This paper describes a cost-effectiveness model developed for the National Oceanic and Atmospheric Administration (NOAA) Fleet Replacement and Modernization (FRAM) program, and how the concepts illustrated by the model relate to and meet federal requirements for lease-vs-buy analysis.

The NEM performs lease-vs-buy analysis by calculating a stream of lease payments based on economic and market conditions, and comparing these payments with government acquisition of a ship. The NEM also performs operate-vs-charter analysis. The combination of these analyses and other cost elements results in life cycle cost estimates for various acquisition alternatives, in accordance with OMB Circular A-94.

The NEM compares four acquisition alternatives for NOAA research vessels: (1) government owned, government operated - straightforward government acquisition; (2) contractor owned, government operated - a lease arrangement; (3) contractor owned, contractor operated - a charter arrangement; and (4) government owned, contractor operated - contracting out of services. There are 43 required user inputs arranged in two groups: global factors and cost factors.

Ms. Wigler is a Senior Cost Analyst with Program Management Associates, Inc. in Silver
Spring, MD. She has seven years experience in logistics and cost engineering for various government
agencies. Currently, Ms. Wigler is supporting the National oceanic and Atmospheric Administration
(NOAA) System Program Office in all aspects of economic analysis.

Prior to joining PMA, Ms. Wigler provided economic and logistics decision support for agencies
including the Department of Defense, Internal Revenue Service, National Security Agency, Federal
Bureau of Investigations, and the National Aeronautic and Space Administration. She has presented
papers describing her work at the Annual DOD Cost Analysis Symposium, the Washington Operations
Research/Management Science Symposium, and was the operating and support cost track chairperson
at last year’s SCEA conference.

Acknowledgements

The author would like to thank Mr. Richard Pombrio and Mr. Bernard Sykes for their
participation in the NEM development, and for their guidance and support in the preparation of this
report. The author would also like to thank Mr. Rannie Boyd, FRAM PM, for his contribution and
sponsorship of the NEM.
Meeting the Requirements for Lease-vs.-Buy Analysis: A Case Study

"This technical paper and its contents are solely the product of its author and references to the U.S. Department of Commerce, NOAA or to the Fleet Replacement and Modernization Program (FRAM) do not represent an endorsement of any kind from the U.S. Department of Commerce, of the paper's author, employer, or sponsors."

Introduction

With the recently-released OMB Circular A-94, "Guidelines and Discount Rates for Benefit-Cost Analysis of Federal Programs," the issue of how to perform a useful cost-benefits and/or cost-effectiveness analysis to assist government acquisition is once again on the table in the cost analysis community. Experience has shown that cost analysis is an ever-changing science, and modeling efforts are continuing to keep in step with new requirements and to reflect new practices. This paper discusses a model developed to assist the National Oceanic and Atmospheric Administration (NOAA) with lease-vs.-buy analysis for the Fleet Replacement and Modernization (FRAM) Program. This model incorporates the latest OMB guidance and is flexible enough to meet changing economic and market conditions as well as changes in government and business practice.

Background

Various studies over the past five years have identified NOAA research vessels as some of the oldest ships in the federal fleet. These studies recommended that NOAA either replace or upgrade their fleet. Based on these recommendations, the NOAA Fleet Replacement and Modernization Plan was issued in March 1991 and updated in September 1991. The NOAA FRAM Program Office exists to manage the upgrade of the existing fleet of research vessels.

The NOAA Economic Model (NEM) was developed to support the ship acquisition decision and meet federal requirements for cost analysis. The NEM is the result of extensive primary and secondary research, working closely with the NOAA FRAM Program Manager (PM), and an Independent Verification and Validation (IV&V) by an internationally recognized consulting firm with specific experience in ship acquisition.

