ABSTRACT

The problem with the Model-based Mobile robot Language (MML) processor is that the code is unstructured, causing the system to be unstable; it is very difficult to read because of deficient source code documentation; and because of poorly defined function interfaces and extensive functional coupling, the system is hard to maintain.

To fix the MML processor, we performed a manual static analysis of the existing source code to understand its structure. Based on the analysis, the software system was restructured and the functionality enhanced. Finally, explicit source code documentation was added in the form of comments.

There are several results with the new system. First, global variables are reduced from 152 to zero. Secondly, function interfaces are clearly defined and function coupling is enhanced. Finally, the source code is extensively documented. Following from these results, the new system is more stable, easier to read and understand, and simpler to modify.

I. INTRODUCTION

With the changing world environment, the military's structure has changed to meet those needs. In particular, with the demise of the USSR as a threat, US military forces have decreased significantly in the recent past. With this down-sizing, the military is now required to do more with less. This requirement has led the armed forces to rely more on automation to fill the gap of reduced personnel and equipment. One key element to this move to more automation, is autonomous vehicles. These vehicles will continue to play a greater role in this nation's defense. At the Naval Postgraduate School (NPS), the Yamabico robot is an example of active research in the area of land based autonomous mobile robots.

Yamabico is a real-time mobile robot that is able to sense its surrounding and plan its motion. The software system that supports Yamabico is called the Model based Mobile robot Language (MML). As an on going research project, many people have contributed to research over the years. Unfortunately, software engineering practices have not always been followed. As a result, MML has become very unstable and difficult to maintain, causing a hinderance to research.

A. PROBLEM STATEMENT

The problem addressed in this thesis is how to construct a software system for an autonomous mobile robot that is stable, readable and modifiable. Specifically, this research is an improvement of the original Yamabico software system named MML10. In our work, the motion control rules are developed to provide path planning, as with various supporting modules such as the geometric functions and sequential commands. The software system developed as the result of this research is called MML11.

B. YAMABICO BACKGROUND

The Yamabico-11 mobile robot translates in two dimensional space and is controlled by MML. The Yamabico architecture consists of several systems. They are the CPU.
wheels, sonar, and Input/Output systems. In the next few paragraphs we will give a brief overview of these systems, however, for more in-depth information, see (Scott, 93) and (Book, 94).

The CPU system consists of a SPARC-4 based mother-board, with power supplied by two 12 volt motorcycle batteries. One communicates with the robot either through a 9600 baud port connected to a laptop MacIntosh Power Book, or a telnet connection from a Sun work station. Compilation and downloading can be accomplished from any Sun work station. Once the kernel is made, there is a process that automatically copies the kernel to a holding directory. When the command is given to download the kernel, either from a Sun work station or the laptop computer on the robot, the kernel is then downloaded over an ethernet connection.

The wheels system includes a VME bus interface card that provides the user a means of communication with the wheels system. Power is provided by two DC motors and a motor control circuit card manipulates the motors based on information from the interface card. Finally, the shaft encoders provide information that helps determine the speed and distance travelled. (Scott, 93)

The sonar system is used to gather sonar information from the forward, rear, lateral, and diagonal directions. This system consists of twelve 40kHz ultrasonic sensors. The sonar interface card is used to collect information and control the sensors. (Book, 94)
Figure 1: Yamabico-11 Mobile Robot
C. MML BACKGROUND

MML is a high level software system that controls the Yamabico robot. Its design goal is to be a general purpose standard language for autonomous mobile robots, independent of any physical attributes of the robot.

The hardware interrupts are used to provide the real-time aspect of MML. With these interrupts, background processes achieve pseudo-concurrent processing. It is pseudo-concurrent and not fully concurrent because no code for a process is ever interleaved with another, because processes are not allowed to share the same priority. Hence, processes are interleaved, but their code is not. Therefore, this type of process concurrency is limited to the interrupts provided by the CPU architecture. (Scott, 93)

The MML architecture is rather simple conceptually. It has two process levels: foreground and background. The user program runs in the foreground and the motion control functions operate in the background. There are two sets of function libraries that provide the user with control of the robot. They are called immediate and sequential
functions. Immediate functions are executed immediately when they are read. However, sequential functions are first stored in an instruction buffer and executed sequentially.

