SEVERE WEATHER GUIDE
MEDITERRANEAN PORTS

29. PALERMO

DTIC ELECTED
AUG 10 1989

DISTRIBUTION STATEMENT A
Approved for public release
Distribution Unlimited
QUALIFIED REQUESTORS MAY OBTAIN ADDITIONAL COPIES FROM THE DEFENSE TECHNICAL INFORMATION CENTER. ALL OTHERS SHOULD APPLY TO THE NATIONAL TECHNICAL INFORMATION SERVICE.
This handbook for the port of Palermo, one in a series of severe weather guides for Mediterranean ports, provides decision-making guidance for ship captains whose vessels are threatened by actual or forecast strong winds, high seas, restricted visibility or thunderstorms in the port vicinity. Causes and effects of such hazardous conditions are discussed. Precautionary or evasive actions are suggested for various vessel situations. The handbook is organized in four sections for ready reference: general guidance on handbook content and use; a quick-look captain's summary; a more detailed review of general information on environmental conditions; and an appendix that provides oceanographic information.

FOREWORD

This handbook on Mediterranean Ports was developed as part of an ongoing effort at the Naval Environmental Prediction Research Facility to create products for direct application to Fleet operations. The research was conducted in response to Commander Naval Oceanography Command (COMNAVOCEANCOM) requirements validated by the Chief of Naval Operations (OP-096).

As mentioned in the preface, the Mediterranean region is unique in that several areas exist where local winds can cause dangerous operating conditions. This handbook will provide the ship's captain with assistance in making decisions regarding the disposition of his ship when heavy winds and seas are encountered or forecast at various port locations.

Readers are urged to submit comments, suggestions for changes, deletions and/or additions to Naval Oceanography Command Center (NAVOCEANCOMCEN), Rota with a copy to the oceanographer, COMSIXTHFLT. They will then be passed on to the Naval Environmental Prediction Research Facility for review and incorporation as appropriate. This document will be a dynamic one, changing and improving as more and better information is obtained.

W. L. SHUTT
Commander, U.S. Navy
PORT INDEX

The following is a tentative prioritized list of Mediterranean Ports to be evaluated during the five-year period 1988-92, with ports grouped by expected year of the port study's publication. This list is subject to change as dictated by circumstances and periodic review.

iv
Environmental phenomena such as strong winds, high waves, restrictions to visibility and thunderstorms can be hazardous to critical Fleet operations. The cause and effect of several of these phenomena are unique to the Mediterranean region and some prior knowledge of their characteristics would be helpful to ship's captains. The intent of this publication is to provide guidance to the captains for assistance in decision making.

The Mediterranean Sea region is an area where complicated topographical features influence weather patterns. Katabatic winds will flow through restricted mountain gaps or valleys and, as a result of the venturi effect, strengthen to storm intensity in a short period of time. As these winds exit and flow over port regions and coastal areas, anchored ships with large 'sail areas' may be blown aground. Also, hazardous sea state conditions are created, posing a danger for small boats ferrying personnel to and from port. At the same time, adjacent areas may be relatively calm. A glance at current weather charts may not always reveal the causes for these local effects which vary drastically from point to point.

Because of the irregular coast line and numerous islands in the Mediterranean, swell can be refracted around such barriers and come from directions which vary greatly with the wind. Anchored ships may experience winds and seas from one direction and swell from a different direction. These conditions can be extremely hazardous for tendered vessels. Moderate to heavy swell may also propagate outward in advance of a storm resulting in uncomfortable and sometimes dangerous conditions, especially during tending, refueling and boating operations.

This handbook addresses the various weather conditions, their local cause and effect and suggests some evasive action to be taken if necessary. Most of the major ports in the Mediterranean will be covered in the handbook. A priority list, established by the Sixth Fleet, exists for the port studies conducted and this list will be followed as closely as possible in terms of scheduling publications.

vii
1. GENERAL GUIDANCE

1.1 DESIGN

This handbook is designed to provide ship captains with a ready reference on hazardous weather and wave conditions in selected Mediterranean harbors. Section 2, the captain’s summary, is an abbreviated version of section 3, the general information section intended for staff planners and meteorologists. Once section 3 has been read, it is not necessary to read section 2.