In addition to federal requirements for cost analysis, the particular needs of the FRAM office were considered during model development. The ship acquisition decision will be made over time for each ship and is intended to be made objectively and independent of various biases that may exist. The NEM facilitates the acquisition decision by being flexible and independent of bias. Flexibility allows the NEM to meet changing economic, market, and legislative conditions over time, and the ability to process a wide range of input values allows the NEM to be free of mathematical bias. However, the model sacrifices simplicity in order to incorporate these two key characteristics. The 43 variable user inputs are all mathematically linked to the cost output of the model and should be selected carefully by a user who is acquainted with the mathematical algorithms of the model and the ship acquisition process in general.

The NEM is implemented in Excel 4.0 for Windows, and provides the user with a friendly menu-driven software package that accepts input values in pop-up edit windows and worksheets, transforms these inputs into alternative acquisition life cycle cost estimates, and provides a function for viewing and printing various output reports.
In addition to the key requirements of providing flexibility and freedom from bias, the IV&V determined that the NEM meets government and industry requirements for performing a lease-vs.-buy analysis. The following sections discuss these requirements, how the model meets requirements through its mathematical algorithms and logical flow, and how the model may be specifically applied to a given scenario.

Government Requirements

Draft OMB Circular A-94, "Guidelines and Discount Rates for Benefit-Cost Analysis of Federal Programs," dated 13 July 1992, provides guidance in performing cost decision support analysis. According to the guidance, there are two basic decisions that should be made as a part of the analysis: (1) public investment, and (2) lease-vs.-buy.

The public investment decision applies to analysis of programs that provide benefits and costs to the general public. This decision would be made in determining whether to acquire a ship, not in determining how to acquire the ship. The NEM applies to selecting an acquisition alternative after the decision to acquire has already been made.

The lease-vs.-buy decision is addressed by the NEM. Specific guidelines are offered by OMB Circular A-94 for performing this analysis. The model meets all of these guidelines using standard techniques for cost analysis.

Foremost, the NEM performs a cost analysis by comparing the present value of the life cycle cost of leasing and the present value of the life cycle cost of purchasing the ship using a discount rate and/or inflation rate schedule specified by the user. The system life in years is specified by the user as well. The variable nature of these important economic inputs is recognized, and the model allows for inputs that reflect current economic conditions.

Life cycle costs meet the requirements of the Circular by allowing for the inclusion of the following significant cost elements:

• Research and development costs
• Ship investment costs
  -- Ship purchase cost, or
  -- Stream of lease payments, including lease extension periods, over the life of the ship
• Additional management costs (i.e. government oversight of lease agreement)
• Operating and support costs over the life of the ship
• Mid-life ship upgrade costs
• Imputed insurance costs
• Additional costs associated with leasing
• Disposal costs associated with purchasing
• Terminal Value associated with purchasing

At this time, no significant tax benefits are allowed by legislation, so none are included in the NEM. However, the model accommodates Investment Tax Credit (ITC) and accelerated depreciation, should tax laws change in the future.
The NEM software allows for sensitivity analysis by including a capability for user input and edit of variables and including a file save function. These capabilities are useful in making multiple runs of the model while varying input values. OMB agrees that performing multiple runs while varying the input values is a reasonable approach to treating uncertainty.

**Industry Requirements**

Interviews with representatives of government and industry involved in the ship acquisition process identified four acquisition alternatives. The NEM compares these acquisition alternatives for NOAA research vessels:

- Government owned, Government operated (GOGO) - straightforward government acquisition. GOGO life cycle cost is described by the following equation:

\[
\text{Investcost}_{\text{baseyr}} + \sum_{t=1}^{\text{Syslife}} (\text{Govt OS Cost})_{\text{baseyr}} + \text{Disposal}_{\text{baseyr}} - \text{Terminal}_{\text{baseyr}}
\]

where

- **Investcost** is the ship investment cost, including research and development costs, if any,
- **Govt OS Cost** is the annual government O&S cost,
- **Disposal** is the disposal cost of the ship, if any,
- **Terminal** is the residual value of the ship at the end of its useful life,
- **baseyr** is the economic base year in which life cycle costs are compared,
- **Syslife** is the system life of the ship in years within the constraints of the user's inputs to the model,
- **t** is generally a year between the first year of acquisition and the last year of system life; in this case it represents years during the ship's service life where O&S costs are realized.

