The Antisubmarine Warfare System Evaluation Tool (ASSET) is a generic high-level antisubmarine warfare (ASW) modeling tool, designed to aid ASW personnel in the development and refinement of ASW top-level warfare requirements and the ASW Master Plan. The primary objective of this thesis is to analyze and implement the improvements suggested in previous evaluations of various sub-areas of ASSET. The glimpse rate model for submarine detection used in ASSET has been substituted with compound Lambda-Sigma jump model. There is a different target radiated frequency in each environmental region. Each target will have its own detection rate to reflect the differences in its operating characteristics. Multiple engagements between platforms are used to eliminate the limitations of interaction between opponent platforms. The glimpse rate model is used to determine detection opportunities of maritime patrol aircraft (MPA) and to approximate a continuous-looking sensor pattern. A different criterion of selecting search probability area (SPA) and MPA pairs using the ratio of MPA's time on-station over the SPA size was implemented. The feasibility of converting current ASSET code to CLOS was investigated. In addition, part of the code was converted to CLOS.

ABSTRACT

The Antisubmarine Warfare System Evaluation Tool (ASSET) is a generic high-level antisubmarine warfare (ASW) modeling tool, designed to aid ASW personnel in the development and refinement of ASW top-level warfare requirements and the ASW Master Plan. The primary objective of this thesis is to analyze and implement the improvements suggested in previous evaluations of various sub-areas of ASSET. The glimpse rate model for submarine detection used in ASSET has been substituted with compound Lambda-Sigma jump model. There is a different target radiated frequency in each environmental region. Each target will have its own detection rate to reflect the differences in its operating characteristics. Multiple engagements between platforms are used to eliminate the limitations of interaction between opponent platforms. The glimpse rate model is used to determine detection opportunities of maritime patrol aircraft (MPA) and to approximate a continuous-looking sensor pattern. A different criterion of selecting search probability area (SPA) and MPA pairs using the ratio of MPA's time on-station over the SPA size was implemented. The feasibility of converting current ASSET code to CLOS was investigated. In addition, part of the code was converted to CLOS.

I. INTRODUCTION

A. OVERVIEW OF ASSET

The Antisubmarine Warfare Systems Evaluation Tool (ASSET) is a generic high-level ASW modeling and analysis tool. It is designed to aid ASW personnel in the development and refinement of ASW top-level warfare requirements and the ASW Master Plan. Current version of ASSET (version 1.0) was implemented in Macintosh Allegro Common Lisp (MACL) version 1.3.2 and designed for use on a Apple Macintosh II computer.

The ASSET is used to model open ocean scenarios involving submarines, maritime patrol aircraft (MPA), shore-based command and data-fusion centers, and a variety of passive acoustic sensors. These tactical objects interact in a particular geographic location against an analogous enemy force structure. The simulation scenario is specified by a user-supplied architecture that determines all aspects of environment, command control, sensor interaction, and platform maneuver. This structure is created through a series of predefined windows, each dealing with a specific topic, such as Geoplot Edit Window, Track Input Window, and Region Build Edit Window.

Once the parameters are determined by the user, the scenario is repeated as a Monte Carlo simulation to produce statistically meaningful measure of effectiveness (MOE). Output data regarding the detection, localization, and prosecution of enemy platforms can then provide a quantitative basis for decisions regarding assessments and system appraisals. The modular nature of
the object-oriented structure of ASSET makes expanding the scope of the simulation possible.

The ASSET is programmed in Macintosh Allegro Common Lisp, an object-oriented programming language, which allows related elements in the simulation to inherit data and functionality via hierarchical class structure. The simulated objects in ASSET can be broken into three groups: (1) command, control, and communication (C3) objects; (2) acoustic radiators; and (3) ASW detectors. The C3 objects consist of level 1 commands, level 2 commands, fusion centers, antisubmarine warfare operational centers (ASWOCs), Submarine Operating Authorities, and communication satellites. A more detailed description of ASSET and its capabilities can be found in the ASSET Technical Documentation and User's Manual [RI 90].

Weaknesses of the ASSET that have been identified include the following: unable to use lower-level models, only part of ASW problem is considered, difficult for the novice to use, excessively simple acoustic and maritime patrol aircraft (MPA) modeling, and slow execution time.

B. PREVIOUS WORK AT NPS

Several evaluations on the various sub-models of ASSET have been conducted at the Naval Postgraduate School. [CA 91] examined and evaluated the acoustic detection modeling in ASSET. An alternate detection model has been suggested that incorporates aspects of the glimpse rate model and the more standard Lambda-Sigma (\(\lambda-\sigma\)) model.

[SH 91] evaluated the MPA detection and allocation models utilized by ASSET. It also proposed a potential long term course of action for evolving
ASSET into a comprehensive, flexible, and simple-to-use tool for top level ASW appraisals and assessments.

[VE 91] investigated the mathematical development of the tracking algorithm. Some possible modifications to the existing Kalman filter tracking algorithm were suggested to better match the data input and increase computational efficiency.

C. OBJECTIVES

The primary objective of this thesis is to implement and verify the improvements suggested in previous NPS evaluations of various sub-areas of ASSET. We want to test whether the suggestions are feasible. A second objective is to improve the overall efficiency of the ASSET run-time system. The feasibility of converting current Object Lisp code to Common Lisp Object System (CLOS) is also being investigated.

D. ORGANIZATION OF THESIS

Chapter II provides an overview of object-oriented programming language (OOPL) in simulation application. We review the basic characteristics and benefits of OOPL and some applications in the object-oriented simulation field. Chapter III describes the current detection modeling and possible improvements, followed by a description of implementation changes. Chapter IV contains the description of the current MPA modeling, possible improvements, and the details of implementation. Chapter V presents the work of converting current version to CLOS. Finally, Chapter VI is the conclusion and summary along with a brief statement of recommendations for future work. Appendix A contains the source code of revised and new modules of ASSET.
II. OBJECT-ORIENTED SIMULATION

In discrete event simulations, we normally simulate the behavior of various objects that may be mathematical or statistical constructs, or in most cases, physical and observable entities. For example, in a manufacturing factory, the objects are the machines of interest, the types of parts that are to be produced, and the operations needed to complete their manufacture. Such objects are usually the central focus of the simulation studies and are easy to identify. The purposes of simulations are to find a convenient means of modeling the objects and to manipulate and control their behaviors, including the interactions between the objects.

