Length: 100 Pages

Abstract

This thesis describes a new method for modeling complex dynamic processes using object-oriented techniques. These techniques are applied to develop a sophisticated model of the software development process. This object-oriented approach has many advantages over non-object-oriented System Dynamics models. Non-homogeneous resource allocation can be explicitly modeled. This allows resource allocation strategies and management decisions to be modeled and assessed in a realistic manner. Since software development tasks and resources are modeled as objects, they can be flexibly created and manipulated to capture the dynamics of a particular project. Furthermore, the principles of object-oriented inheritance lets the modeler or analyst easily extend the model to include new resources and tasks. The thesis addresses major considerations in modeling the software development process, as well as the detailed development of an object-oriented software process model in C++. A comparison is done between this dynamic model and the empirical predictions of the popular COCOMO software estimation system. This new object-oriented approach is not limited to software process modeling and could be applied to a wide variety of scientific, business, and social simulations.

Problem Overview

The challenge of developing software on-time and within budget has grown exponentially over the past ten years, mirroring the exponential growth in size and number of software projects. Of the 500 projects Tom DeMarco has studied, a full 15% produced nothing. Of the projects of 25 or more person-years, 25% failed. The complexity of managing the development of a large software project requires more efficient tools for planning and controlling the software development process.

Types of Planning Tools

- Empirical or Traditional Tools: Current project management tools make empirical estimates of time and manpower to complete a project based largely on the size or number of functions in the project. These estimates are often based on statistical studies of historical data collected from a number of projects. This group of tools includes such popular planning tools as Barry Boehm's COCOMO estimation model, and the Putnam Estimation Model. These models have limitations in that they do not take into account variables that may change with time including management decisions, new requirements, errors generated, and the state of the work force. The empirical modeling approach will not be discussed in great detail here. For a complete discussion see Pressman’s Software Engineering book. These tools are widely in use today, and most software managers have used at least one of these tools in software development.

- Dynamic Modeling Tools: The dynamic software process model differs from the empirical in that it attempts to model the behavior of the development process over time. This type of modeling is based on the System Dynamics techniques developed by Forester and others at the Sloane School of Business at MIT. These models use a system of linear differential equations to determine the interactions between the people, process, and work
accomplished. The first major application of this modeling technique to the software process was done by Abdel-Hamid and Madnick. They developed a software process model using the DYNAMO modeling language to model the tradeoffs in manpower, errors and work completed in a typical development process.

In 1991, the Charles Stark Draper laboratory began a research and development project in dynamic software process modeling. This Internal Research and Development produced Draper's Software Process Model. The Draper Software Process Model expands on the work of Abdel-Hamid and Madnick by incorporating a number of additional factors and effects. The Draper Process model uses the same system dynamic principles as the Abdel-Hamid model, and is implemented in a graphical modeling language called STELLA. The Draper model will be used as the basis for comparison when evaluating the new object-oriented approach to modeling described in this thesis.

- **Object-Oriented Dynamic Tools:** The main purpose of this thesis is to describe a new object-oriented approach to dynamic modeling. This approach uses an object-oriented structure and programming language to implement a dynamic model of the software process. This model uses the same System Dynamics principles as the dynamic software process models described above, but the model is implemented in an object-oriented language rather than currently available modeling languages like DYNAMO or STELLA. The main advantage of this approach is a large increase in flexibility when modeling other types of processes.

**Limitations of the Draper Software Process Model**

Draper's approach to implementing a model of the software process used a graphical modeling language tool called STELLA to model a waterfall software development process. A fairly sophisticated system dynamics model was built using STELLA to model production, error creation, the state of manpower, and a number of interacting effects. This prototype model
expanded greatly on the work of Abdel-Hamid by explicitly detailing error feedback effects in each phase, incorporating additional productivity factors, modeling phases in the waterfall individually, and allowing a manager to make decisions interactively during a modeling session.

This prototype model has met with some success as a training and planning tool. One of the Draper model's major limitations, inherent in the use of current modeling tools like STELLA™, is that the process model is not particularly flexible. To apply the model to a Spiral or Incremental process for example would require rewriting the model. Even a simple task like modeling two different development teams would require major changes to the model.

Further, the original model implementation is limited in the types of resources it can easily represent. It would be very difficult to distinguish the separate skills of different groups of people. It is hard to model the differing abilities of people who do analysis, programming, design and testing, for instance. Using current modeling tools, a different manpower subsystem would need to be implemented for each group of specialist.

While the model is excellent for modeling the traditional waterfall life-cycle project, done by a homogeneous group of workers, it is very difficult to model any other type of process done by non-homogeneous workers.

**Key Object-Oriented Concepts**

A number of key features of object-oriented languages make an object-oriented approach appropriate for modeling. These include:

- **Data Abstraction.** Each class in an object oriented language may be used arbitrarily as a data type much like integers or character strings are used in non-object oriented languages. In modeling, this allows a modeler to define abstract types to represent modeled entities.

- **Data Hiding.** Objects may be treated as black boxes with defined interfaces. The internal data members and implementation can be hidden from the user. This allows a modeler to use
an object without worrying about internal implementation details. This significantly eases the use and reuse of objects.

- **Inheritance.** Inheritance is a property that allows objects to be built from other objects. The advantage is that a modeler can inherit all of the properties of an object, and then either modify or add to its properties and behavior. This allows a modeler to build a hierarchy of objects from simple to more complex without re-implementing common features. A modeler can eventually develop a library of common modeling objects that can be used or reused in new models.

- **Messages.** Objects communicate via messages. A message is essentially a command that one object sends to another. A message is an abstract command. This process is conceptually similar to a function call, but objects need not respond in the same way to the same message. For example, the user might send a message to tell some modeling objects to step forward one time step. The objects might respond to this message in different ways depending on what is necessary for them to step forward one time step.

- **Methods and Member Functions.** An object contains both an abstract collection of data and the methods that the object performs. These methods are implemented as member functions for the object. Since different objects may have different member functions associated with them, they may behave differently. Using inheritance we can make two objects behave in different ways to the same message. For example, a Task object and a Resource object in the model can both process a step() message, but the two objects will have vastly different behaviors when they receive that command.

**Anticipated Advantages of OOPS Method**

To overcome the limitations of current modeling tools outlined above, a prototype of a software process model in the C++ object-oriented language was developed. Using an object-
oriented language allows greater flexibility in adapting the model to different development processes. Specifically:

- Process objects can be defined and assembled in an arbitrary order, letting one model the traditional waterfall life cycle model as well as many other software development paradigms.
- Process objects can be derived from other process objects using inheritance. This allows us to define new process elements with minimal work.
- Resource objects can be defined generically, allowing us to model manpower as well as other development assets. New resources can be defined by inheritance directly from these base resource objects.
- Groups of resources with distinct capabilities can be modeled. In particular groups of manpower that have different capabilities (i.e., analysts, programmers, testers) can be modeled with different productivity factors for each task.
- Resource allocation strategies can be modeled and evaluated. Groups of resources can be assigned to tasks in a multitude of ways. With the object-oriented model one can explore different allocation strategies and their impact.

**Process Features**

To model the software process, extensive research was conducted to determine the essential characteristics of the process. The research done for the original Draper Software Process Model as well as Abdel-Hamid's model were drawn heavily upon to develop the object-oriented model.
The Waterfall Software Process

The starting point for the design of the object-oriented model was the traditional waterfall process as specified in Mil-Standard 2167A. From the standard waterfall process we selected a simplified waterfall process to use as a basis for the model. The simplified waterfall process with error feedback is shown in Figure 1.

![Waterfall Development Process](image)

**Figure 1**

*Waterfall Development Process*

The waterfall diagram represents a portion of a traditional software development life cycle. Production flows from requirements, to design, coding and testing. Errors discovered in later phases are returned to earlier phases to be reworked. The selection of phases was made largely to facilitate calibration of the model. However, using object-oriented techniques, new tasks may be dynamically added to the model to duplicate other development paradigms.

**Productivity**

Normal production is modeled in the task object. Productivity is determined by the nominal productivity of the individual resources applied to a project. The nominal work rates for a project were determined initially by research from a baseline of 10 lines/day per person based on the reference *Software Metrics*. This rate was subsequently adjusted during model calibration to
reflect COCOMO productivity rates and modeling effects. The final calibrated rate used was 13 lines/day.

Each resource object has productivity objects associated with it for different tasks. In the general model, each resource is assigned a productivity rate based on the overall nominal rate described above. It is possible to assign different resources unique productivity's to reflect individual talents. Also productivity of a resource may be affected by other factors such as overtime and schedule pressure. These are discussed further in the section on Resource Attributes.