Figure 2: MML System after (Lee, 93)
Recent developments have significantly improved various aspects of the MML system. First, Scott Book, in his research, developed a solid core system that localized hardware dependencies and reduced assembly code to a single module (Book. 1994). Frank Kelbe, the Yamabico group software design coordinator, designed and implemented data tracing functions for both the motion control and sonar modules. He also redesigned the instruction buffer module and implemented timer functions.

D. ORGANIZATION OF THESIS

This thesis is organized around the construction steps taken for the new version of MML. First, in the next chapter, we describe software attributes that are desirable in any software system. Then in Chapter III, we analyze the original Yamabico code to understand its structure. From this analysis, we develop a methodology in Chapter IV to constructing MML. Next, in Chapter V, we document the implementation phase, describing major milestones reached in the process. We describe the resultant function specifications in Chapter VI, and discuss the results in Chapter VII. Finally, we conclude in Chapter VIII with a summary and recommendations for future research.
II. DESIRABLE SOFTWARE ATTRIBUTES

For any software system, there are certain attributes that are desirable. They provide a common standard by which all software systems can be compared to and judged. These attributes are cohesion, coupling, modifiability, modularity, readability, and robustness.

An important term to understand when applying these attributes is the module. One must consider logical relationships and physical storage properties in order to describe a module. First, a module is a logical break down of routines that have a common functionality or who’s functionalities are related. In reference to physical storage, modules are best if kept as small as possible: one module per file (Scott, 93).

Cohesion measures the strength of relationships between code segments in the same module. Two code segments are related if they reference the same element. Accordingly, it is desirable for related segments to be collected in the same module to the element referenced. Coupling describes the strength of references between modules. As coupling increases, maintainability and readability decreases. There are two types of coupling: common and control. Common coupling applies to references to internal data elements or data structures by another module. Control coupling occurs when flags, used to modify the behavior or actions of a routine, are used between modules. (Scott, 93) and (Book, 94)

A system is modifiable if changes can be made to one segment of code without generating adverse side effects in another segment. The degree that a system is modifiable is directly related to the system’s measure of coupling and cohesiveness. Once produced, a modifiable system is easily changed and maintained. Modularity is defined as the partitioning of the system into small segments. There are two major goals associated with modularity. First, this process is to design each segment around a particular logical function performed by the system. The result is a system that has strong cohesion. The second goal is to minimize the amount of coupling. This is done by using a clean and concise interface. (Book, 94)
In the Yamabico research group, as with others, often the person who implemented part of the system is no longer available. For this reason, it is crucial that systems are readable. A system is readable when it exhibits the same behavior during operation as expressed in the source code. Small modules with independent, well defined and clearly documented behavior are the most readable (Scott, 93). Systems that can detect errors and recover are considered robust. This requires the addition of exception handling functions and procedures to the system. These code segments allow the system to process exceptional conditions such as division by zero or value out of limits (Scott, 93).
III. ANALYSIS OF THE EXISTING SYSTEM

In this chapter, we present two techniques used to help describe the structure of MML10. This description of the original system helps in the design of MML11. Specifically, we take the results of the analysis in this chapter and use it as a starting point for our design goals. The desirable attributes discussed in the previous chapter are the ending point. We then report the results of the analysis on the code. This information will be used in the next chapter to develop a design philosophy.

A. CALL-HIERARCHY TRACING

Call-hierarchy tracing is an analysis technique to describe function categories. It is used for identifying whether a called function's scope is local or global. This tracing method also provides a physical picture of the present software system. Finally, it helps in determining where to place functions. Function calls fall into one of three categories. They are either local, module, or global.

A local category happens when a function is called by only one other function. In Figure 3, which is an example of the local category, function B is called only by function A. With this category, one can place both functions in the same module. If a function is

![Figure 3: Local category](image)

A

B
called by several other functions that all have related operations. They can be placed in the same module. This type of function call falls into the module category. An example of which is given in Figure 4.