1.1.1 Objectives

The basic objective is to provide ship captains with a concise reference of hazards to ship activities that are caused by environmental conditions in various Mediterranean harbors, and to offer suggestions for precautionary and/or evasive actions. A secondary objective is to provide adequate background information on such hazards so that operational forecasters, or other interested parties, can quickly gain the local knowledge that is necessary to ensure high quality forecasts.

1.1.2 Approach

Information on harbor conditions and hazards was accumulated in the following manner:

A. A literature search for reference material was performed.
B. Cruise reports were reviewed.
C. Navy personnel with current or previous area experience were interviewed.
D. A preliminary report was developed which included questions on various local conditions in specific harbors.
E. Port/harbor visits were made by NEPRF personnel; considerable information was obtained through interviews with local pilots, tug masters, etc.; and local reference material was obtained.
F. The cumulative information was reviewed, combined, and condensed for harbor studies.
Emphasis is placed on the hazards related to wind, wind waves, and the propagation of deep water swell into the harbor areas. Various vessel locations/situations are considered, including moored, nesting, anchored, arriving/departing, and small boat operations. The potential problems and suggested precautionary/evasive actions for various combinations of environmental threats and vessel location/situation are provided. Local indicators of environmental hazards and possible evasion techniques are summarized for various scenarios.

CAUTIONARY NOTE: In September 1985 Hurricane Gloria raked the Norfolk, VA area while several US Navy ships were anchored on the muddy bottom of Chesapeake Bay. One important fact was revealed during this incident: Most all ships frigate size and larger dragged anchor, some more than others, in winds of over 50 knots. As winds and waves increased, ships 'fell into' the wave troughs, BROADSIDE TO THE WIND and become difficult or impossible to control.

This was a rare instance in which several ships of recent design were exposed to the same storm and much effort was put into the documentation of lessons learned. Chief among these was the suggestion to evade at sea rather than remain anchored at port whenever winds of such intensity were forecast.
2. CAPTAIN'S SUMMARY

The Port of Palermo is located on the north coast of the Italian island of Sicily at approximately 38°08'N 13°22'E (Figure 2-1).

Figure 2-1. The Island of Sicily and Surrounding Seas.
The Port is situated between Punta del Corsaro and Punta Arenella on the west side of Golfo di Palermo (Figure 2-2). Steeply rising terrain lies close to Palermo on the south, west, and northwest sides of the Port. A valley extends a few miles southwestward from Palermo, but quickly loses its identity in the rising terrain. Elevations commonly exceed 1,640 ft (500 m) within 5 n mi of the Port, with some peaks extending well above 2,800 ft (853 m).

![Figure 2-2. Approaches to Palermo.](image)
The main harbor at the Port of Palermo is entered through an 840 ft (256 m) wide entrance which passes between Diga Foranea and the north end of Molo Sud (FICEURLANT, 1987). See Figure 2-3. The harbor is formed and protected by Diga Foranea, Molo Martello, Molo Nord, and Molo Sud.

Figure 2-3. Palermo Harbor.
The Port of Palermo is considered to be a "deep draft" port, and has berths capable of accommodating aircraft carriers. About 10 large ships can be handled at any one time. Due to the limited berthing space, normal pier side visits are limited to 3 days, but visits can be extended if space allows (FICEURLANT, 1987). According to local authorities, smaller ships moor at Banchina Quattroventi or Pontile Vittorio Veneto, but other berths can be used if needed and available. But the Port Directory for Palermo, Sicily, Italy, (FICEURLANT, 1987) states: "Once inside the inner breakwater, Med mooring to north mole is required.... Depth at north mole is sufficient to moor stern first for most destroyer type ships."

Anchorages are assigned by port authorities. Local authorities state that anchoring can be anywhere within the harbor complex. However, in the Mediterranean Pilot (Hydrographic Department, 1963) it states that holding ground in the harbor is bad, but good holding ground can be found outside the harbor, and in depths of 9 to 10 fm (16.5 to 18.3 m) about 3 to 6 n mi east of the Port.

