16. **ABSTRACT**
   - At the Naval Postgraduate School, computer science students are currently working on a multimedia database management (MDBMS) project. This prototype designed in 1988, has the ability to capture, store, manage, retrieve and present both standard data, like alphanumeric and numeric, and media data. Media data in this thesis refers to graphics, signals, sound and image and is stored using the abstract data type (ADT) concept. The MDBMS is built upon a conventional INGRES DBMS using ADT's. The multimedia database management system (MDBMS) can integrate audio, image, and formatted data so that these forms of data can process in the following ways: create tables, insert, delete, and retrieve. A complete database management system, requires deletion and modification operations to remove data already stored in a MDBMS or modify data in MDBMS storage. Formatted data is passed directly to INGRES for all types of processing. However, the inclusion of media data types in the MDBMS requires additional data structures and applications for modifying data that the INGRES catalog management cannot process directly. The special handling, SQL operations required to process data are discussed. This thesis concentrates on the design and implementation operations for deletion and modification of formatted and unformatted data in the MDBMS.

ABSTRACT

At the Naval Postgraduate School, computer science students are currently working on a multimedia database management (MDBMS) project. This prototype designed in 1988, has the ability to capture, store, manage, retrieve and present both standard data, like alphanumerics and numerics, and media data. Media data in this thesis refers to graphics, signals, sound and image and is stored using the abstract data type (ADT) concept. The MDBMS is built upon a conventional INGRES DBMS using ADT's. The multimedia database management system (MDBMS) can integrate audio, image, and formatted data so that these forms of data can process in the following ways: create tables, insert, delete, and retrieve. A complete database management system, requires deletion and modification operations to remove data already stored in a MDBMS or modify data in MDBMS storage. Formatted data is passed directly to INGRES for all types of processing. However, the inclusion of media data types in the MDBMS requires additional data structures and applications for modifying data that the INGRES catalog management cannot process directly. The special handling, SQL operations required to process data are discussed. This thesis concentrates on the design and implementation operations for deletion and modification of formatted and unformatted data in the MDBMS.

ACKNOWLEDGEMENT

I am grateful to all the instructors and students for their interest and research in the multimedia database management (MDBMS) project who, at this point, are too numerous to mention by name but are referenced heavily in my thesis. Without their work, I would not have become involved with the prototype. I thank Daniel Keim for his contributions and valuable input to the MDBMS prototype, and my thesis companions, Charles A. Peabody and Huseyin Aygun, with whom I worked as a team to develop the current MDBMS. I express sincere thanks to Professor Vincent Lum, Daniel Keim and Suleyman Bayramoglu for their encouragement and support in the conception and preparation of writing my thesis.
I. INTRODUCTION

A. BACKGROUND

The increasing demands in automating many applications intensifies the need for ways to gather, store and manage varied forms of data. Today's computer technology allows better and more efficient methods to perform many operations. Standard data, in the form of numerics and alphanumerics, is easy to handle and requires relatively small storage space in database management systems (DBMS). However, other types of data are needed in the workplace today. The medical, educational, and military fields are examples of areas that need instantaneous access to graphics, photos, images, sounds, signals and videos in conjunction with standard text data. These forms of data are generally referred to as media data or sometimes as unformatted data. Multimedia database management systems (MDBMS) handle the storage, retrieval, and manipulation of media (or unformatted) as well as standard (or formatted) data.

A major operation on accessing DBMS data is by means of content search. In a MDBMS, content search is difficult to achieve since the media data is unstructured, complex, and intrinsically rich in semantics. One way to build on the content search methodology and to simplify the work involved is to perform the content search on verbal descriptions of the multimedia data. A project using this technique is introduced here.

In the Computer Science Department at the Naval Postgraduate School, a multimedia database project was established in 1988. The goal of the project is to build a prototype multimedia database management system (MDBMS) for capturing, storing, managing, retrieving and presenting both standard and media data. This project, called the Multimedia Database Management System (MDBMS) Project, integrates audio, image and formatted data providing the ability to create tables for the storage of data and to insert, delete, and retrieve the data. [Ref. 9]

Each media graphics, image, signal or sound type has peculiarities in capture, storage and retrieval because of the varied manner that the media type is comprised. Sound media
data requires sampling rate, frequency and duration. Image data requires pixel size information. The space to store these objects in a computer varies from a few thousand bytes to several megabytes. In the MDBMS prototype these media data types are represented as one unique value or object using the Abstract Data Type (ADT) concept. This concept allows each media type to be treated as one unique value of the type “media” [Ref. 10]. The ADT concept permits the media data to be handled by the conventional database management operations of create, retrieve, modify and delete.

B. RELATED WORK

In other locations around the globe, research projects involved in the processing of multimedia data are devising ways to manage complex media data. At the University of Waterloo, a team developed the MINOS project. This system manages highly structured multimedia objects that consist of attributes as well as text, image, and voice parts. MINOS is an object-oriented multimedia information system that provides integrated facilities for creating and managing complex multimedia objects. Intricate browsing and user interface features facilitate the browsing of the schema and synchronized updates. [Ref. 5] A database program that undertook several multimedia projects by establishing database requirements for multimedia applications is the MCC Database Program, ORION [Ref. 21]. In this program, requirements for a data model and for the sharing and manipulation of multimedia data were identified. ORION is an object-oriented database management system developed at MCC in Austin, Texas. ORION contains a Multimedia Information Manager (MIM) for processing multimedia data [Ref. 21]. MODES1 and MODES2 are two “mixed-object database systems” developed in the IBM Tokyo Research Laboratory [Ref. 8]. An ESPRIT project designing a multimedia filing system called MULTOS [Ref. 2, Ref. 3] is a European contribution to the field. These projects are discussed in detail in [Ref. 10, Ref. 11, Ref. 12] and will not be presented in more depth in this thesis.

Other related research areas are hypertext and hypermedia for individual computer systems. This concept of hypertext came into the computer systems arena in the 1960’s.
Initially designed to manage linked text segments, it now has become “hypermedia” in its extended version of managing images and sound [Ref. 10, Ref. 11]. The ARGOS project being developed at the Naval Postgraduate School uses Macintosh computers with a hypercard application [Ref. 21]. Hypertext and hypermedia data management uses the hierarchical data structure technique that forces queries to follow a hierarchical tree structure to process media data. This method does not permit queries of the data as in conventional database management systems. An interpreter is required to process the user commands. Because hypertext and hypermedia are found on personal computer systems and are not networked, the sharing of data as in most database systems does not usually occur. The MDBMS was initially designed to overcome the shortcomings and disadvantages of hypertext and hypermedia systems.[Ref. 21]

C. SCOPE OF THE THESIS

The MDBMS project continues to conduct research and improve its MDBMS prototype. The design of the system and many of the operations, including table creation, data insertion, and data retrieval, have been presented by Meyer-Wegener [Ref. 11], Lum [Ref. 10], Atila [Ref. 1], Pongsuwan [Ref. 15], and Pei [Ref. 14]. Thesis by Aygun, [Ref. 2] covers complex retrieval and nested query operations for the MDBMS. A natural language parser in PROLOG was created that would understand the meaning of the natural language captions which describe the content of the media data. The parser recognizes the syntax and semantics of the natural language descriptions the user makes in a query. The parser interacts with the multimedia database to locate the appropriate data items [Ref. 6, Ref. 7, Ref. 16]. The parser, designed for content based search for media data, aids the user in the retrieval of the image description stored with the actual image.

The current version of the prototype has the ability to create the tables, input both formatted and unformatted data, and to retrieve that data from the database. The MDBMS needs deletion and modification portions to provide all the basic database management operations. This thesis will concentrate on the complex methods and operations of data
modification and deletion in the MDBMS specifically the deletion and modification of data involving image and sound and the integration of media with formatted data. With the completion of the deletion and modification procedures of the NPS MDBMS project, the prototype will be a database management system complete with the capability to manage different types of media data.

D. OVERVIEW OF THESIS

This thesis comprises six chapters and four appendices. Chapter II provides the discussion of the previous work done and the background development of the MDBMS project. The chapter covers key features of the system environment, including the software and hardware architecture of the system, and the data structure design for the implementation of the system modules. The design for the deletion and modification sequences are first mentioned in this chapter. Chapter III, presents the modularization work on the MDBMS project programming code. Chapter IV concentrates on the design and implementation of how information already stored in the database is deleted. This deletion procedure implementation is an important preliminary step to replacing and modifying existing code in a MDBMS. Chapter V concentrates on the details of the design and the implementation operations of the modification procedures. Chapter VI, summarizes the work and its performance by presenting conclusions and recommendations for future work, as well as work currently in progress or planned. The program code for the modification and deletion modules appear in the Appendices. Appendix A presents the deletion procedures sequence code as arranged in the Retrieve.c module. Appendix B has the modification procedures code. Appendix C has an example of running the database. Appendix D consists of the Makefile and sample parser dictionary.
II. SURVEY OF MDBMS

A multimedia database management system (MDBMS) is defined as a system that manages media data: image, text, voice, and signals along with formatted data. Several mechanisms are necessary in the MDBMS to manage data properly; e.g. concurrency control, consistency checkers, and recovery capabilities. Provisions for query language and query processing are also requirements for a MDBMS to operate. The MDBMS architecture is given in this chapter, including the actual hardware, software and interconnections of the MDBMS. All areas have evolutionary discussions explaining their current state of development. The data organization for multimedia objects and the manner in which the media objects interface with the conventional data are important concepts to be explained. Presentation of the natural language parser and the implementation of the running modules of the MDBMS are also presented in this chapter. Previous work on the MDBMS is discussed in detail in the works of Atila [Ref. 1], Pei [Ref. 14], and Pongsuwan [Ref. 15]. Enough information to familiarize the reader with the general hardware and software environment and the assumptions made for the research are given without restating the previous theses.

A. DEVELOPMENT OF MDBMS

The initial 1988 hardware architecture for the MDBMS proposed by Lum [Ref. 9], was changed over time as more individuals worked on the project. The major concern of all involved was to have an architecture that would allow the processing of multimedia data as timely and conveniently as it is to process standard formatted data within a conventional database. The MDBMS is a system developed on top of an existing DBMS such that it allows the processing of media data. The Intelligent Retrieval Subsystem, the natural language parser and matcher, are added to define operations that would help support content search. Content search is important in order to allow an easy but powerful retrieval of the multimedia data. Content search is difficult to achieve because of the complexity and
the different characteristics inherent to the different media types. A content search, performed on the media attributes only, is the task of locating the media data corresponding to a specified content. An example of a content search is a database with ships. How can we determine what type of ship is pictured in the photo? To find out if the ship is a cruiser, destroyer, or submarine, more information aside from the photo is necessary. Another example is an image of a weapon. How do we know if it is one carried on a ship or one carried by a sailor? Or if the weapon is a U. S. weapon or from another country? A very observant individual needs to analyze the photos and record all the contents in such a manner that the contents could be retrieved based on objects or actions seen in the photo. Technology today is not able to answer the question on the type of ship or the make of the weapon. We can locate this information using two areas of research: Artificial Intelligence (AI) and Information Retrieval (IR). We can define the contents of the photo (multimedia data) into text captions and use the text description equivalent to the media data to match and then retrieve the data.

B. SYSTEM ENVIRONMENT

The MDBMS prototype consists of hardware, software, and the interaction of these two configurations. In this section, the hardware, the software, and the implementation of prototype are presented. In the discussion of the implementation, the internal structures necessary for the module operations are mentioned.

1. Hardware Configuration

The hardware design of the prototype MDBMS is a SUN-3 workstation in a UNIX environment connected by an ETHERNET to an IBM PC. The IBM PC is used to manage the sound data. The hardware design requires the use of the multiple languages and management systems to make the system work.
2. Software Configuration

As mentioned, the MDBMS prototype was built on top of an existing DBMS system, INGRES, to support formatted and multimedia data. INGRES has the ability to manage stored data. INGRES possesses many positive traits desired in a DBMS. However, INGRES does have many restrictions which prevent it from being the optimal management system such as it does not support the ADT concept. The ADT concept provides the best way to perform data storage for the data management of media data, and, therefore, it was chosen to implement the MDBMS prototype. INGRES uses an internal catalog system. This type of catalog system prevents the user from readily accessing data already stored. INGRES does support embedded SQL with C as a host language. The user must pre-compile the SQL statements into INGRES low level code for execution where no high level function calls are available. Query statements to the database are in the embedded SQL (ESQLC) format. [Ref. 15] Examples of the SQL statements are found in Chapter IV and V.

