13. ABSTRACT (Maximum 200 words)
A 2 Part Task.
The first task constructs a 6 monitor display around a Simulated Abrams M1A1 Tank Commander location. The scene is displayed on three monitors at a time and switches to an adjacent three as a function of the head motion sensed from the Tank Commander. Production simulator difficulties were studied.

The second task integrates 'eye phones' and Cyber Face' to various image generators, especially ESIG500 and SIMNET IG. Simulation usefulness issues were researched.

Abstract

This document is the Final Report of a two year project at the Institute for Simulation and Training supported by PM-TRADE under contract #N61339-90-C-0041.

This project has two components. The first component is the construction of a six-monitor head-tracking display (HTD) to provide the tank commander (TC) in a SIMNET M1A1 Abrams simulator with a 360-degree panoramic view into the SIMNET database, without requiring additional image generation hardware. This component successfully demonstrated the concept and highlighted some of the difficulties to be overcome in building a production simulator using HTD technology.

The second component is the investigation of low cost head-mounted display (HMD) technology for simulators. This component included attaching HMDs to several available realtime image sources, and describing the difficulties and techniques used to overcome the difficulties. Ultimately, four image sources were used:

- Silicon Graphics Iris workstations;
- An Evans & Sutherland ESIG-500 image generator;
- The SIMNET simulator's image generator; and
- A low-cost (PC-based) Sense8/Intel DVI graphics system.

The two best-known commercial HMDs costing less than $10,000 were evaluated: VPL's EyePhones (in two versions) and PopOptix Labs' CyberFace. Of the three product versions, only VPL's second-edition EyePhones approached an acceptable level of resolution for training simulation. The devices' limitations, and technical trends, are discussed, with recommendations for further studies.
I. Introduction

One of the most obvious limitations of low-cost simulation technology, as exemplified by the SIMNET team training system is the restricted field of view. In a real M1A1 tank, six "vision blocks" (periscopes) provide the Tank Commander (TC) with essentially a complete 360 degree field of view (FOV). Each block spans approximately a 45 degree static horizontal FOV, but the TC can move his head from side to side to view more than 60 horizontal degrees of the surroundings from each vision block.

In the SIMNET system, in order to achieve an acceptable pixel density for target acquisition and navigation, three 320 x 128 visual displays were
placed side-by-side to simulate one M1A1 commander's vision block. Each display was set to span 8 degrees (vertical) by 20 degrees (horizontal), thus achieving a 60 degree effective horizontal FOV, and a pixel density of 3.75 arc-minutes per pixel in the horizontal direction.

SIMNET's vertical pixel density is essentially the same, and henceforth we will discuss only horizontal FOV and pixel densities. The aspect ratio (horizontal to vertical) of 2.5:1 will remain constant throughout these discussions unless noted.

In the healthy human eye, an image centrally presented can generally be resolved into details spanning 0.5 arc minute, and so clearly the SIMNET visual system is far from realistic. However, its designers determined that within the criterion of a 3.5 km maximum range to horizon, 3.75 arc minutes was adequate for target detection when targets were moving against the simplified background of a SIMNET database.

The SIMNET TC turret rotates under the control of a thumb switch on the simulator's machine gun control handle, requiring approximately 12 seconds to rotate 350 degrees. A stop prevents complete rotation (to protect electronic cables from twisting). This can be a severe limitation if the TC needs to look in a direction opposite to the tank cannon.

The central hypothesis of this study was that the tank commander in a SIMNET unit is operating in a handicapped mode, compared to a real tank commander. First, an operational TC usually operates in POP-hatch ("Protected Open Position") mode unless under direct attack or chemical/biological threat conditions. The massive hatch cover is horizontally suspended above the hatch opening to protect from downward fire or fragmentation, but the TC is looking out through a horizontal slit.

No equivalent POP-hatch experience is provided in the SIMNET system.

Second, even when forced to close the hatch, the TC still has six high-quality vision blocks and the ability to see in any direction as rapidly as he can turn his head.

The questions we therefore proposed to study were the following:

1. For closed-hatch operation: would a TC's performance in navigation and target acquisition be improved if the experience of having six instantaneously available vision blocks were simulated, instead of requiring the TC to rotate the SIMNET cupola?

2. For POP-hatch operation: would it be possible to provide visual stimuli, using low-cost head mounted display technology, so that a TC's POP-hatch performance in navigation and target acquisition could be incorporated into the SIMNET experience?
Despite numerous difficulties in working with SIMNET prototypical equipment, some answers to these questions were achieved. We first discuss common technical elements in both projects, namely, the ability to track the subject's head position and orientation. We then discuss the HTD project, which took place mostly in 1990. Finally we discuss the HMD project, which took place in 1990 and 1991.

II. Head Tracking Technology

During the first two months of this task (February-March 1990) we engaged in a literature and product-information search. This search provided us with information that was useful for both projects under this task. In general, this search provided us with information concerning availability and cost of head-tracking equipment and head-mounted displays.

In the realm of head-tracking, at the time of the start of this project, there were only two feasible schemes: magnetic and infra-red. The only IR tracker we came across was used in the CAE-Link head-mounted display. This system was custom-built, and replication would have cost at least $20,000 (our estimate). At the time of the start of this project, the Polhemus magnetic tracker was the only commercially available magnetic tracker, although others have since become available. For this reason, the Polhemus Isotrak was chosen. This is a six degree-of-freedom ten-bit tracking device in wide usage.

The Polhemus product comes in two versions: an economical model for $3,000, and a high-resolution model for $10,000. The economical model tracks spatial positions with a static accuracy of 0.13 inches while source to sensor separation is less than 15 inches, and a static angular accuracy of 0.85 degrees within this range. Data is reported with a resolution of 0.9 inches and 0.35 degrees.

The high resolution model tracks spatial positions with a static accuracy of 0.1 inches, and angular position accuracy of 0.5 degrees. Its resolution of reported data is .046 inches and 0.1 degree, within a 30 inch radius of the emitter. Both models respond at a 30 hz rate. Two sensors can be used with a single emitter and a time-multiplexed System Electronics Unit, thus cutting in half the effective response rate of both sensors.

We selected the economy model upon the recommendations of VPL Research, since it was incorporated with the VPL EyePhones, and it proved adequate. The high resolution tracker is usually used for CAD applications as a manual input device (stylus), where extreme spatial accuracy is needed. The head tracking function is less demanding of positional precision.

Since our purchase of the Polhemus, a new 12-bit magnetic tracking device has become available. This higher resolution device, known as the Bird, is made by Ascension Technology, has some advantages, as well as one
disadvantage. The primary advantages are higher resolution and less sensitivity to environmental distortions (metals, EMF, etc.).

The one known disadvantage of the Bird products is a two-foot radius of accuracy, vs. a three-foot radius for the Polhemus. A version of the Bird with an eight-foot radius of accuracy is expected soon from Ascension Technology in 1992, as well as a Flock of Birds that can use up to six sensors with a single source. The Bird products cost around $3000 for a single sensor/emitter pair, equivalent to the economy model from Polhemus. The Flock of Birds uses a single emitter and several (up to six) sensors, each with its own electronics module. Thus no time multiplexing is required and all devices continue to respond at 30 hz. Each additional sensor/electronic setup costs approximately $1500.

In 1992 as the project is ending, a number of other tracking devices are becoming available. Logitec has produced an acoustically based "3d Mouse", which uses a triad of ultrasonic emitters arranged in a triangle approximately 15 cm on a side, and a triad of detectors approximately 10 cm on a side, attached to a three button mouse. Unlike the Polhemus and Bird products, the 3d mouse will not function in all orientations; the sensors must "see" the emitters. This product costs $1000.

III. Head Tracking SIMNET Commander Display (HTD)

The purpose of the HTD is to simulate the M1A1 Abrams tank commander's (TC) cupola, which has six vision blocks. Each vision block has a 45x15 degree field of view (FOV) (approximately). SIMNET provides a single 60x8 degree FOV using three channels of the image generator.

The HTD design allows us to drive six monitors with the TC's three channels of the SIMNET image generator. This is accomplished through the use of a video switcher and the Polhemus magnetic tracker, under control of an IBM PC-AT. The control computer reads the tracker, controls the video switcher, and controls the direction of view (DOV) on the image generator (IG).

We first describe the video switcher and display setup. We then discuss the experiments which were conducted.

A. The Head Tracking Display Testbed

In the HTD, only the three monitors in front of the TC's head are active at any time, with each monitor presenting approximately the same FOV as a real vision block. This gives the TC a 140x16 degree instantaneous FOV. Under control of the PC-AT, the video switcher and the Polhemus tracker activate the three monitors in front of the TC. As the TC turns, the control PC shifts the output signals to the appropriate three monitors. The switcher is designed to give an instantaneous change of view in order to eliminate the time now required for the cupola to rotate mechanically.
through the same distance. For example, a 180 degree rotation that requires six seconds in the mechanically rotating cupola takes approximately one fifth of a second in the HTD.

The video switcher was designed and constructed by IST. It takes four composite video input signals and routes them to any of six output channels under the control of the control computer. (Figure 1)

The control computer also controls the DOV of the IG through a digital-to-analog converter. This converter mimics the potentiometer in the mechanically rotating cupola to change the DOV of the IG.