In a simulation, the user creates computer models of the various elements of the simulation, describes how they will interact with one another, and sets them moving. This is similar to typical object-oriented programming, in which the user creates the entities in the universe for the program, describes how they will interact with one another, and finally sets them in motion. Due to the similarities, there are many advantages in using the object-oriented paradigm for discrete event simulations.

A. BASIC CONCEPTS OF OBJECT-ORIENTED COMPUTING

1. Objects, Classes, and Inheritance

Object-oriented languages combine the descriptions of data and procedures within a single entity called an object. An object consists of a well-defined set of variables (called slots within the object) that can be manipulated only by a set of methods defined exclusively for that purpose. A class is a
description of one or more similar objects. It is used to specify the implemented data structures and the operations that can be performed.

The variables making up an object can be divided into two kinds: class variables and instance variables. A class variable is the one we associate to the class itself and is shared in both name and value by all instances of a class. An instance variable is shared in name only by all instances of a class.

A method is a procedure or operation that is defined for an object. A message is the instruction sent to an object to perform one of its methods. Ideally, the only way to access any of the variables making up an object is by sending the object a message. In this way, an object is said to be encapsulated in that its internal structure may be modified without affecting user-written code that accesses the object.

Inheritance can be defined simply as code sharing mechanism. It allows a new class to be defined based upon the definition of an existing class without having to copy all the existing code. A child class (or subclass) inherits all the variables and methods defined for its parent class (or superclass). Inheritance is usually transitive, so a class can inherit features from superclasses many levels above. Exceptions can be handled at any level by altering the values of the affected variables.

Inheritance means that the behavior and data associated with child classes are always extensions of the properties associated with parent classes. A subclass must have all the properties of the parent class, and others as well. On the other hand, since a child class is a more specialized (or restricted) form of the parent class, it is also, in a certain sense, a contraction of the parent type.
2. Encapsulation

Data abstraction is a methodological approach to problem solving in programming where information is consciously isolated and hidden in only one part of a program. In particular, the programmer develops a series of abstract data types. Each abstract data type can be viewed as having two faces. From the outside, a client (user) of an abstract data type sees only a collection of operations that together characterize the behavior of the abstraction. On the other side of the interface, the programmer defining the abstraction sees the data variables that are used to maintain the internal state of the object. For example, in a graphics package, a graphical object may be defined to have interval values of position, shape, and extent; on the other hand, operations such as moving and combining objects are all that the user needs to change the internal values of an object. Once declared, the graphical object then becomes a data type within the language. In a data base application, a record becomes a general data type and its operations may include storage and retrieval of the records.

3. Polymorphism

Polymorphism can be defined as allowing a method to operate on objects of different data types. True polymorphism allows the various operations to be created and tested independently of one another. Adding a new version of the operation has no effect upon the existing code at all. Polymorphism allows the definition of flexible software elements amenable to extension and reuse.

Simple polymorphism allows each of different classes to have its own implementation of an operation. Multiple polymorphism allows each class to
have several operations with the same name. The proper operation is chosen based upon the arguments provided.

4. Dynamic Binding

Many benefits of object-oriented programming result from its dynamic binding. When you call a function in a language such as C, the compiler and the linker cooperate to generate a call to a physical address. While this is very efficient, one must take care to associate the function with the appropriate data structures. Strongly typed languages attempt to catch mismatched data types at compile time. Others do a poorer job of catching these errors, and sometimes the problems are not detected until the output starts looking strange.

In object-oriented programming languages, the programmer is relieved of the burden of calling the right method with the specific data structure. Instead, the programmer uses a generic name for the function, and the receiving object looks up for the proper method. This run-time binding is sometimes called "late binding" and has several advantages. In the programming world, late binding means that references are symbolic and methods can be compiled without re-compiling all its callers. The same symbolic names are used, despite the type of object. Finally, a single message can invoke several methods. This is known as polymorphic behavior and it allows code to be written independent of the receiver.

For simulation, late binding means that the specific machine needed for the part can be determined when the part finishes its previous operation. It doesn't have to be established at the start of the simulation. The time to complete the part can also depend on the current set of resources and the state of the system. For example, consider a conveyor handling packages. How those
packages occupy space on the conveyor is determined at the time they are placed there, not in some predetermined set of fixed-size bins.

B. MODELING PERSPECTIVES

Modeling with objects focuses on what the objects are in the real system, instead of what the objects in a simulation language represent. In a simulated system the general entities can be grouped as classes, and specific entities should be objects. If the objects appear to share some common characteristics, then they can be a subclass of a more general class. Methods should be defined for specific operations if needed. Division of objects into classes, recognition of methods, and the organization of hierarchies form the basic approach to object-oriented modeling.

1. Potential Benefits of Object-oriented Approach

a. Modular Implementation

Object-oriented programming enables the programmer to define an organization of classes that models the relationships among the various kinds of objects. The programmer can define classes that serve as building blocks. Each individual aspect of structure and behavior is abstracted and defined separately. The programmer then creates new classes that inherit the desired combination of building blocks. Therefore, object-oriented approach allows for a modular implementation.

b. Conveniently Extensible

The Object-oriented simulation is conveniently extensible. Using a set of classes with documented structure and behavior as building blocks, users can create new classes and add customized behavior. Through function and operator overloading, old symbols take on additional meaning. Inheritance
permits new objects to be defined from existing ones, only the differences need to be noted. Old models are reusable because their methods and objects continue to be useful.

c. Reduced Code Size

In side-by-side comparisons code written in object-oriented programming languages are substantially smaller than that written in procedural languages [CO 87]. The reduced code size means that a single person can manage more tasks. In the simulation of complex systems, building larger and more realistic models are possible without an increase in manpower.

d. Natural Representation of Objects

Objects in most simulations tend to be physical and real, and can easily be represented pictorially. Therefore, object-oriented simulation models often have a natural pictorial (iconic) representation and are easily animated. The user can often translate directly his simulation model into an animated simulation without additional conceptual changes.

