} - \frac{B_x e^{j\phi_m} - e^{-j\phi_m}}{2j} \]

\[ = \frac{A_x + jB_x}{2} e^{j\phi_m} + \frac{A_x - jB_x}{2} e^{-j\phi_m} \]

\[ = \frac{A_x + jB_x}{2} e^{j\phi_m} (\frac{f + \alpha_1}{f_s})^m + \frac{A_x - jB_x}{2} e^{-j\phi_m} (\frac{f + \alpha_1}{f_s})^m \]

The complex signal \( X_m(f) \) contains two frequencies with different amplitudes.

To understand the character of \( X_m(f) \), it is important to evaluate which is the dominant term in the above expression.

\[ A_x + jB_x = \sum_{n=0}^{N-1} \left[ \cos\{2\pi(f + \alpha_1) \frac{n}{f_s}\} + j \sin\{2\pi(f + \alpha_1) \frac{n}{f_s}\} \right] e^{-j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=0}^{N-1} e^{j2\pi(f + \alpha_1) \frac{n}{f_s}} e^{-j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=0}^{N-1} e^{j2\pi x_1 \frac{n}{N}} \]

\[ = \frac{1 - e^{j2\pi x_1}}{1 - e^{j2\pi x_1}} \]
From Appendix C

\[ |A_x + jB_x| > |A_x - jB_x| \]  \hspace{1cm} (4.18)

Therefore \( \frac{A_x + jB_x}{2} e^{j\phi_m} \) is the dominant term of \( Y_m(f) \).

In similar way, the complex output signal of BPF2 can be calculated as follows

\[ Y_m^*(f) = \sum_{n=0}^{N-1} \cos(2\pi(f + \alpha_2) \frac{n}{f_s}) e^{j2\pi \frac{n}{N}} \]
\[ = \sum_{n=0}^{N-1} \left[ \cos(2\pi(f + \alpha_2) \frac{n}{f_s}) \cos \phi_m - \sin(2\pi(f + \alpha_2) \frac{n}{f_s}) \sin \phi_m \right] e^{j2\pi \frac{n}{N}} \]
\[ = \cos \phi_m \sum_{n=0}^{N-1} \cos(2\pi(f + \alpha_2) \frac{n}{f_s}) e^{j2\pi \frac{n}{N}} - \sin \phi_m \sum_{n=0}^{N-1} \sin(2\pi(f + \alpha_2) \frac{n}{f_s}) e^{-j2\pi \frac{n}{N}} \]
\[ = A_v \cos \phi_m - B_v \sin \phi_m \]
\[ = A_y e^{j\phi_m} + e^{-j\phi_m} \]
\[ = \frac{A_y + jB_y}{2} e^{j\phi_m} + \frac{A_y - jB_y}{2} e^{-j\phi_m} \]
\[ = \frac{A_y + jB_y}{2} e^{j2\phi \frac{(f + \alpha_2)}{f_s}} m + \frac{A_y - jB_y}{2} e^{-j2\phi \frac{(f + \alpha_2)}{f_s}} m \]

The complex signal \( Y_m^*(f) \) contains two frequencies with different amplitudes.
Even though $Y_n(f)$ is similar in form to $X_n(f)$, it is not obvious which term is dominant.

\[ A_y + jB_y = \sum_{n=1}^{N-1} \left[ \cos\left(2\pi(f + \alpha_2) \frac{n}{f_s}\right) + j\sin\left(2\pi(f + \alpha_2) \frac{n}{f_s}\right) \right]e^{j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=1}^{N-1} e^{j2\pi(f + \alpha_2) \frac{n}{f_s}} e^{j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=1}^{N-1} e^{j2\pi(2f + \alpha_2) \frac{n}{N}} \]

\[ = \frac{1 - e^{j2\pi(2f + \alpha_2)}}{1 - e^{j2\pi(2f + \alpha_2) \frac{1}{N}}} \]

\[ = \frac{1 - e^{j2\pi \alpha_2}}{1 - e^{j2\pi \alpha_2 \frac{1}{N}}} \] \hspace{1cm} (4.20)

\[ A_y - jB_y = \sum_{n=1}^{N-1} \left[ \cos\left(2\pi(f + \alpha_2) \frac{n}{f_s}\right) - j\sin\left(2\pi(f + \alpha_2) \frac{n}{f_s}\right) \right]e^{j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=1}^{N-1} e^{-j2\pi(f + \alpha_2) \frac{n}{f_s}} e^{j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=0}^{N-1} e^{-j2\pi \alpha_2} \frac{n}{N} \]

\[ = \frac{1 - e^{-j2\pi \alpha_2}}{1 - e^{-j2\pi \alpha_2 \frac{1}{N}}} \] \hspace{1cm} (4.21)

From Appendix C

\[ |A_y - jB_y| > |A_y + jB_y| \]

Therefore \( \frac{A_y - jB_y}{2} e^{j\phi_0} \) is the dominant term of $Y_n(f)$. 