C is the main language used in this prototype system. This language is a general purpose programming language and is generally used in the coding to build user utilities and interfaces for this project and other systems. INGRES is used as the information base since it is flexible enough to manage the unformatted data information within its catalog management facility. Early on in the project, a version of the INGRES catalog management was chosen to organize the data tables. Newer versions of INGRES have since been available on the commercial market and provide better, more efficient operations for the MDBMS than the one being used. However, the budgeted cost for this prototype, which is only a demonstration model, did not justify the enormous expenditures for the newer INGRES version. The recoding of all the prototype code completed thus far on the database project was another reason that no conversion to the newest software was made. In addition, the IBM PC is necessary to maintain the audio portion of the database because management of sound was not available in the early SUN workstations.[Ref. 1, Ref. 15]

ETHERNET, a Local Area Network (LAN), is the mode in which the sound data is transferred to the SUN Workstation from the IBM PC. This transport system software
provides the conduit that allows the sound data to pass through to the rest of the entire database. Quintus Prolog is a programming language used to interpret the natural language descriptions and then to match them to those descriptions stored in the dictionary. User applications such as the parsing are implemented with minimal difficulty.

3. Natural Language Parsing

A natural language parser to process the description of the image and the sound data was incorporated in the MDBMS in 1989. The natural language understanding capabilities of the parser is limited to captions which are a subset of the natural language. The limited interpretations are controlled by the parser component using the application dependent dictionary as a semantic base. To accomplish the goal of content retrieval of multimedia data, only this limited caption interpretation is required instead of complete understanding of natural language description of the media data.

a. Multimedia Data Described in Natural Language

Retrieval of multimedia data is performed by matching the natural language descriptions with the given query specifications. Based on the Artificial Intelligence (AI) technology of today, if the natural language were unrestricted, then the processing of queries would be difficult to accomplish. The natural language needed to describe multimedia data is very formal compared to daily spoken English. Therefore, instead of natural language descriptions, captions are used to describe multimedia data. Captions are a natural, yet stylized way of writing descriptions within a subset of the natural language. Captions are much easier to interpret and to parse than generic natural language. The important aspect of the natural language is to access entities in a database removing the need to have a complete understanding of all meanings of a word. For a particular multimedia application, the universe of discourse is usually quite constrained. The universe of discourse is the narrow domain of the system’s ability to understand everything written in the natural language and the words that are inserted in the dictionary. Nouns are usually concrete objects and, thus, most multimedia databases emphasize still photographs. Other
types of fixed time graphics are not usually the objects media databases emphasize, as few verbs can be applied to them and are used to describe the media data. With this in mind, natural language parsing and interpretation becomes a simpler process.

b. Representation Of Media Data Objects

Many researchers in the multimedia field arrange their media data using the Abstract Data Type (ADT). The acceptable Abstract Data Type (ADT) serves a useful purpose in the MDBMS. The media data object models, which in this database refer to sound and image, consist of three parts: the registration data, the raw data, and the description data. A generic example of the media object model's three parts are shown in Figures 2.1 and 2.2. Registration data pertains to the display and the interpretation of the media object. The registration data uniquely depicts which type of media object is stored within the database. Most registration data is of fixed format since the field lengths of information needed to access the media data are known. As listed in the figures, Figures 2.1
and 2.2, the techniques used to encode and to capture the media data give the user a text explanation of the type of media data. The raw media data displays the actual media object the system manages. For images, a pixel matrix is one example of a raw data entry. Signals and sounds have bit string representations that are the result of digitizing the original media objects. Description data describes the object representation of the raw data in a natural language. This data is used for content search in the computer. A natural language form is entered by the user. After the description is added to the dictionary in the MDBMS, the sentence or phrases are run through a natural language parser written in the PROLOG language. [Ref. 6] The content search is complete and successful when a match is made of the media data description and when the items are entered in the dictionary.

The relational model is the basis for the design of the prototype of the MDBMS. The relational model is a leading model in the database field in which much
research is being done. If a relation has a media type attribute such as sound or image, then a media relation is created for storing the registration and the description data as displayed in Figures 2.1 and 2.2 [Ref. 14]. A separate media relation is created for each attribute with a media data type. A generic relation called OBJECT has the media attributes photo and voice along with the other conventional data type attributes. See Figure 2-3. When an attribute of image type is in the relation, a media relation is created for the image called PHOTO. The PHOTO relation has an integer value called i-id that is used as the reference table key number to locate the media relation and link it to the OBJECT relation. Another attribute, file-id, keeps track of the path to the raw data where the image object is maintained. Along with the raw data is the description and the registration data. The description data is a natural language description of the image content. The registration data consists of the height, width, and depth of the image object.

<table>

</tr>
</tbody>
</table>

Figure 2.3 Schema for Modeling Relationships Between Standard Objects and Media Objects
Media sound attributes are handled in a similar fashion as shown in figure 3. The voice attribute of the OBJECT relation has a created media relation called VOICE. The VOICE relation has a \$id\$ that functions like the \$id\$ does for the image. \$id\$ is the table key and file_id records the path to the file where the raw data for the sound object resides. The description part holds the actual sound and the natural language description of the sound while the registration data part of the sound holds the variables for recording the sound. The registration data part includes the encoding, duration resolution, size, and sample rate of the sound object.

c. The Application Dependent Dictionary

The MDBMS requires auxiliary information from a dictionary. The dictionary is important for parsing and providing every possible natural language word through semantics, parts of speech, grammatical form, and the literal forms needed to represent it. The dictionary is domain dependent since the same word may have different meanings in different application areas. However, conjunctions and qualifying adjectives are consistent in meaning across a wide range of domains. Interpretations from existing natural language systems can be borrowed and included in the dictionary. Some words change significantly between applications. These are generally nouns and some verbs. Because they change in meaning, they must be defined for each application domain. To make matching easier, the properties and the relationships are limited to a small set of primitives. Because we are just looking for the main intent of the English expressions not to capture the media data's full meaning, the following expressions are not defined between relationships asserted by the terms within, inside, part of, containing, including and compromising.

d. Natural Language Interpretation in the Parser

The parser translates the text description into a set of predicates called the meaning list. By transforming them into a set of predicates, the ambiguity and imprecision of the natural language descriptions are reduced immensely. These predicates state facts
about the multimedia data real world entities, like their properties and relationships. First order predicate calculus is the parsing method chosen as the formal representation of the description data. The dictionary is responsible for turning the descriptions into predicates for the parser. The parser's task is to use the dictionary to check the syntactic context to resolve lexical ambiguities and resolve synonyms.

Other features of the parser are the use of supercaptions, a generalization of captions and frames for stereotypical actions. These allow a set of predicates to be derived from terms in the media description. Details of the parser and the predicates are beyond the scope of this thesis but are provided in Dulle [Ref. 6], Keim [Ref. 9], and Rowe [Ref. 14].

The parser is implemented in Quintus Prolog and runs on a SUN SPARC workstation. The parser in its current configuration uses augmented-transition network parsing and interpretation routines. One example of a natural language description and translation into an equivalent set of predicates using the parser is:

**Media Description:** “She has blue eyes”

**Predicates:** officer(x), component(x,y), color(y).

All the descriptions must be defined in the dictionary so that the correct set of all predicates for the description are recognizable. See Appendix D for a sample of the dictionary. Choosing the right set of predicates is a challenging task similar to knowledge acquisition for expert systems [Ref. 16]. In this thesis, it is enough to state that the dictionary contains all the words the parser can recognize, all the parts of speech associated with any word, and the predicates to use when a word appears in a media description.

4. **System Architecture**

There are four main areas in the overall MDBMS. These areas are the User Interface, Query Processor, Data Access Subsystem and Intelligent Retrieval Subsystem. See Figure 2.4. The **User Interface** provides the user and the database with the interactive information necessary for the query processing to occur. The **Query Processor** acccents queries from the user. The Query Processor interconnects the components of the systems by
calling the other components when the user queries the system. The Data Access Subsystem consists of the Conventional Data Manager and the Media Data Manager. The Data Access Subsystem controls the access to the actual data stored in relational and media DBMS. The Intelligent Retrieval Subsystem is comprised of Parser, Generator, Matcher, and Description Manager.

The queries are then executed by the Query Processor which accesses the other components. If a media data value receives a new description, then the query processor calls upon the parser. The parser then must reference the dictionary and create the first-order predicates pertaining to the description. These predicates are then returned to the query processor. The Description Manager receives the predicates which then links the

![Figure 2.4 The Current MDBMS Architecture](image)
description to its multimedia and conventional data managers. The standard formatted data is managed as in other database management systems by the conventional data manager. Queries related to just the standard data are managed in this region. The Media Manager deals with the queries when media attribute types are involved in the user interactions. The Media Manager has two sub-area managers, one for image and one for sound. Lum [Ref. 9] presents the detailed description of the MDBMS architecture. The Media Data Manager handles the processing of both the formatted and unformatted data as media data is not usually in a relation by itself, it usually is part of an relation that includes some formatted data. The Abstract Data Type concept was considered the best method for this model's taskings. Abstract data type is not the same as the usual data types like characters, integer, and boolean since the storage of ADT's are not the same every time the ADT are used. The new media data "values" are handled differently in the processing. The relations with the media data values have an additional relation_id, identifier for the tuple relations.[Ref. 7]

C. IMPLEMENTATION OF THE MDBMS PROTOTYPE

The implementation of the MDBMS prototype became possible with some internal storage structures and the various operation modules. The internal data structures are temporary storage locations while the sub-parts of the user query are attaining the solutions to their sub-query. Along with the internal data structures, a summary for each of the operations (table creation, insert, retrieve and the design ideas for the delete and modification portions) are presented in this section for better understanding of the entire MDBMS.

1. Internal Data Structures Used to Implement the Other Modules

For there to be a need for delete or modification procedure, there has to be a method to have created, inserted, and retrieved the data in the database management system. Internal data structures for temporary storage assisted in placing the necessary data into the proper structures. The data is arranged in tables for storing the catalog information. A detailed description of the create table is provided in Pei [Ref. 14].
The four tables and their functions are outlined below: (1) **Table List**: The integers are the pointers of the database and the keys for searching, sorting, and maintaining the data located within the other tables by means of the Table Array. (2) **Table Array**: Retains the formatted data, possesses the tuple names, and the data if a sound or image attribute is connected with a specific tuples information. (3) **Media Array**: Tracks the media data located in the database by type, be it sound or image. (4) **Att Array**: Contains the attribute names and data types for both formatted and media data for every attribute. It is an interface of the media (image and sound) data.

A fifth array, called a **Value Array**, exists in this database arrangement. This array provides the valid value types of the attribute entries as they are entered in the attribute array. The values are the traditional char, integer and real plus the special value of media data. These items become very important when attempting to relocate a specific file or piece of data for modification. [Ref. 10, Ref. 15]

### 2. Table Creation

Table creation is one of the major operations in MDBMS. The user defines the template for the data storage structures based on the arrays listed in Section C above. The acceptable table name size, values, and categories of attributes necessary for table creation are given to the user in order to create the data table relations. The user must place the relation name, attribute name, and the data type of each attribute in the system. The information is captured and stored in the MDBMS system tables. An active media list is generated and maintained to keep track of the media ADT's created and in current use. [Ref. 14]

### 3. Data Insertion

After the data storage structures are defined, the information the user wants to store is then inserted into the system. This operation is the first operation where data values are placed into the MDBMS prototype. The data insertion procedures are explained in detail in [Ref. 14]. The five types of data supported by the prototype are character, string,
integer, float, image, and sound. Three of these are formatted and two are media data types in MDBMS. Five value arrays are designed for data insertion. The value arrays are discussed in Chapter V. These arrays function as temporary tables. Tracking the pointers in the value arrays is very important to the modification portion of the database. Replacing the data stored in the correct relation requires the knowledge of the pointers' locations.