Productivity by Phase

The nominal productivity in the sample model is divided among the different tasks in the waterfall to determine individual task productivity's. The baseline figure of 13 lines/day represents overall productivity for the process. This overall productivity was divided out for the four tasks in the waterfall process. The following table illustrates the time breakout for a typical project. Grady-Caswell\textsuperscript{14} estimate Requirements: 14.8%; Design: 20.1%; Coding: 37.4%; and Documentation: 27.7%. In our model we rounded these figures to arrive at the following breakout (Table 1)

<table>

<td>25%</td>
</tr>
</tbody>
</table>

Process Rigor

A unique feature borrowed from the Draper Software Process Model\textsuperscript{15} is the notion of rigor in a development process. The idea behind rigor is that there is a subjective measurement of the degree to which a manager maintains rigorous development and testing process. For
example, if a development process is done ad-hoc, it is considered non-rigorous. Conversely if a development process is first carefully planned, requirements are documented in detail, and the code faces regular reviews and verification, we consider the process rigorous. It is assumed assertion that less rigorous processes generally speeds the process but leads to more errors. Conversely a more rigorous process takes more time to complete but produces less errors.

In the object-oriented model each productivity object has a rigor variable associated with it. Managers may adjust the rigor for each resource productivity to reflect individual resource abilities. A rigor value of 1.0 is considered nominal, with 1.5 corresponding to roughly 2/3 nominal productivity and 2/3 the nominal error rate. Conversely a rigor setting of 0.5 will result in roughly double the productivity and double the error rate.

**Error Modeling**

A critical feature of the object-oriented software process model is the explicit tracking of errors. The following system borrows heavily from the Draper Software Process Model which uses a very similar process for explicit error creation and detection. A causal diagram for the error and error detection process is shown in Figure 2. As shown, errors are created during a production stage, and removed by error discovery in subsequent phases.

![Error Model Diagram](image)

*Figure 2  
General Error Model*
Since this system is duplicated for each task in the system, errors are explicitly tracked for each phase in the software process. Error creation occurs linearly, by multiplying the resource error rate by the amount of work done. Using a resource error multiplier allows us to better distinguish between skilled and unskilled resources. Error rates were derived using a pre-testing average of 50 Errors/KDSL (KDSL= thousands of lines of delivered source code) from Boehm,17 Grady and Caswell,18 and Abdel-Hamid's19 figures as input. The following error creation rates were used in model calibration and testing (Table 2)

<table>
<thead>
<tr>
<th>Phase</th>
<th>Percent of Errs</th>
<th>Errors/KDSL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirements</td>
<td>18%</td>
<td>9.25</td>
</tr>
<tr>
<td>Design</td>
<td>52%</td>
<td>26.0</td>
</tr>
<tr>
<td>Coding</td>
<td>30%</td>
<td>15.0</td>
</tr>
</tbody>
</table>

Error removal and rework depends on the percent of errors detected in later phases. Since no phase detects 100% of errors, residual errors are a major output of the model. Further this system, through rework, accurately simulates the growth in project effort and size as errors are discovered and reworked later in the project. In essence, errors feed back into the system for correction as they are reworked.

An error is defined as "any flaw in the specification, design, or implementation of a product."20 Default error rates may be set in the main module (EXAMPLE.CPP) for any resource. These default error rates are typically modified by the resource to factor in resource state information such as level of workforce burnout. Similarly, error detection may be adjusted both by adjusting the percent of errors detected in each phase and the error rework multipliers for each phase in the same way.

**Effort Estimation**

An important feature of the model is the effort estimation system. This system tries to determine how many resource-days of effort are needed to complete the project based on
current productivity rates and work waiting in all tasks. This estimation gives the user an estimate of how well the project is doing relative to a fixed schedule or budget, and also is used to calculate schedule pressure effects on the workforce (described under Resource Attributes below). This estimation is conceptually similar to Abdel-Hamid’s work estimation system, but in this model the estimation is explicit for all tasks in the model.

The estimation used in this model is a straightforward division of work that is waiting by current productivity rates in all tasks. Errors accumulated in each task are not included in the estimation. This reflects the fact that many managers do not include error estimates in their work estimates, because they are largely unknown to the manager.

The fact that Task objects in the model may apply conversion rates to work as it is done, and the fact that one Task may send its output to multiple Tasks in parallel complicates the work estimation process. Fortunately, a Task object can simply call the work estimation member functions for its list of next tasks to get an estimate of how long work in this task will take to complete. Since each Task’s estimation function then calls the estimation function for its next tasks, the work estimation will mirror the actual work list, and produce an accurate estimation. If we repeat this process for all Tasks with work waiting in them, we get an accurate picture of the overall effort required to complete the project.

**Resource Attributes**

Since manpower is the primary resource in software development, this section will focus on the People class attributes rather than the general Resource class. Though the Resource class provides a generic framework for modeling other types of resources, the emphasis here is on manpower.
Resource Allocation

The model allows many instances of the same Resource class to be attached to a single process. This lets one flexibly model multiple work groups and their allocation to the tasks at hand. Since each resource can have unique attributes with respect to each task, it is relatively easy to model groups with varying ability, specializations, and attributes.

In our particular implementation, allocation is recorded in an Allocation object. Allocations link the resources to the tasks they work on. Each time step, these allocations are assessed and adjusted by the model's Allocate() member function. Since this function can be overridden using inheritance, it is possible for new models to be defined with alternative allocation strategies.

Currently the Allocate() function does an iterative allocation based on average work waiting for each task. The allocation function does the following: First, the average productivity for each task is estimated and used to determine the number of resource days required for each task. Next, for each resource, the function allocates resources based on the number of resource days required for each task the resource can perform. Finally, actual Allocation objects are created based on the allocations made. Other allocation schemes are possible, like allocating on an ability basis or even first come first served. This particular algorithm was chosen because it was similar to that which is used in the Draper model. Since we wished to do a direct comparison with the Draper model, this allocation scheme seemed most appropriate. Exploring the effects of allocation algorithms on the project was left as an open subject for future research.

Workforce Turnover

Any project of moderate length generally has turnover in its workforce. Reasons include quitting, reassignment, and retirement. According to Abdel-Hamid, turnover in many software projects can run as high as 34%. Our model defines turnover in terms of average retention time. Each People object has a retention time attribute which may be set when an object is
instantiated and adjusted during a run. As the model executes, the number of people in the resource is divided by the average retention time to determine the losses for a given step.

Communication Overhead

Probably the most significant factor affecting workforce productivity is the degree of communication overhead. The more people involved in a project, the more overhead experienced. This is because adding one person to a project increases the number of possible communication paths by the number of people already on the project. This means that overhead initially goes up as the square of number of people. Clearly this effect is bounded at some point, or large organizations would get no work done. We estimate the peak overhead to be approximately 60% of total work done. A graph of the relationship is shown in Figure 3. The communication overhead is factored into the productivity of each People object based on the total number of people assigned to the project.

![Graph: Communications Overhead](image)

**Figure 3**

Communications Overhead

Training Effects

Often a project has a group of trainees. One of the principal advantages of the object-oriented approach to modeling is that groups of trainees can be modeled easily as separate
People objects. It is a well documented fact that trainees have lower productivity than experienced workers. Abdel-Hamid places the actual productivity of trainees to be between 0.33 and 0.5 that of an experienced worker. To allow for variations, we implemented a simple system where the modeler can set both the initial productivity level and the average training time for an object. Each time step the productivity of the object is increased by the difference between 1.0 (full productivity) and the current training level divided by the average training time. This has the effect of slowly raising the productivity of the trainees over the average training time until they reach full productivity. Groups with different training periods may be modeled as different objects. This simple scheme is similar to Abdel-Hamid's approach to training, but our object-oriented approach allows for differences in the training of different work groups.

Overtime and Burnout

When people work an extended period of overtime, productivity and quality generally suffer. While such effects are minor for short periods, extended periods of overtime do have significant effects. This model uses a detailed overtime and worker burnout system based on Abdel-Hamid's work as well as the Draper Software Process Model. The assertion is that productivity falls and error generation increases as workers suffer the physical and emotional effects of extended overtime.

The implementation of these burnout effects is fairly straightforward. A variable keeps track of the percent of burnout for each People object. A second variable is used to indicate hours worked per week. As a workweek exceeds 40 hours per week, small amounts are added to the burnout value each time step in proportion to the level of overtime. As this burnout level accumulates, it is used as a factor in reducing productivity as shown in Figure 4 below. This lowering of productivity offsets the positive productivity effects of overtime. Further, as burnout increases, it is used as a multiplier in error generation. Though overtime initially adds to productivity, burnout will increase over time and eventually hurt both productivity and quality. In
the absence of overtime, the model reduces the burnout level so that workers freed from
overtime will eventually return to their original productivity. Currently the time to burnout at a 60
hour workweek is set to 50 work days, and the burnout recovery period is set to 60 work days.