17
Since the two output sequences \( \{X_\nu(f)\} \) and \( \{Y_\nu(f)\} \) have two sinusoidal components each, their product \( \{X_\nu(f)Y_\nu(f)\} \) has four sinusoidal components. The four frequencies are
\[
\omega_1 = 2\pi \frac{(\alpha_1 - \alpha_2)}{f_s}, \quad \omega_2 = 2\pi \frac{(\alpha_2 - \alpha_1)}{f_s}, \quad \omega_3 = 2\pi \frac{(2f + \alpha_1 + \alpha_2)}{f_s}, \quad \omega_4 = -2\pi \frac{(2f + \alpha_1 + \alpha_2)}{f_s}
\]
with \( \omega_1 \) the sinusoid with the largest amplitude and \( \omega_2 \) the sinusoid with the smallest amplitude.

The product of the output of the filters is given by
\[
X_m(f)Y_m^*(f) = \frac{A_x + jB_x}{2} e^{j\phi_m} \frac{A_y - jB_y}{2} e^{-j\phi_m} + F(\alpha_1, \alpha_2, x\phi_m, y\phi_m)
\]
\[
= \frac{(A_x + jB_x)(A_y - jB_y)}{2} e^{j(\phi_m - \phi_m)} + F(\alpha_1, \alpha_2, x\phi_m, y\phi_m)
\]  \hspace{1cm} (4.23)

where \( F(\alpha_1, \alpha_2, x\phi_m, y\phi_m) \) represents the three low amplitude frequency terms.

When using the AR model as described in chapter III, at a high SNR (i.e., \( SNR \to \infty \)), a 4th order AR model detects all of the four frequencies given above. When the SNR is low (i.e., 20 dB), only one dominant sinusoid is detected with frequency
\[
\omega_1 = \frac{2\pi(f + \alpha_1)}{f_s} - \frac{2\pi(f + \alpha_2)}{f_s}
\]
\[
= 2\pi \frac{(\alpha_1 - \alpha_2)}{f_s}
\]  \hspace{1cm} (4.24)

Since we can detect \( \omega_1 \) and know the value of \( f_s \), \( \alpha_1 - \alpha_2 \) can be estimated by using an AR model.

**B. DIFFERENTIAL TIME DELAY ESTIMATION**

To detect and localize a target, it is important to find the differential time delay of signals arriving at two sensors. Let us assume that signals at the two sensors are as given in Figure 6 (i.e., zero differential time delay) For the remainder of the figures, the time axis is scaled to be 64 points per second.
We can estimate the differential time delay and differential Doppler using two different approaches. The first approach uses the cross power spectrum while the second approach uses the coherence.

1. **Differential time delay and differential Doppler estimation using the cross power spectrum.**

Figure 4 shows the block diagram of the coherence estimator using AR modeling. In this figure, the output of the FFT can be interpreted as the cross power spectrum. Using this cross power spectrum, we can estimate the differential time delay and the differential Doppler. But when we use the highest peak of the cross power spectrum, the peak is sometimes not detected at the proper time delay nor at the proper Doppler shift. We will show a special case in which the peak of the power spectrum is not detected at the proper time delay nor at the proper Doppler values.
a. Special case.

For our test case the data duration is six seconds, two seconds of the noisy signal and four seconds of noise only. Linear transformation of this data leads to one of three types of outputs. The first type represents full information, while the second type represents partial information. The third type represents a noise only condition. Generally when two signals are lined up in time, the AR model should give the highest output power. But this is wrong in some cases. In the full information case, the magnitude of transformed signal is high and constant. For some reduced information case, even though the magnitude of the transformed signal decreases, it still may have large magnitude of spectral components. This phenomenon can be explained as follows.

Define two functions depending on $k$

\[
k A_y = \sum_{n=0}^{N-1-k} \cos(2\pi f_2 \frac{n}{f_s}) e^{j2\pi f_2 \frac{n}{N}}
\]

\[
k B_y = \sum_{n=0}^{N-1-k} \sin(2\pi f_2 \frac{n}{f_s}) e^{j2\pi f_2 \frac{n}{N}}
\]

where $f_2 = f + \alpha_2$.

$k$ denotes the number of lost data at BPF2 input vector.

We assume that we know when the BPFI signal starts. If this information is not available, we need to examine the signal at the output of BPFI, to obtain a candidate time frame. Consider the input of AR model as shown in Figure 7.

The input data size to the AR model is the number of linearly transformed data points during a given period (i.e., input size is $N = f_s$). The BPFI output represents full information (i.e., each output element is produced from the signal information points). Therefore, as shown in the previous section, the dominant output sequence is

\[
k_1 e^{j0}, k_1 e^{j\phi_1}, k_1 e^{j\phi_2}, k_1 e^{j\phi_3}, ..., k_1 e^{j\phi_{N-1}}
\]

where

\[
k_1 = \frac{1}{2} \frac{1 - e^{j2\pi x_1}}{1 - e^{j2\pi x_1} \frac{1}{N}}
\]
Figure 7. AR model and its driver source.

\((1)\) 0 second delay case. We already defined the input vector \(X_m(n)\) and \(Y_m(n)\) to BPF1 and BPF2. This vector can be interpreted as a time snap shot. Each output of the BPF requires \(N\) input points. If we require \(N\) output points from the BPF, even using maximum overlap in the processing, we require at least \(2N - 1\) points at the BPF input. Figure 8 shows the \(2N\) input to BPF1 and BPF2. Both \(2N\) input points contain the signal and some noise. As shown in Figure 8, in the zero delay case, the two input vectors \(X_m(n)\) and \(Y_m(n)\) \((0 \leq m \leq N)\) provide full information. So the linearly transformed output \(X_m(f_i)\) and \(Y_m(f_i)\) also represent full information.