Since the objects contain their own functionality, intelligence can be built directly into this functionality using the machinery of artificial intelligence and expert systems. In addition, objects provide a natural basis for concurrency. The idea is that each object could be assigned to its own processor and run independently until some form of coordination is needed. Although it isn't clear exactly what form the coordination should take, there is a natural division among the simulation components when viewed as objects.

e. Reusable Software Systems

By reducing the interdependency among software components, object-oriented programming permits the development of reusable software
systems. Such components can be created and tested as independent units, isolated from other software components.

2. Disadvantages

a. Run-time Cost

Dynamic binding is flexible but with some run-time cost. Dynamic method binding requires the execution of some run-time mechanism to match a method to a message. The cost of dynamic typing involves a run-time search to discover the code to execute every time an operation is used on a data value.

b. Memory

Object-oriented environments (like CLOS) require machines with lots of RAM. In addition, the use of any software library frequently imposes a size penalty over the use of systems especially constructed for a specific project. With the advance in hardware technology, however, this has become less serious.

c. Program Complexity

Although object-oriented programming is often touted as a solution to the problem of software complexity, overuse of inheritance often replaces one form of complexity with another. Understanding the control flow of a program that uses inheritance may require several multiple scans up and down the inheritance graph.

Some object-oriented languages require extensive class libraries be understood before becoming proficient. This increases the learning time and forces users to become more dependent on documentation and high-level debugging tools.
d. *No Standard Model*

Different object-oriented approaches use different terminology to define similar concepts. There is no single, agreed upon standard for object-oriented model.

C. *SIMULATIONS WITH OBJECT-ORIENTED IMPLEMENTATIONS*

Many object-oriented systems are suitable for performing simulations. None have clearly been proven to be generally superior as research into understanding object-oriented programming continues. Among the widely used languages, Simula was designed as a simulation language, Smalltalk [GO 83] contains an extensive set of classes and methods to support simulation, and C++ [ST 87] was designed to be applied to simulation. Uses of Smalltalk as a simulation language and environment can be found in [GO 83], and in the tutorial of [KN 86, KN 87].

There are several Lisp-based object-oriented languages with mechanisms for abstraction, polymorphic typing, and dynamic binding. These include Flavors (which supports a more primitive function than an object), CommonLoops, and New Flavors. A Lisp based object-oriented simulation system is described in [ST 88]. DEVS-Scheme is an implementation of DEVS for hierarchical, modular system within an object-oriented framework [KI 87]. DEVS is a simulation formalism developed in [ZE 84].

There are also several hybrid object-oriented systems that combine the object-oriented approach with traditional procedural features. For example, Objective-C [CO 87] adds objects, similar to Smalltalk, to the definition of C. With the similarity between Smalltalk and Objective-C, a translator has been
recently introduced to convert Smalltalk into Objective-C [SC 87]. Thus Smalltalk could be used for design and prototyping, and later converted to C through Object-C for efficient execution. Actor [DU 86] provides a Smalltalk type environment with Pascal-like procedural programming and artificial intelligence features.

Object-oriented systems provide a practical approach for those who design simulation software. Object-oriented languages provide a natural framework for development. The information hiding and abstraction facilities make it easy to develop and maintain complex software components. The extensible platform is an attractive way to add new concepts and features to an existing simulation. It is just a matter of time before existing simulation languages attempt to exploit various aspects of the powerful features of the object-oriented systems.
III. ACOUSTIC DETECTION MODELING

A detection-rate model is used in ASSET version 1.0 to model acoustic systems in which detection opportunities occur over continuous intervals of time. It is used for modeling the detection capabilities of submarines, maritime patrol aircraft (MPA), fixed area sensor (FAS), mine fields, and trip wires.

The first section gives a brief description of the existing ASSET model and its possible problems. The second section reviews the alternate model suggested in [CA 91] and provides some additional ideas on improving the current model. The implementation details for improvement are discussed in the third section.

A. EXISTING ASSET MODEL

1. Glimpse Rate Model

Because of computational limitations, ASSET uses a discrete glimpse rate to model the continuous process of passive acoustic detection. By drawing an exponentially distributed random variable for the time of the next glimpse (i.e., detection opportunity), run time for complex simulations can be held to an acceptable level.

In the glimpse rate model, detection opportunities occur at times determined by a Poisson process with user specified rate $g$. When an opportunity occurs, the target is detected if and only if signal excess ($SE(t)$) is greater than zero. The details of glimpse rate model used in ASSET can be found in [RI 90].

The glimpse rate is a user input which greatly affect the results of a run. [CA 91] points out that there is no good guidance for selecting the glimpse rate $g$. If $g$ is small, the time between glimpses can be quite long. Rapid changes in the
mean signal excess may be missed, causing searchers to have little to no success detecting other platforms. If \( g \) is too large, the time between glimpse can become small enough that the model approaches continuous glimpsing, resulting in an unrealistically high cumulative detection probability \( CDP(t) \). This happens because ASSET draws an independent fluctuation value for each look, possibly underestimating the expected correlation between signal excess values at closely spaced times.

Another major drawback is that currently there is only one radiated frequency for each acoustic platform in ASSET. In addition, there is a single mean glimpse interval by all searchers regardless of the searcher type or mission.

2. Interaction between Acoustic Platforms

During the period of a hostile encounter, a platform can engage with (or be engaged by) only one opposing platform. If a platform is engaging with an opponent, then it will not be detectable by any other platform.