Module X

![Module diagram](image)

**Figure 4: Module category**

Finally, the global category occurs when a function is called by several functions that have unrelated operations. An example of a global category function is given in Figure 3. with functions A-C, which are in different modules, call function D. Global category
functions are usually found in libraries of utility functions. (Scott, 93) An example in

MML is the geometry file which has all of the geometric utility functions used by several different modules.

**B. GLOBAL VARIABLE TRACING**

Global variable tracing is used to categorize global variables in a software system. Variables are either module or globally visible. These types of variables are not passed into a function as a parameter nor declared locally. Globals need to be analyzed to see whether they should stay global, local to a module, converted to a locally declared function variable.
or passed in as a parameter. The goal is to minimize the use of global variables. The benefit of reduced globals is increased readability and reliability, because of better defined interfaces (Scott. 93).

C. RESULTS OF ANALYSIS

There are several interesting results from the call-hierarchy and global variable tracing analysis of MML10. First, there is an extensive use of globals variables used throughout the entire system. Specifically, there are 152 global variables, with all motion control variables being global. Secondly, all functions are globally visible. There are no static definitions of variables or functions. As a result, all variables and functions defined have a global scope: they can be seen and accessed by any other function in the system.

One significant implication is that function interfaces are blurred. Instead of passing or locally declaring variables, most functions simply access and modify variables directly. This directly influences coupling. Since code segments from different modules commonly reference the same element, coupling is tight. Figure 6 provides an example of this challenge in MML10. The function that calculates the commanded velocity, get_velocity(), in the motion control module, references elements in the instruction buffer
module directly without using a function interface. Accordingly, this causes a strong dependency between these two distinct modules. Since function interfaces are blurred by the extensive use of global variables, function cohesion suffers also. For example, code that enables the robot to rotate is found in the motion control module and the instruction buffer module. However, this functionality belongs in one module.

Because of its structure, modifiability is very difficult. One has to understand the entire system prior to making any changes because an element manipulated in one module

Figure 6: Example of blurred function interfaces in MML10
may affect or be affected by another potentially unrelated function in another module. Since all functions and variables are visible globally, one has to check the entire system prior to making modifications. This is not only tedious and time consuming, it makes modifying the code a much more difficult task that it should be.
IV. METHODOLOGY

From the last chapter we understand the present structure of MML10 and its shortcomings. We now take that information while considering the desired software attributes, and in this chapter develop a methodology for constructing MML11. Although all software attributes are important in a software system, some are more pertinent depending on the particular situation. With MML, the environment that it is used in significantly influences which software attributes need to be the center of focus.

The Yamabico research group is a dynamic environment. Members are continuously joining or moving on to other projects. As a result, it is important to design a system with the following assumptions: 1) Different people will be working on various parts of the system at different times and 2) Few people have a need to know and understand the entire system.

Understanding these assumptions, we can focus our attention on those software attributes that best support our design assumptions. Specifically, we are most interested in code that has excellent readability, modifiability, and coupling attributes. It is essential that the code is very readable. Since different people are working on the code at different times, one cannot assume that the author of a particular code segment will be available to explain its functions. Therefore, documentation is the critical link. Since one of the first steps in modifying code is understanding what it does presently, documentation also enhances modifiability. Finally, by having a software system that is easily modifiable, the research process is enhanced.

With people specializing in different subsystems of MML, it is important that the variables and code modified in their areas do not have unexpected negative effects on routines in other unrelated parts of the system. A software system that displays loose coupling provides this type of environment.

To obtain a system with the above mentioned desirable software attributes, design goals are needed as a guide in the development of the new system. Our design goals are
three-fold. They are the elimination of global variables, clearly defined function interfaces, and highly explanatory documentation. These goals will best guide the development of MML11 to obtain the software attributes and support our design assumptions.

A. GLOBAL VARIABLES

Our biggest and most challenging task is the removal of global variables from MML10. In this version of MML, the structure of the software system is driven by procedural control. In other words, the key decision making factor is how the flow of control is effected. This emphasis on flow of control minimizes the focus on data grouping. If your code is developed with the grouping of data as the priority, you place your functions in modules where they can best access the needed data for their operations. However, the easiest way to develop a system where flow of control is the priority, is to have the least amount of restriction on data accessibility. This is done in MML10 by making variables global. Additionally, with these variables being global, they are initialized in one location, the system main module.