Local mariners state that, except for a 2 to 3 kt current which enters the harbor toward Banchina Quattroventi during southeasterly Scirocco winds, currents are negligible. Tidal range inside the harbor is less than 1 ft (0.3 m) year round (FICEURLANT, 1987).

Specific hazardous conditions, vessel situations, and suggested precautionary/evasive action scenarios are summarized in Table 2-1.

<table>
<thead>
<tr>
<th></th>
<th>EFFECT - PRECAUTIONARY/EVASIVE ACTIONS</th>
</tr>
</thead>
</table>
| (1) Moored - Inner harbor. | a. The inner harbor affords good protection from waves, but offers little protection from wind.  
   * Vessels should double mooring lines. |
| (2) Anchored - outside breakwaters. | a. The waters outside the breakwater system offer no protection from winds or waves.  
   * Unless a strong outbreak is forecast, good holding ground should enable ships to remain at anchor.  
   * Two anchors may be required.  
   * If a strong outbreak is expected, ships should weigh anchor and move to a berth in the inner harbor or evade at sea. |
| (3) Arriving/departing. | a. Strong winds/high waves pose problems for ships entering or leaving the harbor.  
   * It is possible to leave the harbor during strong winds (45 kt or greater) but entering the Port would be very difficult.  
   * Entering or leaving the harbor during periods of high waves would be difficult.  
   * Ships could anchor, provided winds/waves were not high and 2 anchors were used to forestall dragging.  
   * If a strong event is expected, vessels should accelerate or delay arrival/departure to avoid the strongest conditions. |
| (4) Small boats. | a. Boat runs to/from anchorages outside the breakwaters should be curtailed until conditions abate.  
   * Boating in the inner harbor should not be affected. |
| (1) Moored - Inner harbor. | a. The current induced by the wind reaches Banchina Quattroventi.  
   * The current causes ships moored to the quay to pound against it unless precautions are taken. Proper use of an anchor will prevent the pounding.  
   * Banchina Quattroventi is the only quay affected. |
| (2) Anchored - outside breakwaters. | a. The offshore component of the wind precludes significant wave generation in the coastal waters.  
   * Since the anchorages offer no protection from a SE wind, two anchors may be required to prevent dragging in a strong event. |
| (3) Arriving/departing. | a. Strong winds (45 kt or greater) make it very difficult to enter the harbor, but departures would still be possible.  
   * If a strong event is expected, vessels should accelerate or delay arrival/departure to avoid the strongest conditions.  
   * Inbound units assigned to Banchina Quattroventi should be aware of the problems posed by the wind generated current and deploy an anchor as necessary. See 2(1)a. above. |
| (4) Small boats. | a. Boat runs to/from anchorages outside the breakwaters should be curtailed until conditions abate.  
   * Boating in the inner harbor should not be affected. |
SEASONAL SUMMARY OF HAZARDOUS WEATHER CONDITIONS

WINTER *(November through February)*

* Northeast to east winds: Called Gregale (northeast) or Levante (east), the winds create the worst conditions at Palermo. Wind speeds are typically 35 to 40 kt, with a maximum of 50 kt. Waves are usually 6 ft (2 m) but waves to 13 ft (4 m) are possible. May be caused by high pressure over central Europe or the Balkans and low pressure over North Africa near Libya, or the passage of a low pressure system moving eastward south of Sicily. Duration may vary from 1 to 5 days depending on cause. Low clouds on Mt. Pellegrino (located just north of the Port) indicates Gregale/Levante winds will occur within 24 hours.

* Southeast winds: Called Scirocco. Little effect on the Port, except for a 2-3 kt induced current which reaches Banchina Quattroventi. Sciroccos may occur anytime but are most common from October to mid-May, and normally last about 3 days. Low clouds in thin bands to the east or south indicate the start of a Scirocco within 12 to 24 hours. Scirocco conditions crossing Sicily produce strong and gusty foehn-type winds on the north and east sides of the island. It has been noted that during these situations, ships experience better weather south of Sicily than north of the island. Sea conditions, however, would be better north of Sicily due to the short fetch (Brody and Nestor, 1980). During a Scirocco, dense belts of altocumulus castellanus approaching from the southwest are at times associated with radical and sudden changes in both the direction and speed of the wind.