The control computer reads the Polhemus magnetic tracker and, based on the orientation of the user's head, sends signal to the IG to update the DOV. The control computer then routes the four input channels to some subset of the six monitors. The routing of input signals to output channels is completely configurable, and any input signal can be routed to any output channel, the only restriction being that only one input signal can be routed to a particular output channel at a given time.

Three of the input channels come from the SIMNET image generator, and the fourth input channel is available for neutral imagery from any video source, or can be left blank.

The control functions of the PC-AT are provided by a combination of hardware additions to the PC-AT and the simulator host and control software on the PC-AT. The hardware additions to the PC-AT consist of a parallel output channel with some logic circuitry and a digital to analog converter. The output channel is used to transmit control signals to the video switcher, and the converter is used to control DOV on the image generator. Both the output channel and the converter reside on a single prototype bus card (called the interface card) in the PC-AT. In addition to this interface card, a game port card has been added to read the synchronization signal from the simulator host.

The modification to the simulator host consists of a small circuit that detects when the simulator A/D card has been read by the host. This circuit sends a signal to the control PC-AT to allow for a measure of synchronization.

The control program for the HTD is fairly simple at a conceptual level. (Figure 2.) It has two basic responsibilities: sending the TC's DOV to the IG, and telling the video switcher which input signals to route to which channel. The control program reads two inputs: the magnetic sensor and the synchronization signal. The only two outputs from the program are a control word for the IG, and a control word for the video switcher.
**HTD Electronic Operation:**

The outputs from the image generator are in the form of four signals: red, green, blue, and sync. There are three channels: Tank Commander Left (TC-L), Tank Commander Middle (TC-M), and Tank Commander Right (TC-R). To reduce cabling requirements and switcher complexity, the signal is encoded using a Vid I/O video encoder. Output signals from each channel of the IG are connected to the RGB and Sync inputs of a Vid I/O box, as shown below. The connecting cables use BNC connectors. The terminating switches for each channel are set to OFF (vice 75 Ohm) so that the RGB and Sync outputs can be routed to the standard SIMNET monitors. This prevents requirements for recabling when the HTD is not in use.

![HTD Control Program Block Diagram](image)

Figure 2. HTD Control Program Block Diagram
The composite video outputs of the Vid I/O boxes (Figure 3) are connected to the inputs of the video switcher. The input connectors of the video switcher (Figure 4) are labeled 0, 1, 2, and 3. The outputs of the IG are connected to the inputs of the video switcher as follows (with video switcher input channel 3 left open):

<table>
<thead>
<tr>
<th>IG Output Channel</th>
<th>Video Switcher Input Channel</th>

<tbody>
<tr>
<td>TC-L</td>
<td>0</td>
</tr>
<tr>
<td>TC-M</td>
<td>1</td>
</tr>
<tr>
<td>TC-R</td>
<td>2</td>
</tr>
</tbody>
</table>

The outputs of the video switcher are then connected to the color monitors. These outputs are labeled 0, 1, 2, 3, 4, and 5. The video switcher should be switched on prior to connection to the PC in order to prevent damage to the video switching chips.
Figure 4. Video Switcher External View

The interface card is connected to the video switcher through a standard six foot DB-25 male to DB-25 male parallel cable. The digital to analog converter is connected to the SIMNET using a cable with a BNC connector at the interface card end and a four pin connector at the SIMNET cupola interface.

The select lines of the video switcher are addressed from the interface card. The interface card has a sixteen bit latch (really two eight bit latches that can be addressed as a single sixteen bit latch) that can be written from the control program using C or assembly language instructions. See figure 5. The base address of the latch is 30Ch. The control program outputs a sixteen bit word to the latch. The first four most significant bits of the address will be ignored, and the twelve low order bits are output to the video switcher.
The TC's DOV will be controlled by a digital to analog converter. In its normal operation the field of view is controlled by a potentiometer mounted on the rim of the cupola track. The voltage dropped across the pot varies as the cupola rotates. The voltage drop is converted to a digital value by a A/D converter in the simulator and the DOV is modified accordingly. The HTD bypasses this potentiometer and sends a control voltage from the D/A converter on the interface card to the simulator's A/D converter. The D/A converter is controlled similarly to the video switcher, by outputting a control value to a sixteen bit latch on the interface card. The base address of the D/A converter is 302h.

**HTD Physical Configuration:**

A simple plywood structure was created to support six Sony 13" video monitors. Standing on six "2 x 4" legs, the hexagonal structure had a sturdy planar top approximately 65" above the floor, with a 30" diameter central hole. A laboratory swivel chair placed on a 6" high platform provided a seat for the subject, whose head projected through the hole in the table into the simulated cupola.

The SIMNET cupola was simulated by a cardboard enclosure. Black poster board was fabricated into a hexagonal chamber 30" in diameter, with six apertures the same size as SIMNET vision blocks. Four sided cardboard cones connected these openings to the Sony TV screens, providing the appropriate fields of view. See Figure 6 below.
Because the testbed was in a different room from the SIMNET M1A1 simulator, it was necessary to use walkie-talkies to communicate between experimenters, and the SIMNET intercom for the TC subject to communicate with the driver. These intercoms proved troublesome and unreliable, as has been reported in general with the SIMNET system.

B. Visual Parameters of the Testbed

It was necessary to use three SIMNET channels to drive the three turned-on vision blocks in the HTD system for several reasons. First, these were the only trio of IG channels available to the experimenters. Second, we were comparing a new candidate SIMNET display to the existing displays and thus should be using the same visual databases. Third, a fair comparison should put the same amount of information in front of the subjects in both the experimental and control groups.

However, a SIMNET TC channel was designed to support an 8 x 20 degree field of view. The HTD required that this be re-scaled to span 16 x 40 degrees which represents a 4x increase in angular FOV. Under normal circumstances, this would be expected to overload an image generator's polygon and pixel capacity. The experimenters hoped to "get away" with this situation for the following reasons.
Each SIMNET channel is actually paired with another. Each TC channel is paired with a driver channel, with the TC channel having priority. The combined channel has a polygon capacity of 2000 polygons per frame, at 15 frames per second. SIMNET visual databases are constructed under the assumption of at most 1000 polygons being visible at one time, allocated approximately as follows: 300 terrain polygons, 300 culture (buildings, etc.) and 400 target (tank, Bradley ...) polygons.

Thus, the database was expected to contain at most 300 polygons in any 8 x 20 degree FOV. If a FOV was selected with no culture or targets, even a 4 fold increase in this "worst case" terrain polygon count should have remained within the 2000 polygon capacity of the IG (although we would expect the driver's channels to degrade when the maximum single channel capacity of 1000 polys/sec was exceeded.)

This assumption would only be valid if the view contained few or no culture and targets; or if targets occurred in settings where the polygon density for terrain was well below the maximum design limit. As it turned out, these conditions were often but not always met. Route planning and the search for ways to conceal targets sometimes led to the use of the most complex available terrain, which increased the terrain polygon count.

The SIMNET image generators' performance degraded under these circumstances, producing irregular visual artifacts such as flickering and occasional missing frames. However, a more severe problem with the SIMNET IG's soon manifested itself.

Because of chronic difficulties in accessing the source code for SIMNET during the transition from BBN to Loral's operation of the SIMNET-D site, the project attempted a "black box" approach to SIMNET. That is, we intended to drive the IG/simulator system by stimulating it with signals, but with no modifications to the internal code. Thus, to specify the viewing direction of the TC cupola, an analog driving voltage (described in the previous section) was provided, to emulate the output of the cupola tracking potentiometer.

This voltage changed values whenever the subject's head direction changed. However, the resulting change of IG view direction, and the switching of channels in the video switcher, were unsynchronized, resulting in the unfortunate situation where the subject saw a "pop", or a temporarily incorrect view, on the screen to which he had just turned. An attempt was made to detect the timing of the SIMNET's reading its own A/D converter, but without full access to the scheduling algorithm in the simulator, this external approach could not fully solve the synchronization problem.

Consequently, two classes of visual artifacts occurred in the Head Tracker which were not present in the rotating TC cupola (the control condition for
the experiment). As will be seen, these artifacts were reported by the subjects as having a strong influence on their performance.

C. Experiments with Head Tracker

The experiment utilized a within-subjects design, in which each subject receives all conditions in a counterbalanced arrangement. To accomplish the counterbalancing, a Latin Square design is employed, in which each condition immediately precedes and follows the other three conditions once. For example, the first four subjects receive the condition orders shown below in Figure 7.