![Figure 4](image.png)

**Figure 4**  
*Productivity vs. Burnout*

**Schedule Pressure vs Productivity**

Another well documented worker phenomenon is that schedule pressure can increase
workforce productivity. Abdel-Hamid attributes this effect to the fact that workers generally have
a certain amount of free or social time as part of their regular work day.\(^2^6\) As pressure to
perform increases, workers tend to spend less of their workday on social or personal activities
and more time doing work. Sensitivity research done on the Draper model indicates that up to a
10-20% productivity gain can be observed.\(^2^7\) In the model this productivity gain is modeled
based on the estimated and actual mandays remaining in the system. From these manday
estimates, the number of additional people to complete the project can also be estimated. This
manpower shortfall is used as a basis for the modeling the productivity gain. The model will
increase productivity due to schedule shortfall to make up for the shortfall until the limit of 20%
additional productivity is reached.
Class Hierarchy for Model

Model Design

To develop a comprehensive object-oriented model for software development, a straightforward object-oriented design is used. At the highest level, modeling objects can be categorized as Resources, Tasks, and Allocation objects. These three classes represent physical resources, tasks, and allocation of resources in the development process. The common data elements in these three main objects led to formation of the Value class, the Base class, and the NamedBase classes shown in Figure 5. These classes are used primarily to maximize inheritance for the common elements in subsequent classes.

One advantage of object-oriented modeling becomes clear in this organization. Object-oriented languages have complete support for data abstraction. This feature is sorely lacking in current modeling tools. Where a traditional dynamic model might represent a task or resource as an aggregate group of variables, the object-oriented modeler can organize the model to represent real physical entities. Further, since the interfaces to an object are well defined in terms of its member functions, modeling objects can be developed independently. A traditional model is typically developed with global equations. An object-oriented model can be developed to take full advantage of data abstraction and data hiding.

Inheritance is also fully exploited using object-oriented modeling. The Resource, Task and Allocation classes all have common roots back to a simple data Value class. Further specific classes can be derived from more general classes. An example of this is shown in the derivation of the People class from the more generic Resource class. This leads to a high degree of reuse in the model.

A final advantage that was exploited in this model is the dynamic creation of objects. C++ allows one to create multiple instances of the same object. Thus, separate tasks in a project (requirements, design, coding, testing) are instances of the same Task class. Similarly multiple
resources are instances of the *People* class. This gives tremendous flexibility in adapting the model to new processes without modifying the underlying classes.

**Overview of Model Classes**

**Class Definitions**

The object-oriented software process model class hierarchy is diagrammed in Figure 5. Classes are described fully in Appendix A. The code for defining the classes is contained in Appendix B.

**Model Class Hierarchy**

The class hierarchy for the model was derived from the standard class library for the Borland object-oriented C++ compiler. These standard classes are all derived from a single abstract base class called *Object*. The standard class library has many useful data structures pre-defined and implemented, letting us form *abstract* data structures without implementing them from scratch. For example, if we need an array of *Task* objects, we can define an *Object Array* and place our *Task* objects in it since the *Task* class was derived from the common *Object* class. The standard library has arrays, hash tables, dictionaries, strings, bags, ordered arrays, and many more objects that can be used to store our objects. Figure 5 illustrates the class hierarchy for the model. In Figure 5, standard library objects are shown in *italics*.

The root class for our derived model is a class called *Value*. The *Value* class is used to represent a single variable in the model. The *Value* class has an initial value, current value, and a rate of change value. *Value* objects can be initialized, calculated, stepped, and restarted. The class is fully specified later in this document.

An *Allocation* class is derived from the *Value* class. This object represents allocation of a particular resource to a particular task. Allocations are recalculated each time step, as resources and tasks change. This class is detailed below.
The Base class is simply a Value object with an additional Type data member. The Type data member is used to represent the type of resource (people, machines, etc.) or task (Requirements, Design, Testing, etc.) represented by the object. The Prod class is the only class derived directly from the Base class. Prod objects are attached to each Resource to represent the nominal productivity of that resource on a particular type of task. Prod objects represent the nominal productivity as well as the nominal error rates and nominal error detection rates for a particular task. A Rigor level can also be associated with a Prod object to represent the rigor with which the resource approaches the assigned task.

The NamedBase class is used as a base for remaining classes. The NamedBase class adds a Name data member and unique ID identifier to the base class, letting us uniquely identify a particular task or resource. This allows two task objects of the same type (perhaps two testing objects) to be distinguished. The Name data member is used in reports on tasks and resources.

The Task, Resource, and Model classes are all derived from the Named base class. Each is a fairly complex object, fully detailed in the Class descriptions in Appendix B. From the Resource class, the People class is derived, which adds effects such as communication overhead and overtime burnout to the abstract resource definition.
Value Class

class Value: public Sortable; - The Value class is used as a root class for the model. It represents all time dependent values in the model. Each Value object can be reset to its initial value to restart the simulation. Each time step the calculate() member function is called to calculate the value for the next time step, then the step() member function is called to actually step to the new value.

Base Class

class Base: public Value; - The Base class is an abstract class used by later classes to identify a particular resource or task. The Base class inherits all of the functions and data
members from the Value class and adds a new data member called type. The type is used to identify a particular group of resources (i.e. people) or a particular task (i.e. requirements work) in derived classes.

NamedBase Class

class NamedBase: public Base; - The NamedBase class inherits all of the data and member functions from the Base class and adds a unique identifier called Id as well as a Name for the object. It is an abstract class used to develop tasks and resources.

Productivity Class

class Prod: public Base; - The Prod class is used to define a resource's productivity for a particular task. Several productivity's are associated with each resource, defining that particular resource's base productivity for accomplishing a particular task. For example a group of programmers might have productivity's associated with the requirements, design, coding and documentation tasks. This class is derived from the Base class, so the value of the productivity as well as the task type are inherited directly from the base class.

Task Class

class Task: public NamedBase; - The Task class forms the basis for the production system. A task is any phase of the production process. Tasks can be chained together so that the output from one task becomes the input for another task. The main Value data member for the task keeps track of the work still to be done. Separate Error and ConversionRate data members are maintained to keep track of errors for this task and the conversion of work as it is processed.
Allocation Class

class Allocation: public Value; - The Allocation class is used to keep track of allocations of a particular resource to a task. Allocations are made each time step by the main model, and management of allocations is done by the main model class. The allocation objects simply store the resulting allocations. The class is derived from the Value class with the main Value specifying the number of resources allocated.

Resource Class

class Resource: public NamedBase; - The Resource class defines a generic resource and allows the user to attach productivities for different production tasks to the resource. Each resource has a name, type, and array of productivities for different tasks. Resources are derived from the NamedBase class with the main Value used to keep track of the number of resources available.

People Class

class People: public Resource; - The People class is derived from the generic resource class and inherits all resource characteristics. In addition the People class adds communication overhead and overtime effects to People resources.

Model Class

class Model: public NamedBase; - The Model class represents a model of a complete project including all tasks and resources assigned to it. Stepping the model forward in time effectively steps all of the objects associated with the model forward in time.
Class Hierarchy for Windows Displays

Overview

Class Definitions

The windows class hierarchy is shown in Figure 6, and described in the sections that follow the figure. Complete descriptions of the data members and member functions for the hierarchy is in Appendix A. Code for defining the hierarchy is in Appendix B.

Window Class Hierarchy

In addition to the Model classes, several Windows classes were derived from Borland’s ObjectWindows™ library to produce a primitive Microsoft Windows™ interface. While the interface currently produces only simple tables and graphs showing values of key variables, it could easily be extended to allow the user to input variables much like the Microworlds™ interface lets us interact with the current software process model.

The hierarchy is derived from the TWindow and TFrameWindow classes defined as part of Borland’s ObjectWindows library. Borland library classes are shown in italics on the class hierarchy diagram, Figure 6. The TWindowFrame class provides a multi-document window suitable for displaying several subwindows and a menu. The TWindow class is then used to derive the sub-windows for the model, with each window displaying information about a particular portion of the model. GraphWindows also use two small classes called GPoint and Graph used to store the data necessary for a graph.
ModelViewer Class

class ModelViewer: public TMDIFrame; - The ModelViewer class forms the main multi-document windows class for the model. This class handles requests from the user (menu commands) and serves as a backdrop for the other windows.

ControlWindow Class

class ControlWindow: public TWindow; - The ControlWindow class displays a small window with four buttons on it. The buttons allow a user to step, restart, run continuously, and quit from the model. Pressing the corresponding button results in a message being sent to the main ModelViewer window where it is processed.