The dominant part of the BPF2 output is the sequence

\[
k_2 e^{-j\theta_0}, \ k_2 e^{-j\phi_1}, \ k_2 e^{-j\phi_2}, \ k_2 e^{-j\phi_3}, \ldots, \ k_2 e^{-j\phi_{N-1}}
\]  

(4.29)

where

\[
k_2 = \frac{1}{2} \frac{1 - e^{-j2\pi2}}{1 - e^{-j2\pi2} \frac{1}{N}}
\]  

(4.30)
The dominant input sequence to the AR model is given by
\[ \{ k, k_2 e^{j(k\phi_k - j\phi_s)} \}, \quad k = 0, 1, 2, \ldots, N - 1 \]  
(4.31)

where the magnitude is \( k \).

\( 2 \) - 1 second delay case. Figure 9 shows the 2N input to BPF1 and BPF2. The 2N input data points of BPF1 contain the signal and noise. During the first \( N \) points the input to BPF2 contains the signal plus noise while during the second \( N \) points only noise is present. The input vector \( X_s(n) \) of BPF1 contains full information, but input vector \( Y_s(n) \) of BPF2 does not contain full information. In the \( Y_s(n) \) case, every element of \( Y_s(n) \) is full information. But when \( k \) is not equal to zero then \( Y_s(n) \) consists of \( N - k \) information elements and \( k \) noise elements.
Figure 9. Two signals, -1 second delay at the sensors.

The output from BPF2 represents partial information while the output from BPF1 represents full information. The BPF2 output sequence is given by

\[ \left\{ \frac{kA_y + jkB_y}{2} e^{j\phi_k} + \frac{kA_y - jkB_y}{2} e^{-j\phi_k}, \quad k = 0, 1, ..., N - 1 \right\} \] (4.32)

The derivation of Eq. (4.32) is given in Appendix B.

Assuming that \( \frac{kA_y - jkB_y}{2} e^{-j\phi_k} \) is the dominant term, which is a valid assumption for our test case with \( f_i = 64Hz, f = 23Hz, \alpha_1 = 0.4Hz \) and \( \alpha_2 = 0.001Hz \), then the input sequence to the AR model is dominated by

\[ \left\{ k_i \frac{kA_y - jkB_y}{2} e^{j(\alpha_k + \phi_k)}, \quad k = 0, 1, 2, ..., N - 1 \right\} \] (4.33)

with \( k_i \) is defined earlier (Eq. (4.2S)).
The magnitude of dominant input sequence is obtained by examining

\[ k \cdot A_y - j_k B_y = \sum_{n=0}^{N-1-k} \left[ \cos(2\pi(f + \alpha_2)) - j \sin(2\pi(f + \alpha_2)) \right] e^{j2\pi fc/N} \]

\[ = \sum_{n=0}^{N-1-k} e^{-j2\pi(n + \alpha_2) fc} e^{j2\pi f c/N} \]

\[ = \sum_{n=0}^{N-1-k} e^{-j2\pi \alpha_2 \frac{n}{N}} \]

\[ = 1 - e^{-j2\pi \frac{N-k}{N} \alpha_2} \]

When we compare the magnitude of the sequence in Eq. (4.27) and the magnitude of the dominant term in Eq. (4.32), the magnitude of \(|k_y|\), \(-j_k B_y|/2\) where

\[ k = \frac{1}{2} \frac{1 - e^{-j2\pi x_2}}{1 - e^{-j2\pi x_2}} \]

and

\[ \frac{\mu \cdot A_y - j_k B_y}{2} = \frac{1}{2} \frac{1 - e^{-j2\pi \frac{N-k}{N} \alpha_2}}{1 - e^{-j2\pi x_2}} \]

\[ = \frac{1}{2} \frac{e^{0}}{1 - e^{-j2\pi x_2 \frac{1}{N}}} - \frac{1}{2} \frac{e^{-j2\pi x_2}}{e^{2\pi \alpha_2} \frac{1}{N}} \]  

We note that Eq. (4.35) has two frequencies (i.e., 0 and \(\frac{\alpha_2}{N} 2\pi\)).

The magnitudes of both terms are

\[ \frac{1}{|1 - e^{-j2\pi x_2 \frac{1}{N}}|} \]

Now, note that as long as \(|\alpha_2| < \frac{1}{6}\), then the magnitudes of both terms in Eq. (4.35) are larger than \(|k_y|\).

Due to the symmetry a positive delay results in a similar response to a negative delay, and hence Eq. (4.35) holds also for delay of +1 second. Equation (4.35) can be interpreted as having large responses at shifted Doppler values at a delay of 1 second and a delay...
of -1 second. Proper delay can not be established nor can the Doppler value be established. This cross power spectrum algorithm will not give good information about either Doppler difference or time delay.