B. SUGGESTED IMPROVEMENTS TO ASSET

1. Compound Lambda-Sigma Jump Process

The Lambda-Sigma jump process as described in [WA 91] is a model where the times of random fluctuations in signal excess occur according to a Poisson process with rate \( \lambda \) per unit time. The amount of the fluctuation at time \( t \) \( (D(t)) \) is drawn independently from a normal distribution with mean zero and standard deviation \( \sigma \). The deviation value remains constant until the next fluctuation occurs in the Poisson process, at which time a new deviation is drawn, independent of previous values. The deviation step function is added to the mean signal excess curve, resulting in a discontinuous signal excess curve. Like the glimpse rate model, a detection occurs if signal excess is nonnegative.
The advantages of using the Lambda-Sigma jump process in ASW analyses are:

1. It models random fluctuations of signal strength in a handy and adaptable manner.
2. It captures the idea of correlation in signal excess between closely spaced times.
3. For simple geometries, close-form expressions for CDP \( t \) are available.
4. It is extremely easy to simulate.

a. **Global Lambda-Sigma Jump Process**

The ocean fluctuation value determined by a Lambda-Sigma stochastic process is used to simulate global area environmental correlation for all targets. This value is used as one of the variables in computing the signal excess.

b. **Individual Lambda-Sigma Jump Process**

To reflect the acoustic environmental differences among the various searchers' local environment regions, an individual Lambda-Sigma value is also used as one of the variables in computing the signal excess.

c. **Total Signal Excess**

Total signal excess is the sum of the mean signal excess plus the global and individual Lambda-Sigma fluctuation values.

2. **Target's Radiated Frequency**

The most detectable radiated frequency of a target will be selected from a list of environment-frequency pairs according to the environmental region it is in. The frequency is then used to determine propagation loss and sweep width in computing the signal excess. This will allow a different target radiated frequency in each environmental region.
3. Target's Detection Rate

Each target will have its own detection rate to reflect the differences in its operating characteristics. Consequently, each searcher-target pair will have its own mean time (between glimpse) for scheduling detection opportunity events.

4. Multiple Engagements between Submarines

When a platform is engaging with an opponent, it is still detectable to other opponent searchers, but it will not detect any more platforms before it finishes the engagement. Thus it is possible for a platform to be detected and attacked while it is engaging a third platform. To simplify the calculation of the probability of a kill in this complex engagement, the events of engagement are sequentially processed. The probability of a kill is treated independently among all searcher-target pairs involved in this multiple engagement. The system will check that either the searcher or target is active before processing engagement events and platform kill events.

5. Responding False Alarm Target

When a false target appears during search, the searcher will send a detection report and will continue the search operations. Also, the platform having a false detection will still be detectable to other unengaged platforms.

C. IMPLEMENTATION OF IMPROVEMENT IDEAS

In this section we describe implementation ideas of the improvements mentioned above. The changes can be classified into three categories: data structures, modified functions, and new functions. They are categorized by their physical locations in the application package distributed by Metron.
1. **Structure File**
   
   **a. PlatformacousticParms**
   
   The structure PlatformacousticParms specifies acoustic parameters of a platform. The following data fields are modified:
   
   - `individualSigma`  Sigma for individual Lambda-Sigma process
   - `LambdaSigmaValue` Individual fluctuation of target's signal excess
   - `meanInterval`  Mean time between fluctuation
   - `detectableInterval` Target's detectable interval (1/Lambda)
   - `env-freq-list`  List of target's radiated frequencies in each region

2. **RB-Installer File**
   
   **a. New Radio Buttons**
   
   Two new radio buttons are added for input of the compound Lambda-sigma jump process:
   
   - `lambdaSigmaProcess-rb` Radio button for input of Lambda-Sigma parameters
   - `env-freq-rb` Radio button for input of environment-frequency pairs of a acoustic platform

3. **Class Umpire**
   
   The class Umpire describes the variables and methods to perform the setup of platform detection and engagement event schedules. It is modified as follows:
a. **Data Field Deleted**

FOMglimpseInterval

b. **New Data Fields**

- **globalSigma**: Sigma for global Lambda-Sigma process
- **globalLambdaSigmaValue**: Global fluctuation for signal excess
- **globalMeanInterval**: Mean time between global fluctuation

c. **New Method**

- **updateGlobalLambdaSigmaValue**: Updates global Lambda-Sigma value and schedules for next update.

d. **Modified Functions**

- **setupForReplication**: Initializes globalLambdaSigmaValue and schedules for next update.
- **setNextDetectionOpportunity**: Allows engaged target being detectable to searchers that are not yet engaged. It also checks range when scheduling next detection opportunity for engaged platforms.
- **processDetectionOpportunity**: Engaged platforms will not detect any other target.
   - **setNextDetectionOpportunity**: Allows engaged target being detectable to searchers that are not yet engaged. It also checks range when scheduling next detection opportunity for engaged platforms.
- **processDetectionOpportunity**: Engaged platforms will not detect any other target. Engaged platforms is detectable to unengaged searchers.
**getDetectionOppResult**: Determines target's most detectable radiated frequency. Uses global and individual Lambda-Sigma value to adjust mean signal excess.

**processPlatformKill**: Checks if the platform had been killed already.

**setNextFalseAlarm**: Checks if the platform is active before it sets up another false alarm.

**processFalseAlarm**: Checks if the platform is active before it processes the false alarm.

4. **Class EnvironmentManager**

   The class EnvironmentManager contains the acoustic characteristics information for each environmental region, and defines the methods of getting propagation loss and sweep width. Its modifications are described as follows:
   
   a. **Data Fields Deleted**
      
      `sigma`
   
   b. **Modified Functions**
      
      `getPL-AN-Sigma`: Target's most detectable frequency is used to determine propagation loss and ambient noise.
      
      `getSweepWidth`: Target's most detectable frequency is used to determine sweep width.