TaskWindow Class

class TaskWindow: public TWindow; - The TaskWindow class displays a list of all task names, the work to be done, and the errors generated for each task associated with a model.
ResourceWindow Class

class ResourceWindow: public TWindow; - The Resource window displays the name of each resource associated with the model along with the number of resources. The display is updated with each time step.

AllocationWindow Class

class AllocationWindow: public TWindow; - The AllocationWindow shows a list of all resource allocations currently active in the system. For each it shows the task the resource is allocated to and the number of resources allocated. The display is updated as the model is stepped.

SummaryWindow Class

class SummaryWindow: public TWindow; - The SummaryWindow shows a report of the key outputs of the model including mandays expended, size of project, and errors per thousand lines of code. The display is updated as the model is stepped.

GPoint Class

class GPoint: public Sortable; - The GPoint class is a simple class used to store points for a particular Value object in the model as the model is run. These points can then be displayed in a GraphWindow.

Graph Class

class Graph: public Value; - A Graph object represents the storage of a single Value object over time. Graphs are ultimately displayed as single data series lines on GraphWindows.

GraphWindow Class

class GraphWindow: public TWindow; - The GraphWindow class simultaneously displays multiple Graph objects in a window on the screen. This class takes care of drawing and scaling multiple data sets on the same graph.
Sample Model Structure

The sample model was created to demonstrate the capability of the new model as well as create a baseline for comparison with Draper's model and Boehm's COCOMO model. The sample model is structured as shown in Figure 7. Complete code for creation of the model is attached in the Appendix B as file EXAMPLE.CPP.

Figure 7
Sample Waterfall Model Structure

The waterfall model shown above closely duplicates the structure of the existing Draper STELLA™ model. However this new model could easily be extended to include more advanced structures. For example, by adding only a few lines to the EXAMPLE.CPP file one could create a second People object and populate it with specialized productivities. This might be used to model the role that a group of requirement and design specialists take in the process. Assuming the same model definitions and variables defined in EXAMPLE.CPP, here's the code for adding a second set of people that specialize in programming but do not do design well. Results from running this example are included in the section on Calibration and Testing later in this thesis.
#define PROGRAMMERS 101  // Unique resource type for new specialists

// Create new requirements people with seven specialists in the group

r = new People(m, "Programmers", PROGRAMMERS, 7.0, WILL_USE_OT);

// Make these new people specialize in programming by adding
// to the programming ability and reducing the design productivity.
// Make them do programming twice as fast and design half as fast

r->add(* (new Prod(REQUIREMENTS, RQTS_RATE, RQTS_ERR_RATE,
                 RQTS_ERR_MULT)));

r->add(* (new Prod(DESIGN, DESIGN_RATE*.5, DSGN_ERR_RATE,
                       DSGN_ERR_MULT)));

r->add(* (new Prod(CODING, CODE_RATE*2.0, CODE_ERR_RATE,
                       CODE_ERR_MULT)));

Similarly if we wished to extend the waterfall to include initial requirements research or
system integration, we need only know the relative productivity and error rates for these
processes. We would create new Task objects for the new processes, add productivities to the
appropriate resources, and chain the new tasks to the current tasks. More complex productivity
models could be developed where the process forks into two production lines and then rejoins at
some future production phase, since the generic Task object can easily send its output to more
than one other task.
**Sample Output**

Below are several screen shots of different windows from the prototype object-oriented model running under Microsoft Windows™ version 3.1. Additional examples are in Appendix C.

Figure 8 shows the model in its initial state. There are 13.6 people (Resource Window) assigned to the sample model, with 32K waiting in the requirements task queue. The control panel with the step, quit and restart buttons is seen in the lower right corner. Total mandays expended is currently displayed in the summary window just to the left. All graphs are in their initial state.

![Sample Model](Image)

**Figure 8**

*Initial Model Display*
Figure 9 shows the model after it has stepped 200 days into the project. The Tasks window displays the work waiting in each task. The Work Done and Errors graphs show graphically the work being done and errors accumulating and being discovered in each task. The Summary window provides a summary of key project outputs.
Figure 10 shows the model at the completion of this 14 month project. The tasks are all completed, as all work currently resides in the Work Done! task. Residual errors for each task are displayed in the Errors graph. The summary window shows that 3549 mandays were expended on this original 32K project.

![Completed Project](image-url)
Model Calibration and Testing

Comparison with COCOMO and Draper Model

The completed model was set up to mirror the waterfall process as shown in Figure 1 earlier in this paper. Task objects were created to model each of the phases of the waterfall (i.e. requirements, design, coding, testing). Similarly a single People object was created, with nominal parameters, to model a homogeneous workforce. The automatic overtime feature was turned on for this group, but workforce attrition was turned off so that the workforce level would remain constant for the life of the project. Some initial model calibration was done to bring productivity in line with intermediate embedded COCOMO for a 32K line project, resulting in a final productivity rate input of 13 Lines/day overall. COCOMO was chosen as the baseline, because it is one of the most widely used estimation models in the software industry.

Next the model was run over a wide range of projects, using the intermediate embedded COCOMO as a guideline. The COCOMO model provided the initial schedule and manpower estimated based on project size. Using these schedule and manpower settings, the model was run for project sizes ranging from 16 K to 1024 K lines, and resulted in the following comparative results. (Table 3)

</tbody>
</table>
As evident in the results, the dynamic object oriented model performed very well over a wide range of project sizes, with an average deviation of -0.80% from COCOMO. This striking accuracy mirrors results from Draper's software process model, which consistently comes within 1% of COCOMO over the same project range.\textsuperscript{33} This degree of accuracy is really quite striking when we compare the methods used. COCOMO is simply an exponential curve fit to a database of existing project data, with some linear work multipliers factored in. The object-oriented software process model, however, is a time-dependent simulation of a development process. What is significant in these results is that one can accurately simulate the non-linear relationships between resources, task, and time using dynamic modeling. Further, the accuracy of this object oriented model is very close to that of the Draper model on which it was based. This fact is further proof that an object oriented model has many of the advantages of that a non-object oriented model can.

**Prototype Paradigm Experiment**

As a demonstration of the flexibility of the model, a model based on the fast prototype paradigm was created and run. A fast prototype is a quick development stage that precedes the traditional requirements phase. A prototype is developed to help refine the requirements so that requirements and design of the final product can be done faster and with less errors.\textsuperscript{34} We simplified the prototype phases by lumping them as one prototype task. This was done by creating a new prototype Task object and adding it to the model before the formal requirements phase. The model was populated with fictitious data using the assumptions stated below. We could find no reliable study of actual prototype projects to base this on, and decided to make this a demonstration of model flexibility rather than a test of modeling accuracy.
The following assumptions were used in adding a prototype stage to the traditional waterfall shown in Figure 1. These are all fictitious, and not designed to represent a real project.

1. All starting requirements were input to the prototype stage.
2. The prototype stage took approximately 15% of the overall project schedule.
3. The prototype stage allowed the requirements and design phases to proceed with half the error rate that they normally would have because errors were discovered during prototype.
4. The design phase was sped up from taking 20% of a traditional project to only 13% in the prototyped project. Similarly, the requirements phase was reduced from 15% of the project to 7%. Both speedups were due to work that could be taken from prototypes.
5. The prototype stage had error rates comparable to a normal requirements phase.

The intention overall was to make the prototype project and waterfall project be comparable in overall percent of scheduled time to complete. Though in reality a prototyped project might take longer to complete, we wanted to normalize the two to determine if the significant reduction in errors and time to complete the requirements and design phase would overcome the cost and errors of prototyping. This model is reflected in the final EXAMPLE.CPP file in Appendix B, with the conditional compile flag PROTO defined.

We used a baseline 32K project, with a 26% day schedule and 13.6 people assigned to it, just as in the original COCOMO calibrations from the previous section. The results are summarized in Table 4.

<table>
<thead>
<tr>
<th>Paradigm</th>
<th>Mandays</th>
<th>Errors/KDSL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Waterfall</td>
<td>3584.0</td>
<td>10.81</td>
</tr>
<tr>
<td>Prototype</td>
<td>3413.6</td>
<td>9.37</td>
</tr>
</tbody>
</table>
As shown in Table 4, the prototype model, running with the assumptions made above, proved to be a cost-and-error-saving strategy. Apparently the savings from the prototype stage did overcome the additional errors and cost of implementing the stage. Please note that this is a fictitious example, so no real life conclusions should be drawn from it. Still, this example does an excellent job of underscoring the flexibility of the object-oriented approach. By changing a few lines in the EXAMPLE.CPP file we were able to add an entirely new phase to the model and run it. This kind of flexibility is not possible without major changes in non-object-oriented models such as the Draper software process model.