Data is added to the database by creating relations and placing the data in the relational structure identifier tables the user created in the table creation procedure. Each attribute is checked to ensure that a media type is not encountered. If a media type is encountered, special processing must occur.

a. Formatted Data Insertion

Placing conventional formatted data in a relational structure is simple. The relations structure used requires the attributes and the attribute data types to be clearly defined. The relation name, attribute names (in sequence), and the attribute data type must be integer, real or character. Each attribute data type must be followed by its length for exact definition. When standard formatted data types alone are used, which means media data is not involved, the standard data and the create table command are passed directly to INGRES. This is accomplished by means of the create table command in SQL. Because the media data type cannot be handled by the INGRES system directly, media data inclusions follow another procedure for getting added to the database. [Ref. 16, Ref. 18]

b. Media Data Insertion

When media data type attributes are encountered, the applicable media type, audio or image, is entered in the Att_Array Table under the appropriate data type value image or sound. A request to INGRES to create a media relation specifically for this attribute is processed. The structure of the media relation differs depending on whether it is image or sound. \( I\_id \) is the system assigned internal identification that is used for each value to be entered in the media image table. For the sound data type, the \( s\_id \) is the system
assigned internal identifier that is used as the value to be entered in the attribute voice of
the user relation OFFICER. Both are integer indexes in their respective tuple relations.

For example, photo, an attribute of the user specified in the relation OFFICER
is arranged in the database in the following files. I_image_f is the file where information
on the image and the exact path where this file exists. I_image_d is where the natural
language description of the content of the image. The parameters of the height, width, and
depth for the image file are necessary to reproduce the recorded image data. For the sound
data type, the s_id is the system assigned internal identifier that is used as the value to be
entered in the attribute “voice” for the user relation OFFICER.

Frequency, sample, resolution, and encoding are the parameters that are
necessary to reproduce the recorded sound data. The way that the audio and image data are
added to the database requires the integration of the IBM PC and SUN systems. The last
attributes for any new relation are the media types image and sound. This provides the
indexing and pointing necessary to attain access to the media storage of the database.
Another example: if a user desires to add the additional data of an image to his OFFICER
relation, the user must first digitize the image in the correct format on an IBM PC for the
system to display back on the SUN system at a later date. At the present, a video camera
recorder is used to record the photo that is then converted to GIF, Graph Interchange
Format, on an IBM PC file. From the IBM PC, this digitized image is then transferred to a
SUN workstation where the GIF file is converted into the SUN raster format [Ref. 15]. The
image the user wanted in the OFFICER file is now available for use modification and/or
display by using the SUN workstation. A more in depth discussion is presented in [Ref. 15].

For audio, the data insertion is entered in the same manner. The difference is
that the sound file is stored in the PC instead of the SUN workstation [Ref. 1]. No
duplication of the sound file is necessary. In the MDBMS, a text file is generated to keep
the information of the sound by giving it a file name, taking the registration data of that
sound object to include parameters of frequency, resolution and the duration. This file
assists in locating the actual sound maintained in the IBM PC. The majority of the
parameter information is decided before the actual recording of the sound file datum and is stored in a way that simplifies the processing of sound in the MDBMS. The *active_media_list* discussed in the create table module is used the processing of the media data insertion as well. For accessing data for the modification procedure, understanding the proper manipulation of the *active_media_list* counter is necessary.

4. Retrieval of Data

Retrieval is the most important operation in the MDBMS. The deletion and modification operations depend on the proper retrieval of data from the database prior to commencing the removal or the update of the queried data. Simple retrieval was discussed in [Ref. 15]. More complex queries that support nested conditions and multiple selections are presented in [Ref. 2]. For this thesis only, basic retrieval queries are used for demonstrating the deletion and modification operations the on MDBMS prototype.

a. Retrieving Formatted Data

Retrieving formatted or standard data in the MDBMS is precisely the same as in any other database management system. When media data is not involved in a query, the user request is passed directly to INGRES. INGRES handles the request by retrieving the information from a temporary table for the user to review and then returns the data by erasing the temporary table.

b. Retrieving Unformatted Data

If the retrieved data contains a media attribute, the query is broken down into multiple sub-queries to a level that the INGRES embedded SQL can decipher. It is divided into two parts: one part involving standard data and the other part involving media data. Each sub-query part is processed individually by either using the natural language parser or by passing to INGRES directly. Both result with pointers to the qualified data. The pointers are combined for accessing the corresponding standard and media objects. These results that have been reconstituted provide the user with the final result for the given user.
conditions. This is a difficult maneuver if a media image is actively part of the user request. By outlining sub-queries so INGRES can handle them, the user request gets processed more efficiently [Ref. 15].

5. Modification and Deletion Requirements in System Design

Because of the hardware configuration and the software used in the NPS MDBMS prototype, special structures in both software coding technique and the storage data structures are necessary. There are three areas to consider when describing the update and modification portions of the database management. They are modifying straight standard data, modifying media data with sound, and modifying media data with image.

Queries to standard data are passed directly to INGRES to process. No special requirements come into consideration until media (unformatted) items are involved in a query [Ref. 13, Ref. 15]. To process the multimedia data, some items must be repeated in the catalog tables. This, unfortunately, can cause some inefficiency and inadvertent errors.

For updating the sound, a rerecording or rewriting of the description is permitted. Each time the audio portion is pulled from the tables for a query, all the recorded sound file segment attributes are revealed. These must be checked and can be changed. The description and text that accompanies the actual audio in the MDBMS can be altered without listening to the sound data. Rerecording the sound or changing the speed, frequency, or other key attribute values does, in itself, change the present sound sample.

The media data of type image requires several preliminary steps before combining the sub-query answers and reconstituting the final response to the users initial request. The temporary tables and their use were touched upon earlier in this chapter in the create table, insert, and retrieve sections. The concept of temporarily holding the user supplied information until verification and then passing it to INGRES for the proper storage are executed in the same manner for the deletion and modification processes. The completion of the modification and update procedures provide the MDBMS users with a total database management system. This MDBMS then allows the users the capability to
correct data errors already inserted in the database and remove superceded data information stored previously.
III. MODULARIZATION

The modularization of the MDBMS prototype was performed by a team effort. As a result of the joint work, the written discussion of the modularization is also joint. Hence, this chapter also appears in total content in [Ref. 2].

A. DEFINITION OF MODULARIZATION

We used two software principles to assist in the development of the MDBMS prototype: the concepts of modularization and version management. Both will be discussed in this chapter. Modularization is a way to structure programs. It is called modularization because the process is to break the program down into smaller parts called modules. A module usually consists of a collection of related programming-language entities such as procedures and data types. Modules are designed small enough to be understandable by themselves thereby enhancing the clarity of the program. This is important to software engineers and users. The different modules of a program are in relationed to each other resulting in a module hierarchy. Modules on a higher level of the hierarchy use functions or procedures of lower level modules. Large projects with numerous people working on them prefer this method of programming since modularization lends itself to allotting each individual their piece of the program in which to be creative without interfering with others.

For the version management, we used the Source Code Control System (SCCS) provided by the UNIX operating system. A version manager is very beneficial in a continual software project that will have people working on the programming long after the original programmers have departed. The initiation of both modularization and version management the increased efficiency in developing the MDBMS prototype.

B. REASONS TO MODULARIZE

There are principle reasons for modularizing a program. It makes the software development process easier because modules are more understandable. A program which does not consist of substructures is hard to understand. Dividing a program into modules
makes it easier to follow. The modularized programs are much easier to write as work can be divided among a team of software engineers which reduces the time to complete the final product. Modularizing also reduces testing time, as an established hierarchy aids in developing a testing pattern. Testing of modules is easier than testing a program code without any structure. Modules can be altered more quickly than an entire program if changes and improvements are added. When the need arises to change the program code, changing one or a few modules will be enough to get the desired result. When a new system is to be built, it is possible to reuse modules of a previous system if the same or similar functionality is needed in another program. In the following section, the advantages of modularization is discussed in detail.

1. Comprehensibility

A program without delineated structures and substructures is difficult to follow. Over time, it has been proven that modular programs possessing high cohesion and low coupling results in easier-to-understand systems. A module is highly cohesive if the functions and objects within the module are closely related to one another. Low coupling refers to the manner that each module interacts with each other. The smaller or narrower the interface is, the better the system. With the interface minimized, changes to one module will not effect the entire system less those interfaces between that module are too great. A module hierarchy allows the user to follow the program and see how the modules interrelate and to understand how each module effects the other modules.

2. Division Of Work

To complete a large task in a reasonable time, it must be divided among the people participating in the project. This can be done using modules as basic units. When more than one person is working on a program, dividing the work into modules increases the efficiency in the production of the program. Each module given to a person of the project should be small enough to be implemented within a relatively short period of time. Programming team members can work independently on their modules. Each small part of
the program should run independently. This arrangement also makes the team work run more smoothly. A team member is able to compile his work in shorter time periods. Working modules appear more quickly, with completion of debugging modules in smaller time increments. If the implementation of a module takes too long, then it is necessary to break it into smaller pieces.

3. Easier To Write

Modules are smaller pieces of code to work with which means they are created more quickly and implemented easily. The smaller parts are then built upon as a larger section of related code. This modularized approach lends itself to work that can be divided. By writing programs in parts, the testing takes less time and the program becomes much more adaptable to change and discovery of errors.

4. Easier To Change

Change is a fundamental characteristic of software systems. Improvements in software and hardware occur frequently and quickly. Users may ask for new features or changes to old ones; the system may move to new hardware or a new operating system; bugs may be discovered during testing; and/or performance measurements may show bottlenecks. Costs of these changes can be enormous if entire programs must be rewritten to meet the new equipment or software requirements. A modular format lends itself to change with minimal effort. If better ideas for program functioning are incorporated in the program, the modular structure allows interchanges of the units with minimal restructuring. Changing a module instead of an entire system is less costly in many ways. The building block formation can use general interfaces in order to achieve the connectivity necessary to have the program run smoothly. Overall, to modularize is to achieve better quality programs more efficiently and in less time.
5. Reusability

Another advantage of modularization is that some of the modules can be reused with little or no restructuring of the base module. When you build a new system, you may need the same functionality that you used in a previous system. An example is a module providing advanced string or window operations. This module can be used without changes for many applications. Instead of rewriting these modules, it saves much effort if you can reuse modules of a previous system.

6. Easier To Test

Having smaller parts to work with facilitates debugging and testing of the capabilities of the modules. In a large system, each module should be tested individually and large collections of modules should be slowly built up to test the whole system. Since modules are much smaller units than the whole program, errors can be found faster. Debugging is the process of locating errors, defects, or problems that effect the outcome of the module. Debugging often involves a lot of detective work. Testing is working the system module by module for accurate and predictable answers. Testing has much broader scope and usually assumes you have finished most of the debugging. Testing may uncover problems which may lead to more debugging as the programmer may discover other flaws in the software.

In addition to these advantages, a modular system provides other improvements to software programming projects. Modularization can be used to achieve two basic principles in systems development: information hiding and abstraction (or encapsulation). Information hiding is the software designers decision to "hide" data structures and operations that the user does not need to know. Some reasons for information hiding are to prevent data structures details from being revealed to the user, keep algorithms that perform operations from being shown, or protect the details of an interface to an operating system. Information hiding and abstraction focus on different aspects. Information hiding focuses on what to hide; abstraction focuses on what to reveal. Information hiding tries to protect
you from change you ask what design decisions might change, and arrange to hide them so you cannot depend on them. The sorts of decisions one might hide include the algorithm for carrying out some operation or the representation of some data structures. Other examples are the details of an interface to an operating system or to special purpose hardware, or the policy for allocating some resource ordering certain operations. Every abstract data type is an information hiding module; however, a module may not be an abstract data type. A module can also be a set of unrelated functions. An abstract data type module provides a collection of procedures for manipulating the encapsulated data structure. For example, a module might hide the representation of a stack. It would provide operations for pushing elements onto a stack, popping elements off the stack, reading the top element of the stack, and initializing the stack. These four functions are called the interface procedures of the module.

C. HOW TO MODULARIZE

There are steps to follow in order to modularize a program or system. First, the major sections of the design decisions and the sub categories located within those sections must be identified. The major groups become the top levels in the generic module hierarchy. A decomposition record is maintained that keeps track of the rearranging and regrouping of the system into modules. This decomposition record is important. When the design decisions call for information hiding, the decomposition record keeps track of all the hidden information. Then the project secrets are accessible to software engineers. As mentioned earlier, the size of a module should be manageable by one person. If the module is too large, then it can be further divided into smaller parts. However, one person may have more than one module on which to work.