<table>
<thead>
<tr>
<th>Subject</th>
<th>Condition Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>C1 C2 C3 C4</td>
</tr>
<tr>
<td>2</td>
<td>C3 C1 C4 C2</td>
</tr>
<tr>
<td>3</td>
<td>C3 C4 C1 C3</td>
</tr>
<tr>
<td>4</td>
<td>C4 C3 C2 C1</td>
</tr>
</tbody>
</table>

Figure 7: Latin Square Condition Ordering

The four conditions are:

- **C1**: Terrain Reasoning (Navigation) using Head Tracking Display
- **C2**: Target Acquisition using Head Tracking Display
- **C3**: Terrain Reasoning using the Standard TC Cupola
- **C4**: Target Acquisition using the Standard TC Cupola

**Terrain Reasoning Task.**

Subjects are shown a 2D paper and pencil map of a section of range at Hunter-Ligget. A start point, an end point, and a general vehicle path are marked on the map, and the Subjects are given two minutes to familiarize themselves with the map before being placed in the M1 simulator or HTD testbed. The subject will then instruct a confederate driver via the SIMNET intercom to drive the stipulated route. The Subject notifies the experimenter when he believes he has arrived at each checkpoint.

Dependent measures include the total time taken to traverse the intended route, and gross location accuracy. The location accuracy is measured by overlaying the Subject’s laminated map with marked locations onto the master locator map and measuring the distance from the marked location of the checkpoint to the correct location. The Subject’s actual track is also recorded using a simultaneous video/audio recording from a Plan/View
Display, with the audio track containing the Subject's instructions to the driver.

**Target Acquisition Task**

Subject is shown another 2d paper and pencil map of a range at Hunter Ligget. As in the Terrain Reasoning Task, a start point, an end point, and a general vehicle path are marked on the map, and the Subject is given two minutes to familiarize themselves with the map before being placed in the simulator or testbed. A confederate driver then drives a predetermined and well-practiced route that corresponds to the path outlined on the map. Targets in the form of T-72 tanks are placed along the path at various bearings, distances and orientations.

When the Subject has acquired a target, he will say "Target [right or left]", indicating that the target was located either to the right or left of the vehicle's path of motion. The TC's voice will be recorded and synchronized in time with video taken from the Plan View Display (PVD). The dependent measure for this task will be the number of targets correctly located.

**D. Results**

Presumably because of the factors described in *Visual Parameters* above, the results reflect no clear preference for either the traditional SIMNET cupola or the HTD. On the terrain reasoning task, two courses were used. On both courses, subjects performed better (by the latency measure) during the early portion of the course (between Checkpoints 1 and 2) with the SIMNET cupola, and better during the period between Checkpoints 2 and 3 with the HTD. This could perhaps be interpreted as saying that subjects were learning how to take advantage of the HTD during the session.

With regard to navigational accuracy, medians show no clear differences. Over Course 1, the cupola showed a less accurate performance; whereas for Course 2, the opposite was observed.

With the target acquisition task, results were similarly unclear. For course 1, the HTD was more successful. For course 2, the cupola was slightly more successful.

Twelve subjects were used. The variance in performance was very large, and no statistical significance can be attributed to any of the above observations. However, the wide variance in itself testifies to the effect of the basic technical problems, on the experiment's ability to measure results.

A subjective evaluation measured preferences and opinions of subjects. In general, they expressed a slight subjective preference for the HTD when asked questions such as "Rate your ability to perceive locations accurately: 1=very easy; 5=impossible". However, the same subjects voted 8 to 4 in favor of the SIMNET cupola when asked "which simulation do you think would
be most beneficial for training" and 7 to 5 for the SIMNET cupola when asked "Which simulation do you prefer".

Most significantly, when asked "Do you think your performance would have changed if the head-tracked display did not have popping and flickering?", 11 of the subjects responded YES.

Additional Results. In response to a request from the sponsor, a preliminary concept paper for an advanced version of the Head Tracking Display for POP-hatch operation was developed. This device would have used large monitors to provide an open-hatch display, rather than a simulation of a rotating cupola. This concept paper is attached as Appendix J.

E. Conclusions

1. It is technically possible to build an economical head tracked display device, with video switching to distribute three channels across six displays. The entire prototypical hardware suite cost less than $8,000 in parts, not including the image generators or labor to assemble. A hardened, "simulator ready" version of this equipment would cost perhaps $12,000 in materials, with a fiberglass shell in place of the wooden superstructure.

2. It is technically risky to attempt to use an image generator for any purpose without the full support of its vendor. Artifacts may result which cannot be overcome via purely external means, and which will render experiments difficult or meaningless.

3. The Polhemus magnetic tracking system is reliable and simple to use. However, its latency must be carefully factored into the initial design of the viewing system, as the time required for serial transmission of information is a significant portion of a simulation cycle.
IV. Low Cost Head Mounted Displays (HMD)

A. Head Mounted Display Technology

We looked at various types of head-mounted display technology. HMD's can be opaque (in which only the artificial world is seen) or semi-transparent (in which both artificial imagery and real objects are seen). To date, two main types of HMDs have been constructed.

Pupil-Forming Systems. One type of display is optically implemented as a pupil-forming system\(^1\). Again, there are two types of pupil forming HMDs. The first uses small (1/2 inch diameter) monochrome CRT's mounted on the side of the helmet. The image is projected through on helmet optics and bounces off a beam-splitter (for semi-transparent operation) or a mirror, into the users eyes. This kind of pupil-forming system costs on the order of $50K and up. Honeywell manufactures this kind of HMD. Monochrome CRT's are usually used to minimize weight.

A variation on these systems uses fiber optics to pipe the image from off-helmet image sources, such as GE light valves. This adds color capability, but is also very expensive. The CAE-Link helmet is of this type.

Infinity-Optics Systems. The other type of HMD uses two small LCD displays mounted directly in front of the user's eyes. Wide angle plastic lenses increase the apparent field of view and provide a virtual image at optical infinity. These systems provide color imagery at a lower cost than the pupil-forming systems but have lower resolution. The NASA VIEW system is a monochrome version of the LCD helmet, and VPL's Eyephones is "nominally" a 442 x 238 pixel color version. This actually represents the number of distinct single-color pixels which are arranged in "triads". The effective resolution if these triads are regarded as single "pixels" is 256 x 137.

The one-eye field of view of the EyePhones is 86 degrees, which yields a horizontal angular resolution of 20 arc minutes per pixel. With a vertical FOV of 76 degrees, the vertical angular resolution is 33 arc minutes per pixel. For details of these computations, please see Appendix I.

VPL has released a high resolution version of the Eyephone with twice the horizontal and vertical resolution, but its cost is approximately $40,000, again making it fairly expensive.

---

\(^1\) The exit pupil of a pupil-forming optical device is a disc-shaped region in space, to which all of the light from the system converges and from which it diverges. When the eye's pupil is entirely within the exit pupil, the full field of view is perceived at maximum brightness. If the eye's pupil partially overlaps with the exit pupil or is too near or far from the image source, "vignetting" (partial occlusion of the image) occurs, and brightness and clarity diminish.
We are using the medium resolution Eyephones for the HMD Project, and also acquired a variant for the Evans and Sutherland ESIG-500, called Cyberface II by PopOptix Labs (Boston, MA). This firm is owned by Eric Howlett, who produced the lenses for the original VPL Eyephones.

Other Research. There are several on-going low-cost HMD R & D projects going on around the country at this time. One of the most ambitious is the development of micro-laser scanning displays. This project is going on at the University of Washington in Seattle, and, if successful, could provide low-cost, high-resolution, lightweight HMD's in the medium-range future (1993-95).

A second HMD project of interest is underway at IST. Dr. Tom Clarke, with DARPA funding, is constructing an experimental variable-acuity HMD. Using custom electronic hardware, Dr. Clarke's device will pre-distort imagery to concentrate information on the central visual field. A uniform (and thus low-cost) LCD image source will be used. Nonlinear optics will then reverse the pre-distortion, and will result in a varying pixel density in the central and peripheral visual fields. Prototypes should be available in 1993.

B. Driving the EyePhones with Silicon Graphics Workstations

As a first experiment, a testbed was constructed in conjunction with the Dynamic Terrain Project, another PM-TRADE sponsored IST project. A suite of software was constructed which provided stereo displays from two different Silicon Graphics (SGI) workstations, and which was networked to two additional workstations providing models of moving tanks.

It is necessary to set output code in the SGIs to produce NTSC composite video, and to use two Vid I/O boxes to convert the resulting RGB signals to composite. This was accomplished without difficulty, and the Eyephones responded well. The Polhemus controller provided with the EyePhones was interfaced to the SGI via a serial port. This was IST's first experience with Polhemus devices, and served to open the pathway for other uses including the HTD display previously described.

These early VPL Eyephones suffered from a number of problems. On two occasions the devices failed and were returned to the vendor for warranty repairs. The diffuser screens produced a "screen wire" appearance which was quite distracting and had the opposite effect than intended, which was to provide a subjective pixelization of the image. Nevertheless, the first use of the Eyephones was successful in showing that stereo images could be displayed, inter-ocular adjustment provided in software, and a SpaceBall navigation paradigm used with workstation signal sources.
C. Attaching a HMD to the SIMNET System

The original idea was to explore EyePhones as a possible POP-hatch viewing device. Several obstacles presented themselves, as a consequence of the inaccessibility of the SIMNET system's internal details:

1) There was no convenient way to achieve vertical deflection, comparable to the horizontal deflection achieved by the HTD tracker via an emulation of the cupola potentiometer. Instead, the SIMNET IG accepted only the position of a three position switch, to tilt the FOV upward or downward by five degrees from the horizontal.