**Multiple Resource Example**

As a demonstration of a project with non-homogeneous resources, the model was run with a second *People* object of programming specialists, using code described in the previous section on *Sample Model Structure*. The scenario used was again a 32 thousand-line project, with a total of 13.6 people assigned, and overtime allowed. The workforce this time was divided into two objects. The first object had the same nominal 13 lines/day productivity used to calibrate the model against COCOMO, and consisted of 6.6 people. The second object had the same productivity as the first for all but the design and programming specialists and consisted of seven people. These "programming specialists" worked at twice the default speed during the coding phase, and only half the normal speed during design. Though this example is fictitious, the purpose was to demonstrate that non-homogeneous resources do make a difference in model output.

When the model was run with this additional *People* object, and the output compared to model output with a single resource object the following results were obtained (Table 5).
Table 5
Homogeneous vs Non-Homogeneous Resource Example

<table>
<thead>
<tr>
<th>Paradigm</th>
<th>Mandays</th>
<th>Errors/KDSL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Homogeneous</td>
<td>3584.0</td>
<td>10.81</td>
</tr>
<tr>
<td>Non-Homogeneous</td>
<td>3413.6</td>
<td>10.83</td>
</tr>
</tbody>
</table>

Table 5 shows that the project with the homogeneous group of people took longer than the project with the non-homogeneous mix with programming specialists. The point is not that one is larger than the other, since the example was fictitious. The main point is that the two are different. Indeed the difference would probably be much larger if we used a more realistic mix of specialists in each task and included an allocation algorithm that would take resource skills into account. However, this limited test did demonstrate that multiple resources with different specialties can easily be added to the model, and that these resource specialties do affect the outcomes of a project.
Advantages and Disadvantages of the Object-Oriented Approach

Advantages

- The object-oriented approach allows for easy extension of the Task and Resource classes. The People class, for example, was derived from the generic Resource class by simply adding additional productivity and error factors associated with people.

- The object-oriented approach allows many types of processes to easily be modeled by simply chaining process objects together in different ways. For example, the waterfall life cycle model could be extended by adding a maintenance phase after the testing phase. Doing this using a non-object-oriented model would require almost a full redevelopment.

- The object-oriented approach can accurately model multiple resources with different production abilities. Further, specialized resources (i.e. analysts, programmers, designers, testers) can be modeled in a way that accurately reflects their specialization.

- The level of effort associated with tailoring the object-oriented model is significantly less than with a non-object-oriented approach. Currently someone tailoring the model will still require a degree of object-oriented knowledge, but that could be overcome if an interactive model-builder is built. Such a tool would take advantage of the fact that objects can be created and destroyed dynamically to let a user develop their own models based on pre-defined classes.

Disadvantages

- The introduction of resource specialization complicates the problem of effective resource allocation. While the sample Model class implements one solution by having each resource allocate to its tasks based on resource days required for the task, the model does leave open the option of developing alternative resource allocation strategies. This
is not a problem for a non-object-oriented approach since it assumed largely homogeneous resource pools whose productivity was based primarily on experience.

- Implementation of an object-oriented model requires more up-front design and planning. While traditional models allow global variable access, and unstructured modeling, object-oriented modeling requires a high degree of organization, with well defined interfaces between objects. As a result, some initial design work is needed to define an object-oriented model that is both functional and flexible.
Future Directions

The current object-oriented Software Process Model was designed as a proof of concept, with the focus primarily on the model, and not on the interface. As a result the user interface is quite primitive. In addition, the research has yielded some new, promising additions that could be implemented in future research.

Model Enhancements

Areas that could be improved upon include the following:

- **Alternative Resource Allocation Algorithms:** While the current implementation does accurately model the fact that managers generally make allocation decisions at a local level, many other allocation schemes are possible. A global allocation system based on worker ability would lead to better overall resource allocation in an organization.

- **Develop Generic Object-Oriented Modeling Tools:** One significant outcome of the research was a realization of the shortcomings of coding objects in a compiled language like C++. Though an object-oriented model is unusually powerful and flexible within the range of its usage, it would be nice if there was a language or tool specifically designed for object-oriented modeling. Clearly C++ and other object-oriented languages are outside the realm of many modeler's capabilities. In theory, an object-oriented modeling language or graphical tool could be developed to specifically support modeling applications. Such a tool might have pre-defined objects to represent various modeling constructs, as well as container objects that let a modeler handle multiple instances of an object. Separate methods for defining and instantiating runnable object would need to be defined.

- **Implement and Test Other Development Models:** The waterfall development cycle modeled here and in the original software process model is only one paradigm for
software development. We could easily generate other types of models (i.e. spiral, rapid prototype, etc.) using the building blocks from this object-oriented model. Though we have prototyped the structure of a rapid prototype paradigm, no industry data was available to serve as a fair comparison for the model. It would be most interesting to test these models against actual project data.

- **Develop Model using Object-Oriented Design Process:** Although the final product of this development effort is neatly organized, clearly improvements could be made in the structure of the model. It is likely that a modeler familiar with formal object-oriented design who approached the problem from scratch might take a different approach. For example, object attributes might better be stored in an array within the object so that generic `restart()`, `step()`, and `calculate()` functions can be written. Similarly, one might want to differentiate between the System Dynamic entities of stocks, flows, constants and converters, implementing each as a different object. In our model the differentiation is somewhat blurred as all are implemented using `Value` objects. The fact that we heavily used the Draper model for a basis may also have biased our design, since it was implemented in a traditional unstructured modeling language. Clearly developing an object-oriented model requires additional effort in planning and design.

**Windows Interface Enhancements**

The object of this thesis was to focus on the modeling aspects. As a result the windows interface for the model is very primitive, consisting primarily of simple tables that display critical model values while the model runs. Several enhancements could be made:

- **Improved User Interface:** To meet the time constraints imposed by a single semester thesis, a conscious decision was made to emphasize the model over the user interface. Though the present model does present informative graphs and tables in an interactive
Windows environment, the interface is somewhat awkward and unpolished. Another entire semester could be spent to design and implement a friendly interface.

- **Control of Decision Values**: It would be nice to be able to modify resource and task variables during a simulation run. This includes both initial project variables and time dependent decision variables. The model itself does not preclude changing variables in mid-project, but a full interactive interface must be developed. This would probably be implemented with popup dialogs for each resource and task class.

- **User Definable Reports, Tables and Graphs**: The user needs an easy way to be able to define their own reports, graphs and tables. This would probably be done from a menu or control panel selection. Currently the reports and graphs are instantiated in the model and can only be modified within the code.

- **Saved Variables**: The user may want to be able to save the state of the model at any point so they can come back to that project at a later date. This could easily be implemented by having each object write its current state to a file.

- **Interactive Model Development**: Since models can be created dynamically, it is feasible that an interactive model-builder could be developed. Such a tool would let the user choose from a set of resource and task types, assemble them in any order, seed them with appropriate values, and run the resulting model. This kind of tool would take a significant expenditure of resources to develop, but would bring the flexibility of the object-oriented model directly to users who have no knowledge of object-oriented programming.
Conclusion

This first implementation of an object-oriented software process model achieved the following:

- Established a base simulation engine for running a system dynamics model in the absence of a commercial modeling language. This model may be stepped and restarted freely.
- Defined an abstract object-oriented class hierarchy for modeling typical software processes. This class hierarchy is capable of allocating multiple resource pools to arbitrarily chained tasks. Neither multiple task pools nor arbitrarily chained tasks could be implemented using current non-object-oriented modeling tools.
- Demonstrated the use of object-oriented inheritance to derive specific objects from abstract classes. Defined a specific resource called People from the generic Resource class definition. The People class adds overtime and communication overhead multipliers to the generic Resource class definition. The generic Task class could also be extended by inheritance to include more complicated process elements.
- Designed, implemented and tested a primitive Microsoft Windows interface to the object-oriented software process model, including graphical output of key variables.
- Used the class hierarchy to model a classic waterfall software development. This sample development (EXAMPLE.CPP in Appendix B) was seeded with nominal productivity values and run to completion.
- Made a quantitative comparison between the object-oriented model and Boehm's COCOMO model, with surprising accuracy. The object-oriented approach achieved the same high degree of accuracy we have observed in calibration of the traditional Draper software process model against COCOMO over a wide range of project sizes.
• Made a comparison of the advantages and disadvantages of the object-oriented model when compared to the current implementation of Draper's Software Process Model using the non-object-oriented STELLA modeling language.

• Proposed areas for future enhancements to both the model and the Windows interface.