The program structure is reflected by a module hierarchy. The module-hierarchy shows the dependencies between the modules. The boxes represent the modules. A top-down design displays relationships of the modules to one another by the line links or connections. Figure 3.1 shows the dependencies of the modules. Module 1 calls three
modules on the next level of the hierarchy, Module 2, Module 3, and Module 4. They in turn call on modules they are connected to on the next level down.

![Generic Module-Hierarchy](image)

Figure 3.1 Generic Module-Hierarchy

Another document, entitled the module *dependency document*, defines the module dependencies and a module hierarchy for a given system (see Figure 3.1). The system module dependencies are shown by the line connections. The *program document*, after the division process is complete, resembles separate modules. Now the dependency relationship with other modules is identified. These are recorded as import and export interfaces listed in the documentation of each module (see Figure 3.2). An *import interface* is the listing of all functions called from other modules that are necessary to perform the modules given task. The *export interface* consists of the functions provided by the module in question. Figure 3.2 is an example of how each module in the hierarchy is structured.
module name

D. MODULARIZATION OF C PROGRAMS

The MDBMS Prototype systems are implemented in the C programming language to include the MDBMS prototype. Unique advantages and disadvantages exist with any programming language and some of both will be discussed in this section. In C, there does not exist viable support for the principle of modularization.

1. No Support For Modularization in C

The C-programming language does not support modularization. To write modular programs in C, the code has to be subdivided into separate parts which are stored in separate files. Because everything is listed in separate files, a programmer may perform separate compilations or can use the include mechanism. Using separate files does not reflect a modular structure as obvious recognition of where functions are imported from or exported to is not biantantly displayed.

Other languages such as Modula 2, ADA or object-oriented languages like Smalltalk or C++ do support the modular format better. However, these languages are not available for use for the completion of this MDBMS prototype. Transferring an existing program from one language to another is not a viable option as it creates great amounts of overhead. Therefore, in order to achieve the advantages of modularization, a concept for modularization in C was developed.

2. A Concept For Modularization In C

Organizing the program by dividing the data structures and functions in separate files corresponding to their purpose gives some of the benefits as a program constructed in a language that supports a modularized format. As mentioned before, C files can be compiled independently and larger C programs can be divided into more manageable and smaller sections to emulate the benefits of modularization. Similar functions, previously separated, can often be condensed into more general, parameterized functions thereby
gaining clarity, uniformity, and reusability. Since C files can be compiled independently, it is convenient to partition large C programs into smaller and more manageable parts to achieve some advantages of the modularization concept. Independent compilation allows files containing C program components to be checked separately for syntactic and semantic errors. Moreover, when a program is modified, it is only necessary to recompile the effected components. The Unix utility *make* is used to automate this process. This special option *make* is a recursive call to update files according to their dependencies. Make can review all the separate files after one or more have been altered and define in which order the effected files must recompile. The *make* utility is explained in detail in Appendices C and D.

Another mechanism used to achieve some kind of C modularization is the *include* mechanism. Arbitrary files can be textually included in a C program by means of the *include* instruction. The capability to include files textually in a program allows common constant, data, type and function declarations and definitions to be kept in separate files. These common declarations and definitions can then be used in all parts of the program. Keeping common declarations and definitions in separate files and then including them in C programs is a popular style used for writing C programs. Examples are constant data, type, and function declarations or definitions, and the standard input/output declaration file *stdio.h* and math algorithms. As mentioned before, although the C language does not support modularization, we can achieve the following advantages can be achieved by dividing the existing program code into separate parts:

* Program modules can be developed independently.
* Changes to the program can be done by only changing single modules.
* Clarity of design and structure.
* Program code is easier to understand.
* Maintainability.
* Reusability of modules.
* Uniformity.
a. Similarities Between C and Modularization

Separate files of a program can be developed independently as can modules. Having the program code in separate files, the program is easier to understand and provides a better clarity of design than a program without any structure. The import/export information contained in the files gives the impression of a modular hierarchy. As improvements or changes occur in the program, single files or modules are all that are effected. A revision of the entire program is unnecessary. Separate files are maintainable and reusable just like modules. The uniformity of the files with the import/export interfaces defined is another positive similarity to the modular format. Through the division of an existing program code into separate files, C cannot fully support the modular format but does possess some important characteristics of modularization.

b. Making Dependencies Between Modules Visible

To make the dependencies between the different parts of a modularized program visible the export and the import interfaces have been added to the separated files. In C, they should be put in the documentation header of each file. If all modules are compiled separately, it is only necessary to recompile the module someone is working on and link it with all imported modules to get an executable program. A list of all necessary files used for the system should be available, making the module hierarchy visible. For each file, the purpose and its place in the module hierarchy. Figure 3.4 shows the style of documentation we used for the MDBMS. The export interface of the module shows the functions that are called by other modules, which modules they are exported by and which module this function is imported. The insert_tuple() function is exported to the Delete.c module.

The import interface displays the functions that are brought in from other modules. C files can be used to partly implement data abstraction and information hiding. An abstract data object, as defined in the previous section, is an object that can be manipulated using only the operations supplied by the definer of the object. The user cannot
directly manipulate the underlying implementation of an abstract data object. Details of how an abstract data object is implemented are hidden from the user. Hiding the details prevents the user from: making programs dependent on the representation. The representation of an abstract data type can be changed without effecting the rest of the program. For example, the abstract data type set may be initially implemented as an array, but this representation may be changed to an ordered list later on for storage efficiency. Integrity of abstract data type objects is preserved by forcing the user to manipulate these objects using only the operations provided by the designer of the abstract data type. Examples of abstract data types are stacks, queues, sets, databases and binary trees. However, a C file is not a true data abstraction facility, because it only partially supports data abstraction. If you link an independently compiled C module to some other parts, you
can not prevent the user from accessing all functions and even the internal data structures of other modules.

************** InsertModule.c **************

Title: InsertModule.c
Author: Su Cheng Pei
Date: November 15, 1990
History:
Description: This module implements the insertion process in the Multimedia Database System.

Export Interface:
print_all_table(): Prints out the table catalog information on the screen.
insert_tuple(): Inserts a tuple of a particular relation.
display_tuple(): Displays the tuple before insertion.
check_media_description(): Checks the media description by connecting to the parser.
ql_insert_tuple(): Translates SQL statement to insert a standard tuple.

Import Interface:
get_sound_value(): Gets a sound value of a media attribute from the user input.
yes_no_answer(): Gets yes or no answer from the user.
   from UserInterface.c
check_table_name(): Checks if the table name is duplicate.
get_media_name(): Gets media table name by appending table_key at the end of att_name.
   from CreateModule.c

Figure 3.4 Export/Import Interface of a Module

E. MODULARIZATION OF MDBMS

The MDBMS prototype is implemented in the C programming language. The majority of the original program was in a single file and was very difficult to follow. Three students were working with the prototype. Considering the size of the program and that multiple students were working on three different parts of the project, namely complex query processing, graphical user interface, modify and delete, it was decided to modularize
the MDBMS prototype. Before beginning work on the modification and deletion sections of the MDBMS, the program was first broken into large chunks of code in order to understand how the program worked. When modularization of the MDBMS prototype was begun, the module hierarchy was as shown in Figure 3.5. The existing program code into separate files corresponding to their purpose. Then each part was divided again until the final module hierarchy was obtained.

![Module Hierarchy Diagram]

*Figure 3.5 Existing Module-hierarchy*
The resulting modular format is shown in Figure 3.6. The main program calls the functions and routines imported from the modules to make the system operate. Modularization of the MDBMS was not completed as we could almost spend the entire thesis on modularization. Instead, we incorporated large basic modules containing related functions and procedures. The MDBMS module hierarchy now consists of 6 levels. In Figure 3.6, each box represents a module. For instance, the module 'MDBMS', which is the main program calls the modules 'Catalog Management', 'Create', 'Insert', 'Modify', 'Delete', and 'Retrieve'. In the diagram, the straight lines show the dependencies between modules. Although the module 'MDBMS', which is at the first level of the hierarchy, calls
some of the modules on the third level of the hierarchy, the dependency is not shown on the diagram.

There is, however, still much to do on modularization. Considering the time needed to complete our parts the complex query processing and modification working on modularization was stopped at this point. To make the dependencies between the different parts of the MDBMS program visible, import and export interfaces were added in the documentation header of each module (Figure 3.5). Functions that can be used by other modules are placed in the export interface sections of each module. The export interface therefore summarizes the functionality provided by a module. For example, the function print_all_table() taking place in the export interface of ‘Insert’ Module can be called by the ‘Retrieve’ Module.[Ref. 7]

In the import interface of each module, functions that are called from other modules are mentioned. For instance, the function get_sound_value() taking place in the import interface of ‘Insert’ Module, is called from the ‘User Interface’ Module. In addition to our work on modularization, we also used some helpful tools provided by the UNIX system were used, namely sccs, lint, make, and dbx.

F. TOOLS USED WITH MDBMS

Some UNIX tools were used to improve the development of the MDBMS prototype. The three presented are lint, dbx and the SCCS version manager. The fourth, make, is discussed in Appendices C and D of this thesis.

1. Lint - A Program Checker

Lint is one of the UNIX operating system utilities. The lint command is incorporated in the make file of the MDBMS program to automatically assist in the debugging and discovery of the prescribed errors. Lint attempts to detect features of C program files that are likely to be bugs, non-portable or, wasteful. Lint performs stricter type checking than the C compiler. It runs a preprocessor as its first phase which allows certain questionable code to be altered or skipped by lint. Its second pass checks the files
for compatibility and consistency. Some of the main items lint manages to find are unused arguments and variables, inconsistent function calls, and ignored function returns. During the compilation of C programs, lint helps to find unused arguments, unused variables, variables which are set but not used, inconsistently used function calls, and always ignored function returns. The lint command was put in the Makefile so that during compilation, lint is invoked automatically by the Makefile. The make utility, which is a command generator, is explained detail about ‘make’ and its use in Appendices C and D.

2. DBX - A Debugger

DBX is a utility for source-level debugging of execution of programs. Run time errors during the execution of a program can be found using dbx. To run dbx, type “dbx <executable file name>”. To run the program in dbx, type “run”. Dbx is a source-level debugger. One of the options of dbx is the trace command. To trace in a function, type “trace in <function name>”. This allows a user to run the program and trace in a function that may not work properly. This tool was used to find some run time errors during execution of a program.

3. SCCS - A Tool for Version Management

Another item that is very important to team programming is the use of a version manager. We chose the Source Code Control System (SCCS) provided in the Unix system which possesses various utility programs to allow more than one version of a file. Programmers have access to the latest version or return to any previous version of a module. All changes are stored as a new version number and can be accessed at any time a question may arise about the changes in a program module or procedure. Using the SCCS worked well for this project, as each of the team members had a stabilized version of all modules except the one(s) that the individual was modifying. If you want to try another way to implement a module, you can work on a version of that module while you still keep the older versions. You can always go back and work on any older version you want. As I worked on the modification portion of the MDBMS, I maintained a copy of a retrieve
module that performs basic retrieval operations. Other team members were able to continue
to improve upon the existing retrieval module without interfering. I could also test another
way to code the modify operation and work on it but still have the older versions.

SCCS is ideal for team projects that require access to overlapping code and
historical changes. The cataloging is very accurate, easy to use, and quite space efficient
for database storage as only the changes are saved with each version that is created and
stored. To use the SCCS, a directory must first be created and given the name SCCS. Files
must already exist that you want to start version managing. Some basic commands for use
of the SCCS are create, delget, edit, prs, info. Examples of how to use them are shown
below. To create the initial version of a file, one must type “sccs create <filename>” at the
prompt. You should not be in the SCCS directory at this time. If you want to work on this
version and still maintain a pure copy, then the command “sccs delget <filename>” is what
should be used. What you have done is created a version number for the initial version and
set up another copy of that version for editing. It is not available for editing until the
command “sccs edit -r<version number> <filename>” is typed. The version number is
shown when a delget is started. The -r option is used in case the desired version is not the
latest version. The “r” stands for revision. An example of editing a previous version is if I
want to edit the InsertModule.c version 1.6.3.4. I would type “sccs edit -rl.6.3.3
InsertModule.c”. To see how many versions of a particular module exist, the command
“sccs prs <filename>” is the way to access that information. The command “sccs info”
shows exactly which versions of all files are currently being edited.
IV. DELETION IMPLEMENTATION

My ideas for solving the deletion problem began with designing and/or enhancing functions and procedures that are compatible with the currently working modules and procedures in the MDBMS system. The MDBMS prototype architecture outlined in Chapter II and modularization discussed in Chapter III were the first steps towards building a complete system. Three students commenced work to complete the basic operations of the MDBMS operations not currently implemented and to enhance the quality of some prototype operations already running. We continued to modularize, incorporate complex query handling, modify the user interface, and develop the deletion and modification operations [Ref. 2, Ref. 15].