2) Stereo viewing required the use of two channels of imagery with a horizontal offset, and precise control of the distance between the views. No two SIMNET channels, as originally set up, had these properties. A data block was identified which could respecify fields of view, etc (and was used in the HTD for this purpose).

3) The viewing blocks in SIMNET had a 20:8 aspect ratio, whereas the NTSC signal required for EyePhones required a 4:3 ratio. Only the Stealth configuration of SIMNET would support this viewing situation, and IST's Stealth system had limited hours of availability.

4) Tank commanders often need to look back and forth between the "outside world" and a paper map, but EyePhones did not support this possibility. An alternative would be to treat the EyePhones as binoculars, which could be raised to the face or put down when map viewing was desired.

Meanwhile, IST received from PM-TRADE a supposedly working set of source code for the SIMNET hosts. With the assistance of Warren Katz, one of the software's authors and now a private consultant, IST began to decipher and recompile the SIMNET simulation host source code.

In order to investigate the possibilities, we embarked upon an attempt to integrate the Polhemus system into the SIMNET source code. After some effort with Warren Katz' assistance, we were able to integrate the Polhemus into the Simnet code. We built an internal analog to the external version of the HTD. In essence, we turned off the code which read the cupola potentiometer, and forced in the values from the Polhemus. We managed to extend the Polhemus code to compensate for the "dead spot" where the cupola could not rotate. Thus, full 360 degree rotation about the vertical axis became possible.

The integration of vertical motion was attempted. The problem was traced in the source code back to the way the cupola rotation was stored as an M1 state variable. Only the rotation about the vertical axis is stored. Substantial work would be required to change the source code so as to allow rotation around three axes. Without BBN support, this was not feasible.
We also considered modifying the Stealth system's source code so as to take advantage of its ability to move the viewpoint freely, but found that only about half the Stealth code was actually available. As time and resources were running out, we abandoned further efforts to integrate the EyePhones with the SIMNET system.

D. Attaching a HMD to the ESIG-500 System

The second task attempted under the HMD project was the use of a low-cost head-mounted display on the Evans and Sutherland ESIG-500 image generator. This image generator has several characteristics that made it an attractive platform for this work. First, since the image generator was not tightly coupled with a training simulator, it was hoped that control would be a simpler matter than on the SIMNET, where image generator control code was imbedded inside simulation code. Secondly, it was felt that the higher update rate of the ESIG-500 (50 Hz vice 15 Hz on SIMNET) would provide information on the effects of update rate on users.

The original intention was to use the VPL Eyephones with the ESIG-500. We thought the ESIG-500 was capable of running at a visual system vertical refresh rate (update rate) of 60 Hz. This would allow us to use video encoders to encode the red, green, blue, and sync signals into an NTSC composite signal, which could be used by the Eyephones. Evans and Sutherland told us this would be possible if we did a hardware modification by replacing the timing crystal on the ESIG with a faster crystal, and if we were willing to accept a reduced polygon budget (they said that the update rate times the polygon budget was an invariant, so that as update rate increases, polygon budget decreases). This also would require some microcode patches, which Evans and Sutherland agreed to provide. However, tests showed that the fastest update rate we could achieve was 57 Hz. This was not close enough to the rate required to obtain an image on the Eyephones.

Additionally, we attempted to modify the Eyephones to bring the signal synchronization rate down to 57 Hz. However, it was determined that the cost of producing a crystal that would allow the Eyephones to synchronize at 57 Hz was prohibitive, since it was not a standard crystal and would require a special production run to create. Additionally, it was reported that the circuitry would require substantial modification to allow the Eyephones to synchronize at 50 Hz, even with commercially available crystals.

The next solution we explored was the use of scan converters to modify the ESIG-500 signal from 50 Hz to 60 Hz. Each scan converter could modify one channel and cost $15,000, for a total cost of $30,000. This was clearly a prohibitive cost.

Finally, we were able to locate a different HMD, the Cyberface II, by Pop Optix Labs, that was capable of accepting separate red, green, blue, and
synch signals. The Cyberface II is also capable of synchronizing at both 50 Hz or 60 Hz, and therefore can be used directly on the ESIG-500. The ESIG-500 produced a signal with levels inappropriate for the Cyberface II. The images were washed out and detail was difficult to see. These signal strength problems that were solved by circuitry designed and constructed at IST, and incorporated into a housing with the power supply for the Cyberface II. This circuitry provides the ability to adjust each of the red, green, and blue signals individually. This allows us to adjust the brightness and color balance for each display in the Cyberface II HMD system, even where differences in source signals exist. The Cyberface II will be described in more detail later in this report.

Use of a head-mounted display with an synthetic image source such as the ESIG-500 requires control over the image source. With the ESIG-500 this control can be effected through the terminal keyboard attached to the ESIG-500 or through a host computer connected to the ESIG-500 with an Ethernet network. Because it is desirable to use a magnetic tracking device to control eyepoint orientation and, to a lesser degree, eyepoint position, it is necessary to use a host computer controlling the ESIG-500 over an Ethernet connection. The magnetic tracking device is connected to the host computer using a serial connection.
Polhemus Isotrak

Serial Link

Host Computer: IBM PC Clone with 3Com Ethernet card

Dedicated Ethernet Link

Visualization Platform: ESIG 500

Cyberface II

Figure 8: ESIG/CyberFace Configuration
The control program can be summarized by the pseudocode below:

```
initialize serial port
initialize tracker
initialize Ethernet
initialize viewport

while (!done) {
    get a position/orientation record from the Polhemus
    determine the center screen (the one the TC is looking at)
    if (center screen changed) set screen changed flag

    look up the corresponding IG control word
    look up the corresponding video switcher control word

    if (sync signal from IG) {
        if (center screen changed) {
            send BLANKING control word to the video switcher
            set delay counter
            clear screen changed flag
            set change the switcher flag
        }
        send the IG control word
    }

    if (change the switcher) {
        if (delay counter > 0)
            decrement delay counter
        else {
            send video switcher control word
            clear change the switcher flag
        }
    }
}
```

The ESIG-500 host interface follows IEEE 802.3 hardware and software standards for communication protocol. The communication protocol frame format is shown below:

<table>
<thead>
<tr>
<th>preamble</th>
<th>sfd sync</th>
<th>dest addr</th>
<th>src addr</th>
<th>length</th>
<th>data</th>
<th>crc</th>
</tr>
</thead>
</table>

**Figure 9: Frame Format**

The preamble, sfd sync, and crc fields are filled in by the Ethernet hardware. The user on the host computer specifies the destination address field, the source address field, the length field, and the data field. The data field contains the command(s) to the ESIG-500 from the host computer. The data field can contain multiple opcodes, with each opcode being followed by
any required parameters. The data field must be at least 46 bytes and no more than 1500 bytes.

The Ethernet standard corresponds to the Physical Layer and the Data Link Layer of the OSI protocol stack. Higher level communications protocols, such as IP and TCP, are not understood by the ESIG-500. For ease of implementation, it was decided to use a PC clone as the host computer. This provided easier access to low level Ethernet communication. It also allowed isolation from network traffic (using higher level protocols) not intended for the ESIG-500.

The Ethernet card used to connect the host PC to the ESIG-500 is a 3Com 503 Ethernet adapter. The host interface library to control the ESIG-500 was originally written in 80x86 assembler using Ethernet adapter control libraries written by the 3Com company and provided with the 503 adapter. The 3Com library was very poorly written. For this reason, for this project, the host interface library was rewritten in the C programming language. The new host interface library uses a public domain 503 adapter control library, also written at IST.

For the purposes of this project, two functions were used from the ESIG-500 host interface library. These two functions are the escs() function call and the esviewpoint() function call.

The esviewpoint() function gives us control over various aspects of the viewport presented on each channel. This allows setting up the image presented to each eye so that the user is able to fuse both images into a three-dimensional image. Different people's eyes have different inter-ocular distances (IOD), and this must be considered when setting up the viewing parameters on each channel. Parameters to this function include the channel number, the x, y, and z coordinates of the eye position, and the heading, pitch, and roll angles of the eye.

These values must be specified for each eye. The esviewpoint() function is called twice, once for each eye, during program initialization.

The escs() function gives us control over the position and orientation of the eyepoint during run-time. This function is called repeatedly during runtime to continually update the user's point-of-view, based on inputs from a magnetic head-tracker.

The ISOTRAK magnetic tracker used to sense head position and orientation is connected to a serial port on the host computer. This part of the software is similar to the code written to control the HTD described above.

There are some hardware conflicts that may occur between the serial port and the Ethernet adapter. The PC prioritizes interrupts based on IRQ
levels. The Ethernet adapter can be set during initialization to use IRQ levels 2, 3, 4, or 5. The serial ports on a PC typically use IRQ levels 3 or 4. Care must be take to ensure that the IRQ level set for the Ethernet adaptor do not conflict with the IRQ level set for the serial port.