- Contractor owned, Government operated (COGO) - a lease arrangement. COGO life cycle cost is described by the following equation:

\[
\sum_{t=1}^{\text{Syslife}} (\text{Leasepmt}_t + \text{Misc Mgmt Cost}_t + \text{Govt OS Cost})_{\text{baseyr}}
\]

where

- **Leasepmt** is the annualized lease payment,
- **Misc Mgmt Cost** is any miscellaneous additional cost that is not included in the calculation of the lease payment (i.e., government oversight of the lease contract),
- **Govt OS Cost** is the annual government ship O&S cost,
- **baseyr** is the economic base year in which life cycle costs are compared,
- **Syslife** is the system life of the ship in years within the constraints of the user's inputs to the model,
- **t** is generally a year between the first year of acquisition and the last year of system life; in this case it represents years during the ship's service life where O&S and lease costs are realized.
Contractor owned, Contractor operated (COCO) - a charter arrangement. COCO life cycle cost is described by the following equation:

\[
S_{\text{syslife}} = \sum_{t=1}^{\text{Syslife}} (\text{Lease}\text{pmtn}_t + \text{Misc Mgmt Cost}_t + \text{Cont OS Cost}_t)_{\text{baseyr}}
\]  

(3)

where \text{Lease}\text{pmtn} is the annualized lease payment. \text{Misc Mgmt Cost} is any miscellaneous additional cost that is not included in the calculation of the lease payment (i.e., government oversight of the charter contract). \text{Cont OS Cost} is the annual contracted ship O&S cost. \text{baseyr} is the economic base year in which life cycle costs are compared. \text{Syslife} is the system life of the ship in years within the constraints of the user's inputs to the model. \(t\) is generally a year between the first year of acquisition and the last year of system life; in this case \(t\) represents years during the ship's service life where O&S and lease costs are realized.

Government owned, Contractor operated (GOCO) - contracting out of services. GOCO life cycle cost is described by the following equation:

\[
S_{\text{syslife}} = \text{Investcost}_{\text{baseyr}} + \sum_{t=1}^{\text{Syslife}} (\text{Cont OS Cost}_t)_{\text{baseyr}} + \text{Disposal}_{\text{baseyr}} - \text{Terminal}_{\text{baseyr}}
\]  

(4)

where \text{Investcost} is the ship investment cost, including research and development costs, if any. \text{Cont OS Cost} is the annual contracted ship O&S cost. \text{Disposal} is the disposal cost of the ship, if any. \text{Terminal} is the residual value of the ship at the end of its useful life. \text{baseyr} is the economic base year in which life cycle costs are compared. \text{Syslife} is the system life of the ship in years within the constraints of the user's inputs to the model. \(t\) is generally a year between the first year of acquisition and the last year of system life; in this case \(t\) represents years during the ship's service life where O&S costs are realized.

**Model Flow**

Figure 1 is a graphical representation of the NEM logical information flow. The inputs are mathematically linked to the transforming algorithms and result in estimated life cycle cost for each of the four acquisition scenarios. Then, a comparison is made between the alternatives. The model consists of seven major components:

1. Government ship investment costs, including R&D costs, if any
2. Contractor ship investment costs
3. Ship lease costs
4. Government operating and support costs
5. Contractor operating and support costs
6. Terminal value and disposal costs
7. Net present value comparison of alternative scenarios
Figure 1. NOAA Economic Model Information Flow
Government and contractor ship investment costs

The first two components of the NEM are basic conversions from current dollars entered in a cost element structure to present value dollars for the year of economic comparison. The cost element structure for the input of ship investment costs is shown in Table 1.