My design makes use of existing data structures and implementations for some of the underlying retrieval operations. Additional data structures to capture the necessary user information are found in the modification operations for the formatted and media data. By working with the existing structures, integration of my procedures into the MDBMS was less cumbersome. An overview of the design, discussion of the implementation, and examples of the deletion operation are in the following sections.

A. INTRODUCTION

Design issues for the modification of information stored in the MDBMS were first discussed in 1988 when INGRES was the DBMS chosen to build the MDBMS. The catalog management system is very important for all these major operations in the MDBMS prototype. The restrictions with the INGRES version to implement the MDBMS prototype have been mentioned in Chapter II. Newer versions of INGRES have eliminated some of the restrictions; however, all the prototype code would have to be rewritten in order to work with a newer version of INGRES. The SUN corporation improved its SUN workstation. Current SUN models directly support sound functions. The prototype source code would need restructuring and substantial recoding if the new hardware and software were
purchased. Instead of making these investments, the original configuration of the prototype with an IBM PC as a backend server for sound data management in the MDBMS, would continue. The IBM PC is connected to the SUN workstation via the local area network, ETHERNET [Ref. 1]. The constraints of the hardware structure and the older versions of the software due affect the design and implementation of the deletion procedures. However, since this is only a prototype system and not one for the commercial market, my work was to complete the deletion and modification portions of the current system structure with its current design. The principles involved with these operations can be demonstrated on this prototype without the costly upgrades.

1. Why Deletion Operations are Important

Deletion of outdated or no longer needed information is one of the basic processes expected in every database management system. In order to perform the deletion operation, the user must already have created a table (i.e., defining the relations), inserted some tuples of data and stored that data within the database. The user can now remove any extraneous data by means of a deletion operation. A retrieval of the tables or files where the information is stored is first performed. This is executed based on the user's requirements and the relational conditions placed on the database retrieval system. After the conditions are provided, the database searches for the given conditions. Once the data are retrieved, removal occurs. An in depth, step-by-step example of removing media and formatted data in the MDBMS is found in Section C of this chapter. Formatted data removal is the easiest method of deletion to perform. A method to remove media data in the multimedia systems is more complex to remove for a database because of the storage requirements. For deletion, use of the integer table key and the integer value of the media type provide the user with the ability to access the proper media table during the execution of the procedure.

2. Schema of Database Relations

The MDBMS database relational schemes are examples of a practical way to store information about a U.S. Navy fleet. Records maintained on the ships, weapons, officers,
missions of the ships, and ship homebases are common items that must be accounted. The information stored in the database on the objects listed above are shown in relational form in the Figures 4.1 through 4.3. For a ship, the name, number, type, year it was built, displacement, current mission, captain and executive officer are important pieces of information to access. For a record on weapons, the name, type, range, power, and description are key items to store on weapons. Officer files are another set of files that should be stored in a fleet database. The officer name, rank, identification number, salary, reporting year date, along with a current photo and recording of his voice are items the fleet should have available for review. Base ship home ports listed by name, location and size are other key pieces of information. Mission assignments with the directions, goal and task outlined provides the fleet an accounting of the total area of involvement for members of the fleet at any given time. See Figure 4.1.

The primary keys are user defined and indicated by the underlines. The media data types are the abstract data types defined in the MDBMS prototype. Each media attribute has an integer associated with the location of the separately stored media relation. As described in chapter II, media objects are created and stored as the media data types image and voice. These media relations are not visible to the user. Ship is the first relational table created in the MDBMS. An example of how the media storage table is created for the SHIP relation is as follows the table key for ship is “1” as it is the first table in the database. The media relation table for the ship photos is called PHOTO1 to correspond with the SHIP table key number “one”. In Figure 4.2, the media image attributes added for each SHIP tuple relation are placed in the created media table PHOTO1. For each of the ship tuples that contains an image attribute, it is stored in the media image table PHOTO1. The image identifier (i_id) which is an integer acts as index. The i_id for each media relation will indicate where the particular SHIP image is stored. The WEAPON table is the third table in the database; hence, PICTURE3 media relation table is created for the weapon relation pictures. Another example is the fourth table in the database is OFFICER. The two media relation tables created for the OFFICER.photo and OFFICER.voice are media tables
PHOTO4 and VOICE4 respectively as shown in Figure 4.2 and Figure 4.3. Figure 4.3 is used to explain the design and implementation of the deletion process.

B. DESIGN AND IMPLEMENTATION OF DELETE

The key to the deletion and modification procedures of the MDBMS is to understand how each of the different tables are located and manipulated. Gaining access to the relation conditions is simpler in theory than in practicality with the MDBMS configuration. Data, once stored in the system must be retrieved, stored in a temporary location, manipulated, and then the final, newly acquired resultant data returned to the original table in the

Figure 4.1 Navy Ship Database Relational Schemes
database system. Some code revisions to get the deletion process operating are given in section C.

![Figure 4.2 Media Relation Schemes for Navy Ship Media Attributes](image)

Some of the procedures require user supplied conditional information. This user information sometimes must be restructured so that INGRES can perform operations in formats that INGRES can manipulate. The work began with methods to delete formatted data. This is the easiest type of information to delete, as it is in conventional coding format. Because formatted data is handled in a data type directly accepted by INGRES, formatted data can be retrieved, deleted, and the table reconstituted for storage in the database with minimal effort.

With the aid of Figure 4.3, we will talk through the insertion, retrieval and deletion of data for the table relation OFFICER. The table contains the attributes o_id (integer), o_name (character 20), rank (integer), salary (float), rep_yr (integer), photo (image), and
voice (sound), created during the initial execution of the create table operation [Ref. 14].
INGRES separates the creation into three parts to set up the relation OFFICER, one for the
formatted Officer relation, one for the image media relation and one for the sound media
relation. These are shown in Figure 4.3. The suffixes on the media tables have been
explained earlier. The input data to the attribute photo and voice in the OFFICER relation
are integer type and are used as the indexes to the i_id of the PHOTO4 relation and the s_id
of the VOICE4 relation respectively. Data for Jeff Kulp is added and the values stored
temporarily in the data value arrays prior to INGRES insertion. He is the first entry in the
relation OFFICER. When the user prepares to insert a media data attribute value, the image
or sound filename must be input at this time. In the case of image, “/n/virgo/work/mdbms/
 gif/jeff.ras” is typed into the system. The system inserts that filename into the field f_id of
the relation PHOTO4 which represents the media attribute photo. All the data pertaining to
the file, height, width, depth, are extracted from the header file and inserted into the relation
PHOTO4. The i_id index is assigned (which is 1 in this example) and then the i_id index
number is placed in the relation OFFICER photo attribute column. The system inquires as
to the description of the photo which is “big head”. This is inserted into the “description”
attribute column of the relation PHOTO4. The same operation occurs for the sound
relational data. The sound filename, “/n/virgo/work/mdbms/snd/jeff”, goes in the f_id of
relation VOICE4. The user gives the description of the voice as “slow voice” which is
inserted. Once inserted, the data remains in the database management system until it is
deleted. Other tuples are inserted in the same manner. An understanding of the retrieval
process must occur first to understand the deletion operation. Examples of the retrieval
operation and MDBMS deletion processing are now presented.

1. Retrieval of Information for a User Query

Simple queries designed and implemented by Pongsuwan [Ref. 15], are reviewed
since it is the first step of deletion. I built the deletion operation on the existing retrieval
process created by him. After completing the deletion and modification operations, these
were joined with the work of my companion and can now process complex query
modification and deletion. Retrieval by the user issuing query conditions to the MDBMS
is accomplished via the main menu. The MDBMS retrieves the user data requirements as
specified and places them into temporary structures that are mentioned in Chapter II. At this
point, the user is shown the data to ensure that the data retrieved meets the criteria the user
stated. Each set of formatted data and the attached image or sound media data, as
applicable, is displayed tuple by tuple. The user is asked if he wants to see the media data
of the parent relation. The tuples will be displayed in the order they are retrieved from the
database. If the user wants to see the photo or hear the voice from the fourth tuple meeting
the conditions, he is not able to alter the previewing order in the MDBMS prototype
configuration Pei designed [Ref. 14]. In the current implementation for complex query
processing Aygun [Ref. 2], the user is given a choice as to the order of the tuple media
picture data he desires to see first. He will also have the option of which voice he wants to
hear. This more user friendly style allowing the user to choose is the contribution of Aygun
[Ref. 2] to the prototype. Also in [Ref. 2], additional operations such as nested queries and
aggregate functions - in, max, in, intersection, and union - have been added to the prototype.

Understanding the temporary table functions was the first step for construction of
the deletion and modification operations that include media. First, I had to learn what
INGRES precompiled code results are produced when user query conditions are expressed.
To work with precompiled code, I logged directly into INGRES (shown in the Appendix)
and created small database operations for INGRES to manipulate. Some of the INGRES
precompiled commands are in Chapter V. As mentioned, the user must retrieve the tuples
from the tables first in order to remove the items based on user conditions. To illustrate this,
we will query the database for a formatted example of retrieval and then retrieve data
including media attributes. In the first query, we want to see the name and rank of the
officers who reported in 1990 from the OFFICER relation. In the second query, we want to
view the officer’s pictures, hear their voice and see their names from the OFFICER relation
when the officer’s reported in 1990 and has the voice description “slow voice”.

Figure 4.3 Media Relation Schemes for Navy Ship Media Attributes
Since the retrieval operations have been summarized in Chapter II, I will concentrate on the actions surrounding the temporary tables and the removal of the data from the MDBMS database.

a. **Formatted Data Retrieval Operation**

Examples to illustrate retrieval of formatted data are shown below.

**Formatted QUERY 1:**

*What are the officers names and ranks that reported in the year 1990?*

The SQL equivalent statement for this query is written as follows:

SELECT: o_name, rank *(which attributes are wanted)*

FROM: table *(which relation table is the information coming from)*

WHERE: officer.rep_yr = 1990 *(condition)*

Because this query contains only formatted data, it is passed directly to INGRES to retrieve the result. The result is placed in a temporary table away from the stored data and then displayed for the user to review.

Another example of formatted data retrieval:

**Formatted QUERY 2:**

*What is the captain's name on the U.S.S. Elliott?*

The SQL statement for this query is written as follows:

SELECT: o_name

FROM: ship, officer *(two tables are necessary to process this query)*

WHERE: ship.s_name = “Elliott” and ship.capt_id = officer.o_id.

Again, this is an example of a query that contains only formatted data. The query is passed directly to INGRES to get the result.

b. **Media Data Retrieval Operations**

When media data is included in the query, the query is decomposed into two parts as mentioned in Chapter II. The first sub-part is of the formatted data and is sent directly to INGRES for processing as shown in the examples above. The media data sub-
part must be handled separately and the two sub-part results reconstituted into the final result. The user only sees the recomposed final result. Sample queries with varied holdings are shown below.

Media QUERY 1:

What are the names of the officers to see their photos and hear their voices if they reported in 1990 and have "slow voice". Show the officer photos that meet the conditions and play the voices.

The extended SQL statement for the query is written as follows:

SELECT: o_name, picture, voice
FROM: officer
WHERE: officer.rep_yr = 1990 and officer.voice(CONTAINS, "slow voice");

The decomposition of the query is listed below:

CREATE TABLE T1 as: (temporary formatted data table)
SELECT * (all)
FROM officer
WHERE officer.rep_yr = 1990;

CREATE TABLE M1 as: (temporary media data table)
SELECT s_id
FROM VOICE4
WHERE VOICE4(CONTAINS, "slow voice");

CREATE TABLE RESULT as:
SELECT o_name, picture, voice
FROM T1, M1
WHERE T1.photo = M1.i_id

The final result is in an INGRES relation. This result of the officer names, the officer photo and hearing the officer voice are what will be seen by the user.