**Status of ESIG-500 Testbed**

At the conclusion of the project, it is possible to demonstrate a working head mounted display system with the CyberFace display and the ESIG-500. There are still some problems with the head tracking software. However, the principal obstacle to practical use of this system is the poor optical and human-engineering properties of the CyberFace. The display is even fuzzier than the first generation VPL EyePhones, and the head mount is essentially unusable.

The University of North Carolina Head Mounted Display research team led by Dr. Henry Fuchs has reached similar conclusions regarding this device.

We remain hopeful that we can re-engineer the CyberFace for improved performance, since it is the only presently available device which accepts ESIG signals. A number of experiments are being contemplated, in collaboration with the Army Research Institute, which would require a display device with the rapid update rate and high scene quality of the ESIG-500, together with a more competent display device.

**E. Attaching a HMD to the Sense8 System**

In January of 1992, an opportunity arose to test the VPL EyePhones with an extremely low-cost image source, to wit an IBM PC containing Intel DVI boards. The PC was provided by an industrially funded IST project; the DVI boards by Dr. Tom Clarke’s DARPA-funded IST project. The software, titled *WorldToolKit* from Sense8 Corporation (Sausalito, CA) was donated by Sense8. This system uses a substantial amount of photo-derived texture arranged in 128 x 128 texture maps, which are warped onto polygons in real-time by the DVI boards.

The EyePhones work remarkably well in this context, considering the limitations of the image sources. The image system can produce between one and ten frames per second of imagery, which is similar in speed to the Silicon Grapics Iris demonstrations described above. However, the addition of texture increases the amount of visual content and of visual flow (motion cueing), so that the user’s sense of presence is enhanced.

Of the four image sources used with HMD’s as part of this project, the Sense8 system is by far the lowest-cost. The entire hardware suite (without EyePhones and Polhemus tracker) cost less than $8,000, and prices continue to drop. The Sense8 software retails for $3,500.
This combination of equipment will be demonstrated at the final presentation of this Project's results in March of 1992.

F. Conclusions

1) With regard to commercially available low cost head mounted display hardware as of the end of 1991, we do not recommend the immediate application of these displays for training purposes. They are neither of sufficiently high resolution, nor physically robust enough for inclusion in training systems.

2) It is likely that the remaining problems of resolution and physical comfort can and will be overcome by a combination of academic and industrial research and development during the next 24 to 36 months. The primary driving force in this market is commercial/entertainment, with a number of new devices appearing on the market as this report is written.

3) The continuing rapid development of low cost image sources such as the Sense8/DVI system will exert an equally strong market force in favor of this technology. Video games of all sorts will appear in 1992 incorporating both low cost HMD's and realtime textured 3d imagery, and this technology should be closely monitored for use in military training.

ABSTRACT

A chronic problem for visual simulation is the requirement for a wide field of view which provides sufficient pixel and object density close to the central viewing axis. In high-fidelity (high cost) flight simulators with dome displays, high definition area of interest inserts have been used to increase the subject's ability to acquire and track targets.

The authors have designed three display systems to explore low-cost solutions to this problem. These systems have been designed as retro-fits to the SIMNET M1A1 tank simulator. The common problem being addressed is that of a tank commander's view of the world. The three systems are:
- a six-window simulation of the M1A1's vision blocks, to simulate closed-hatch operations;
- a head-mounted display, to simulate protected-open position (POP) hatch operations; and
- a ten-monitor panoramic display, to simulate POP hatch operations without the encumbrance of the head-mounted display.

This paper describes the magnetic sensor technology used to detect the tank commander's viewing direction; the switching technology required to distribute image generator (IG) channels across multiple devices; and the resolution and slew rate requirements and capabilities of the IG used in each design.

A concluding section describes experiments to assess the training effectiveness of the implemented designs with regard to navigation and target acquisition tasks.*

INTRODUCTION

The SIMNET M1A1 tank simulator (hereinafter referred to as SIMNET) is a team-trainer that supports the training of four man teams, including a driver, a loader, a gunner, and a tank commander (TC). The trainees can observe the "world" outside the simulated tank through vision blocks that attempt, more or less, to simulate the periscopes and sights provided for a crew in a real M1A1 tank. There is a total of eight vision blocks; one each for the loader and gunner, and three each for the driver and TC. The image generator used in the SIMNET is a BBN GT101.

In the standard SIMNET, the TC's three vision blocks each provide a 20x8 degree field of view (FOV) into the visual database. These views abut each other, for a total FOV of 60x8 degrees. The direction of view (DOV) is controlled by the TC, and can be mechanically rotated through (just less than) 360 degrees. This represents a low cost solution to the requirement for a wide FOV.

However, because the DOV is mechanically changed, a relatively large delay is introduced when the TC wishes to change the DOV. It takes approximately six seconds to rotate the DOV through 180 degrees. At the Visual Systems Laboratory of the Institute for Simulation and Training (VSL/IST) at the University of Central Florida, the authors have designed three low cost solutions to this problem that change the DOV at electronic speeds. At the time of this report, one of the designs has been implemented and a second is under construction.

All of these systems use magnetic head-tracking technology to sense the direction the TC is looking. Two solutions use this head-tracking information to switch video sources to output channels and update the DOV. The third solution also uses the information to update the DOV, but the TC uses a head-mounted display to view the image, so no video switching is required.

* This work was sponsored by the Army's Project Manager for Training Devices (PM-TRADE).
THE POLHEMUS MAGNETIC TRACKER

Each of the systems described in this paper uses a head-tracking device to determine the position and orientation of the user's head. Head-tracking systems typically either use a magnetic source and sensor, or infrared diodes and video cameras. Our systems use magnetic tracking technology. Other magnetic trackers are also available, but Polhemus trackers are probably the most commonly used. The Polhemus 3SPACE® Isotrak® is a low cost magnetic tracker and was used in the projects described in this paper.

The Polhemus Isotrak is a six degree-of-freedom measuring device. The Isotrak can provide Cartesian coordinate (x, y, z) and orientation (yaw, pitch, roll) information about a sensor relative to a source positioned near the sensor. The Isotrak will provide this information within a specified accuracy (position - 0.25 inch RMS, orientation - 0.85° RMS) and resolution (position - 0.18 inch RMS, orientation - 0.36° RMS) up to 30 inches away from the source. The host-Isotrak interface is by RS-232C serial link, with user selected baud rates from 300 to 19,200 baud. The information can be in ASCII or binary format, and the highest output update rate is 60 Hz at 19,200 baud in binary format. (Polhemus 1987)

HEAD-TRACKING DISPLAY SYSTEMS

Two of the systems described in the introduction are head-tracking display systems not based on either dome projection systems, which are high cost, or on head-mounted display technology. These two systems, called the Head-Tracking Display (HTD) and the Extended Head-Tracking Display (EHTD), are based on the use of standard video monitors with video switching technology. This allows the use of a number of IG channels with a larger number of monitors to reduce the cost of image generation resources while not reducing the apparent number of output channels.

The VSL/IST Video Switcher

The video switcher used in the Head-Tracking Display systems was designed and built at the Visual Systems Laboratory. The switcher was constructed to take four NTSC composite video input signals and route them to any of six output channels under control of a host computer. It is constructed from six four-to-one composite video multiplexers with two select lines each.

A DB-25 pin connector allows connection of the switcher to the host through a parallel port. Twelve lines of the parallel port are read as a control word to select which input signals are routed to which output channel.

The routing of input signals to output channels is software configurable through the control word. Any input signal can be routed to any output channel, the only restriction being that only one input signal can be routed to a particular output channel at a given time.

The design can be scaled up using additional video multiplexers. It may also be possible to improve signal quality by using RGB video multiplexers instead of composite video multiplexers, but this would increase switcher circuitry complexity and video cabling requirements. (Dunn-Roberts et al. 1991)

The Head-Tracking Display

The first implemented display system is the Head-Tracking Display (HTD) (figure 1). This display system has been implemented and is in use with SIMNET.

Figure 1. The Head-Tracking Display (HTD)

The purpose of the HTD is to simulate the M1A1 Abrams tank commander's (TC) cupola, which has six vision blocks. Each vision block has a 45x15 degree FOV (approximately). SIMNET provides a single 60x8 degree FOV using three channels from the SIMNET IG. The HTD design allows us to drive six monitors with the TC's three channels of the SIMNET IG. This is accomplished through the use of the video switcher and the Polhemus Isotrak magnetic tracker, under control of an IBM PC-AT. The control computer reads the tracker, controls the video...
In the HTD, six 13” (diagonal) monitors are placed in a ring around the TC’s cupola. The cupola is constructed from white cardboard with six openings equally spaced around the TC’s head, through which the TC views the images on the monitors. Only the three monitors in front of the TC’s head are active at any time, with each monitor presenting approximately the same FOV as a real vision block. This gives the TC a 140x16 degree instantaneous FOV. Under control of the PC-AT, the video switcher activates the three monitors in front of the TC. As the TC turns, the control PC shifts the output signals to the appropriate three monitors. The switcher is designed to give an instantaneous change of view in order to eliminate the time now required for the cupola to rotate mechanically through the same distance. For example, a 180 degree rotation that requires six seconds in the mechanically rotating cupola takes approximately one fifth of a second in the HTD.