The object-oriented modeling technique overcomes many of the limitations of traditional modeling techniques. The high degree of accuracy and flexibility shown in this model makes this technique a promising new modeling approach for System Dynamics. The results of this project indicate that further research and development in object-oriented modeling shows great promise as a more structured technique for modeling complex dynamic systems. This base model can be extended to provide a more robust and flexible software process model.
Appendix A

Class Member Descriptions
Model Class Descriptions

Value Class

class Value: public Sortable; - The Value class is used as a root class for the model. It represents all time dependent values in the model. Each Value object can be reset to its initial value to restart the simulation. Each time step the calculate() member function is called to calculate the value for the next time step, then the step() member function is called to actually step to the new value.

Data Members

double value; - The current value of this variable for this time step.
double flowvalue; - The value of any flows to be added to this variable for the next time step.
double startvalue; - The initial value of this variable at the start of modeling. This variable is reset to this value when the restart() member function is called.

Member Functions

Constructor Value(double v); - Creates a new value with initial value equal to v.
Constructor Value(); - Creates a new value initialized to zero.

virtual double getValue() const; - Returns the current value of this variable.
virtual void initValue(double val); - Initializes this value and the startvalue to val.
operator double(); - Calls getValue() to return the current value.

void addFlow(double flow); - Adds the value flow to the current value when the next time step takes place. Used when a variable changes over time (like a stock).

virtual void paintTo(HDC hdc, PRECT r); - Windows function that paints the current value to a given device context at location specified by rectangle r.

virtual void restart(); - Sets the value back to its initial value (startvalue).
virtual void calculate(); - Dummy function used in inherited classes to perform calculations for the next time step.

virtual void step(); - Adds any pending flows to the actual value. Effectively steps the value forward one time step.

Base Class

class Base: public Value; - The Base class is an abstract class used by later classes to identify a particular resource or task. The Base class inherits all of the functions and data members from the Value class and adds a new data member called type. The type is used to identify a particular group of resources (i.e. people) or a particular task (i.e. requirements work) in derived classes.

Data Members

IDTYPE type; - An integer used to identify the type of task or resource. Used in later classes that require ID's.
Member Functions

 Constructor Base(IDTYPE t); - Creates a new base object with type set to t and an initial value of zero.
 Constructor Base(IDTYPE t, double val); - Creates a new base object with type set to t and an initial value of val.

 IDTYPE getType() const; - Returns the type data member of this object.
 void setType(IDTYPE t); - Sets the type data member to be equal to t.

**NamedBase Class**

class NamedBase: public Base; - The NamedBase class inherits all of the data and member functions from the Base class and adds a unique identifier called Id as well as a Name for the object. It is an abstract class used to develop tasks and resources.

Data Members

 static IDTYPE id_seed; - A shared seed used to give each NamedBase object a unique ID. Each resource and task will get a unique ID number based on this seed.
 IDTYPE Id; - A unique ID for every task and resource in the system. Used to identify a particular task or resource.
 LPSTR Name; - The name of the resource or task. A string.

Member Functions

 Constructor NamedBase(LPSTR name, IDTYPE t, double val); - Creates a NamedBase object with Name set to name, of type t and with value val.

 LPSTR getName() const; - Returns the Name of this object.
 void setName(LPSTR s); - This function can be used to rename a NamedBase object.
 IDTYPE getId() const; - Returns the unique Id associated with this object.

**Productivity Class**

class Prod: public Base; - The Prod class is used to define a resource’s productivity for a particular task. Several productivities are associated with each resource, defining that particular resource’s base productivity for accomplishing a particular task. For example a group of programmers might have productivities associated with the requirements, design, coding and documentation tasks. This class is derived from the Base class, so the value of the productivity as well as the task type are inherited directly from the base class.

Data Members

 Value ErrorRate; - The error rate associated with this particular resource attempting this particular task. This is the nominal error rate, still subject to error multipliers associated with the resource.
 Value ErrorDetMult; - The error detection multiplier used in determining the difficulty of error detection. This multiplier is usually set based on 70% of the project size.
**Value Rigor;** - The rigor with which this resource approaches this task. May be changed over time using the `addRigor()` member function.

**Member Functions**

*Constructor Prod(IDTYPE t, double rate, double err_rate=0.0, double err_det_mult=1e6, double rigor=1.0);* - Creates a new Prod object for task of type t, with production rate=rate, and error rate, detection, and rigor defaulted or set to provided values.

`virtual double getValue() const;` - Gets the effective productivity rate.

`double getErrorRate() const;` - Returns the current `ErrorRate` data member's value.

`double getErrorDetMult() const;` - Returns the `ErrorDetMult` data member's value.

`double getRigor() const;` - Returns the `Rigor` data member's value.

`void addErrorRate(double v);` - Increases the error rate at the next time step.

`void addErrorDetMult(double v);` - Increases the error detection multiplier at the next step.

`void addRigor(double v);` - Increases the rigor value at the next time step.

`virtual void restart();` - Sets all values back to their initial value (startvalue).

`virtual void calculate();` - Calculates the productivity values for the next time step.

`virtual void step();` - Adds any pending flows to the actual values. Effectively steps the values forward one time step.

**Task Class**

*class Task: public NamedBase;* - The Task class forms the basis for the production system. A task is any phase of the production process. Tasks can be chained together so that the output from one task becomes the input for another task. The main Value data member for the task keeps track of the work still to be done. Separate Error and ConversionRate data members are maintained to keep track of errors for this task and the conversion of work as it is processed.

**Data Members**

*Model *model;* - The model this task is attached to. The task calls the `addTask()` member function of this model on startup to attach itself to this model.

*Array *NextTasks;* - This task will send its output to each task in the `NextTasks` array by calling their `addWork()` member functions. Tasks can be arbitrarily chained together in this way so that the output from one goes to several tasks or the output of several tasks goes to one particular task.

*Value Errs;* - This value maintains the total errors for this task.

*Value ConvRate;* - This value stores the conversion rate for the task. This conversion rate is used to convert input units to output units. The default is 1.0.

*double ResDays;* - This is a temporary value used during resource allocation. The allocator calculates the number of resource days required to finish this task and stores the value here. The allocator then allocates resources to each task based on the resource days required by that task.

*Value ErrReworkMult;* - The error rework multiplier. Discovered errors are multiplied by this multiplier to determine the amount of work needed to correct an error.

*Value PctErrcDet;* - The percent of errors from previous phase that may be detected in this phase. Used to determine error discovery for previous tasks.

*Value WorkDone;* - The amount of work accomplished on this task for the current phase. Used to determine work estimates in the next time step.
**Member Functions**

*Constructor Task(Model *mod, LPSTR name, IDTYPE type, double work, double err_rework_mult=0.0, double pct_err_det = 0.0);* - Creates a task with name and type specified and assigns work to this task. The task is attached to the task list for the model specified. The ErrReworkMult and PctErrsDet values are set based on the corresponding inputs to this function.

~Task(); - Destructor that deallocates the task when the model is done.

Array *getNextTasks(); - Returns the NextTasks data member.

double getConvRate(); - Returns the value of the ConvRate data member.

virtual Value *getErrors(); - Returns a pointer to the Errs data member.

double getResDays(); - Gets the number of resource days required for this task.

void add(Task &t); - Adds a new task to the NextTasks member, so that output from this task will go to the task specified.

void addWork(double w); - Adds new work to the work waiting on the next time step.

void setResDays(double v); - Sets the number of resource days required to the value specified.

double getErrorsDetected(); - Returns the portion of errors from previous tasks detected during this task.

double getPctErrsDet(); - Returns the value of the PctErrsDet data member.

void initConvRate(double conv_rate); - Sets the work unit conversion rate to the value specified.

void detach(Task &t); - Removes the specified task from the NextTasks list.

void EstimateResDays(double work_in); - Estimates the number of resource days it would take to complete work_in amount of work including all later tasks given current work rates. This function is the heart of the work estimation system.

virtual void restart(); - Resets all of the task's values to their initial state.

virtual void calculateTask(Resource &r, double num, Prod &p); - Calculates the work done and errors created for this task using the number of resources specified with the productivity specified.

virtual void step(); - Steps all values for this task to the next time step's values.

**Allocation Class**

*class Allocation: public Value;* - The Allocation class is used to keep track of allocations of a particular resource to a task. Allocations are made each time step by the main model, and management of allocations is done by the main model class. The allocation objects simply store the resulting allocations. The class is derived from the Value class with the main Value specifying the number of resources allocated.

**Data Members**

Resource *res; - Specified the resource being allocated.

Task *task; - The task this resource is allocated to.

Prod *prod; - The productivity of this resource for this task. Used during work done calculations for the task.