2. Modified cross power spectrum.

To detect the signal, input signals to the AR model should be preprocessed as shown Figure 10. If the BPF2 output signal is magnitude normalized, then this normalized signal retains good phase information. When we normalize the BPF2 output, one of two conditions can occur. The first condition (i.e., synchronized) leads to the magnitude normalization of Eq. (4.29) and provides accurate frequency and delay estimation. The second condition occurs when the signal in channel-2 is not lined up in time with the signal in channel-1 (i.e., during the delay search). Under this condition smaller peaks in the time Doppler plane appear at incorrect values of time delay and Doppler. Above 70 dB SNR, the correct peak is the dominant one and allows proper estimation. Information from contour plots can be used at values of SNR between 70 and 10 dB (see Appendix D).

![Figure 10. Modified cross power spectrum block diagram.](image)

2. Differential time delay and differential Doppler estimation using the coherence.

Another way detecting the signal is normalization of the AR output with the squared root of the product of $P_{xx}(f)$ (auto spectrum of $x$) and $P_{yy}(f)$ (auto spectrum of $y$). This can be done using two additional AR models as shown in Figure 11.
Using the AR approach, $\rho_{xx}$, $\rho_{yy}$, $\rho_{xx}$, and AR coefficients can be obtained. Therefore we get

\[ P_{xx}(f) = \frac{T\rho_{xx}}{|A_{xx}(f)|^2} \]  \hspace{1cm} (4.36)

\[ P_{yy}(f) = \frac{T\rho_{yy}}{|A_{yy}(f)|^2} \]  \hspace{1cm} (4.37)

\[ P_{xyxy}(f) = \frac{T\rho_{xyxy}}{|A_{xyxy}(f)|^2} \]  \hspace{1cm} (4.38)

Figure 11. AR model of coherence.
\[ P_{yy}(f) = \frac{T \rho_{yy}}{|A_{yy}(f)|^2} \]  
(4.37)

\[ P_{xyxy}(f) = \frac{T \rho_{xyxy}}{|A_{xyxy}(f)|^2} \]  
(4.38)

where \( P_x(f) \) is the power spectrum of \( X_t \),
\( P_{yy}(f) \) is the power spectrum of \( Y_{t-d} \),
\( P_{xy}(f) \) is the power spectrum of \( X_tY_{t-d} \),
\( A_{xx}(f) \) is the AR power spectral density of \( X_t \),
\( A_{yy}(f) \) is the AR power spectral density of \( Y_{t-d} \),
\( A_{xyxy}(f) \) is the AR power spectral density of \( X_tY_{t-d} \) cross term,
\( \rho_x \) is the driving noise variance of \( X_t \),
\( \rho_y \) is the driving noise variance of \( Y_{t-d} \),
\( \rho_{xy} \) is the driving noise variance of \( X_tY_{t-d} \), and
\( T = \frac{1}{f} \).

We obtain a coherence estimate from the three power spectra, by assuming that
\[ |P_x(f)|^2 \approx |P_{xy}(f)| \, . \]

\[ \hat{\gamma}^2 = \frac{|P_{xy}(f)|^2}{|P_{xx}(f)P_{xy}(f)|} \approx \frac{|P_{xyxy}(f)|}{|P_{xx}(f)P_{yy}(f)|} = \frac{1}{T} \frac{\rho_{xyxy}}{\rho_{xx}\rho_{yy}} \frac{|A_{xx}(f)A_{yy}(f)|^2}{|A_{xyxy}(f)|} \]  
(4.39)

\[ \hat{\gamma} = \sqrt{\frac{1}{T} \frac{\rho_{xyxy}}{\rho_{xx}\rho_{yy}} \frac{|A_{xx}(f)A_{yy}(f)|^2}{|A_{xyxy}(f)|}} \]  
(4.40)

This approach provides good information about the differential time delay and differential Doppler down to SNRs of 20 dB.
V. RESULTS

This chapter presents graphical results obtained by applying the analytical results of the previous chapters to specific examples and carrying out the required computations on the computer.

A. AR MODEL

This section provides the AR model performance tests. As we discussed in chapter III, Burg's algorithm is applied to this AR model. The FPE criterion is used to find the AR model order. Figure 12 is the power spectrum of two test signals \(\sin(\omega_1 Tn)\) and \(\cos(\omega_1 Tn)\). Figure 13 shows the power spectrum of two other test signals \(\sin(\omega_2 Tn)\) and \(\cos(\omega_2 Tn)\). Both sets of test signals have an \(SNR\) of 20 dB. The frequency \(f_1\) is 13.45 Hz and \(f_2\) is 23.45 Hz and \(T = \frac{1}{64}\) second.

Theoretically, the power spectrum of these signals have two impulse functions at \(f_i\) and \(-f_i\) (\(i = 1, 2\)). Figures 12 and 13 show experimental results agreeing with the theoretical results. Figures 12 and 13 indicate which frequency has high power but they provide no phase information.

The AR model is sensitive to frequency but is not sensitive to the phase. For any selection of frequency \(f\) which satisfies the Nyquist theorem, the AR model provides good frequency estimation provided the \(SNR\) is sufficient large.
Figure 12. AR model performance test 1 (SNR = 20 dB).
Figure 13. AR model performance test 2 (SNR = 20 dB).
B. DOPPLER ESTIMATION

In section A of chapter IV, we discussed five items.