The control computer also controls the DOV of the IG through a digital-to-analog (D/A) converter. This converter mimics the potentiometer in the mechanically rotating cupola to change the DOV of the IG.

The control computer reads the Polhemus magnetic tracker and, based on the orientation of the user’s head, sends a signal to the IG to update the DOV. The control computer then routes the four input channels to some subset of the six monitors.

Three of the input channels come from the SIMNET IG, and the fourth input channel is available for neutral imagery from any video source, or can be left blank.

The control functions of the PC-AT are provided by a combination of hardware additions to the PC-AT and the simulator host and control software on the PC-AT. The hardware additions to the PC-AT consist of a parallel output channel with some logic circuitry and a D/A converter. The output channel is used to transmit control signals to the video switcher, and the converter is used to control DOV on the IG. Both the output channel and the converter reside on a single prototype bus card (called the interface card) in the PC-AT. In addition to this interface card, a game port card has been added to read a synchronization signal from the simulator host.

The control program for the HTD is conceptually simple. It has two basic responsibilities: sending the TC’s DOV to the IG, and telling the video switcher which input signals to route to which channel. The control program reads two inputs: the magnetic sensor and the synchronization signal. The only two outputs from the program are a control voltage for the SIMNET IG, and a control word for the video switcher.

The outputs from the SIMNET IG are in the form of four signals: red, green, blue, and sync. To reduce cabling requirements and switcher complexity, the signals are encoded using a commercial video encoder. Output signals from each channel of the SIMNET IG are connected to the RGB and Sync inputs of the encoders. The composite video outputs of the encoders are connected to the inputs of the video switcher. The outputs of the video switcher are then connected to the color monitors.

The select lines of the video switcher are addressed from the interface card. The interface card has a sixteen bit latch that can be written to by the control program using C or assembly language instructions. The control program writes the control word to the latch, and the twelve low order bits are written to the video switcher.

The TC’s DOV is controlled by a D/A converter. In SIMNET normal operation the DOV is controlled by a potentiometer mounted on the rim of the cupola rotation track. The voltage dropped across the pot varies as the cupola rotates. The voltage drop is converted to a digital value by an analog-to-digital (A/D) converter in the simulator and the DOV is modified accordingly. The HTD bypasses this potentiometer and sends a control voltage from the D/A converter on the interface card to the simulator’s A/D converter. The D/A converter is controlled similarly to the video switcher, by writing a control value to a sixteen bit latch on the interface card.

The hardware modification to the simulator host consists of a small circuit that detects when the simulator A/D card has been read by the host. This circuit sends a signal to the control PC-AT to allow for a measure of synchronization. However, even with this modification to the SIMNET host, synchronization is not exact, and a blanking interval of approximately one frame is required. (Dunn-Roberts et al. 1991)

**The Extended Head-Tracking Display**

There is significant interest in extending the functionality of the SIMNET M1 trainer to include the Protected Open Position for the tank commander (referred to as the “POP hatch”). The authors have also designed an Extended Head-Tracking Display. This display system has not yet been implemented. The purpose of the EHTD is not only to simulate the M1A1 Abrams TC’s cupola, but also to provide for POP hatch operations, while conserving IG channel capacity.
Two possible designs have been considered for the EHTD. In both designs, a ring of ten 27" (diagonal) video monitors provides the 360° horizontal FOV POP hatch view. In one design, actual periscopes pointing at the ring of monitors provide the view through the TC's vision blocks (figure 2). In the other design, the view through the vision blocks is provided by a second ring of six monitors, just as in the HTD (figure 3).

The EHTD uses the same video switching technology as the HTD. Depending on the design chosen, video signal switching from the IG can be accomplished either with a single switcher, or may require two switchers or a scaled up switcher. This also depends on whether the POP hatch view will activate three or five monitors in the TC's DOV. This question will be addressed with IG requirements later in this paper.

Limitation on requirements for vertical FOV is based on the 6" high opening available under the elevated hatch and the commander's head position relative to the radius of the hatch. Also, the capability for providing high vertical FOV is limited by the aspect ratio of off-the-shelf NTSC monitors.

In the EHTD, the POP hatch view will adjust for head motion within the cupola. Since the commander has a range of available head motion within the cupola (approx. 32° in diameter in SIMNET), the view out the monitors should adjust for the correct head position.
This requires head position information be passed over to the SIMNET host and used to adjust the viewpoint generated by the SIMNET IG. Engineering development will be necessary to provide this level of control over the IG (greater than in the existing SIMNET cupola or in the current HTD).

Visible elements of the tank (the tank hull, the main gun, etc.) will need to be displayed in the views from the POP hatch. Since the commander’s eyepoint will be above the top of the turret in the POP hatch position, portions of the tank will often be visible. The visible tank features must be modeled or mocked up so they will be displayed correctly.

The cupola will rotate in the EHTD. The current SIMNET allows the commander's cupula to mechanically rotate but provides only a restricted view out of one vision block of the cupula. In a real tank, the cupula is sometimes rotated so as to position the machine gun out of the forward line of sight, or to aim the machine gun. Using an existing SIMNET hull and cupula mechanism, the required vision blocks and a simulated hatch cover and machine gun mount will be incorporated so as to rotate within the panoramic monitor display.

In the EHTD, the user will be able to use the six vision blocks simultaneously with the POP hatch views. The commander will be able to support training in normal mode (through the six vision blocks) or POP hatch (through the out-the-hatch monitors). Both of the designs described earlier for the EHTD support this capability. (Moshell et al. 1991)

**Image Generator Characteristics**

A fundamental goal of the POP hatch display is to allow the platoon commander to acquire targets and to navigate. It would be unacceptable if his visual image were less accurate than those provided through the vision blocks of the SIMNET in its standard configuration.

When the FOV is greatly expanded, two distinct costs are incurred.

- Additional pixels must be supplied so that the visual angle subtended by pixels remains constant; and
- Additional polygon capacity must be supplied so that the greater scene complexity doesn’t overload the geometry engine.

To accomplish these goals, the EHTD would require the addition of a BBN GT120 image generator (or equivalent) to the existing SIMNET GT101.

With three screens active simultaneously, the horizontal FOV would be 108°. If five screens are live, the active area would be 180°. (Moshell et al. 1991)

**Three Active Screens** The GT120 can provide two medium resolution channels of 320 x 240 pixels with 3000 polygons, and one high resolution channel of 640 by 480 pixels with 6000 pixels.

This will provide a central channel whose pixels subtend 3.4 minutes of arc (compared to 3.75 minutes in SIMNET), with a polygon density of 6.5 polygons per square degree (compared to 6.25 in SIMNET). Thus, the central channel will slightly improve upon SIMNET's scene and pixel density capacities.

The two adjacent channels will have pixels which subtend about 6.5 minutes of arc (essentially what one sees on the SIMNET Stealth displays) with a polygon density of 3.3 polygons per square degree. These channels will be somewhat more susceptible to overloading on complex scenery than the central channel. (Moshell et al. 1991)

**Five Active Screens** Optionally, the SIMNET could sacrifice some channels from its original IG so that two additional adjacent channels could be rendered. The pixel density is not bad - in fact, at 320 x 256, it is somewhat better than the medium-resolution channels of the GT120.

However, these channels can support only 2000 polygons. With an angular density of only 2.2 polygons per square degree, these channels would quite often overload.

To provide these two channels would require consuming four of the eight SIMNET channels, presumably leaving one each for the the gunner and loader and two channels for the driver. The horizontal field of view for the driver's two channels could be expanded to equal the total FOV of the original three channels. (Johnston 1987; Moshell et al. 1991)

**HEAD-MOUNTED DISPLAY SYSTEM**

We are also designing a third system that utilizes head-tracking information to control the visual display system. This system would use a color LCD head-mounted display (HMD) with a SIMNET IG to present the POP hatch view to the TC.

The first design problem is the interfacing of the magnetic head-tracker with the SIMNET IG. As described above, the HTD uses a voltage to control the TC's DOV. This allows control of the yaw of the DOV, but not the pitch or roll. To allow the TC six degrees-of-freedom with the HMD, the SIMNET host will have to be modified to change the DOV based on the position and orientation of the TC's head as read by the head-tracker. This will require greater control over the the SIMNET host software than is required in either the HTD or the EHTD.
In addition, the HTD uses the existing SIMNET IG to produce three half-height video images. To use the HMD with the M1A1 simulator would require hardware modifications to produce two full-height video channels. Optionally, IST/VSL has a SIMNET Stealth Vehicle simulator that produces three full-height video images that may be used to drive the HMD.

Another challenge is that human eye does not have constant characteristics over the entire visual field. For an image to be as realistic as possible, some predistortion needs to be done to the image before it is presented in a conventional HMD. At IST, this problem is being addressed in a separate project to construct a HMD that more closely matches the image perceived by a human eye. (Clarke 1990)

Perhaps the most difficult problem is how to present an image of the inside of the tank, complete with working controls. An alternative is to mount the HMD in such a fashion as to allow the TC to look through the HMD to see the POP hatch view, and to remove the HMD to work inside the tank cupola. Still, modeling of the exterior of the tank will be necessary to present the TC with a "realistic" view out of the POP hatch.