Understanding the present challenges with global variables in MML10 presented in the previous chapter, our approach is focused more on the grouping of data. Since we want to eliminate global variables, all variables have to be either declared locally in a function, or module. To accomplish this, we have to first determine how we to group the data. Initially, we consider breaking the data down into hardware and system related variables. However, this quickly proves to be unmanageable because there are so many variables that do not fit into either of these categories very well.

We next attempt to group variables based on the frequency they are used in a file. We would declare a variable in a module that has the most references to that variable. A tool that is of great assistance is the unix grep command. This allows us to count the times that the variable appears in a file. There are three cases that we face when attempting to group these variables. In all three cases, the variables are initialized in the main module of MML10. First, in the easy case, when a variable is used only in one file, we statically
declare the variable locally to that file. Next, the more difficult case is when a variable is used mostly in one file but also found in others. In this case, we still statically declare the variable in the file where it is used the most. We then write function interfaces to allow functions from the other modules to access the variable. The most difficult case, however, is when different modules reference the same variable with about the same frequency. In this case, we go into each module and determine how critical the variable is to calculations in the local functions. For example, there could be two modules that reference a variable the same amount of times. However, module 1 modifies the variable while module 2 references the variable. In such cases, the variable is more critical in module 1 because it is not only accessed, but updated. Accordingly, the variable is placed in module 1 with function interfaces written in module 1 for access by module 2.

After all variables are grouped into modules, the process is repeated at the module level to determine whether a variable would stay visible at the module level or be declared in a function. If the variable is only used in one function, then it is declared there. However, when a variable is used by several functions, it retains its module level visibility. For example, in the motion control module, this method is used to determine whether the variable that held the value for the current vehicle configuration, (named vehicle) would remain at module level or be declared in a function. After analyzing the code, we find that several functions in the motion control module use vehicle. For this reason, vehicle is declared local to the entire motion control module.

With all global variables removed, we still need to initialize variables. Different from MML10, we require an initialization routine in each module in MML11. Although this requires more code than the approach used in MML10, initializations are now easier to manage. We are not concerned with a huge file of variable initializations anymore, but instead with several smaller routines that are specifically related to the file that they support. This makes maintaining and modifying them much easier.
B. FUNCTION INTERFACES

In earlier versions of MML, data access can not be controlled through function interfaces because global variables usurp the need to pass parameters. As a result, critical regions are vulnerable. Specifically, a function can be interrupted while updating a variable because critical regions are not controlled. However, the goal with MML\textsubscript{I} is to have all data in functions to be either locally declared, passed in as a parameter, or local to the module. Inter-module communications therefore, is limited to function interfaces. This additional control in MML\textsubscript{I} ensures control in critical regions because variables can only be accessed through a function interface. With this limited access, interrupts can be disabled if deemed necessary, within the function.

This design goal has a significant impact on the structure of MML\textsubscript{I}. In MML\textsubscript{0}, immediate functions are grouped together into one file. Since few parameters are passed in the older version of MML and data grouping is not a concern, it is logical that these functions are placed in the same file. However, in the design of MML\textsubscript{I}, we find that this structure is unacceptable. The immediate functions fall basically into two categories. They either work with data that is updated by the motion control module, or they maintain data that is only assessed by motion control and other modules. As a result, we group the functions that access variables that are updated by the motion control module, into motion control. In this way, any other module that needs these variables access them through function interfaces in motion control. The alternative would have been to maintain the original structure with all of the immediate functions in one file. Function interfaces would still have been written in the motion control module to provide access to variables for those immediate functions that need them. We then would have to call these functions from within the immediate function. The method we use thus allows us to cut out the extra unneeded step in accessing variables that are controlled by motion control. The immediate functions that do not access variables controlled by motion control are still kept in a separate file.
C. DOCUMENTATION

Our review of MML10 greatly influences our documentation goals for MML11. We found it very challenging to understand MML10 without someone available who is already familiar with the code. Functions usually have sparse comments if any. Variable naming also makes it difficult to follow because they are usually very short and non-descriptive. Therefore, with MML11, following our assumption that people who wrote the code will not be available, we decide to thoroughly comment our code and provide descriptive file, function and variable names.