5. **Class AcousticPlatforms**

   The code that describes the variables and operations of an acoustic platform is changed as follows:
   
   a. **Data Fields Deleted**
      
      `glimpseInterval`  Now using target's detectable interval
b. *New Data Fields*

- **individualSigma**: Sigma of individual Lambda-Sigma process.
- **lambdaSigmaValue**: Individual fluctuation for signal excess.
- **meanInterval**: Mean time between updating individual Fluctuation.
- **detectableInterval**: Target's detectable interval used to schedule next glimpse.

c. *Modified Functions*

- **editEnv-Freq**: Inputs environment-frequency pairs of a platform.
- **setForStart**: Initializes env-freq-list, Lambda-Sigma process parameters, target's detectable interval and schedules event for next update of individual Lambda-Sigma value.
- **setForStart**: Initializes env-freq-list, Lambda-Sigma process parameters, target's detectable interval and schedules event for next update of individual Lambda-Sigma value.

d. *New Functions*

- **updateLambdaSigmaValue**: Updates Lambda-Sigma value and schedule event for next update of individual Lambda-Sigma value.

6. **Changes on User Inputs**

This section explains the changes on some necessary inputs that the user needs to specify in setting up the simulation. The details of setting up a whole simulation run can be found in [RI 90]. The user now should enter Global Mean Interval ($1/\lambda$) and Global Sigma during setting up Umpire Parameters. This can be
done by choosing the Edit Umpire Parameters menu item under Simulation menu, which displays the Simulation Umpire Edit window shown in Figure 1.

![Figure 1. Simulation Umpire Edit Window](image)

The Edit Submarine window in Figure 2 contains added radio buttons: Lambda-Sigma Process, Detectable Interval, and Frequency Environment Pairs. To create or edit a submarine object, the user needs to specify appropriate parameters in Lambda-Sigma Process Edit window shown in Figure 3. For each environmental region the user must enter a most detectable frequency of the platform. The Frequency Environment Edit window is shown in Figure 4.

IV. MPA MODELING

In this chapter we review ASSET's current MPA detection rate model and allocation model, including discussion of the disadvantages and suggested improvements. This is followed by a description of the implementation details.

A. CURRENT MPA DETECTION RATE MODEL

The MPA acoustic detection model uses a detection rate scheme to decide whether a detection is made. This model is derived from the passive sonar equation and the random search formula.

The MPA is assumed to lay buoys in a pattern to provide uniform coverage of the designated search region. When an MPA is cued to a search region, the search area is the 86% containment region provided by the tracker-correlator. If the MPA is not cued, then the search region has user-input size, and is randomly located in the user-input area search region. If a target is in the designated MPA search region at the beginning of the MPA's time on-station, then it is assumed that the target remains in the search region for the entire MPA's time on-station. And, if the target is outside the search region at the beginning of the MPA's time on-station, then it is assumed that the target remains outside the search region for the entire MPA's time on-station.

1. Detection Rate Calculation

The ASSET calculates a detection rate for each target that lies within the search region when the MPA arrives on-station. The detection rate is the ratio of the area searched per unit time over the total area of the search region. ASSET uses a constant detection rate $\gamma$ given by:
\[ \gamma = NVW / As \]

where \( N \) is the number of sonobuoy channels processed, \( V \) is the average target speed, \( W \) is the acoustic sweep width of a single sonobuoy, and \( As \) is the search area.

The number of sonobuoy channels processed, \( N \), is the smaller of following two values: user-selected number of buoys per search, or the user-selected number of buoys that can be processed.

The single buoy acoustic sweep width, \( W \), is calculated as twice the maximum detection range, \( R_{\text{max}} \), the maximum range at which the adjusted or actual figure of merit (FOM) is equal to the propagation loss from the user-entered Proploss Table. Mean FOM is given by:

\[
\text{FOM} = SL - NL + DI - DT.
\]

where \( SL \) is the target radiated source level, \( NL \) is the total noise level (self-noise + ambient noise), \( DI \) is directivity index of the receiver, \( DT \) is the detection threshold or recognition differential.

Actual FOM is obtained by adding a value representing the environmental uncertainty correction to the mean FOM. The uncertainty correction is a normally distributed random variable with a mean of zero and a standard deviation of 9 dB. ASSET generates a single uncertainty correction, and thus a single \( R_{\text{max}} \), that is used for the entire MPA search period. \( SL \), \( NL \), \( DI \), and \( DT \) are user-entered parameters for the particular MPA-submarine pair.

2. Determination of Detection

After the detection rates are calculated for each submarine that is within the search region when the MPA arrives, ASSET sums each of these rates with the user-entered false alarm rate to obtain a collective contact rate (\( \Gamma \)). The
probability distribution for the time to initial contact is an exponential distribution with a rate equal to the collective contact rate. ASSET generates an exponential random number $t$ that represents the time when the MPA detects a real or false target. The exponential random number is obtained from

$$t = -\ln(U[0, 1]) / \Gamma$$

where $U[0,1]$ is a uniform random number between zero and one. A detection is reported at time $t$ if $t$ is less than or equal to the total time that the MPA is on station.

To determine if a target in the search region is detected, ASSET stacks the detection and false alarm rates end to end. ASSET then draws another uniform random number, on the interval $[0, \Gamma]$, to determine whether a submarine (or false alarm) will be reported as the contact. ASSET only allows one detection (real or false) per MPA mission.

3. Evaluations of Current Model

[SH 91] has indicated several drawbacks in current ASSET's MPA model. Targets outside of the search region at the beginning of MPA's on station are excluded the search. So an MPA can not detect targets crossing the search region boundary during its searching.

The ability of an MPA to detect and kill a target is affected by the MPA and submarine false alarm rate. Apparently due to the limitation that engaged platforms are not detectable by opponent platforms, even extremely small submarine false alarm rates significantly reduce the detectability of the submarine.