Table 1 contains the cost elements found in the actual input spreadsheet for NEM government and/or contractor ship investment costs. The purpose of the cost element structure is to provide an indentured list of significant cost elements that should be considered in the analysis. Note that the model will accept numbers at lower levels of indenture and sum these to the next highest level, or accept numbers at higher levels of indenture and override the summing function.

The next step in calculating ship investment costs is to allocate the total cost to the years in which expenditures will be made. Table 2 shows the case study outlay schedules for government and contractor, by month. The outlay schedule may be changed by the user to model different scenarios.

</table>

The model sums the monthly outlay schedule to provide annual percentage outlays and allocates the investment cost to outlay years. No inflation is applied within a year, because the ship investment cost as shown in the cost element structure is assumed to reflect a negotiated contract that already includes the effects of inflation. Annual ship investment costs are simply:

\[
\text{Ship Inv Cost}_t = \text{Total Ship Inv Cost}_{\text{start acq year}} \times \text{Outlay \%}_t, \tag{5}
\]

where the ship investment cost, as input to the cost element structure

\[
\text{TOTAL SHIP INV COST}_{\text{start acq year}}
\]

OUTLAY \% is the percentage of total costs paid in the current year \( t \)

\( t \) is generally a year between the first year of acquisition and the last year of system life; in this case \( t \) represents the years of acquisition expenditure outlays.
The final step in calculating ship investment cost for the government or the contractor is to convert current dollars to present value. If the economic base year specified by the user for purposes of comparison is greater than the year in which ship investment dollars are presented, an inflation factor is used to arrive at present value:

\[ \text{Total Ship Inv Cost}_{\text{base year}} = \sum_{t=1}^{\text{Outlay}} \text{Ship Inv Cost}_t \times (1 + \text{INFL})^{\text{base year} - t} \]  

(6)

where \( \text{SHIP INV COST}_t \) is the ship acquisition outlay allocation for year \( t \) as calculated in Equation 5.
\( \text{OUTLAY} \) is the number of outlay years.
\( \text{INFL} \) is the user-specified inflation factor for the year in which the outlay occurs.
\( t \) is generally a year between the first year of acquisition and the last year of system life; in this case \( t \) represents the years of acquisition expenditure outlay.

If the economic base year specified by the user is less than the year in which ship investment dollars are presented, the discount rate is used to arrive at present value:

\[ \text{Total Ship Inv Cost}_{\text{base year}} = \sum_{t=1}^{\text{Outlay}} \text{Ship Inv Cost}_t \times \frac{1}{(1 + \text{DISC})^{\text{base year} - t}} \]  

(7)

where \( \text{SHIP INV COST}_t \) is the ship acquisition outlay allocation for year \( t \) as calculated in Equation 5.
\( \text{OUTLAY} \) is the number of outlay years.
\( \text{DISC} \) is the user-specified discount rate.
\( t \) is generally a year between the first year of acquisition and the last year of system life; in this case \( t \) represents the years of acquisition expenditure outlays.

Ship lease costs

Calculating the ship lease cost is perhaps the most complex component of the model. The computations in NEM reflect current business practices.

There are two integrated phases of a build-to-lease acquisition alternative. First the ship is constructed by a shipbuilder and financed with the shipbuilder's line of credit. As costs are incurred, the shipbuilder uses the line of credit. Interest accrues, but no debt service payments are made during ship construction. When ship construction is completed, the ship is purchased by the lessor, using a combination of equity investment and debt to acquire the ship. This contractor owns the ship and leases it to the government for a specified period of time. Lease costs are a function of: ship investment costs to the contractor; the required rate of return on the contractor's equity to account for inflation, risk, and profit; and other cash outflows from the contractor. Figure 2 is a graphic representation of the logical flow of the lease algorithms.
In the shipbuilding phase, ship investment cost is transformed into a greater ship investment cost that includes interest accrued during construction. In the leasing phase, ship investment cost is once again transformed into a ship investment cost that reflects debt service payments and profit.