SPRING *(March through May):*

* Early spring conditions are much the same as winter. Most of the bad weather at Palermo is over by the end of May.

* Early morning visibility is infrequently (2 to 3 times per year) reduced to near zero in fog, usually in May.

SUMMER *(June through September):*

* Summer weather is generally good with light winds.

AUTUMN *(October):*

* Short transition season with winter-like weather returning by the end of the month.

NOTE: For more detailed information on hazardous weather conditions, see previous Table 2-1 in this section and Hazardous Weather Summary in Section 3.

PORT VISIT INFORMATION

MAY 1988. NEPRF Meteorologists R. Fett and D. Perryman met with Pilots Mr. Tralongo and Mr. Porretto to obtain much of the information included in this port evaluation.
3. GENERAL INFORMATION

This section is intended for Fleet meteorologists/oceanographers and staff planners. Paragraph 3.5 provides a general discussion of hazards and Table 3-1 provides a summary of vessel locations/situations, potential hazards, effects, precautionary/evasive actions, and advance indicators and other information by season.

3.1 Geographic Location

The Port of Palermo is located on the north coast of the Italian island of Sicily at approximately 38°08′N 13°22′E (Figure 3-1).

![Figure 3-1. The Island of Sicily and Surrounding Seas.](image-url)
The Port is situated between Punta Del Corsaro and Punta Arenella on the west side of Golfo di Palermo (Figure 3-2). Steeply rising terrain lies close to Palermo on the south, west, and northwest sides. A valley extends a few miles southwestward from Palermo, but quickly loses its identity in the rising terrain. Elevations commonly exceed 1,640 ft (500 m) within 5 n mi of the Port, with some peaks extending well above 2,800 ft (853 m).

Figure 3-2. Approaches to Palermo.
The main harbor at the Port of Palermo is entered through an 840 ft (256 m) wide entrance which passes between Diga Foranea and the north end of Molo Sud (FICEURLANT, 1987). See Figure 3-3. The harbor is formed and protected by Diga Foranea, Molo Martello, Molo Nord, and Molo Sud.

Figure 3-3. Palermo Harbor.
The Port of Palermo is considered to be a "deep draft" port, and has berths capable of accommodating aircraft carriers. About 10 large ships can be handled by the harbor at any one time. Due to the limited berthing space, normal pier side visits are limited to 3 days, but visits can be extended if space allows (FICEURLANT, 1987). According to local authorities, smaller ships moor at Banchina Quattroventi or Pontile Vittorio Veneto, but other berths can be used if needed and available. But the Port Directory for Palermo, Sicily, Italy, published in 1979 and reissued in 1987 by Fleet Intelligence Center Europe and Atlantic, Norfolk, VA states: "Once inside the inner breakwater, Med mooring to north mole is required.... Depth at north mole is sufficient to moor stern first for most destroyer type ships."

Anchorages are assigned by port authorities, and are not indicated on charts. Local authorities state that anchoring can be anywhere within the harbor complex. However, Mediterranean Pilot, Volume I, published by the Hydrographic Department, London, England in 1963, states that holding ground in the harbor is bad, but good holding ground can be found outside the harbor, and in depths of 9 to 10 fm (16.5 to 18.3 m) about 3 to 6 n mi east of the Port along the coast.

3.2 Qualitative Evaluation of the Port of Palermo

Most of the inner harbor at the Port offers excellent protection from heavy weather because of the orientation of the breakwater system. The harbor is exposed to winds from the northeast quadrant, but waves from the same quadrant have little effect on inner harbor operations. Precautionary actions, such as
Doubling of mooring lines, will allow ships to remain in port during strong winds. Entering and leaving the Port is difficult during high wave conditions. Southeasterly Scirocco winds do cause problems for ships using Banchina Quattroventi. Due to the location and orientation of the Port entrance, a strong Scirocco outbreak generates a 2 to 3 kt current which enters the harbor and reaches ships moored to Banchina Quattroventi. The current impacts the ships on the beam and pounds them against the pier unless precautions are taken. Local authorities say the pounding can be eliminated by proper use of an anchor. The problem is unique to Banchina Quattroventi. The anchorages outside the harbor are exposed and vulnerable to winds and waves from the northeast quadrant, and to southeasterly Scirocco winds.