**Member Functions**

*Constructor Allocation(Task *t, Resource *r, double num, Prod *p);* - Creates an allocation object with data members as specified in the arguments.
Task *getTask(); - Returns the Task data member for this allocation.
Resource *getResource(); - Returns the resource (res) data member for this allocation.
Prod *getProd(); - Returns the productivity of this resource for this task.
virtual void calculateTask(); - Calls the calculateTask() member function of the
assigned task with arguments taken from this allocation. Calculates the work
done by this allocation of resources.

Resource Class

class Resource: public NamedBase; - The Resource class defines a generic resource and
allows the user to attach productivities for different production tasks to the resource. Each
resource has a name, type, and array of productivities for different tasks. Resources are derived
from the NamedBase class with the main Value used to keep track of the number of resources
available.

Data Members

Model *model; - The model object that this resource is attached to.
Array *Prods; - Array of productivities for this resource assigned to a variety of tasks.
Productivities may be assigned or de-assigned using the add() and detach() member functions.

Member Functions

Constructor Resource(Model *mod, LPSTR name, IDTYPE type, double num); -
Creates a new resource with name, number and type specified and attaches it to
the named model object. The resource is initially created with no productivity
objects assigned. These must be adding using the add() member function.
~Resource(); - Deallocates the Prod objects associated with this resource.

Array *getProds(); - Returns a pointer to the Prods array of productivity objects.
Prod &getProd(IDTYPE task_type); - Looks up the particular productivity object for
tasks of type task_type.
virtual double getProdMult(); - Gets the current productivity multiplier associated with
this resource. Nominal productivities from the Prods array are multiplied by this
productivity multiplier when work done is calculated. The default member
function simply returns 1.0.
virtual double getErrMult(); - Returns the error multiplier associated with this resource.
Again the nominal error rate is multiplied by this multiplier when calculating
errors created. The default member function returns 1.0.
void add(Prod &p); - Adds a productivity object to this resource, thus specifying the
nominal productivity for this resource assigned to a particular task type.
void detach(Prod &p); - Removes a productivity object from the productivity list for
this resource.

virtual void restart(); - Restarts the resource - assigning all values to their initial value.
virtual void calculate(); - Calculates all values associated with this resource.
virtual void step(); - Steps all values for this resource one time step forward.
**People Class**

```cpp
class People: public Resource; - The People class is derived from the generic resource class and inherits all resource characteristics. In addition the People class adds communication overhead and overtime effects to People resources.
```

**Data Members**

```cpp
static Value TotalPeople; - A data member shared between all people resources. This variable tracks the total number of people active on this project. It is used to calculate mandays expended and communication overhead effects.

Value HoursPerWeek; - The number of hours per week assigned for this group of people. Anything over 45 hours per week is considered overtime, and is subject to burnout effects.

Value Burnout; - The burnout level for this group of people. Ranges from 0.0 to 1.0.

Value TrainLevel; - The training level as a portion of the potential productivity of the group of people. This level will increase over the TrainDelay time until the workers reach full productivity. Range is 0.0 to 1.0.

Value TrainDelay; - The training delay. The time, on the average, that it takes for this group of people to reach full productivity if they start with a training level below 1.0.

Value RetentionTime; - The average retention time for this group of people. Workers will suffer attrition over this average time.

double WillUseAutoOT; - A calibration feature that allows the modeler to enable automatic management of overtime. Using the automatic feature, the model will automatically assign overtime to this work group to compensate for resource shortfalls in the model. A value of 1.0 turns this on, while 0.0 turns it off.
```

**Member Functions**

```cpp
Constructor People(Model *m, LPSTR name, IDTYPE type, double num,
double AutoOT=0.0, double train_level=1.0, double train_delay=1.0e8,
double retention_time=1.0e8); - Creates a people object with name, type, and number of people as specified and attaches this object to the specified model object. Corresponding data members are set based on the optional inputs AutoOT, train_level, train_delay, and retention_time.
```

```cpp
virtual double getCommLoss(); - Computes the current communications overhead. Used by the getProdMult() member function to compute overall productivity.

virtual double getOTMult(); - Computes the current overtime multiplier for this particular resource based on the burnout level and current HoursPerWeek. This function is also called by the getProdMult() member function.

virtual double getProdMult(); - Computes the productivity multiplier for this group of people taking into account the effects of burnout, overtime, training level, and communication losses.

virtual double getErrMult(); - Returns the error multiplier based on current overtime, and training level.

virtual double getTrainLevel(); - Returns the value of the current TrainLevel variable.

virtual double getRetentionTime(); - Returns the value of the RetentionTime variable.

virtual double getTrainDelay(); - Returns the value of the TrainDelay variable.

Value &getHoursPerWeek(); - Returns a reference to the HoursPerWeek variable.

Value &getBurnout(); - Returns a reference to the Burnout variable.
```
virtual void addFlow(double num_people); - This function can be used to add to the pool of existing workers.

virtual void restart(); - Restarts the resource - assigning all values to their initial value.
virtual void calculate(); - Calculates all values associated with this resource.
virtual void step(); - Steps all values for this resource one time step forward.

**Model Class**

class Model: public NamedBase; - The Model class represents a model of a complete project including all tasks and resources assigned to it. Stepping the model forward in time effectively steps all of the objects associated with the model forward in time.

**Data Members**

Array *tasks; - A collection of all of the tasks to be processed in this model.
Array *resources; - A collection of all resources assigned to this model.
Array *allocations; - A list of allocations of resources to tasks. This list is updated every time step.
Array *graphs; - A list of all of the graphs for the model which must be stepped each time step.
double CurTime; - The current time (in days) simulated by the model.
int stop; - The stop time for the simulation in days.
Value Mandays; - The number of mandays used for this project.
Value EstResDays; - The current estimate of resource days to compete the project based on work remaining and current work rates.
Value ResDaysRemain; - The actual number of resource days left until the schedule expires.
Value Schedule; - The current scheduled completion for this project in days.
Value TotalPeople; - The total number of people assigned to the project.

**Member Functions**

Constructor Model(LPSTR name, int stop_time); - Creates an empty model with no resources, tasks, or allocations attached. Sets the stop variable to the stop_time specified. Model will simulate a total of stop_time days.
~Model(); - Destructor for model - deallocates all resources, tasks and allocations.
void InitArrays(); - Internal function used to set up the task, resource and allocation arrays.
Array *getTasks(); - Returns the array of tasks for this model.
Array *getResources(); - Returns the array of resource for this model.
Array *getAllocations(); - Returns the resource allocations for this model.
Task &getTask(IDTYPE id); - Gets the task from the task array with identifier id.
Value &getMandays(); - Gets the mandays value associated with the model.
void addTask(Task &t); - Adds a new task to the task list of the model.
void addResource(Resource &r); - Adds a new resource to the resource list.
Value &getMandays(); - Returns a reference to the Mandays variable.
int getCurTime(); - Returns the current time in days.
Value &getSchedule(); - Returns a reference to the Schedule variable.
void initSchedule(double sched_value); - Initializes the Schedule variable.
void setResDaysRemain(double v); - Sets the ResDaysRemain variable.

virtual double getEffWorkMult(); - Gets the effective productivity multiplier due to schedule pressure on the workforce. Called by People resource objects to determine additional productivity due to schedule pressure.

virtual void Allocate(); - Computes all allocations for this time step based on the work waiting for each task and the resources available. Results are put in the model's allocations array.

virtual void EstimateResDays(); - The function that Allocate() uses to estimate the number of resource days required to finish a project.

void flushAllocations(); - Flushes the current allocations from the allocations array so that the next time step's allocation can be computed.

virtual void restart(); - Restarts the model - assigning all values to their initial value.

virtual void calculate(); - Calculates all values associated with this model.

virtual void step(); - Steps all values for this model one time step forward.

virtual void stepModel(int n); - Calculates and steps the model forward n time steps.
Windows Modeling Classes

ModelViewer Class

class ModelViewer: public TMDIFrame; - The ModelViewer class forms the main multi-document windows class for the model. This class handles requests from the user (menu commands) and serves as a backdrop for the other windows.

Data Members

Model *model; - The main model object to be displayed. This is the model class defined previously in this paper.
int nsteps; - The number of steps to move forward each time the model is stepped. The default is 20 days.
LPSTR Name; - The name of the model - used to title the window.

ControlWindow *control; - Control window - lets user step, restart, and quit the model.
ResourceWindow *res; - Window to display all active resources.
TaskWindow *tasks; - Window to display all active tasks.
AllocationWindow *allocations; - Window to display resource allocations.
SummaryWindow *summary; - Window to display summary report.