Figure 2. Logical Flow of Ship Lease Financing
Equity investment is a function of the user-specified equity percent applied to the contractor's ship investment cost. This equity investment is then transformed by the NEM into present value dollars as of the beginning of the lease period using the discount rate as applied in Equation 7. Then, equity service payments are calculated using a standard annuity payment formula:

\[
Total \text{ Equity Svc Prm} = \frac{EQUITY_{start \ lease \ year}}{1 - \frac{1}{(1 + \text{ROR})^{LEASE \ YEARS}}} \tag{8}
\]

where  \(EQUITY_{start \ lease \ year}\) is the total equity investment in present value dollars as of the first year of the lease  
\(\text{ROR}\) is the profit rate or rate of return on the equity investment  
\(\text{LEASE \ YEARS}\) is the number of years of the lease

The result is a stream of equal payments over the term of the lease in current dollars which may be converted to present value in terms of the user-specified economic base year.

The NEM accounts for the lessor's deferring profit until later years in order to make the lease arrangement more attractive to the government. The total equity service payment may be adjusted by a user-specified cash flow rate to pass lower equity service payments on to the government in the first lease period. The balance of equity and profit that is unpaid continues to accrue interest at the profit rate and the new balance is used to calculate new equity service payments in the same way as shown in Equation 8 in the next lease period.

Debt service payments are calculated in a similar manner as equity service payments, except that there is no option for payments to be deferred to future lease option periods. This is because a bank will not be likely to finance a ship construction that is not secured with lease payments high enough to begin paying back the loan immediately as it comes due.

The total debt is a function of the user-specified debt percent applied to the contractor's ship investment cost. The debt service payments are calculated using a standard annuity payment formula:

\[
Debt \text{ Svc Prm} = \frac{DEBT_{start \ svc \ year}}{1 - \frac{1}{(1 + \text{INTR})^{LOAN \ YEARS}}} \tag{9}
\]

where  \(DEBT_{start \ svc \ year}\) is the total debt in present value dollars as of the first year of the lease  
\(\text{INTR}\) is the long term interest rate  
\(\text{LOAN \ YEARS}\) is the number of years of the loan

The result is a stream of equal payments over the term of the lease in current dollars which may be converted to present value as of the user-specified economic base year.
Insurance costs to the lessor are calculated in the NEM and passed through to the government in the lease payments. Insurance increases as a result of inflation, but also decreases as the ship's value decreases. Each year's payment is calculated using the following equation:

\[
\text{SYSLIFE} = \sum_{t=1}^{\text{INSURANCE}} \text{INSURANCE} \times RV_t \times (1 + \text{INFL})^t
\]  

where

- **INSURANCE** is the insurance payment
- **INSURANCE %** is the user-specified insurance cost expressed as a percent of residual value
- **RV** is the residual value of the ship at time **t** using straight-line economic depreciation
- **SYSLIFE** is the system life of the ship in years within the constraints of the user's inputs to the model
- **INFL** is the inflation factor in each year as input by the user

At a user-specified time in the life cycle of the ship, the insurance will remain a percent of the same residual value from that time forward to the end of the life cycle. The result of the computation shown in Equation 10 is a stream of current dollar insurance costs over the duration of the lease. These may be converted to present value terms as illustrated previously.

Contractor General and Administrative (G&A) and overhead expenses are input as a percent of total annual costs of the lease:

\[
\text{GA/OH Cost}_t = \text{GA/OH} \times (\text{Equity SVC} + \text{Debt SVC} + \text{Insurance})
\]  

where

- **GA/OH %** is the user-specified overhead cost as a function of all other costs
- **EQUITY SVC** is the equity service payment for the current year
- **DEBT SVC** is the debt service payment for the current year
- **INSURANCE** is the insurance cost for the current payment

Finally, the total lease payment is calculated by summing up the present value of the costs discussed in this section. It is assumed that in real life, the contractor calculates the lease payment as a function of all applicable costs as of the year in which the lease begins. Therefore, total lease cost is adjusted to present value at the first year of the lease. Then, the lease payment is calculated using the annuity formula described previously:
where $\text{TOTAL LEASE COST}_{start \text{ lease year}}$ is the sum of the equity service payment, debt service payment, insurance, and G&A/overhead in present value as of the beginning of the lease period.