1. BPF1 and BPF2 outputs have two sinusoidal components each.

2. For BPF1, the dominant frequency is designated as $\omega_x$ and for BPF2, the dominant frequency is designated as $\omega_y$, where

   \[
   \omega_x = \frac{2\pi(f + \alpha_1)}{f_s}
   \]

   \[
   \omega_y = \frac{-2\pi(f + \alpha_2)}{f_s}
   \]

3. The power spectrum of cross term of BPF1 and BPF2 has four components which can be detected in very high SNR (i.e. $SNR = 100 \text{ dB}$).

4. When the $SNR$ is low (i.e. $SNR = 20 \text{ dB}$), only one dominant frequency component is detected.

5. The dominant frequency of the power spectrum $P_{xy}(f)$ corresponds to the differential Doppler frequency.

Figure 14 shows the power spectrum of the BPF1 output when $f$ is 13 Hz, $\alpha_1$ is 0.45 Hz, and $f_s$ is 64 Hz. Figure 15 shows the power spectrum of the BPF2 output when $f$ is 13 Hz, $\alpha_2$ is -0.45 Hz, and $f_s$ is 64 Hz. As expected both figures show two spectral lines when the $SNR$ is 100 dB. The dominant frequencies are located at $f$ equal 13.45 Hz for BPF1, and at $f$ equal -12.55 Hz for BPF2. Figure 16 shows the power spectrum of the cross term of BPF1 and BPF2. This figure shows four spectral lines at an $SNR$ of 100 dB, while only one dominant frequency is detected at an $SNR$ of 20 dB. Dominant frequencies are always located between $-1 \text{ Hz}$ and $1 \text{ Hz}$. Figure 17 shows a subplot of Figure 16 for frequency between $-1 \text{ Hz}$ and $1 \text{ Hz}$. This figure shows the dominant frequency $f = 0.9 \text{ Hz}$ and the smaller spectral component at $f \approx -0.9 \text{ Hz}$ for an $SNR$ of 100 dB. Only one dominant frequency can be detected at $f$ equal 0.9 Hz for an $SNR$ of 20 dB. Doppler difference from the dominant spectral component corresponds to the true Doppler difference $\alpha_1 - \alpha_2$, which is 0.9 Hz.

Figure 18 shows a comparison for $SNR$ of 20 dB and 10 dB. Figure 19 is subplot of Figure 18 for $-1 \text{ Hz} < f < 1 \text{ Hz}$. From this figure, when $SNR = 10 \text{ dB}$, the dominant frequency is shifted a little bit from the true Doppler difference. We have shown the five issues as we have discussed in the previous chapter. In summary, for $SNRs$ greater than or equal to 20 dB, the power spectrum of the cross term provides good Doppler estimation.

Figure 17. Subplot of the cross power spectrum.
Figure 18. Comparison the Doppler estimation at two different SNR's.
Figure 19. Subplot of the Doppler estimation.
C. DIFFERENTIAL TIME DELAY ESTIMATION

In Chapter IV section B.1.a we discussed the problems associated with using unnormalized quantities and suggested two possible approaches to solve the problem. In this section we will show that for the case of \( |\alpha_2| < \frac{1}{6} \) Hz, the power spectrum of a non-delayed signal is smaller than the power spectrum of a signal delayed by one second (i.e., see discussion following Eq. (4.35)).

To estimate the time delay, we suggest the two different approaches. The first approach is the normalization of the BPF2 output. The second approach normalizes the cross term \( P_{nn}(f) \) with the power spectrum of BPF1 \( P_{1}(f) \) and the power spectrum of BPF2 \( P_{2}(f) \) through the equation defined by Eq. (4.40).

The following figures are simulations for \( f = 23 \) Hz, \( \alpha_1 = 0.23 \) Hz, \( \alpha_2 = -0.02 \) Hz, \( T = \frac{1}{64} \) second, delay of 0 and an S.NR of 100 dB. Figure 20 shows the surface plot of \( P_{nn}(f) \) while Figure 21 shows the contour plot of \( P_{nn}(f) \). Figure 22 shows the cross section plot of Figure 20 with respect to the DELAY axis. This figure shows that the power spectrum has a spurious peak at delay of one second. At the proper delay (i.e., 0 second delay) \( P_{nn}(f) \) has a relatively small value.

\( P_{nn}(f) \) is affected by two terms, namely \( \rho \) and \( \frac{1}{|A_{nn}(f)|^2} \). Figure 23 shows the maximum power spectrum term of the transfer function and Figure 24 shows the driving noise variance. At a delay of \( \pm 1 \) second and of 0 second the transfer function shows a peak while the variance of driving noise has small value. In this case, \( P_{nn}(f) \), the product of the form \( \rho \frac{1}{|A_{nn}(f)|^2} \) at 0 second delay has a smaller value than that at any other delay location. Using the scheme shown in Figure 10, we normalize the BPF2 output and present the result in Figure 25. We can detect the proper time delay and the proper Doppler difference. Figures 26 and 27 show the corresponding contour plot and the power spectrum of the normalized cross term. For any value of time delay and Doppler difference, this approach provides good information about differential Doppler and differential time delay provided the S.NR is greater than or equal to 70 dB.

Results of the second approach (Figure 11) are demonstrated in Figures 28 and 29. This approach also gives good information about differential time delay and differential Doppler. This approach provides good time delay and Doppler estimation for S.NR greater than or equal to 20 dB.