3.3 Currents and Tides

Local authorities state that, except for a 2 to 3 kt current which enters the harbor toward Banchina Quattroventi (see section 3.2 above), currents are negligible. Tidal range inside the harbor is less than 1 ft (0.3 m) year round (FICEURLANT, 1987).

3.4 Visibility

Visibility at Palermo is generally good, reducing to less than 2 n mi only 2 to 4 days per month. Thick fog will reduce visibility to near zero 2 or 3 times per year, usually in May. Lowest visibility normally occurs in early morning and is of short duration.
3.5 Hazardous Conditions

The Port of Palermo is well protected from the effects of most hazardous weather scenarios. The protective breakwater system affords good protection from hazardous waves, but offers little protection from wind.

Although rare, storms having tropical cyclone characteristics with fully developed eyes have been observed on at least three occasions in the Mediterranean Basin: 23-26 September 1969, 22-28 January 1982, and 26-30 September 1983. On the latter occasion the storm moved northwest from the Gulf of Gabes (on the southeast coast of Tunisia), through the Straits of Sicily, along the east coast of Sardinia, and into the Gulf of Genoa. Winds of 100 kt were observed near the eye, while Cagliari, Sardinia reported winds of 60 kt. While the probability of such a storm striking Palermo is remote, the meteorologist must be aware of the possibility.

A seasonal summary of various known environmental hazards that may be encountered in the Port of Palermo follows.

A. Winter (November through February)

The most adverse weather conditions at the Port of Palermo are caused by east (Levante) to northeast (Gregale) winds. Winds during a strong event are typically 35 to 40 kt, with a maximum velocity of about 50 kt. Waves generated by the winds are usually about 6 ft (2 m), but waves to 13 ft (4 m) are possible. Waves from northeast to east are the only ones which affect port operations, as they make entering and leaving the Port difficult. If wind speed reaches 45 kt or more, it would be possible to exit the Port area but very
difficult to enter. East to northeasterly winds may result from high pressure over central Europe or the Balkans and low pressure over north Africa near Libya, or with the passage of a low pressure system as it moves eastward south of Sicily (Reiter, 1975). These winds could also occur in advance of encroaching high pressure following a cold frontal passage through the region. The high winds may persist for 24 hours if they result from a transient low pressure system, or up to 5 days if due to building high pressure north of Sicily and a low pressure system over North Africa.

Southeasterly Scirocco winds reach the Port area, but have little effect due to their offshore component, other than the current problem at Banchina Quattroventi. Scirocco events may occur during any month of the season and usually last about 3 days. A Scirocco is normally caused by a well developed low pressure system over North Africa or winds within the warm sector of a low pressure system. Due to a foehn effect, a Scirocco will result in high temperatures and low humidity along the north coast of Sicily, even during general overall conditions of fog and low stratus (Brody and Nestor, 1980).

Temperatures during the winter season are mild, mean maximum and minimum temperatures range from 68°F (20°C) and 51°F (11°C) in November to 58°F (14°C) and 42°F (6°C) in January, the coldest month. The lowest temperature recorded at Palermo during one 30-year period of record was 29°F (-2°C).

Precipitation is at its yearly maximum during December, when the average rainfall total is 4.5 inches. Thunderstorms are not common nor severe, occurring on 1 or 2 days of each month during the season. Snowfall is uncommon.
B. Spring (March through May)

Early spring weather at Palermo is similar to that of winter, but quickly moderates as the season progresses. Gale frequency is the highest of the year in March (0.6 days per month), but drops to zero days in May. Most Scirocco events are over by mid-May. The gradual northward migration of the jet stream and the associated Polar front reduces the likelihood of extratropical storm activity near Sicily as summer approaches.

Early morning visibility may be reduced to near zero on 2 or 3 days each year, usually in May.

Temperatures warm significantly during the season to mean daily maximum and minimum temperatures of 74°F (23°C) and 54°F (12°C) by the end of May.