First, a naming convention has to be chosen. We decide to adopt one that has recently been designed for the Yamabico research group, because of its simplicity and ease in duplication. Overall, more descriptive names are used. Full words are used as much as possible, and names are chosen that best describe what exactly the variable, function or constants does. For variables, the first letter is lower case. If more than one word is used in the variable name, the first letter of each word other than the first word is capitalized. The capital letters are used to distinguish the words instead of underscores. The benefit is that it requires less space for variable names. Function names are the same as variables.
Constants are written as all capitals. To distinguish between words if more than one word is used for the constant name, underscores are used.

Variable name
kappaCommanded

Function name
motionRules()

Constant
MOTION_CONTROL_CYCLE

Figure 7: Naming convention examples from MML11

Our comments are written with the assumption that the reader is unfamiliar with MML. Also, we provide descriptive names to variables and functions so that their names describe what they do. Each declared variable in a module is documented. Functions also are extensively documented, not only to explain the purpose, but, if appropriate, to give normal uses of the functions. In critical areas, function calls were documented to help the reader. For example, in the main routine of the motion control module, all of the steps of the motion control theory are represented. During each motion control interrupt, this routine is what is called. Because of its critical role in the MML system, each line of this routine is documented to help guide the reader through the module. For example, for each function call, we identify in which module the called function is located.

All locally declared static function prototypes are provided brief documentation so that a reader does not have to search through the entire module to find the full documentation. Function prototypes also provide an added benefit of argument checking. MML10 is written in a non-standard version of the C language. Function prototypes, in this version, do not require an argument to listed in the parameter list, even if arguments are
passed into the function. The advantage of using prototypes under ANSI C is that they allow the compiler to perform compile-time type checking on the arguments of a function. The compiler will check all calls to the function to make sure it has both the correct number and types. Depending on the severity, the compiler may issue a simple warning, such as when an integer is expected, but a character is passed. An error may be issued, instead, for mistakes such as the wrong number of parameters. This type checking simply makes the code more reliable by having the compiler find problems before testing. (Kelbe, 94)

```c
/* calculates the vehicle's next configuration based on the distance travelled in the last motion control cycle */
static CONFIGURATION localize(CONFIGURATION robot, double deltaS, double deltaTheta);

/* calculates the next commanded linear velocity value. */
static double getLinearVelocity(double actualVelocity, double lastCommandedVelocity);

/* calculates the distance remaining on a path to reach a configuration. Used with bline calculation. */
static double restOfPath(void);

/* determines whether the vehicle needs to decelerate. Used in bline calculation */
static int needsToDecelerate(double actualVelocity);
```

Figure 8: Static function prototype documentation examples

Function prototypes in our header files are documented similar to functions in our program files. Specifically, the commented section above the function name in the program files is used in the header file prototype. We do this to provide the most complete documentation for the reader in the header file. Our goal is for a reader to be able to understand and apply functions found in a file simply from reading the header file.
V. IMPLEMENTATION

A. DATA STRUCTURES

With the re-engineering of MML, fewer software structures were needed. Most of MML was described using only five basic data structures. In this section we explain these structures.

1. Point

The POINT structure is used to describe a position in two dimensional cartesian coordinates. The structure is made up of two doubles named X and Y.

![POINT](image)

2. Velocity

The VELOCITY structure is used to describe a two dimensional velocity vector. The data structure is made up of two doubles that represent the linear and rotational elements of velocity. They are appropriately named Linear and Rotational, respectively, in the VELOCITY structure.

![VELOCITY](image)

3. Configuration

The CONFIGURATION is the standard structure for describing location and direction for an object. It consist of Posit, which is of type POINT, which identifies an objects position in two dimensional cartesian coordinates. Next, there is a double called
Theta that describes the object's orientation in relation to the X coordinate. Finally, there is another double in the CONFIGURATION structure called Kappa that represents the curvature of an object's path.

\[
\text{CONFIGURATION} \\
\text{POINT Posit} \\
double θehta \\
double Kappa
\]

Figure 11: Configuration

4. Parabola

The PARA structure is used to describe a parabola. A common use of the PARA data structure is as a configuration that the robot follows. Specifically, it is another type of path that is available in the library of functions for motion types. It consists of a Focus which is of type POINT and a Directrix which is of type CONFIGURATION.