If we use the contour shape, we can also estimate the differential time delay and differential Doppler for S.NR of less than 20 dB. Differential time delay and differential Doppler estimation can be extended down to S.NR of about 0 dB when using the contour of the coherence surface. Figure 30 is a contour plot of using this second approach.
(i.e., coherence approach) for $\alpha_1 = 0.23$ Hz, $\alpha_2 = -0.02$ Hz, $\text{Delay} = 0$, and an $\text{SNR}$ of 0 dB. The contour shape of the second approach has the shape of the letter X. When the $\text{SNR}$ is greater or equal to 0 dB, the proper time delay and Doppler difference seems to be located at the cross over point of the X. When the $\text{SNR}$ is less than 0 dB, the contour shape does not shows an X clearly. In the coherence approach, Figure 31 provides the contour plot, with channel-1 containing only noise and channel-2 containing signal plus noise ($\text{SNR} = 0$ dB). Figure 32 shows the contour plot, when channel-2 contains only noise and channel-1 contains signal plus noise ($\text{SNR} = 0$ dB). Figure 33 shows the contour plot, when both channels contain noise only. The above three figures do not show an X clearly, hence do not allow signal detection for estimation of any parameter. Using this information, we can distinguish the signal combinations from the noise combinations.

When we estimate the time delay and Doppler difference using the contour plot, the modified cross power spectral approach has some problems as discussed in Appendix D.

VI. CONCLUSIONS AND RECOMMENDATIONS

In this thesis, the differential time delay and differential Doppler are estimated using two different approaches. The first approach uses a modified cross power spectrum algorithm while the second approach uses a coherence algorithm. In both cases autoregressive modeling of the required cross spectral component is used. The differential time delay and Doppler difference can be estimated using a threshold at high SNRs and a contour plot at low SNRs.

At high SNRs (i.e., $SNR \geq 70$ dB), the first approach locates the dominant peak at the proper time delay and the proper Doppler. The second approach utilizes two additional AR models and two additional FFTs to obtain the autopower spectrum of channel-1 and channel-2. At moderate SNRs (i.e., $SNR \geq 20$ dB), the second approach has the highest coherence peak at the proper time delay and Doppler frequency. When the $SNR \geq 0$ dB, the contour plot of the coherence has the shape of the letter X. The differential time delay and Doppler difference can be located at the cross over point of the X. In high $SNRs$ we can use the highest peak to detect the time delay and Doppler frequency using either approach. When we use the contour plot, the information about time delay and Doppler depends on the location and the form of the cross over point of the X.

We can estimate the differential time delay and differential Doppler using the AR modeling of coherence. But we can not get the numerically correct value of the coherence coefficient. The following three points are recommended for future study.

1. To get a cross power spectrum, we assumed that $|P_{xy}(f)| \approx |P_x(f)|^2$. This was required since we can not get a cross power spectrum using an AR model. Improvement of the cross power spectrum estimates using an AR model can lead to improvement of the algorithm.

2. Our first approach is not normalized by the auto power spectra. If we find the corresponding auto power spectra, we can also obtain a coherence coefficient estimate.

3. To get a better information at a low SNR, we need to study the characteristics of the contour plots.

54
APPENDIX A. PHASE DERIVATION

Define the phase at instant $k$.

$$x\phi_k = \frac{2\pi(f + \alpha_1)k}{f_s}$$  \hspace{1cm} (4.4)

$$y\phi_k = \frac{2\pi(f + \alpha_2)k}{f_s}$$  \hspace{1cm} (4.5)

Let $x(n)$ denote the sampled analog signal $x(t)|_{t = nT}$ then

$$x(n) = \cos\left\{2\pi(f + \alpha_1) \frac{n}{f_s}\right\}$$

$$= \cos\left\{2\pi(f + \alpha_1) \frac{n}{f_s} + \phi_0\right\}$$  \hspace{1cm} (a.1)

$$x(n + 1) = \cos\left\{2\pi(f + \alpha_1) \frac{n + 1}{f_s}\right\}$$

$$= \cos\left\{2\pi(f + \alpha_1) \frac{n}{f_s} + 2\pi(f + \alpha_1) \frac{1}{f_s}\right\}$$  \hspace{1cm} (a.2)

$$x(n + 2) = \cos\left\{2\pi(f + \alpha_1) \frac{n + 2}{f_s}\right\}$$

$$= \cos\left\{2\pi(f + \alpha_1) \frac{n}{f_s} + 2\pi(f + \alpha_1) \frac{2}{f_s}\right\}$$  \hspace{1cm} (a.3)

$$x(n + m) = \cos\left\{2\pi(f + \alpha_1) \frac{n + m}{f_s}\right\}$$

$$= \cos\left\{2\pi(f + \alpha_1) \frac{n}{f_s} + 2\pi(f + \alpha_1) \frac{m}{f_s}\right\}$$  \hspace{1cm} (4.7)

$$= \cos\left\{2\pi(f + \alpha_1) \frac{n}{f_s} + \phi_m\right\}$$

Similarly
\[ y(n) = \cos\{2\pi(f + \alpha_2) \frac{n}{f_s}\} \]
\[ = \cos\{2\pi(f + \alpha_2) \frac{n}{f_s} + \phi_0\} \quad (a.5) \]