Media QUERY 2:
Find all ship weapon names where the ship has "gas turbine engine" in the photo description.

The extended SQL statement for the query is written below:

```
SELECT: w_name
FROM: ship, ship_weapon
WHERE: ship.photo(CONTAINS, "gas turbine engine") and ship_weapon.s_no = ship.s_no.
```

The decomposition of the query into sub-parts is listed here:

CREATE TABLE T1 as: (temporary formatted data table)
SELECT *
FROM: ship, ship_weapon
WHERE: ship_weapon.s_no = ship.s_no;

CREATE TABLE M1 as: (temporary media data table)
SELECT i_id
FROM: ship
WHERE: PHOTO1(CONTAINS, "gas turbine engine");

CREATE TABLE RESULT as:
SELECT: w_name, photo
FROM: T1, M1
WHERE: T1.photo = M1.i_id

The INGRES operation of cursor_output is executed to process these queries. Cursor_output retrieves the result table data one tuple at a time and displays it to the screen. If media data is part of the RESULT table, then the tuple corresponding to the i_id and or s_id in the result table are retrieved from the media relations. The media data is displayed or played following the corresponding formatted data. The cursor_output format is shown below. See Figure 4.4. The cursor is initiated. The system retrieves everything from the result table and then retrieves the media identifiers (i_id or s_id) from the remitted data table in order to retrieve the media data.
EXEC SQL CREATE CURSOR cursor_output AS
SELECT * (all)
FROM RESULT
EXEC SQL FETCH CURSOR cursor_output;
print formatted data;
EXEC SQL CREATE CURSOR cursor_output AS
SELECT media data
FROM RESULT
EXEC SQL FETCH CURSOR cursor_output
display pictures;
play voice recordings; (not applicable for this example)

Figure 4.4 INGRES Pre-Compiled SQL Code

2. Approach to Deletion of Data from the MDBMS

As outlined in the previous section, the retrieval of the data to be deleted is first gathered based on the user specified query and the result is placed in a temporary table. The data is then displayed to the user before the temporary table of information is destroyed. What the user does not see going on in the delete operations is the matching of the database data to the temporary table data. When a tuple in a relation is to be deleted, not only the tuple in the relation must be deleted, but also the tuples in the media relations, if any, must be deleted as well. The SQL commands to delete from the actual relational data tables where the stored data matches the temporary result must be generated. The process of removing the temporary table is the last step in the deletion operation. INGRES embedded SQL calls this process "dropping" the table.

Initially to get the deletion operation to work in the MDBMS, a switch statement was used in the retrieve module. The retrieve module does half the work of the delete operation as it recalls the information the user no longer wants to store in the MDBMS.
After retrieval, the switch to deletion of this retrieved data, incorporated in the main retrieve process, completed the second part of the process. This technique of reusing portions of the retrieval code is an example of modularization and its benefits. The switch permits the retrieval of data to take place during execution of the retrieve operations as indicated from the main menu in \textit{db}. It allows the execution of the deletion procedure when that mode is indicated by the user selecting deletion from the main menu. As seen in the code, execution of the retrieval operation occurs first. The results are displayed to the user. The temporary result table that stores the formatted data is then compared with the actual data stored and once the match is made, the media data is located in the actual storage area and tagged. Once these matching operations are complete, media data is deleted from the original table. The formatted data is then removed from the actual database and the temporary table is removed.

\textbf{a. Main procedures for the Delete Operation}

The actual operations for the deletion procedure is selected from the main menu are as follows:

\textit{retrieve (DEL\_MODE)}: The main retrieval module is executed to retrieve the user's query conditions. The mode statement flag, DEL\_MODE, is passed in the functions for execution of the eventual deletion of data.

\textit{table\_cursor} = \textit{table\_entry}(): This sets the pointer to the table where data will be deleted.

\textit{get\_all\_atts\_of\_a\_given\_table}(): This function retrieves all the attributes of the tuples that meet the user specified conditions.

\textit{ql\_retrieve(RTRVE\_MODE)}: The retrieval process occurs in this function. Here other procedures are called to locate the media data if it is involved in the query.

\textit{ql\_print\_delete\_data}(): This procedure matches the data stored in the database to the data in the temporary table. Then other sub routines such as \textit{get\_rid\_image} and \textit{get\_rid\_sound}, are called to remove the media data from the database.
ql_retrieve(mode): Using the delete mode this time, this procedure will execute the
deletion of the formatted data that matched the temporary table conditions the user wanted
removed.

drop_table(temp_table): INGRES command to remove the temporary table created
to hold the to-be-deleted data.

The ql_print_delete_data is the procedure where the comparison is made.
This procedure in turn calls the procedure get_rid_image or get_rid_sound if media data is
included. If not, then these operations are bypassed and the retrieve operation is called
again. This time, the delete mode to delete the data stored in the actual table invoked. The
temporary table is "dropped" as specified in INGRES SQL fashion. I was able to make the
switch statement work once I had an understanding of how to modify the SQL commands.

In Appendix A, the Retrieve module shows the code with implementation of
the deletion operations incorporated with an "if" statement where a switch statement was
initially tested. Each of the INGRES precompiled commands within the procedures are
differentiated by their synchronization characters. For the INGRES precompiled command
of retrieve, the synchronization is "0". For delete, the synchronization character is "1", for
insert the character is "3," and so forth. A way to identify precompiled commands is by
locating commands beginning with the "II". All INGRES embedded SQL precompiled
commands have the "II" characters. Examples are "IIwritedb(=")" and "IIcsrQuery((char
*) 0)". More precompiled code examples will be in the A and B Appendices.

b. Testing Methodology

Once the switch mode was integrated into the retrieve module code, trial
executions of a simplified user conditions delete began. The first runs dealt with only one
tuple of strictly formatted data. When several variations of the one formatted data tuple
worked, we then tried the next level of increased media data processing difficulty. The
query was modified such that more than one tuple would meet the user criteria. Another
pointer to loop through the database looking for more than one tuple matching the user query was required. As the pointer looped through to find matches to the query, the accountability of the cursors and pointers gained attention. Several counters to maintain record of the pointers pointing to data stored in the INGRES database management and counters for the cursors to the data in the temporary tables were required.

Once the delete operation for multiple formatted tuples was working, then the obstacle of the one tuple with one media type was next. The operation to delete one tuple of formatted data with one media type image is as follows: first the same retrieval operations had to occur to get the table name and conditions from the user. Once the desired table was retrieved, a check for media data was performed. If media data is included, then the relation table key is found and the media relation table is located by using the table key and the media i_id for image or s_id for sound data. The media data that meets the specific query is deleted. After the media data is removed, then the formatted data is then deleted. This process is repeated and extended to handle an increasing number of tuples possessing one media attribute. When the formatted tuple with one media works for either voice or image, testing returns to just one tuple containing two media attributes. Successful two media data in one tuple test leads to creating another looping mechanism for more than one tuple with two media attributes. This configuration is similar to the one used for the multiple tuple formatted data case. Media tables stored as abstract data types are handled in such a way that the user is unaware of the separate tables accessed when deletion is called.

C. USER INTERFACE EXAMPLE

When the user wants to delete some information already residing in the database, the user must first select the “Delete” option on the MDBMS main menu. The database will prompt the user with line by line commands and instructions for manipulating the data in the database. These instructions will continue to process the user’s query step by step as appropriate responses are provided by the user to each database operation. The retrieval and
deletion of the first query example will be processed as shown on the screen of the MDBMS. User responses are shown in the cursor encased (<> italic bold type. The initial screen below shows the main menu of the MDBMS prototype.

Multimedia Database Management System
====================================
1. Create Table
2. Insert Tuple
3. Retrieve
4. Delete
5. Modify
6. Print out current data information (test purpose)
0. Quit
====================================
Select your choice: <4>

Here is the main menu from the MDBMS that is shown on the screen. The user must select the Delete operation and then hit a carriage return <cr> to continue the operation. The following is the response to the formatted data only query of "List the ships in the database of type 'carrier'?

Your Selection is Delete!

1. Retrieval Conditions - Input Phase

   The user is requested to enter a temporary table name to store the results of the query while it is being processed by the MDBMS. After providing the temporary table name, the user is asked in which table inside the MDBMS he wishes to remove data. The conditions, if they exist, for specific attributes in the chosen table are next requested from the user. If there are more conditions that are expected to be boolean "and" together, then the group condition query needs a <"Y" > from the user.

   Hit return to continue (any other key to QUIT)
Enter a table name to hold the temporary result of the query: `<demo_table>`

Select the table(s) separated by commas `<,>:(<?>` for HELP!)

SELECT TABLE(S): `<ship>`

Any condition? (Y/N): `<Y>`

Group Condition? (Y/N): `<N>`

Enter the attribute name: `<type>`

Enter the Condition: `<= "carrier"`

2. Execution Phase

The checks of a repetitive table name and if the table and attributes given by the user already exist in the database are performed. When all the data provided is correct, then no error statements occur. If the table is not correct or the data given for the attributes does not exist, an error message is returned to the screen. The following was executed as the table and attribute criterias were found.

Searching.....

WHERE = "carrier"

wait...

There are 2 records that match the delete query:

record id 1 name: Elliott

record id 2 name: Ticonderoga

The following photo has been found:

Number: 1

Description:
<<large ship with many weapons.>>

Record no 1 filename: /tmp_mnt/n/virgo/work/mdbms/MDBMS/91133.19734
Do you want to see the photo? (Y/N): Y
Show image...
****(Photo is displayed on the screen if user types in Y)**
Record no 2 filename: /tmp_mnt/n/virgo/work/mdbms/MDBMS/90206.30421
Do you want to see the photo? (Y/N): Y
Show image...
****(Photo is displayed on the screen if user types in Y)**
Do you want to continue to Delete? (Y/N): Y
media data matching the query is being deleted from picture1
data is being deleted from SHIP
**(return to the main menu)**

As stated, the above query execution handled only formatted data, the next example has the media data included in the query.

The above is what the user sees on the screen for the query of ships of type carrier. The following query example is the illustration of the operation from an internal view.

1. CREATE TABLE F1 AS
   SELECT s_name, photo
   FROM SHIP
   WHERE ship.type = "carrier"
2. CREATE TABLE M1 AS
   SELECT i_id
   FROM PHOTO1
WHERE (F1.photo = M1.i_id)

3. CREATE TABLE RESULT AS
SELECT all
FROM F1,M1

4. MATCH TABLE RESULT AS
SELECT all
FROM SHIP, PHOTO1
WHERE ship.attribute = result.attribute AND photo1.i_id = result.i_id

5. DELETE TABLE PHOTO1
WHERE RESULT.i_id = PHOTO1.i_id

**(all items in the result table are those media values meeting the user conditions)**

5. DELETE TABLE SHIP
WHERE RESULT.attribute = SHIP.attribute

**(the items here are all the formatted values in the tuple that meet the user conditions)**

6. DROP TABLE RESULT

**(removes temporary table)**

Query example 2:

This example will show how the MDBMS handles the media data. The subparts remain transparent to the user and the final result is displayed for the user prior to the deletion procedure. More than one table may be accessed to get the relations for the user. The functions and procedures that make the delete operation work are outlined in the previous section. The steps are the same as in the first example except for the handling of the media portion of the query. The actual media operations are not shown. The query is "Display the officer of the ship USS Elliott who has a photo description 'He has big head'?".
Here is the main menu from the MDBMS that is shown on the screen. The user must select the Delete operation and then hit a carriage return <cr> to continue the operation. The following is the response:

Your Selection is Delete!
Enter the table name to hold the temporary result of the query: <demo_table>

Select the table(s) separated by commas <,>(<? for HELP!)

media data matching the query is being deleted from ****photo4*****
media data matching the query is being deleted from ****voice4*****
data is being deleted from ******OFFICER******
**(return to the main menu)**

If the user desires to see and hear the media data types that will be removed, the user may display the photos and play the sound. The main menu is then re-displayed with the basic database management options as the deletion operation occurs in the background. The user can then re-display the table he just altered to verify the operation deleted the data as planned. The above is what the user sees on the screen for the query of ships of type carrier. The following query example is the illustration of the operation from an internal view. Notice that more temporary tables are created as the query becomes more complex.