This system is currently under design and will be implemented in early Fall, 1991. (Altman, Mosnell, and Dunn-Roberts, 1991)

EXPERIMENTAL EVALUATION OF SYSTEMS

We are currently evaluating the HTD system on two tasks: terrain-reasoning and target acquisition. As each of the other systems gets implemented, we will use the same experimental design to evaluate them.

In the terrain-reasoning task, tank commanders observe the terrain database while they are driven through a specified geographic area. Their task is to locate three checkpoints specified on an available map. The TCs give the driver directional and speed commands. They tell the driver to stop when they think that they have arrived at each checkpoint. Dependent measures are speed and accuracy of position identification.

In the target acquisition task, TCs scan for targets as they are again driven through a specified course in the database. TCs do not give directional or speed commands for this task. Dependent measures are number of correct target identifications and target acquisition speeds.

Trained drivers are used for all conditions. A common terrain database, representative of the Ft. Knox range, is used for all displays. We are also collecting preference and "wellness" data (e.g. nausea, eye strain) concerning each cupola simulation. We are using both experienced and novice subjects as tank commanders. Each subject participates in both tasks, target acquisition and terrain-reasoning. Each subject will also use both the SIMNET mechanically rotating cupola as well as the HTD. Counterbalancing of task and cupola conditions is employed to remove the potential for confounding effects.

Results of the evaluation of the HTD will be available in August, 1991.

**  
** FUNCTION LIST:  
-------------  
**  
** FUNC: void interrupt (*old_timer_routine) (void);  
- a pointer to the old timer routine  
** FUNC: void interrupt handle_timer_interrupt(void);  
- our new timer interrupt handler  
** FUNC: void set_timer(void);  
- to reprogram the clock timer to interrupt at 60Hz  
- instead of 18.2Hz  
** FUNC: void reset_timer(void);  
- to reprogram the clock timer back to 18.2Hz  
** FUNC: void readConfig(void);  
- reads configuration information from external file  
** FUNC: void initPolhemus(void);  
- initializes the Polhemus  
** FUNC: void getRecord(void);  
- gets a data record from the Polhemus  
**  
** General Comments:  
This program was written to run on a PC-AT, using  
Borland C++ version 2.0 (with the built-in assembler).  
It is designed to control the operation of the Head  
Tracking Display system.  
**  
** Operational Comments:  
The switcher control program reads the head orientation  
from the Polhemus magnetic sensor and the video sync  
signal from the SIMNET Image Generator. It then  
determines which screens should be turned on (sending a  
control word to the Video Switcher), and determines the  
appropriate voltage to emulate the cupola's  
potentiometer (sending a control word to a digital-  
to-analog converter, and the analog signal is then  
routed to the SIMNET controls). See the figure below.  
**  
** The basic layout is as follows:  
**  
+-------------------+ 15Hz sync signal +-------------------+  
|                   | PC_AT                  | SIMNET MASSCOMP |  
|                   |                        |                |  
| {switcher}        |                        |                |  

For further system details, refer to the project report.

Appendix G:

Software to Control ESIG-500 Head Tracking Display
HEAD MOUNTED DISPLAY - Image Generator Control Program

FILENAME: esighmd.cpp

By: - Visual Systems Laboratory
    - Institute for Simulation and Training
    - University of Central Florida

Copyright (c) 1991 the University of Central Florida
- All Rights Reserved

Author: Richard Dunn-Roberts

FUNCTION LIST:

FUNC: int initializeEthernet( int maxDataSize, int numPackets )
This function initializes the Ethernet packet queues,
the packet manager, and the 3Com Ethernet drivers.

General Comments:
This program was written to run on a PC-AT, using
Borland C++ version 2.0 (with the built-in assembler).
It is designed to control the operation of the ESIG 500
Image Generator for use with a Head-Mounted Display.

Operational Comments:
This program operates as a communications server. It
accepts input from the serial port. This input may be
from a Polhemus magnetic tracker or from another
computer on a network. The input is then converted to
ESIG 500 Image Generator commands and retransmitted
via dedicated Ethernet to the ESIG 500 to control
the direction of the users point of view.

The basic layout is as follows:

+-----------------+ 19.2 kilobaud +-----------------+  
| I/O server      | serial link       |
| (currently       |
| Harris Night-    |
| Hawk)            |
+-----------------|<---+-----------------|
+-----------------+  
| head position   |                  |
| and orientation |
+-----------------+  
+-----------------+                  |
| POLHEMUS TRACKER |
|                  |
+-----------------+                  |
| video output    |                  |
+-----------------+  
| ESIG 500 IG     |
| (two channels)  |
+-----------------+  

For further system details, refer to the project report.

FUNCTION LIST:

FUNC: int esambient(int scene, int ambience, long messageCount)
This function sets ambient light levels.

FUNC: int esanimation(int cs, int select, int parcel, int placeable, int control, int sequence, long messageCount)
This function executes a predefined animation sequence.

FUNC: int eschannel(int number, int display_a, int display_b, int viewport, int color, long messageCount)
This function sets control parameters for specific channel on the ESIG 500.

FUNC: int escloud(long top, long bottom, long messageCount)
This function sets cloud top and bottom heights.

FUNC: int escold(int color, int valid, int automatic, long messageCount)
This function sets characteristics of collision detection indicators.

FUNC: int escoldpt(int number, long x, long y, long z, long messageCount)
This function sets collision detection test points.

FUNC: int escs(int cnum, int select, long x, long y, long z, unsigned int heading, unsigned int pitch, unsigned int roll, long messageCount)
This function controls characteristics of ig coordinate systems.

FUNC: int esdisable(int esig_switch, long messageCount)
These two functions enable and disable simulation characteristics, such as weather, strobes, and collision detection.

FUNC: int esfog(signed int top, long messageCount)
This function sets the height of ground fog.

FUNC: int eshatpt(int number, signed long x, signed long y, signed long z, long messageCount)
This function sets height above terrain test points.

FUNC: int eshorizon(int brightness, int directional, unsigned int heading, long messageCount)
This function sets horizon brightness and direction.

FUNC: int esinstructor(int channel, long messageCount)
This function sets instructor monitor channel.

FUNC: int eslight(int number, int intensity, long messageCount)
This function sets the intensity of light switches.

FUNC: int eslobe(int lights, long messageCount)
This function sets aircraft landing lights.
/*
FUNC: int esmodel(int colocate, int parcel, long messageCount)
This function allows user to load a database.

FUNC: int espolygon(int number, int intensity, long messageCount)
This function sets polygon intensity.

FUNC: int esrvr(long range, long messageCount)
This function sets runway visibility range.

FUNC: int esscene(int select, long messageCount)
This function sets day, dusk, or night scene type.

FUNC: int essun(unsigned int heading, unsigned int pitch, long messageCount)
This function sets sun heading and pitch.

FUNC: int estraffic(int cs, int select, int parcel, int placeable, int control, int scenario, long messageCount)
This function sets information for routed or converging traffic.

FUNC: int esviewport(int channel, int alternate, long x, long y, long z, unsigned int heading, unsigned int pitch, unsigned int roll, unsigned int vertical, unsigned int horizontal, long messageCount)
This function sets viewport characteristics.

FUNC: int esvisibility(long range, long messageCount)
This function sets visibility range.

General Comments:
This library was written to run on a PC-AT, using Borland C++ version 2.0. It is designed to provide functional support to control the ESIG 500 image generator.

Operational Comments:
This library provides the interface to control the ESIG 500 from a user program. The public functions take the user's inputs, converts them into an Ethernet packet, and retransmits the information to the ESIG 500.

The basic layout is as follows:

PC AT ------------------- ethernet link ------------------- ESIG 500
(user program) + (esigcom)

For further system details, refer to the project report.

*/

/* Type, Structure & Constant Defs */

/* Necessary Include Files */

#include <stdlib.h>
#include "esigcom.h"

/* Function Prototypes */
/*---------------------------*/
/*---------------------------*/
/* Globals */
/*---------------------------*/

// Ethernet addresses of this machine (src) and ESIG 500 (dest)
unsigned char src[] = { 0x02, 0x60, 0x8c, 0x43, 0xa7, 0xf1 };
unsigned char dest[] = { 0x00, 0x08, 0x01, 0x57, 0x58, 0x00 };

/********************ical Parameters:
scene - the scene whose brightness is being set.
ambience - the brightness value (0-255).
messageCount - sequence number of this message

Process:
Program to set brightness for the scene. Brightness is a scalar from 0-255, and scene is 0 (night), 1 (dusk), or 2 (day).

Returns:
int - success == 0, failure != 0;

/********************ical Parameters:
scene - the number of the coordinate system.
select - the select switch.

int esambient(int scene, int ambience, long messageCount)

Appendix H: Summary of Results of HTD Experiments
Head-Tracked Cupola Display Preliminary Results

The results of this evaluation with novice subjects indicated that there were no significant differences in performance or preferences between the two simulations (Simnet vs HTD). It appears that for the selected tasks (target acquisition and navigation), subjects performed equally well (or equally poorly) in both simulations. There are several potential explanations for these findings: 1) the two simulations may be close enough in design that performance differences will not be seen for most tasks, 2) the tasks were simply too easy to determine if there were performance differences, and 3) there were too many problems with experimental control (e.g., too many disturbances, equipment failures, etc.) to keep variability low enough to observe any differences.