In addition, currently only a single contact is performed per MPA mission, even if that contact is a false alarm and the MPA has sufficient time to
remain on-station. After the MPA completes one engagement, no further search is conducted.

B. ALLOCATION MODEL

In ASSET each antisubmarine warfare operational center (ASWOC) has a specific non-overlapping ocean area of responsibility and several assigned MPA squadrons, both defined by the user. Based upon fused submarine picture obtained from the ASW fusion center, ASWOCs cue their MPA assets to investigate areas that are likely to contain targets of interest. Remaining MPAs also may be assigned to perform uncued area search. ASWOCs make their MPA search assignments decisions regularly at user-specified allocation intervals. At each allocation interval, the fusion center will provide the ASWOC with an 86% search probability area (SPA) for each suspected target within the ASWOC's ocean area.

ASSET prepares a table that matches all pairs of available MPA and SPAs, giving the times of station, transit time to the SPA, and SPA size at mid-time on-station. Available MPAs include all MPAs on the ground in a ready status and those MPAs conducting uncued search that have not yet reported a detection.

ASSET first eliminates each SPA/MPA pairs whose projected SPA size exceeds a user-entered maximum, and pairs whose computed time on-station is less than the user-entered minimum (uncued, divertable MPA may have a different user-entered minimum). From the remaining pairs, ASSET selects the first SPA/MPA combinations with minimum transit time. This process continues until either all the SPAs or all the MPA have been exhausted. If any available MPA remains, up to a user-entered maximum will be assigned to search a user-designated uncued search region. The MPA's search region is randomly located inside this designated uncued area search region.
[SH 91] points out that the way ASSET selects SPA/MPA pairs can be improved. Also ASSET only allocates MPA at the predetermined allocation intervals.

C. IMPROVEMENTS

[SH 91] has suggested several alternate models of MPA. Most of the MPA modeling improvements mentioned here are derived from that report but with some modifications.

1. Glimpse Rate Model

All the continuous detection sensors in ASSET except the MPA use a glimpse rate to determine detection opportunities. An MPA Glimpse Rate Model (MGRM) approximates a continuous-looking sensor pattern that has a probability of detection (Pd) of less than 1.0 with a glimpsing sensor region that has a Pd of 1.0 (as ASSET currently does with the tripwire sensor). The sensor region would then be glimpsed to provide a detection rate identical with that obtained by a continuous sensor conducting a random search.

Detections for MGRM are based on the random search model where the detection rate is the ratio of the relative area searched per unit time over the total area of search region. Random search predicts that a target, moving randomly through a field of continuous stationary sensors, will be detected at a certain rate. By glimpsing the sensor field at this detection rate, MGRM can produce an identical detection rate regardless of how the target is moving.

a. Area of the Search Region

For a cued search, the sonobuoys will be uniformly placed through the circular search region of tracker-correlator's best estimate of target position.
Otherwise, the search region will be randomly placed within the user-entered uncued search region.

**b. Determination of Detection**

When an MPA arrives on-station, MGRM will calculate a glimpse rate and initial glimpse time for each potentially detectable target. As in ASSET's other glimpse models, a target is deemed potentially detectable if its range from the MPA is less than its maximum speed multiplied by the MPA search time. The initial glimpse time will be determined from an exponential random draw using the inverse of the glimpse rate (or detection rate) as the mean glimpse interval. Detection rate will be computed as ASSET currently does. If the target is within the SPA when the glimpse occurs it is considered a successful detection.

**c. Effect of False Contacts**

The false contacts are generated by a Poisson process with a user-entered false contact rate. An exponentially distributed random number will be drawn to determine the time of the false contact. It will transmit a false target report at the time of false alert if the MPA is still on station and has not yet been killed. The MPA will spend the same amount of buoys for target classification, as it does in a normal engagement. A false contact will not be processed if the MPA is engaged at the time of the false alert.

2. **MPA Allocation Model**

   **a. Determination of SPA/MPA Matching**

   The allocation of the next MPA would be to the MPA/SPA pair with the largest ratio of MPA's time on station to SPA size. This will increase cumulative detection probability without increasing the processing time to perform an allocation.
b. After Prosecuting a Target

When the MPA finishes the prosecution of a submarine, it will stay in the search region until the end of its time on station. This will enable the MPA to have opportunities to detect other targets. Also if time permits, the MPA can be directed to other cues.

D. IMPLEMENTATION DETAILS

This section provides implementation details for the suggested improvements. They are categorized by their physical locations in the application package distributed by Metron.

1. Structure File
   a. MPAstruct

The MPAstruct defines the operation characteristics of an MPA. One data field is added:

```plaintext
engagedP  Indicates whether an MPA is currently engaging with opponent platform
```

2. Class ASWOC

The ASWOC class describes the ASWOC's geographical location, assigned squadrons, specific ocean area of responsibility, and operations. We redefine two of its methods:

   a. Modified Functions

`makeMPAassignment` : The selection of next cue is the cue with the largest ratio of MPA's time on station over SPA size.

`getSearchValues` : SearchValues now contains searchTime, missionCount, MPA, SPA size.
3. Class MPAsquadron

The class MPAsquadron defines variables of its command, operation characteristics, weapon status, and operations. We describe the modification in following sections:

a. Modified Functions

\texttt{dispatchMPAtoAreaSearch} & \texttt{dispatchMPAtoCue}: Schedule detection opportunities for the MPA to every possible submarine target based on the inversion of detection rate to the target.

\texttt{endMPAflight}: Resets MPAs\texttt{struct-engagedp flag to NIL after finishing its flight.}

\texttt{beginSearch}: Schedules detection opportunity for the MPA to every possible submarine target based on the inversion of detection rate to the target.

\texttt{localizeTarget}: Checks if the MPA is on station and the target is active before doing anything.

\texttt{loseMPA}: Checks if the MPA has not being killed yet before doing anything.

b. New Functions

\texttt{setNextDetectionOpportunity}: Schedules next detection opportunity for MPA.