1. CREATE TABLE F1 AS
   SELECT capt_id
   FROM SHIP
   WHERE ship.name = "Elliott"

2. CREATE TABLE F2 AS
   SELECT all
   FROM OFFICER
   WHERE o_id = shF1.capt_id

3. CREATE TABLE M1 AS
   SELECT i_id
   FROM PHOTO4
   WHERE CONTAIN(PHOTO4, "he has big head")

4. CREATE TABLE RESULT AS
   SELECT all
   FROM F1, F2, M1
WHERE (F1.capt_id = F2.o_id) and (F2.photo = M1.i_id)

5. MATCH TABLE RESULT AS
SELECT all
FROM OFFICER, PHOTO4
WHERE officer.attribute = result.attribute AND photo4.i_id = result.i_id

6. DELETE TABLE PHOTO4
WHERE RESULT.i_id = PHOTO4.i_id

**(all items in the result table are those media values meeting the user conditions)**

7. DELETE TABLE SHIP
WHERE RESULT.attribute = SHIP.attribute

**(the items here are all the formatted values in the tuple that meet the user conditions)**

8. DROP TABLE RESULT

**(removes temporary table)**

The deletion procedure is the second in the three phases of modification. Retrieval being the first, deletion the second and the execution of the actual modification the third step in the process. Chapter V will cover the modification procedures beyond what has been presented in these first four chapters.
V. MODIFICATION METHODOLOGY

Solving the modification problem began with designing and/or enhancing functions and procedures that are compatible with the currently working modules and procedures in the MDBMS system. The modularization process discussed in Chapter III of this thesis was the first step. The MDBMS prototype left by Pei and Atila when they completed their work provided ample room for improvements and completion of the system. Aygun and I commenced work on the completion of the MDBMS areas not currently implemented and improved some areas already in the running prototype. My design ideas were to use data structures used in current management systems for implementation of the retrieval module and to design additional data structures necessary to capture the user information required for processing and modifying formatted and media data, such as image and sound, if they existed. I made use of the existing implementations, whenever appropriate, for some of the operations to update the data. Extension of the user interface in the existing MDBMS allows for modification of the various data already stored in the MDBMS.

A. INTRODUCTION

Conventional database management systems have modified standard data for some time. The modifying media data types in the MDBMS provide many researchers the opportunity to discover the ideal method. In the MDBMS prototype, the media data is not placed in a temporary storage structure as the standard data is stored. Media data types are tabbed in their original storage table. If a tuple that possesses a media type is modified, the new media portion is added to the appropriate media table, be it photo or sound. After the newly modified data has been entered, then the s_id and i_id of the original tuple data is removed from the parent table. The data actually is a new tuple relation in the database in regards to the media portion even if the media data is not altered. This technique is designed based on the original structures that Pei created in his insertion operations. The internal catalog system creates new numbers for each new photo imputed.
1. Why We Need a Modification Option

The modification steps are needed because most users are human and make errors when entering data. Another reason is to have the capability to update and modify the existing data is the data continually changes. The fleet database is a living document that continually changes as the area of the home base for many ships and military installations close with force reductions, captains are transferred or retire, ship numbers change as force realignments occur, and newer weapons systems are retrofitted on older ships. These are only a few occurrences of why military business applications and complete database management systems require modification options to the data after it has been stored.

2. How modification works in general

The steps used in the modification construction process are first obtain the data using the retrieval operations described in previous chapters, and second, to use similar modification procedures as those Pei designed to modify data in the insert operation. This way, the re-thinking of pre-compiled INGRES code is minimized. The media data presents some unique problems as the catalog management system generates sequential numbers for each attribute of every tuple when they are first inserted using Pei's functions. Finding the proper way to alter the Pei data structures or to create similar ones that are compatible with the other Pei designed modification procedures became the focus of the operation of modifying already stored data.

3. Design Issues for the Information Storage in the MDBMS

In the prototype construction of the update operation, [Ref. 14] there exists a modification call for data that has not been inserted into the database yet. This data has not been placed in the INGRES system but is stored in temporary arrays. Pei arranged to query the user for changes before the data becomes stored in the INGRES tables. The difference in a modification operation on data already stored in INGRES and data just being added to the database lies in the handling of the data in the temporary arrays. See Figure 5.1. This data was corrected and then inserted, one data type at a time, in the sequential and
numerical order as defined in the relational catalog, one tuple at a time. Retrieval of the data
for modifications is not a problem. Once the user made the corrections on the data, the data
was inserted. Inserting the data in a numerical order is not possible when the modification
is of data already stored in the MDBMS. Therefore, maintaining the knowledge of where
the pointers to the information are, becomes very important. The storage of the values in
respective value array structures proved to be a way to keep track of the information the
user was attempting to modify. Another concern was where to place the data upon
completion of the modification operation so that it does not cause storage addressing
problems when retrieving the data at a later date. User’s do not always want to change
everything in a tuple or in a specific manner. Pei uses an index called the active_media_list
to maintain accountability of the insertion of media data types. His method cannot be
applied to the modification of data inside the database, as INGRES generates numbers
internally that would confuse the indexing mechanism. [Ref. 14, Ref. 15] For modification
of data already stored inside the database, media flags are used in the modifying of stored
data. The media data flags alert the MDBMS that media data is involved in the processing
of the data values the user wants to modify. The media flags, as shown in the prototype
program, let the counters know when they must be incremented as the media data is
processed. If the changes do not occur to the media data, then the same file_id is provided
to the media data in the new tuple relationship.

Figure 5.2 Att_Array for the Catalog Using Officer Table Data Entries
B. DESIGN AND IMPLEMENTATION FOR MODIFICATION

1. Testing Methodology

Once the switch mode structure was integrated into the retrieve module code, trial executions of a simplified data modification began. The first runs dealt with modifying one attribute of formatted data in only one tuple. When several attempts to modify one attribute of formatted data, either integer, character, or float, for one tuple worked, we tried modifying more than one attribute of formatted data for a single tuple. This did not present any problems as the values of the different standard values are each stored in their own value arrays as mentioned in Chapter II. See Figures 5.1 and 5.2. Since each array contains the respective value type, the index to the entry in the value array is entered into the value_entry column of the Att_array for that attribute. These arrays and the media flags that are introduced later provided a means of proper manipulation of the internally stored data. After one tuple was able to be modified, then new queries that would give more than one tuple as a result were tried. This multi-solution method required another pointer to loop through the database looking for more than one tuple. As the pointer looped through to find matches to the query, the accountability of the cursors and the pointers gained attention. Several counters and boolean flags to maintain records of the pointers to data stored in the INGRES database management and the data in the temporary tables were added.

When the delete operation for multiple formatted tuples was working fine, the obstacle of the one tuple with one media type in the relation was the next test of the system. The operations to delete one tuple of formatted data with one media type image are as follows: First the same retrieval operations to get the table name and conditions from the user must occur. Once the desired table is retrieved, a check for media data is performed. If media data is included, then the relation table key is found and the media relation table is located by using the table key and the media i_id for image or s_id for sound data. The media data that meets the specific query is deleted. After the media data is removed, the formatted data is deleted. This process is repeated and extended to handle an increasing
number of tuples possessing one media attribute. When the formatted tuple with one media
works for either voice or image, then testing returns to just one tuple containing two media
attributes. Successful two media data in one tuple test leads to creating another looping
mechanism for more than one tuple with two media attributes. This configuration is similar
to the one used for the multiple tuple formatted data case. Media tables stored as abstract
data types are handled in such a way that the user is unaware of the separate tables accessed
when deletion is called. In the modification process, however, the user participates in the
processing of the media tables to a limited extent because media relation attributes, such as
the media data's f_id and description, can be modified.

After this modification code worked with the simple retrieve operations created by
Pongsuwan, it was integrated into Aygun's complex query version of retrieve. The merging
of the retrieval, modification and deletion modules forced a change in the programming
code structures each of us developed separately. As we worked together, the switch
statement that I mastered for modification and deletion, would not work properly in the
integrated code. The switch statement overlapped a user choice retrieval menu that queried
for complex queries. An if statement was substituted for the switch statement to achieve a
working composite program.

2. Main Procedure for the Modify Operation

Initially, several flags are set to maintain a count on the formatted, image, and
sound types of data in the MDBMS. The actual operations for the modify procedure after
choice five is selected from the main menu are as follows:

retrieve (RTRVE_MODE): The main retrieval module is executed to retrieve the
user's query conditions. The mode statement of RTRVE_MODE is passed first to locate
the data that meets the query. MOD_MODE variable is passed to the main retrieve function
so that the actual execution of the modification on the retrieved data takes place.

table_cursor = table_entry(): This sets the pointer to the table where data will be
matched to the data stored that eventually will be modified and re-inserted.
get_all_atts_of_a_given_table(): This function retrieves all the attributes of the tuples that meet the user specified conditions. The user will then have the tuple available to modify all attributes before re-insertion.

ql_retrieve(MOD_MODE): The modification processes are executed when the modify mode in the if statement occurs in this function call. Procedures are called to locate the media data if it is involved in the modification query.

flags set to false for formatted, image and sound data: These flags help maintain the counts on the indices to the tuples to modify.

print_for_modify(c): This procedure is embedded INGRES code that retrieves the tuple values that meet the conditions the user states and prints out the tuples so that the user may see how many and which tuples are to be modified. The user will be asked to modify each tuple one by one in the next procedure.

process_tuple_by_tuple(r): This procedure is the function that checks for multiple tuples meeting the user query criteria. When more than one tuple needs modification, the first in the database called will be modified first and continue to loop through the database to search for other tuples. After all those that the user requested are modified, this process terminates and each of the tuple changes is shown to the user in the procedure below.

mod_display_tuple(mode, media_counter): This procedure shows the user the tuple information with the changes he has made to the original tuple. This procedure in turn invokes mod_print_tuple and mod_print_media_tuple. If more modification is necessary for the tuple after the user sees it, the user is able to make those corrections during the continued execution of this procedure.

store_data(mode): This procedure is invoked every time the catalog information in the system tables have been updated or modified. The procedure further performs processes from the system tables in the main memory to host three catalog files in external storage devices.

mod ql_insert_tuple(mode): During modification, this procedure generates the user's SQL statements for data modification. It constructs the SQL commands for the
insertion of a modified tuple. The sub-procedure of the modql_insert_tuple is called to generate the user SQL statements for the data insertion of the modified media relations. The SQL commands create the media relations and the INGRES.

**delete_for_modify(r):** This procedure will execute the deletion of the media data that the user wanted modified. This procedure matches the data stored in the database to the data in the temporary table. Then other subroutines are called, such as mod_get_rid_image and mod_get_rid_sound, to remove the media data from the database.

**delete_formated_part_for modify():** This procedure will execute the deletion of the formatted data that the user wanted modified.

**drop_table(temp_table):** INGRES command to remove all the temporary tables created to hold the data while processing the modification operation.

**reset media flags.**

C. USER INTERFACE EXAMPLES

For modification in the MDBMS, the user must follow the modify procedures as outlined in the main menu. As expected, the user must first state the conditions of the modification. The data is retrieved and then tuple by tuple, the user may modify any and all of the attribute values currently stored in the MDBMS. The prototype system prompts the user for the data necessary to process the user request. The actual user responses in this example are encased in the cursor (<> in bold type. Two examples are given, one dealing with formatted data and the other containing some image data.

1. **Query 1 - Formatted Data Modification**

The first query to modify is "Find the officer with the name Fred Pong and change his rank to CAPT and his salary to $8700." In this query, there is not a need to connect to the parser to analyze a media description. The original table information meeting the user conditions will be displayed to ensure it is the correct relation to be modified. After displaying the information, the user will respond to continue to modify or terminate the current operation. When continuing the modification operation, the user is asked which
items need modification. The retrieve and deletion operations will not be explained in depth
as they are stated in previous chapters. Refer to Figure 4.3 to see the values of the relations
and Figure 5.3 to see the values upon completion of the modification operation.