Precipitation amounts decrease throughout the season, with May averaging only 1.1 inches accumulation.

C. Summer (June through September)

Strong winds are rare at Palermo during the summer season, with no gale force winds recorded for June through August during a 5-year period of record. September did experience gale force winds, but in each instance the wind was from the southeast or south, offshore flow that would have minimal impact on port operations.

Mean daily maximum and minimum temperatures are 81°F (31°C) and 65°F (18°C) during July and August, the warmest months of the year.

Precipitation is at a yearly minimum during July, with only 0.2 inches accumulating during an average month. By September, however, the monthly average increases to 2 inches.
D. Autumn (October)

As is the case over much of the region, the autumn season is limited to the single month of October. The transition to winter-type weather occurs rapidly as the extratropical storm track moves southward. The potential for gale force winds increases as low pressure systems again move through the Mediterranean Basin.

Daily temperatures gradually decrease, while precipitation amounts increase significantly, with an accumulation of 3.7 inches being average for the month.

3.6 Harbor Protection

As detailed below, the inner harbor at the Port of Palermo offers good protection from most hazards, but ships anchored outside the protective breakwaters are largely exposed and vulnerable to strong winds and waves.

3.6.1 Wind and Weather

The Port of Palermo is exposed to wind from the northeast quadrant, but wind alone causes few problems at the Port. Ships berthed in the inner harbor can double mooring lines and remain alongside. Ships moored to Banchina Quattroventi may need to deploy an anchor to reduce pounding caused by a current. Strong wind is from the southeast (Scirocco). Inbound or outbound ships may experience problems. It is possible to depart the harbor during high winds, but entering is very difficult.

Ships anchored outside the breakwaters may experience wind related problems, but none were mentioned by local authorities during on-site interviews. Anchor dragging would be a potential
problem in a strong wind, but a second anchor on the good holding bottom may forestall even that hazard.

3.6.2 Waves

Vessels moored in the inner harbor should experience no problems from waves. North and northeast waves are the only waves affecting port operations; entering and leaving the Port is made difficult because of high waves. Similarly, high waves from north or northeast may place ships which are anchored outside the breakwaters in a hazardous position, as the wind and wave forces would tend to force vessels toward the coast if anchor dragging should occur.

3.7 Protective and Mitigating Measures

3.7.1 Sortie/Remain in Port

Ships moored in the inner harbor should find no need to sortie if strong winds are forecast. Mooring lines should be doubled.

3.7.2 Moving to a New Anchorage

Unless a strong event with high waves is forecast, ships anchored outside the harbor should be able to remain. A second anchor may be advisable. Although it may be possible to remain at anchor in a strong event, weighing anchor and moving to a berth in the inner harbor or evading at sea should be considered.
3.8 Local Indicators of Hazardous Weather Conditions

Northeast to East Gregale/Levante Winds
Low clouds on Mt. Pellegrino indicates Gregale/Levante winds will occur within 24 hours. Mt. Pellegrino is a 1,968 ft (600 m) steep, barren mountain with a dark red color located just north of the Port.

Southeasterly Scirocco winds
Low clouds in thin bands to the east or south of Palermo indicate the start of a Scirocco within 12 to 24 hours. Increasing southerly winds at coastal stations along the northeast coast of Libya indicate the start of a Scirocco (Brody and Nestor, 1980).

Forecast a strong Scirocco if two conditions are met: (1) an upper trough is present over the Balkans with a strong jet stream along its southern boundary; and (2) large pressure falls (after the diurnal pressure change is removed) are observed at stations along the east coast of Tunisia (Brody and Nestor, 1980).

Scirocco conditions crossing Sicily produce strong and gusty foehn-type winds on the north and east sides of the island. High temperatures and low humidity can be expected even during general conditions of fog and low stratus. It has been noted that during these situations, ships experience better weather conditions south of Sicily than north of the island. Sea conditions, however, would be better north of Sicily due to the short fetch (Brody and Nestor, 1980).

During a Scirocco, dense belts of altocumulus castellanus approaching from the southwest, probably associated with weak upper-level troughs, are at times associated with radical and sudden changes in direction and speed of the wind (Brody and Nestor, 1980).