\[
\text{PARA} \\
\text{POINT Focus} \\
\text{CONFIGURATION Directrix}
\]

Figure 12: Parabola

5. Path Element

The PATHELEMENT data structure is used to describe and store the various types of movements. This data structure consists of config which is of type CONFIGURATION. It holds the configuration of the path that the robot is to follow. PATHELEMENT also contains pathType, which is of type PATH_TYPE. A PATH_TYPE is a data structure used to identify the various paths that are available to the robot. It consists of the mode which is of type MODE and class which is of type CLASS. Type MODE is an enumeration type that gives a name to each path that the robot follows. Presently, the modes that are available include NOMODE, STOPMODE, PATHMODE.
ROTATEMODE, KSPIRALMODE, and PARAMODE. Type CLASS, which is also an
enumeration type, is used to name and categorize the various PATHMODE types. The list
of classes include NOCLASS, LINECLASS, CIRCLECLASS, and BLINECLASS.

6. Significance

With the above mentioned data structures, all motions that are presently
performed by the Yamabico robot, can be described and represented. More importantly,
because of the modular design, additions and maintenance of these data structures is
simplified

B. GEOMETRIC FUNCTIONS

1. Pointers Use Reduced

Pointers are used extensively in the original version of MML. This is because the
language that it was written in, a non-ANSI C, does not support structure passing. As a
result, one would need the following type of function interfaces:

CONFIGURATION * defineConfig(POINT position, double theta, double kappa, CONFIGURATION *configPtr)
Notice that a pointer to a CONFIGURATION was returned. However, a pointer to a CONFIGURATION was also passed in. At first glance, we assume that the pointer to the CONFIGURATION that is passed in, is a duplicated effort because one should just be able to declare a a CONFIGURATION type in the function defineConfig and return its address. However, this would cause a logical error because once the function returns, the value that the pointer is pointing to is discarded with the function. One is left pointing to garbage. So without the ability to pass structures, it is very awkward handling them in function calls. However, with the ability to pass the structures, such as a CONFIGURATION type, the above function interface is written as follows:

CONFIGURATION defineConfig(POINT position, double theta, double kappa)

As one can see, the interface is simpler, and easier to read and understand.

2. Duplicated Functions

In the original version of MML, there are functions that are duplicated. Although they have different names, they perform exactly the same function. In the new version of MML, the duplicated functions are eliminated. One example are the normalize functions. There were two called normalize() and norm(). After inspection, we determined that they perform the same task and have the same logic.

3. Functions Added

There are also geometric functions that are new to the updated version of MML. They are included to support new functionalities added to MML. For example, there is a function that calculates the circular arc. This function is used in conjunction with the composition function to create a new way to localize the position of the robot during its motion control cycle interrupt. This method is cleaner and more efficient. Also, a function to determine the signed difference between a point and a configuration, is added. This is included mainly to support the parabola calculations, however is available to all modules.
C. MOTION CONTROL

Among other things, the design goals would help produce a software system that is easily maintainable. This is very crucial in an ongoing research project such as Yamabico. One area that is critical is the means of representing and categorizing motion control commands. The use of modes and classes is used as a means of describing the various control commands. The mode describes the basic types of motions commands. They include path, stop, rotate, kspiral, and parabola modes presently. Path modes are further broken down into classes. These class descriptions presently include line, circle and backward line path tracking. The benefit of using this taxonomy is that it encourages a modular design. Specifically, when new motion commands need to be added to the library of commands, a new mode or class only needs to be added.

1. Line

In our implementation of these commands, the simplest case—the line—was chosen first. Sequential commands provide a means of putting motion commands into the instruction buffer, to be later extracted sequentially and passed to the motion control module. However, since the sequential commands had not been implemented yet, it was necessary to hard code the line command directly into the motion control module. With this done, we first tested the robot by allowing it to track a line that was configured parallel to the robot's configuration with no offset. This enabled us to ensure that the robot could follow a straight line. When this was accomplished, we allowed the robot to follow a line that was configured parallel to the robot but offset by thirty centimeters. With this test, we confirmed that the robot could correct its path to follow a line that was offset. Finally, we commanded the robot to follow a line that was not only offset but not parallel. When this was accomplished, testing for the simple line case was complete.