In my opinion, explanations one and two are probably both correct. From what I have observed and heard about tank scenarios, in most cases there probably would be no differences in performance between the two simulations. For example, the navigation task required infrequent head turning or cupola rotation to find a checkpoint. The tank commander (TC) was only required to tell the driver to turn, and the TC could easily determine his surroundings while looking straight ahead. I believe that the results from most navigation tasks would be similar. Concerning target acquisition, I have heard that in most situations the tank would be in a defensive position, or it would attack in groups, with each group focusing on a specific sector. In these situations, speed of acquisition would likely be less important. If this is true, then there would be little expectation for differences in performance between the two simulations, which was observed in this study.

However, if speed of target acquisition is important, then I predict that the HTD would provide superior performance. The target acquisition task in this study appeared to be too easy to elicit performance differences between the simulations, even though the 20 targets were placed in difficult locations (hence, the low acquisition mean of 11.75).

I also believe that the lack of experimental control concerning demos, equipment failures, etc., was a problem. However, these factors probably occurred equally over the experimental sessions, so I doubt if they influenced the means, except possibly to reduce them across the board. These problems could have increased the variability, which would require greater differences between the simulations to show an effect. In addition, a larger sample size was needed in order to increase the power to detect group differences.

In conclusion, I would recommend continuing the evaluation based on the importance of target acquisition speed versus the cost/benefits of continuing. If tank training does not focus on speed of target acquisition, then the Simnet is probably adequate for training, and continuing the study
would not be cost effective. However, if speed of acquisition is very important, then we probably should continue with experienced personnel.

If we do continue, I have some further recommendations. We should drop the navigation task, because I doubt if there are any scenarios in which the two simulations would show differences. The navigation task also required more time to complete than the target acquisition task. Dropping the navigation task would allow us to run more subjects in a shorter amount of time.

As you suggested, Ernie, I would run the target acquisition task over a shorter route but with a much higher target density. This would require that the TC scan his environment faster, which may result in performance differences between the HTD and Simnet. I would also have the gunner-tank commander relationship more involved by having the gunner actually try to shoot the targets.

Finally, we need to run this experiment with better control. I would like to have access to two students who are available to run the experiment at any time, not just when they can fit it into their schedules, and I want to be able to limit people from interrupting the study. I realize that these requests may be difficult to accomplish.

10.) Do you think that your performance and preferences would have changed if the head-tracked display did not have popping/flickering?

    Yes = 11  No = 2
Appendix I

Computations Concerning EyePhone Resolution

The low resolution Eyephone has 442 x 238 primary color pixels per eye. The total number of primary color pixels is 105,196. This means 35,065 triads, in an array that I am assuming is 256 x 137. The FOV for each eye is 86 degrees (horizontal) by 76 degrees (vertical). The total horizontal FOV is 108 degrees. The binocular overlap is 64 degrees.

Because of assumptions made above, the following calculations are approximate. The total number of pixels (three color) horizontally is $256 \times 108 / 86$ (pixels per eye x total FOV / FOV per eye). This equals 321 pixels. The number of arc minutes per pixel horizontally is $108 \times 60 / 321$ or approximately 20 arc minutes per pixel.

The number of vertical three color pixels is approximately 137. The number of vertical degrees is 76. This gives approximately 33 arc minutes per pixel vertically.

The same calculations, with the same assumptions, applied to the high resolution Eyephones gives the following results.

Total number of primary color pixels per eye is 345,600 in a 720 by 480 matrix. This gives about 416 horizontal by 277 vertical three color pixels per eye. The horizontal FOV per eye is 86 degrees, and for both eyes is 106 degrees. The vertical FOV is 75 degrees. The total number of horizontal pixels is approximately 513 pixels. This works out to about 12 arc minutes per pixel horizontally. The number of three color pixels vertically is about 277. This works out to about 16 arc minutes per pixel vertically.

VSL Memo 91.6  
2/15/91

There is significant interest in extending the functionality of the SIMNET M1 trainer to include the Protected Open Position for the tank commander (referred to as the “POP hatch”). This document includes the results of a preliminary analysis of this problem.

The major sections of the document are as follows:

I. Project Requirements and Description  
II. Constraints on the Image Generator and Monitors  
III. Miscellaneous Concerns about the Design  
IV. IST Estimates on Time and Cost

I. Project Requirements and Description

List of Project Requirements: The following list covers the main points of the proposed design. This serves as a summary of the overall project goals.

1. Provide a 360° field of view POP hatch display.

2. Allow the commander the maximum possible vertical field of view in the POP hatch display, consistent with tank geometry.

3. The POP hatch view will adjust for head motion within the cupola, so as to provide a high resolution central display, medium resolution lateral displays, and no imagery outside of the central viewing cone. This will conserve image generator channel capacity.

4. Visible elements of the tank (tank hull, main gun, etc) will be visible in the views from the POP hatch.

5. The cupola (including vision blocks, machine gun and hatch cover) will rotate under the control of the machine gun control handle.

6. The capability will be provided of using the 6 vision blocks as well as the POP hatch views simultaneously.
Description of the Requirements: The following paragraphs provide more detail about each of the project requirements stated above.

1. Provide a 360° horizontal field of view. The display will be created by providing a ring of ten 27" (diagonal) video monitors surrounding the tank commander's cupola. This will be an extension of the Head Tracking Display project (HTD) currently underway at IST/VSL. Referred to as the Extended Head Tracking Display (EHTD), this new project will use the same video switching technique employed in IST's HTD: a Polhemus magnetic tracker is used to switch video channels so the commander always has an active video display in the direction his head is facing. (See Figure 1).

![Figure 1 - Top View of the EHTD](image)

2. The commander is given the maximum feasible FOV in the vertical direction: This requirement is based on the 6" high opening available under the elevated hatch and the commander's head position relative to the radius of the hatch. The geometry involved is shown in Figure 2.

   Note: the aspect ratio of off-the-shelf NTSC monitors makes it limits the vertical field of view which can be achieved with a single row of monitors and no optics. See section II for details.
3. The POP hatch view will adjust for head motion within the cupola: Since the commander has a range of available head motion within the cupola (approx. 32" in diameter in SIMNET), the view out the monitors should adjust for the correct head position. This requires head position information be passed over to the SIMNET Host and used to adjust the viewpoint generated by the SIMNET CIG unit. Engineering development will be necessary to provide this level of control over the CIG (greater than in the existing SIMNET cupola).

An additional concern is the obstacle provided by the vertical edges of the monitor housings. This is discussed in section III below.

4. Visible elements of the tank (fenders, gun, etc) will be displayed in the views from the POP hatch: Since the commander’s eyepoint will be less than 6" above the top of the turret in the POP hatch position, portions of the tank will often be visible. The visible tank features must be modelled so they will be displayed correctly.

5. The cupola will rotate. The current SIMNET simulator allows the commander’s cupola to mechanically rotate but provides only a restricted view out of one vision block of the cupola. In a real tank, the cupola is sometimes rotated so as to position the machine gun out of the forward line of sight, or to aim the machine gun.

The EHTD project will support cupola rotation. Using an existing SIMNET hull and cupola mechanism, the required vision blocks and a simulated hatch cover and machine gun mount will be incorporated so as to rotate within the panoramic monitor display.

6. Provide the capability of using the 6 vision blocks as well as the POP hatch views simultaneously: The commander will be able to support training in normal mode (through the 6 vision blocks) or POP hatch (through the out the window monitors). Two competing designs are being considered to support this:
1. Have a set of monitors dedicated to the vision blocks and a set dedicated to the POP hatch display. A side view of this is shown in Figure 3. The monitors would have to occupy a carousel which rotates along with the cupola and vision blocks.

![Figure 3 - Dual Set of Monitors](image)

2. Use a single set of monitors to support both the vision blocks and the POP hatch display. This requires actual "periscope-style" vision blocks and a redesign of the approach used to supply the vision block views. This approach is shown in Figure 4.

![Figure 4 - Single Set of Monitors](image)
IV. IST Estimates on Time and Cost

The following spreadsheet titled *EHTD Equipment Pricing* shows estimated costs for materials for a one-of-a-kind installation. These would diminish by 10 to 20% in a production operation for 10 to 50 units.

The equipment estimate would need to be increased by the (unknown) amount which a contractor would charge for integrating the panoramic display into a production-model SIMNET tank hull for actual training purposes.

The spreadsheet titled *EHTD Personnel Pricing* shows IST's projected labor and overhead cost for performing the construction of a proof-of-concept demonstration. We have no way to estimate the charges a for-profit contractor would levy for similar services.

We estimate that six months would be required from receipt of a commitment to completion and testing of the EHTD system. The principal delays are involved with the acquisition of the IG and the debugging and testing of the host software, some of which would be developed in collaboration with a subcontractor.

This is an estimate, not a *formal quotation*, due to the haste with which the estimate was required.
## Labor Pricing for the EHTD Project