\texttt{processDetectionOpportunity}: Determines target detection; schedule next detection opportunity.

\texttt{targetDetectedp}: Determines it the target is detected by checking if the target is inside search region.
**targetCoveredp**: Checks if the submarine is inside the given search region.

**setNextFalseAlarm**: Schedules false alarm event during MPA's time on station by making exponential draw from mean time between false alarm.

**processFalseAlarm**: Transmit a false target report if the MPA is still on station and not being killed; expends buoys for target classification; schedule next false alarm event.

**endEngagement**: Reset `MPAstruct-engagedp` flag to Nil.

**transmitFalseAlarmReport**: Transmit the false target report to its command.

**prosecuteTarget**: Determines who wins during engagement; if time permit and still carry enough weapons MPA will stay for another detection opportunity.

c. **Deleted Functions**

`getSubInSearchArea`
V. CONVERTING ASSET TO CLOS

The ASSET was implemented in Macintosh Allegro Common Lisp Version 1.3.2 which uses Object Lisp as object-oriented extension of Common Lisp. Recently Apple’s support of this version was stopped, and CLOS became the standardized Common Lisp package for version 2.0 release. For the benefit of future maintenance of the ASSET, we decide to convert the current code to CLOS.

This chapter provides a summary of the differences between Object Lisp and CLOS, the work of converting current ASSET code to CLOS, and the results we have achieved.

A. DIFFERENCES BETWEEN CLOS AND OBJECT LISP

Machintosh Common Lisp (MCL) Version 1.3.2 uses the object protocol Object Lisp which supports multiple inheritance but only simple method combination. In Object Lisp one could make an object submarine with an instance SSN 688, then create SSN 977 which inherits from SSN 688, and SSN 755 which inherits from SSN 977. CLOS uses a class-instance protocol. In CLOS we cannot make a subclass from SSN 688, since it is not a class. Instead, we must create another class, possibly a subclass of submarine.

Binding and scoping have changed substantially. Instead of object variables, there are slots in CLOS classes and instances. Rather than asking an object to run its version of an object function, CLOS applies methods of generic functions to instances. The detailed information of difference between Object Lisp and CLOS
can be found in the user's manual of Macintosh Allegro Common Lisp Version 1.3.2 and [ST 90].

**B. CONVERTING TO CLOS**

1. **Class Definition**

   Generally in MCL 1.3, defobject defines the class hierarchy, and exist creates an object instance and sets its own binding of variables to initial values by using function have. Most frequently, the corresponding material in CLOS goes into the defclass with its slot specifiers. The initialize-instance specifies the values of slots that cannot initialized with initialization arguments or initial forms. It also perform any other necessary initialization. If have is used dynamically in the program, one can transform uses of have into static slots and values in defclass.

2. **Method Definition**

   All object functions must be turned into generic functions. That is, every piece of code of the form

   (defobfun (Die submarine) arguments body)

   must be transformed to

   (defmethod Die ((submarine submarine) &rest-of-args) body)

3. **Replace Free Variables References**

   Since the slot-values and variables do not access the same namespace, we must bring all free variable references into the slot namespace. We have two ways of dealing with free variables: set them explicitly with slot-value or use accessor calls. Using accessors are usually preferable, since they allow us to change the representation of our classes without changing any of the user code.
4. **Remove Calls to Ask**

Instead of `ask`, we now use `slot-value` or an `access` for a value, or a call to a method. Depending on the context, we should choose the appropriate call. We must run methods on instances of a class. All calls must now be directed to instances, not to class object. An Object Lisp asking for the object function `setForStart`

```
(ask submarine (setForStart))
```

becomes a call to the appropriate method of `setForStart` for an instance of `acousticPlatform`, `SSN688`:

```
(setf SSN688 (make-instance 'submarine))
(setForStart SSN688)
```

5. **Create Instance**

Rather than creating all new objects with `oneof`, we create instances with `make-instance`. Similarly, we replace `kindof` with `defclass`. Note that in CLOS, we cannot make instances directly into classes. Instead, we make new classes based on the class we want to specialize, then create instances of those classes.

6. **Change Function Names**

Numerous functions names and other symbols have changed in both Common Lisp and Macintosh Common Lisp. Functions involving dialog items or windows are frequently affected.

7. **Changes of Dialogs**

The implementation of dialog has changed substantially in MCL Version 2.0. Dialogs as a separate class have disappeared. Dialog items may now be
added to all views. Some functions have changed to reflect the new definition of dialog.

C. RESULTS

The source code of ASSET contains about 29,000 lines. Most the work of converting it to CLOS can be done by mechanically transforming the source code. We used a conversion utility program to help converting the class and method definitions, referencing a free variable, running a method, creating a instance, and changing function names. This utility program will accept a text file (of MACL) and try to convert it to MCL program. Unfortunately, due to time constraints we are not able to make the utility program a total solution for the porting. To complete the conversion, we still need to manually convert all window system to the newer version.
VI. CONCLUSION

A. SUMMARY

In this thesis, we presented the idea of object-oriented simulation. In addition, we implemented the improvements suggested in previous evaluations of ASSET in NPS. Some modifications to those suggestions were made during the implementation process. Part of the current ASSET source code is converted to CLOS but more work is needed to complete the task.

1. Detection Model

A compound Lambda-Sigma jump detection model was implemented to simulate the detection of submarines. Also the target's most detectable frequency and detection rate were allowed to vary with environmental region. Multiple engagements between platforms were allowed.

2. MPA Model

A glimpse rate model was used to determine detection opportunities of MPA and to approximate a continuous-looking sensor pattern. The glimpsing sensor field detects a target which is within the sensor region at the time of a glimpse with a probability of detection of 1.0.

ASSET allocates MPA to cues generated from the tracker-correlator by selecting SPA/MPA pairs using the ratio of MPA's time on-station to the SPA size as the selection criterion. If time permits, the MPA will stay on search region after prosecuting a submarine for another detection opportunity.
3. Converting ASSET code to CLOS

We investigated the feasibility and technique of converting current ASSET code to CLOS. We used a conversion utility to help us transform the current ASSET code to CLOS. Due to time constraints, only part of the converting task was completed.