**DISC** is the user-specified discount rate

**LEASE YEARS** is the number of years in the lease

The result is a stream of lease payments over the length of the lease in current dollars, that may be converted to present value using the discount rate. Total lease cost is the sum of all lease payments in present value dollars over the ship's life cycle, to include the primary lease period and all lease extensions.

In addition to the lease payment, there may be some miscellaneous management costs associated with leasing the ship, such as government oversight of the lease. These are added to the lease payment in the year in which they are realized.

**Government and Contractor O&S costs**

Government and Contractor operating and support costs are entered into a cost element structure as shown in Table 3.

Table 3 contains the cost elements found in the actual input spreadsheet for NEM government and contractor O&S costs. As discussed previously, the model will accept numbers at lower levels of indenture and sum these to the next highest level, or accept numbers at higher levels of indenture and override the summing function. The NEM allows input for both government and contractor O&S costs at the cost element structure level, and there is an additional input worksheet for computing contractor crew costs using categories of crew type, quantity of each crew type on the ship, and the labor cost for each crew type.

</table>
The model automatically inflates O&S costs over the life of the ship as discussed previously. Operating and support costs are calculated as follows:

\[
OS\ Cost_t = OS\ cost_{OS\ year} \times \sum_{t=1}^{SYSLIFE} (1 + Inf_{t})^{t-OS\ year}
\]  

(13)

where  
OS Cost is the annual O&S cost  
OS year is the year in which annual O&S costs are input  
SYSLIFE is the system life of the ship in years within the constraints of the user's inputs to the model  
Inf is the inflation factor in each year  
t is generally a year between the first year of acquisition and the last year of system life; in this case t represents years during the ship's service years where O&S costs are realized

The result is a stream of annual O&S costs in current dollars that may be converted to present value in terms of the economic base year and then summed.

Terminal value and disposal costs

The NEM allows for a user-specified percent factor to be applied to initial ship acquisition costs to estimate any residual value of the ship at the end of its useful life. Disposal costs and the year in which these costs are presented are user inputs. Both terminal value and disposal costs are converted into present value dollars using the discount rate.
NPV comparison of alternatives

The life cycle cost of each of the acquisition alternatives is a combination of the computations presented in the previous sections of this paper.

For the first acquisition alternative, government-owned; government-operated, the present value of LCC is reflected by the following equation:

\[
\text{GOGO LCC} = \text{Total Govt Ship Inv Cost}_{\text{base year}} + \text{Govt OS Cost}_{\text{base year}} + \text{Disposal}_{\text{base year}} - \text{Residual}_{\text{base year}}
\]  

(14)

where

- \text{GOGO LCC} is the total life cycle cost as defined within the constraints of the model of the government owned, government operated acquisition alternative
- \text{TOTAL GOVT SHIP INV COST} is the total ship acquisition cost in base year dollars
- \text{GOVT OS COST} is the total government operating and support cost in base year dollars
- \text{DISPOSAL} is the disposal cost in base year dollars
- \text{RESIDUAL} is the residual value of the ship at the end of its useful life in base year dollars

In the case of the leased ship, the present value of Life Cycle Costs is reflected by the following equation:

\[
\text{COGO LCC} = \text{Total Lease Cost}_{\text{base year}} + \text{Govt OS Cost}_{\text{base year}}
\]  

(15)

where

- \text{COGO LCC} is the total life cycle cost as defined within the constraints of the model of the contractor owned, government operated acquisition alternative
- \text{TOTAL LEASE COST} is the total lease cost in base year dollars
- \text{GOVT OS COST} is the total government operating and support cost in base year dollars