MULTIMEDIA DATABASE MANAGEMENT SYSTEM

1. Create Table
2. Insert Tuple
3. Retrieve
4. Delete
5. Modify

2. Query2 - Media Data Modification

This query involves the user specifying the conditions based upon the description of the voice. After finding the data entries that match the user’s conditions, modification operations for this data occurs. The query “locate the officer with a voice description of ‘strong voice’ and change it to say ‘loud voice’ then check his photo and change the description to state ‘wears glasses’ if he has them in the photo”.

*Figure 5.3 Media Relations After Modification of Data Values*
VI. CONCLUSIONS AND RECOMMENDATIONS

A. REVIEW OF THESIS WORK

The NPS MDBMS prototype is a demonstration version of a Multimedia Database Management System which can manage formatted and multimedia data. With the completion of the deletion and modification procedures, the prototype now provides all the conventional database management operations. Items can be deleted or modified now after they are stored. Prior to the completion of this thesis, only the create, insert, and retrieve options were available. The system, as it is now, performs media data processing by means of executing the SQL commands step by step. These commands perform intermediate relations and sub query decompositions/recombination in order to attain the desired output. The final product, a relation containing the tuples is available to the user for review, update, delete, or display the data. Companion theses present the complex query retrieval [Ref. 2] and the ideal user interface for an MDBMS [Ref. 13] also incorporated in the prototype.

Repetitive updates can be made based on the descriptions of image, sound and formatted data can be changed or deleted permanently. The research done to define the deletion and modification operations, and specifically address data involving image and sound and the integration of media with the formatted data, is explained in the body of this thesis. This thesis concentrated on the complex methods and operations of data modification and deletion for the MDBMS. Solutions to some of the issues raised were found. The type of data structures required to capture the user supplied information for modifications on data and the coding for compilation into acceptable INGRES statements are two of these issues. With the completion of the deletion and modification procedures, the prototype, a complete database management system prototype able to manage different types of media data from creation to deletion, is obtained. This multimedia database management system demonstrates the great advantages users possess with a MDBMS over a traditional DBMS.
The prototype's structured foundation was established for the design and implementation of the functions that perform the user requested actions. These actions are implemented interactively with a line by line interface. The transformations of the user's query is entered into an embedded SQL request to be processed in INGRES and written in standard 'C' programming language. This query is replaced by embedded SQL compiled statements. Each corresponds to a set of function calls to operate on the appropriate standard and media sound or image-object relations.

B. FUTURE WORK

Future work areas overlap with those currently being researched as the MDBMS evolves into a better operating prototype. Research is currently going on for the appropriate graphical user interface for the MDBMS [Ref. 13]. This graphical interface will also incorporate a more detailed help tool which the user can easily operate the first time he runs the MDBMS. The design of this user interface uses icons generously. Having better user help pull-down menus or help screens that provide definitions or examples of how the database steps are performed, would surpass the current line by line user interface that supports the MDBMS now. The graphical user interface will display more vividly the way the relations in the database are arranged and the transactions as they occur in the MDBMS. Further work envisioned is the implementation of this ideal graphical user interface designed in Peabody [Ref. 13]. An upgrade to an object oriented language will likely make a difference towards improving the user interface.

The principles of understandability, maintainability, correctness, reusability, and uniformity are team programmers' goals in their products. The module hierarchy reflects the relationships and the way each module interacts with the others. More work can be done with the modularization of the MDBMS. Work completed by Aygun [Ref. 2], and myself was just enough to get the large program separated into some main modules. Due to a lack of time, more work to eliminate redundant code and consolidate similar operations was not
accomplished. Future work in continuing our modularization efforts would make a better prototype.

Another idea for the improvement of the MDBMS is allowing the user to change a table format after it has been created and data inserted into the database. Currently, the data in a table that needs changing cannot retain the data as the table must be removed and then is restructured. The new option to alter the table and continue to use data already stored would be a more efficient way to manage data. An example of this is to alter a personnel table by adding a personal insurance attribute. To alter the personnel table attributes, once it is discovered that a column of data is needed, or is no longer needed would enhance the databases workability for modern day users. Reasons to retain data changes as does the method of storing the data.

C. MDBMS IMPROVEMENT POSSIBILITIES

The current MDBMS can only process up to two types of media data: sound and image. Further work in processing more media types such as graphics, video or signals would broaden the range of the media portion of the project. To process multiple images and/or sound data types for one tuple. An example is having a photo of the ship and the weapons that are on the ship all in the ship relational tuple. Or, having the captain and the executive officer recorded voices accompanying the ship relational tuple. This will take some restructuring of the modification procedures and functions. Maintaining the accountability of the pointers and cursors will be the largest obstacle to overcome for these suggested improvements. More media data types integrated into the MDBMS will prove different styles of creating relations may work better than the ideas presented here on how to modify data existing in a database management system.

A user’s manual to accompany the prototype would be ideal for this demonstration model. It is not easy to work with in the line by line user entry configuration without some basic knowledge of the relations and the terminology of the system. A user’s manual and better exception handling are ways to improve the prototype. Increasing the error control
and checking mechanisms of the prototype would help to eliminate some errors that occur at the time the user interacts with the system. At the present, not all errors are handled in the best manner. Having more checks and clear, more concise system responses for the user to interpret would only enhance the system usefulness.

As more work is done with the project, an upgrade to a current INGRES version would eliminate some of the inherent problems we encountered in working with the prototype. As mentioned in the body of the thesis, much software engineering is necessary to upgrade the code to a newer INGRES version. Work is planned to upgrade the natural language parser with a more reliable content search success. A larger dictionary caption base and possibly using super groups for the caption searches and having a text type are other prototype enhancing ideas.
APPENDIX A: SOURCE CODE FOR DELETION

/********************Retrieve.c********************/

* Title : Retrieve.c
* Author : Aygun/S Stewart
* Date : August 1991
* History : Improvements on Retrieval operations to include complex
* query processing. Also contains the procedures to perform
* the deletion operations. An if clause provides the ability
* to switch options for retrieval or deletion of data
* Description : This module implements the retrieval process in the
* Multimedia Database System.

Export Interface:

* retrieve(RTRVE_MODE):
  incorporates the retrieval process. The user is asked to
  enter the name of table(s) and attribute(s) he wants to
  retrieve. If he does not know the names of the tables or
  attributes, he can type "?" to list all the tables and
  attributes in the catalog.
* retrieve(DELMODE):
  incorporates the deletion process. The user is asked to
  enter the name of the relation table one at a time of what
  attributes in the catalog he wants to delete.

Import Interface:

* print_all_table(): Prints out the table catalog information on screen
  from InsertModule.c
* check_table_name(): Checks the table_name if it is duplicate
  get_media_name(): Get media table name by appending table_key at the
  end of att_name.
  from CreateModule.c
* yes_no_answer(): Gets yes or no answer from the user.
* clr_scr(): Clears the screen.
  from UserInterface.c
* play_sound(filename): Sends command from SUN to PC to play the SOUND
  media file.
  from SoundModule.c

}

This function initializes an array upto size 100.

init_buffer(buffer,j)
char buffer[100];
int j;
{
  int i;
  for (i=0; i<j; i++) {
    buffer[i] = '0';
  }
}

This function drops the temporary media tables used to hold the intermediate results of a query.
To be processed by INGRES, had to call inttostr -integer to string function
drop_temp_media_tables()
{
    int k;
    char l[5];
    char tempstring[100];
    for (k=0; k<10; k++) {
        strcpy(tempstring, "p");
        inttostr(k, l);
        strcat(tempstring, l);
        IlsqlInit((char *)0);
        Ilwritedb("destroy");
        Ilwritedb(tempstring);
        IlsqlSync(0, (char *)0);
        init_buffer(tempstring, 100);
        init_buffer(l, 5);
    }
}

This function asks the user to enter a join condition for retrieval conditions with AND in them.

void help_join()
{
    int i=0;
    if (m > 1) {
        strcpy(join_condition,"?");
        while (strcmp(join_condition,"?")==0) {

APPENDIX B: SOURCE CODE FOR THE MODIFICATION

The programming code for the modify operation is contained in this appendix.

/*************************** ModifyModule.c ***************************
* Title : ModifyModule.c
* Author : Aygun/Stewart
* Date : July 1991
* History : Created based on the PEI insert module modifications
* : prior to the insertion into the MDBMS and the
* : Retrieval operations developed by Pongsuwan and Aygun
* : 
* Description : This module implements the modification of tuples
* : existing (already stored in the catalog management
* : 
* :MDBMS.

Export Interface:
* mod_print_all_table() :Prints out the table catalog information on screen
* mod_insert_tuple() : Inserts a tuple of a particular relation
* display_tuple() : Displays the tuple before insertion
* check_media_descrip() : Checks media description by connecting to the parser
* ql_insert_tuple() : Translates SQL statement to insert a standard tuple
* show_image() : Displays image on the screen by passing pixels and colormap from
* the caller. It might be able to quit the image automatically before
* displaying the next image.

Import Interface:
* mod_check_table_name() : Checks table name to see if it is duplicate
* get_media_name() : Gets media table name by appending table_key at
* the end of att_name.
* from CreateModule.c
* 
* mod_get_sound_value() : Gets a sound value of a media attribute from the
* user input
* yes_no_answer() : Gets yes or no answer from the user
* clr_scr() : Clears the screen.
* from UserInterface.c

APPENDIX C: RUNNING THE DATABASE

The system is configured on the SUN server “VIRGO” under the account /n/virgo/work/mdbms/MDBMS/dbrose. The user can set up the path from any account to reach the directory. The files must be copied from the directory to the directory the user will use. When the directory is copied, then the user must log off and log on again so the system may follow the new paths arranged now for proper execution. The database main program executable object code is called db. The user must type “db” in the working directory to run the MDBMS prototype. However, a check must be made to ensure that the user is an authorized user to the INGRES DBMS. If the user is not an authorized user, then an error message will appear on the screen stating it is unable to access those areas. If questions arise, then the system administrator should be consulted to acquire a path for accessing the INGRES system.

Db is created using the make command, as several other files are needed to run the MDBMS prototype. Make is a command generator that executes a list of shell commands to bring a set of files up to date. Make aligns the dependencies among files. The executable code files are generated by linking the libraries, object files and from the programming language source files. The original program source code is called db.sc. The program is precompiled in the INGRES SQL. This step produces the program in an acceptable C compiler format program db.c. The C compiler creates the object code db.o and links it to the libraries object code listed in the Makefile. Some libraries are Sunwindow library, Sunpixrects library, Suntools library, and INGRES library. More important files that are applications necessary for the prototype are diction.add, image_iimage facts and the prolog_parser. To check for proper compiling and linking, the user must type make db at the prompt. The make command then calls the make file designated for the db executable programming code. The makefile for this db code is not the only copy of a makefile for the MDBMS on the UNIX system. When we worked on our separate modules of the MDBMS, I used a version of the database entitled dbrose. For compiling and accessing the dbrose
code, the user must type "make -f Makerose dbrose" at the UNIX shell prompt in order to ensure that the prototype code is up to date. If the dbrose.sc code needs linking and compiling, then the series of make commands will produce the executable version (dbrose). If db or dbrose are current, a message stating that "db(rose) is up to date" appears on the screen. As one or more of the source files are modified, then recompilation followed by relinking must occur. As in most software engineering projects this process is repeated as each revision is made on the prototype code. An option of make to automatically perform the updating tasks is $make db. After this is issued, the Make utility executes the tasks that must compile and relink after a modification.

A description file usually defines the dependencies between the files and modules. This description file is usually given the name Makefile. Numerous entries comprise the description file. Each of these entries is delineated by a line that contains a colon. The colon indicates the dependency line and the targets. The targets are on the left side of the colon. The files that the targets depend are on the right of the colon. An example is the following:

OBJMODS= ISfunctions.o, comcprologl.o ISroutine.o

#ING_HOME = /ingres

db: db.o $(OBJMODS)
    cc db.c -o db
    /ingres/lib/libqlib/ingres/lib/compatlib
    /-lsuntool -lsunwindow -lpixrect -lm

db.c: db.sc
    esqlc db.sc

These examples display the dependency of the file db.c on the file db.sc. The program db.sc is the precompiled by the INGRES SQL. Makefile is shown in Appendix D