\[ y(n + 1) = \cos\{2\pi(f + \alpha_2) \frac{n + 1}{f_s}\} \]
\[ = \cos\{2\pi(f + \alpha_2) \frac{n}{f_s} + \frac{2\pi(f + \alpha_2)}{f_s}\} \]
\[ = \cos\{2\pi(f + \alpha_2) \frac{n}{f_s} + \phi_2\} \quad (a.6) \]

\[ y(n + 2) = \cos\{2\pi(f + \alpha_2) \frac{n + 2}{f_s}\} \]
\[ = \cos\{2\pi(f + \alpha_2) \frac{n}{f_s} + \frac{2\pi(f + \alpha_2)}{f_s} + \frac{2\pi(f + \alpha_2)2}{f_s}\} \]
\[ = \cos\{2\pi(f + \alpha_2) \frac{n}{f_s} + \phi_2\} \quad (a.7) \]

\[ y(n + m) = \cos\{2\pi(f + \alpha_2) \frac{n + m}{f_s}\} \]
\[ = \cos\{2\pi(f + \alpha_2) \frac{n}{f_s} + \frac{2\pi(f + \alpha_2)m}{f_s}\} \]
\[ = \cos\{2\pi(f + \alpha_2) \frac{n}{f_s} + \phi_m\} \quad (a.8) \]
APPENDIX B. OUTPUT OF BPF2

Define two functions depending on k

\[ k_A = \sum_{n=0}^{N-1-k} \cos(2\pi f_2 \frac{n}{f_s}) e^{j2\pi \frac{n}{N}} \] (4.25)

\[ k_B = \sum_{n=1}^{N-1-k} \sin(2\pi f_2 \frac{n}{f_s}) e^{j2\pi \frac{n}{N}} \] (4.26)

where \( f_2 = f + \alpha_2 \).

A. FULL INFORMATION CASE (N POINTS)

\( N \) points are data points at BPF2 input.

\[ Y_n(f) = \sum_{n=0}^{N-1} \cos(2\pi f_2 \frac{n}{f_s} + y \phi_m) e^{j2\pi \frac{n}{N}} \]

\[ = \sum_{n=0}^{N-1} \left[ \cos(2\pi f_2 \frac{n}{f_s}) \cos y \phi_m - \sin(2\pi f_2 \frac{n}{f_s}) \sin y \phi_m \right] e^{j2\pi \frac{n}{N}} \]

\[ = \cos y \phi_m \sum_{n=0}^{N-1} \cos(2\pi f_2 \frac{n}{f_s}) e^{j2\pi \frac{n}{N}} - \sin y \phi_m \sum_{n=0}^{N-1} \sin(2\pi f_2 \frac{n}{f_s}) e^{-j2\pi \frac{n}{N}} \] (b.1)

\[ = 0 \cdot A_y \cos y \phi_m - 0 \cdot B_y \sin y \phi_m \]

\[ = 0 \cdot A_y \frac{e^{j\phi_m} + e^{-j\phi_m}}{2} - 0 \cdot B_y \frac{e^{j\phi_m} - e^{-j\phi_m}}{2j} \]

\[ = \frac{0 \cdot A_y + j_0 B_y}{2} e^{j\phi_m} + \frac{0 \cdot A_y - j_0 B_y}{2} e^{-j\phi_m} \]
B. PARTIAL INFORMATION CASE ( N-1 POINTS )

N - 1 points are data points at BPF2 input.

\[ y_m'(f) = \sum_{n=0}^{N-1} \cos(2\pi f_2 \frac{m n}{f_s} + \lambda \phi_m) e^{j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=0}^{N-1} \{ \cos(2\pi f_2 \frac{m n}{f_s}) \cos \lambda \phi_m - \sin(2\pi f_2 \frac{m n}{f_s}) \sin \lambda \phi_m \} e^{j2\pi f \frac{n}{N}} \]

\[ = \cos \lambda \phi_m \sum_{n=0}^{N-1} \cos(2\pi f_2 \frac{m n}{f_s}) e^{j2\pi f \frac{n}{N}} - \sin \lambda \phi_m \sum_{n=0}^{N-1} \sin(2\pi f_2 \frac{m n}{f_s}) e^{-j2\pi f \frac{n}{N}} \]  

\[ y_m'(f) = 1 \cdot A_x \cos \lambda \phi_m - 1 \cdot B_y \sin \lambda \phi_m \]

\[ = \frac{1}{2} A_x e^{j\phi_m} + e^{-j\phi_m} - \frac{1}{2} B_y e^{j\phi_m} - e^{-j\phi_m} \]

\[ = \frac{1}{2} A_x - j \frac{1}{2} B_y e^{-j\phi_m} \]

C. PARTIAL INFORMATION CASE ( N-K POINTS )

N - k points are data points at BPF2 input.