The time-charter alternative has a LCC that is reflected by the following equation:

\[
\text{COCO LCC} = \text{Total Lease Cost}_{\text{base year}} + \text{Cont OS Cost}_{\text{base year}}
\]  

(16)

where

- \text{COCO LCC} is the total life cycle cost as defined within the constraints of the model of the contractor owned, contractor operated acquisition alternative
- \text{TOTAL LEASE COST} is the total cost to lease the ship
- \text{CONT OS COST} is the total contractor operating and support cost

Finally, the contracted service alternative, government owned and contractor operated, has a LCC that is reflected by the following equation:

\[
\text{GOCO LCC} = \text{Total Govt Ship Inv Cost}_{\text{base year}} + \text{Cont OS Cost}_{\text{base year}} + \text{Disposal}_{\text{base year}} - \text{Residual}_{\text{base year}}
\]  

(17)

where

- \text{GOCO LCC} is the total life cycle cost as defined within the constraints of the model of the government owned, contractor operated acquisition alternative

The comparison of the results of Equations 14 through 17 will provide a ranking of the four acquisition alternatives in terms of life cycle cost.
Case Study

The case study described in this paper describes a fictional research vessel. Economic variables are those that would be used in a real case and business practice variable inputs are the result of extensive research in the ship building and leasing industry. Table 4 is an actual output of the NEM and contains a summary of the input data used in the test case.

Table 5 is an actual output of the NEM and contains a summary of the comparison of the alternatives. The cost elements are shown at the second level of indenture, and identified by their number in the cost element structure. There are three sections in the summary comparison: current dollar, constant dollar, and present value dollar comparisons. The "Delta" column shows the difference between the acquisition alternatives and the status quo: a government owned, government operated ship. The purpose of the "Delta" column is to show the increase or decrease in costs if an acquisition method other than the status quo is selected.

The test case included sensitivity analysis. Twenty-five test runs were performed using high and low values for each input. Although there is a direct relationship between some input values, such as inflation rate, discount rate, long term interest rate, and rate of return (profit), each input variable was taken in turn in order to isolate the impact of each variable on the total life cycle cost. Certain input variables have significant effect on the outcome of the model. These are:

- ship acquisition costs
- discount rate
- annual inflation rate
- ship O&S costs, including crew costs
- long term interest rate

The model responded logically to the sensitivity analysis. For example, as the discount rate increases, the model output will decrease. As inflation rates rise, the model output will also rise. The sum of the impacts of these opposing input variables will depend on the changes in the discount and inflation rates provided by OMB in the coming years.

Small increases in annual O&S costs result in great increases in life cycle costs. This makes sense, as the small increase is realized every year over the life of the system.

Summary and Conclusions

The NOAA Economic Model (NEM) is the result of an extensive search for an existing model that would assist in the lease-vs.-buy, operate-vs.-charter acquisition decisions that face NOAA. While finding several cost analysis models, each had serious shortcomings with respect to the FRAM decision. Much of the reason for this is the ever-changing science of cost analysis itself. However, each existing model was useful in the development of the NEM. The NEM is a combination of existing cost estimating structures, current economic analysis techniques, expert opinions, and the experience of the model development team.

Several Government and industry organizations were consulted regarding their experience with ship acquisition. The inputs to the test case provided a reasonable scenario for a ship acquisition, and were transformed by the model, as expected, into cost outputs that can aid in decision-making. As proven in the sensitivity analyses performed and the IV&V, the model adequately assists the lease-vs.-buy, operate-vs.-charter acquisition decisions when provided with realistic data.

In its current form, the NEM may be used to assist in FRAM ship acquisition decisions. It meets government and industry requirements, and it calculates accurately. The practicality of the results depend on the user. The user should be thoroughly familiar with the model in order to ensure that logical input data is used. The complexity of the model will always require a user who is experienced in cost analysis and the ship acquisition process specifically.