The surface inversion that occurs over the relatively cool water during a spring Scirocco causes
extremely anomalous radar and radio propagation in the dust-laden atmosphere below the inversion; helicopters are liable to be out of radio contact at a range of 1-2 n mi (Brody and Nestor, 1980).

Weather associated with a Scirocco is largely dependent on both the length of the wind's overwater trajectory and the wind speed. High wind speeds and short overwater trajectories produce large amounts of dust that reduce visibilities, while low wind speeds and long overwater trajectories produce high humidities with fog and poor visibilities (Brody and Nestor, 1980).

3.9 Summary of Problems, Actions, and Indicators

Table 3-1 provides easy-to-use seasonal references for meteorologists on ships using the Port of Palermo. Table 2-1 (Section 2) summarizes Table 3-1 and is intended primarily for use by ship captains.

A. Strong winds from NE or E may result from high pressure over central Europe or
the Balkans and low pressure over N Africa near Libya, or by an E moving low
pressure system passing S of Sicily. The winds could also occur following the
passage of a cold front through the region. Low clouds on Mt. Pellegrino, a 1,968
ft (600 m) steep, barren mountain just N of the Port, indicates NE-E winds will
occur within 24 hr.

B. Scirocco winds are usually associated with a well-developed low pressure system
over N Africa or the warm sector of a low pressure system located N of the
Mediterranean Sea which transports the warm air to Sicily. Low clouds in thin
bands to the E or S of Palermo indicate the start of a Scirocco within 24 hr.
Increasing S'ly winds at coastal stations along the W coast of Libya indicate the
start of a Scirocco. The following conditions indicate a strong Scirocco should be
forecast: (1) an upper trough is present over the Balkans with a strong jet stream
along its S boundary; and (2) large pressure falls (after the diurnal pressure
change is removed) at stations along the E coast of Tunisia. Weather associated
with a Scirocco is largely dependent on both the length of the wind's overwater
trajectory and the wind speed. High wind speeds and short overwater trajectories
produce large amounts of dust that reduce visibilities, while low wind speeds and
long overwater trajectories produce high humidities with fog and poor visibilities.
During a Scirocco, dense belts of altocumulus castellanus approaching from SW are,
at times, associated with radical and sudden changes in both the direction and
speed of the wind.

PORT VISIT INFORMATION

MAY 1988. NEPRF Meteorologists R. Fett and D. Perryman met with Pilots Mr. Tralongo and Mr. Porretto to obtain much of the information included in this port evaluation.
APPENDIX A

General Purpose Oceanographic Information

This section provides some general definitions regarding waves and is extracted from H.O. Pub. No. 603, Practical Methods for Observing and Forecasting Ocean Waves (Pierson, Neumann, and James, 1955).

Definitions

Waves that are being generated by local winds are called "SEA". Waves that have traveled out of the generating area are known as "SWELL". Seas are chaotic in period, height and direction while swell approaches a simple sine wave pattern as its distance from the generating area increases. An in-between state exists for a few hundred miles outside the generating area and is a condition that reflects parts of both of the above definitions. In the Mediterranean area, because its fetches and open sea expanses are limited, SEA or IN-BETWEEN conditions will prevail. The "SIGNIFICANT WAVE HEIGHT" is defined as the average value of the heights of the one-third highest waves. PERIOD and WAVE LENGTH refer to the time between passage of, and distances between, two successive crests on the sea surface. The FREQUENCY is the reciprocal of the period \( f = 1/T \) therefore as the period increases the frequency decreases. Waves result from the transfer of energy from the wind to the sea surface. The area over which the wind blows is known as the FETCH, and the length of time that the wind has blown is the DURATION. The characteristics of waves (height, length, and period) depend on the duration, fetch, and velocity of the wind. There is a continuous generation of small short waves from the time the wind starts until it stops. With continual transfer of energy from the wind to the sea surface the waves grow with the older waves leading the growth and spreading the energy over a greater range of frequencies. Throughout the growth cycle a SPECTRUM of ocean waves is being developed.

A Beaufort Scale table with related wave effects is shown on the following page.