Member Functions

Constructor ModelViewer(LPSTR name); Creates a new ModelViewer window.
virtual void SetupWindow(); - Function that creates all of the subwindows for the model (i.e. ControlWindow, ResourceWindow, etc...) and makes them displayable.
virtual void Refresh(); - Refreshes each subwindow display with the latest model values. This is called each time the model is stepped to update the display.
virtual void CMStep(RTMessage msg); - Menu command that steps the model forward nstep days.
virtual void CMRestart(RTMessage msg); - Menu command to restart the model - to day zero.
virtual void CMContinue(RTMessage msg); - Run the model continuously until the preset stop time is reached.
virtual void CMOK(RTMessage msg); - Tied to the quit button - this function quits out of the model when pressed.
int getSteps(); - Returns the number of steps (nsteps).
void setSteps(int n); - Sets nsteps to the number specified. The default is 20 days.
Model *getModel(); - Returns the Model data member.

ControlWindow Class

class ControlWindow: public TWindow; - The ControlWindow class displays a small window with four buttons on it. The buttons allow a user to step, restart, run continuously, and quit from the model. Pressing the corresponding button results in a message being sent to the main ModelViewer window where it is processed.

Data Members
ModelViewer *model; - Pointer to the main ModelViewer window.

Member Functions
   Constructor ControlWindow(ModelViewer *m); - Creates a new ControlWindow object with parent model window m.
   virtual void SetupWindow(); - Creates buttons in the window and activates them.
   virtual void Paint(HDC hdc, PAINTSTRUCT _FAR &ps); - Called by Windows to repaint the window as needed.
   virtual void CMStep(RTMessage msg); - Steps the model forward one step when the Step button is pressed.
   virtual void CMRestart(RTMessage msg); - Restarts the model when the restart button is pressed.
   virtual void CMOK(RTMessage msg); - Quits from the model when the Quit button is pressed.
   virtual void CMContinue(RTMessage msg); - Run the model continuously until the preset stop time is reached.
   virtual void CMNSteps(RTMessage msg); - Will allow the user to reset the number of days per time step for the model.

TaskWindow Class
   class TaskWindow: public TWindow; - The TaskWindow class displays a list of all task names, the work to be done, and the errors generated for each task associated with a model.

Data Members
   Array *tasks; - A pointer to the tasks array for the model.

Member Functions
   Constructor TaskWindow(ModelViewer *m); - Creates a new TaskWindow object as a subwindow of the ModelViewer m.
   virtual void Paint(HDC hdc, PAINTSTRUCT _FAR &ps); - Repaints the task window updating the display to reflect the latest tasks list.

ResourceWindow Class
   class ResourceWindow: public TWindow; - The Resource window displays the name of each resource associated with the model along with the number of resources. The display is updated with each time step.

Data Members
   Array *Resources; - A pointer to the model's resource list.

Member Functions
   Constructor ResourceWindow(ModelViewer *m); - Creates a new ResourceWindow object as a subwindow of the ModelViewer m.
   virtual void Paint(HDC hdc, PAINTSTRUCT _FAR &ps); - Repaints the resource window updating the display to reflect the latest resource list.
**AllocationWindow Class**

class AllocationWindow: public TWindow; - The AllocationWindow shows a list of all resource allocations currently active in the system. For each it shows the task the resource is allocated to and the number of resources allocated. The display is updated as the model is stepped.

Data Members
- Array *Allocations; - A pointer to the allocation list of the model.

Member Functions
- Constructor AllocationWindow(ModelViewer *m); - Creates a new AllocationWindow object as a subwindow of the ModelViewer m.
- virtual void Paint(HDC hdc, PAINSTRUCT_FAR &ps); - Repaints the allocation window updating the display to reflect the latest allocations list.

**SummaryWindow Class**

class SummaryWindow: public TWindow; - The SummaryWindow shows a report of the key outputs of the model including mandays expended, size of project, and errors per thousand lines of code. The display is updated as the model is stepped.

Data Members
- ModelViewer *m; - A pointer to the main modelviewer window.

Member Functions
- Constructor SummaryWindow(ModelViewer *m); - Creates a new SummaryWindow object as a subwindow of the ModelViewer m.
- virtual void Paint(HDC hdc, PAINSTRUCT_FAR &ps); - Repaints the summary window updating the display to reflect the latest summary information for this particular run of the model.

**GPoint Class**

class GPoint: public Sortable; - The GPoint class is a simple class used to store points for a particular Value object in the model as the model is run. These points can then be displayed in a GraphWindow.

Data Members
- double val; - The value of this point.

Member Functions
- Constructor GPoint(double v); - creates a new point initialized to this value.
- double getValue(); - Returns the value of this point.

**Graph Class**

class Graph: public Value; - A Graph object represents the storage of a single Value object over time. Graphs are ultimately displayed as single data series lines on GraphWindows.
Data Members

LPSTR name; - The name of the variable being graphed.
int count; - A count of the current time step used to determine when to store the next
point.
int point_count; - An interval of how many steps to count in-between data
measurement. Rather than store every data point value, this count may be set
to store every 5 or 10 points of data for long projects.
double minvalue; - The minimum of all points - used in graph scaling.
double maxvalue; - The maximum value for all points - used to scale the graph.
Array *points; - The array of GPoint objects used to store individual data values.
Value *value; - A pointer to the actual Value object being graphed. Every point_count
time steps this value is polled and stored as a new point in the graph.

Member Functions

Constructor Graph(Value *pval, LPSTR name, int pt_count=5); - Creates a new
Graph object which will track the Value object pointed to by pval every
point_count time steps.
~Graph(); - Destructor that deallocates the points associated with this graph.

LPSTR getName(); - Returns the name of this graph.
void AddPoint(double v); - Creates and adds a new point with value v.

virtual void step(); - Steps the graph by sampling the value for this graph if it is the
appropriate time.
virtual void restart(); - Restarts this graph by freeing all current points.

GraphWindow Class

class GraphWindow: public TWindow; - The GraphWindow class simultaneously displays
multiple Graph objects in a window on the screen. This class takes care of drawing and scaling
multiple data sets on the same graph.

Data Members

Array *graphs; - Array of Graph objects to display in this window.
double minval, maxval; - Overall minimum and maximum values for all of the graphs
being displayed. Used to scale axis for the graph window.
ModelViewer *modelv; - Pointer to the model viewer window.

Member Functions

Constructor GraphWindow(ModelViewer *m, LPSTR name); - Creates a new
GraphWindow object with title equal to the name variable. The GraphWindow is
created empty, until graphs are added using the AddGraph function.
~GraphWindow(); - Destructor for the GraphWindow which deallocates all Graphs.

void AddGraph(Value *val, LPSTR name, int point_count=5); - Creates a new Graph
object and adds it to this GraphWindow.
virtual void Paint(HDC hdc, PAINTSTRUCT _ FAR &ps); - Paints all of the Graph
objects to the window including axis and legend.
virtual void Refresh(); - Forces the current window to be repainted.
void LabelYAxis(); - Labels the Y axis based on the current X and Y values.

virtual void step(); - Steps all of the Graph objects forward one time step.
virtual void restart(); - Restarts all of the Graph objects to their initial state.

Appendix C

Sample Graphs
and Reports
Control Window: Used to step, restart and quit the model.

Summary Window: Displays summary of project statistics including current day, mandays expended, size, and total errors per thousand lines of code.

Resource Window: Displays resource names and number of resources.
**Allocation of Resources:** Shows the number of resources assigned from each resource object to each task object.

<table>
<thead>
<tr>
<th>Allocation of Resources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirements People</td>
</tr>
<tr>
<td>Design People</td>
</tr>
<tr>
<td>Coding People</td>
</tr>
<tr>
<td>Testing People</td>
</tr>
<tr>
<td>Requirements Programmers</td>
</tr>
<tr>
<td>Design Programmers</td>
</tr>
<tr>
<td>Coding Programmers</td>
</tr>
<tr>
<td>Testing Programmers</td>
</tr>
</tbody>
</table>

**Tasks:** Report showing the amount of work (in KDSL) for each task and the total number of undetected errors in the task.

<table>
<thead>
<tr>
<th>Tasks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requirements</td>
</tr>
<tr>
<td>Design</td>
</tr>
<tr>
<td>Coding</td>
</tr>
<tr>
<td>Testing</td>
</tr>
<tr>
<td>Work Done!</td>
</tr>
</tbody>
</table>

**Work Done:** Graph showing the work waiting in each task.
**Mandays Graph:** Graph showing the number of mandays remaining in the scheduled project versus the number of mandays estimated to complete the project. Total mandays expended to date are also displayed.

![Mandays Graph](image)

**Errors Graph:** Displays the total number of undiscovered errors in each task object.

![Errors Graph](image)
**Overtime:** Displays a graph of the overtime assigned on the project to date in terms of hours per workweek. Overtime is considered any value over 40 hours per week. In the example shown, no overtime was used.

![Overtime Graph]

**Burnout:** Displays the total burnout level for people assigned to the project. Burnout varies from zero to 100%.