\[ y_m'(f) = \sum_{n=0}^{N-1-k} \cos(2\pi f_2 \frac{m n}{f_s} + \lambda \phi_m) e^{j2\pi f \frac{n}{N}} \]

\[ = \sum_{n=0}^{N-1-k} \{ \cos(2\pi f_2 \frac{m n}{f_s}) \cos \lambda \phi_m - \sin(2\pi f_2 \frac{m n}{f_s}) \sin \lambda \phi_m \} e^{j2\pi f \frac{n}{N}} \]

\[ = \cos \lambda \phi_m \sum_{n=0}^{N-1-k} \cos(2\pi f_2 \frac{m n}{f_s}) e^{j2\pi f \frac{n}{N}} - \sin \lambda \phi_m \sum_{n=0}^{N-1-k} \sin(2\pi f_2 \frac{m n}{f_s}) e^{-j2\pi f \frac{n}{N}} \]

\[ y_m'(f) = k \cdot A_x \cos \lambda \phi_m - k \cdot B_y \sin \lambda \phi_m \]

\[ = k \cdot A_x e^{j\phi_m} + e^{-j\phi_m} - \frac{k}{2} B_y e^{j\phi_m} - e^{-j\phi_m} \]

\[ = \frac{k}{2} A_x - j \frac{k}{2} B_y e^{-j\phi_m} \]
APPENDIX C. AMPLITUDE COMPARISON

Let $C_1$ and $C_2$ be the complex amplitude.

$$C_1 = \frac{1 - e^{j2\pi x}}{1 - e^{j2\pi x} \frac{1}{N}}$$  \hspace{1cm} (c.1)

$$C_2 = \frac{1 - e^{-j2\pi x}}{1 - e^{-j2\pi (2f+x)} \frac{1}{N}}$$  \hspace{1cm} (c.2)

where $|x| < 0.5$, and $N \geq 2f + 1 > 2(f + \alpha)$. The numerators of $|C_1|$ and $|C_2|$ are same, because the magnitude of the complex conjugate is the same. If we show that $|1 - e^{j2\pi \frac{x}{N}}| < |1 - e^{-j2\pi (2f+x)} \frac{1}{N}|$, then we can say $|C_1| > |C_2|$. As shown in Figure 34 $|1 - e^{j2\pi \frac{x}{N}}| = |AI|$ and $|1 - e^{-j2\pi (2f+x)} \frac{1}{N}| = |BI|$.

![Figure 34. Magnitudes of two complex number.](image)

The smallest angle $\angle AOB$ is $\frac{2\pi(2f + \alpha)}{N}$ or $\frac{2\pi(N - 2f - \alpha)}{N} = \frac{2\pi(1 - \alpha)}{N}$.

For positive $f$

$$\angle AOB = \left| \frac{2\pi (2f + \alpha)}{N} \right| > \left| \frac{2\pi \alpha}{N} \right| = \angle IOA$$  \hspace{1cm} (c.3)
Since $|1 - \alpha| > |\alpha|$, 

$$LIOB = \left| \frac{2\pi(1 - \alpha)}{N} \right| > \frac{2\pi\alpha}{N} = LIOA$$

(c.4)

From Eq. (c.3) and Eq. (c.4) $|AI| < |BI|$, therefore 

$$|C_1| > |C_2|$$

(c.5)
APPENDIX D. CONTOUR PLOTS OF MODIFIED CROSS POWER SPECTRUM

For S.NRs greater than or equal to 10 dB the contour plot of the modified cross power spectrum algorithm has the shape of a boomerang. The shape of the boomerang depends on \( \omega_2 \). Figure 35 and Figure 36 show the contour plot of the modified cross power spectrum. The two figures show the boomerang shape and their different directions. For positive \( \omega_2 \) (case 1) and negative \( \omega_2 \) (case 2) the opening of the boomerang is toward the left and right, respectively. In the both cases, we can estimate the time delay and Doppler frequency using these contour plots. The proper time delay and Doppler difference can be detected by locating the point of symmetry of the boomerang. The Figure 37 shows a contour plot when \( \omega_2 = -0.02 \text{ Hz} \). Since \( \omega_2 \) is very small, the contour plot looks like a straight line. In this case, the differential time delay and Doppler difference can still be estimated by locating the point of symmetry of the boomerang (i.e., center point). Figure 38 shows the contour plot, when channel-1 contains noise only and channel-2 contains signal plus noise (i.e., \( \text{SNR} = 10 \text{ dB} \)). Figure 39 shows the contour plot, when channel-2 contains noise only and channel-1 contains signal and noise (i.e., \( \text{SNR} = 10 \text{ dB} \)). Figure 40 shows the contour plot, when both channels contain noise only. Using the modified cross power spectrum technique, the three types of noise only set ups appear as similar plots (see Figures 38, 39 and 40). Figure 38 seems to indicate the presence of signals in both channels, while Figures 39 and 40 appear more like noise. Hence, contour plots of the modified cross power spectrum do not allow clear identification. In this case, it will be difficult to distinguish between the noise only situation and a small \( \omega_2 \) situation.

To use the modified cross power spectrum algorithm at low S.NRs (i.e., \( \text{SNR} < 70 \text{ dB} \)), we need to investigate the contour plot some more.
Figure 35. Contour plot of the modified cross power spectrum (case 1).

SNR=10 DELAY=0 α1=α2=.23
Figure 36. Contour plot of the modified cross power spectrum (case 2).
Figure 37. Contour plot of the modified cross power spectrum (case 3).
Figure 38. Contour plot of the modified cross power spectrum (noise in channel 1 only).
Figure 39. Contour plot of the modified cross power spectrum (noise in channel-2 only).
Figure 40. Contour plot of the modified cross power spectrum (noise only).