B. FUTURE WORK

There are several areas that could be enhanced to improve the ASSET. The user interface could be improved for easier setup of a simulation architecture. It is possible to speed up the overall performance of the ASSET by porting it to a SUN workstation with a more powerful CPU. Various modules such as surface ASW platforms, active and nonacoustic sensors could be added to form a more complete ASW simulation. In addition, it would be useful to add machine intelligence features into platform tactics to better represent smart platforms. The bottle neck of ASSET performance has not been exactly located. It is possible to further speed up ASSET’s performance.
APPENDIX A MODIFIED MODULES OF ASSET CODE

CHANGE LOG:

in (defstruct platformAcousticParms)
new data field added for individual lambda-sigma process and
detection model:
  (individualSigma 0) sigma for individual fluctuation
  (lambdaSigmaValue 0) fluctuation of target's signal excess
  (meanInterval 1000) mean time between fluctuation
  (detectableInterval 1) target's detectable interval(1/lambda)
  (env-freq-list nil) environment-frequency pairs list for a
target used to determine its radiated frequency in a particular environment

in (defstruct MPAstruct)

  (have 'PL-list nil)

; PL-list will be in following form:
; (Freq1 (PL-11 PL-12 ...) Freq2 (PL-21 PL-22 ...) ...) 
; where PL-ij is in form: ("PLname" "PLprimaryRgn" PL-array 
; FreqAtWhichPLdefined)

; NOTE: FreqAtWhichPLdefined will equal FreqK in PL-list
; immediately preceding
; the proploss list (ie all PL-ij's in (getf PL-list FreqK) will
; be: ("PLname" "PLprimaryRgn" PL-array FreqK).
; This info is redundant, but necessary since the proploss,
; PL-ij, can be assigned to an env rgn at *any* frequency.
; Thus, in order to re-constitute the proploss we need to
; know the frequency at which it was defined (not the
; frequency at which it is being used).

CHANGE LOG:

new data fields and input dialogs of global lambda-sigma jump model for signal excess calculation added; user is required to specify them during data input stage:
- globalLambdaSigmaValue
- globalSigma
- globalMeanInterval

setUpForReplication modified
- initializes globalLambdaSigmaValue and schedules event in exponentially separate time to update its value

updateGlobalLambdaSigmaValue added to update global lambda sigma value in exponentially separate time

FOMglimpseInterval and its input dialog deleted;
- now using target's DetectableInterval to schedule next detection event

setNextDetectionOpportunity modified
- it now allows engaged target being detectable to searcher that is not engaged; also check range when scheduling next detection opportunity for engaged platforms

processDetectionOpportunity modified
- engaged searchers searcher won't detect other targets;
- engaged targets is detectable to other searchers

getDetectionOppResult modified
- determines target's most detectable radiated frequency;
- using global and individual lambda-sigma-value to adjust MSE(mean signal excess)

processPlatformKill modified
- check if it was killed before

setNextFalseAlarm and processFalseAlarm modified
- check if the searcher was killed before doing anything
- it won't set the engaged flag of searcher; so it can deal with real target while it is processing FA

CHANGE LOG:

new data fields and input dialogs added for individual lambda-sigma process:

individualSigma
lambdaSigmaValue
meanInterval

glimpse interval deleted now using target's detectable interval to schedule next detection event:
detectableInterval

editEnv-Freq added for inputting environment/frequency pairs of a acousticplatform

setForStart modified
initializes env-freq-list, lambda-sigma process parameters, target's detectable interval and schedules event for updating individual lambda-sigma value

updateLambdaSigmaValue added
update lambda-sigma value and schedule event for next update

(setq acousticPlatform (kindof generalPlatform))

new data field added in MPAsstruct

engage

dispatchMPAtoAreaSearch and dispatchMPAtoCue modified
schedules detection opportunity for the MPA to every possible
submarine target based on the inversion of detection rate to the target;
setNextFalseAlarm added to schedule FA event

endMPAflight modified
reset MPAsstruct-engagedp flag to NIL after finish its flight

beginSearch modified
schedules detection opportunity for the MPAQ to every possible
submarine target based on the inversion of detection rate to the target;

setNextDetectionOpportunity added

glimpse rate detection model used; now target's radiated
frequency is used to get DI, RD, NP, sweepWidth;
then mean glimpse interval is computed
by inverting the detection rate(NVW/A);
excludes submarine target not inside search area before MPA
search ends depending upon range: begin random glimpsing,
or calculate earliest possible time these platforms can come
within range (based on maxDetectionRange MaxClosingSpeed and
GlimpseInterval); engaged MPA won't have further detection on
other targets

processDetectionOpportunity added

if MPA is already engaged then it schedule next detection
opportunity based on target's acoustic parameters (i.e. radiated
frequency, DI, RD, NP) to get sweepWidth and calculate detection
rate of target, then invert the detection rate to get glimpse
interval; otherwise it will check if the target is detected by it

targetDetectedp and targetcoveredp added
check if the target is inside the MPA search circle

setNextFalseAlarm added
schedule false alarm event during MPA on station time
by making a exponential draw from mean time between false alarm (/ 24 computedFAR)

processFalseAlarm added
if the MPA is still on station and not being killed it will transmit a false target message, schedule next false alarm, expend buoys for target classification

endEngagement added
reset MPAspect-struct-engagedp flag to NIL

transmitFalseAlarmReport added
transmit the false alarm report to its command

localizeTarget modified
check if the MPA is on station and the target is active before doing anything

processDetectionEvent modified
check if MPA is on station and the target is active before doing anything

prosecuteTarget added
if time permit and still carry enough weapons MPA will stay for another run after it finish prosecution

loseMPA modified
check if the MPA has not being killed yet