2. Bline

The backward line (bline) tracking command gives the robot not only a configuration to follow, but a location to stop. With the bline command, the robot will stop
at the location described by the bline configuration. During our implementation, we initially had challenges with the robot not stopping. This was because we had overlooked changing the mode to stop mode (thus commanding the robot to stop) when the robot had reached the bline configuration. Once this correction was implemented, the bline command worked as expected.

D. SEQUENTIAL COMMANDS

As discussed earlier, sequential commands were a library of functions that allow the user to interface with the robot. When commands were issued, they were placed into the instruction buffer. They were then extracted and executed sequentially. Our plan was to test the line and bline commands called sequentially using the sequential commands and the instruction buffer. First, we tested the sequential line command. Our only challenges centered around properly initializing functions. This challenge continued throughout our entire implementation phase. With the line case, the instruction buffer module was not being initialized. Next the bline sequential command was implemented with no significant challenges. The testing of these commands was broken down into three stages. First, the robot transitioned from one line that it was following to another. Second, the robot had to transition from a line to a bline. Finally, it was tested from a bline to another bline.
VI. FUNCTION SPECIFICATIONS

In this chapter we list the user and system functions of MML11. With each specification, we provide the ANSI C syntax for the function and a description of the function.

A. USER FUNCTIONS

1. **Set Robot’s Configuration (Immediately)**
   
   Syntax: `void setRobotConfiglmm(CONFIGURATION)`
   
   Description:
   
   This function immediately sets/updates the robot’s configuration. This can be done while the robot is at rest or moving.

2. **Get Robot’s Configuration**

   Syntax: `CONFIGURATION getRobotConfig(void)`

   Description:

   This function returns the current configuration of the robot.

3. **Set Configuration (Immediately)**

   Syntax: `void setConfiglmm(CONFIGURATION NewConfig)`

   Description:

   This function enables the user to update the robot’s position and theta. However, the Kappa is not adjusted with this command.

4. **Track a Line**

   Syntax: `void line(CONFIGURATION config)`

   Description:

   Basically the robot follows a directed path element defined by the configuration that is passed as a parameter. The robot leaves this element when it comes to a transition point or when an immediate motion function are called. The robot's speed is automatically
reduced to allow the robot to make sharp turns. This is reflected by the dependency between Kappa and the robot’s speed. In simple terms, the robot’s speed must be reduced to allow it to move safely with larger values of Kappa.

5. **Track a Backward Line Segment**

   Syntax: void bline(CONFIGURATION config)

   Description:

   The robot follows this directed path element defined by the configuration that is passed as a parameter. The robot will track the line config until it passes config itself and will transfer to the next path segment. If there is no next path segment, the robot will start to slow down at the configuration config and eventually stop with the current acceleration rate. Precisely speaking, the robot leaves the segment config when the robot’s image reaches config (or is downstream of config).

6. **Stop the Robot**

   Syntax: void stop(void)

   Description:

   When this function is processed from the instruction buffer, it calls the immediate command of stop. In doing so, the rotational and linear goal velocities are set to zero.

7. **Set the Robot’s Configuration**

   Syntax: void setRobotConfig(CONFIGURATION config)

   Description:

   The robot’s configuration is set to the value of the parameter config. This function is processed only if the robot is in a stopped position.

8. **Stop the Robot(Immediately)**

   Syntax: void stopImm(void)

   Description:
This function immediately updates the goal velocity to zero in order to stop the robot. The sequential command stop() calls stopImm() once the sequential command function pair is read from the instruction buffer. Also, users can call stopImm() directly.

9. **Set Linear Velocity(Immediately)**
   Syntax: void setGoalLinVelImm(double linearVelocity)
   Description:
   This function sets the goal velocity that the robot will attempt to achieve when it is following a path. This sets the speed of the robot immediately.

10. **Get Linear Velocity**
    Syntax: double getGoalLinVel(void)
    Description:
    This function retrieves the current goal linear velocity that the robot is following.

11. **Set Rotational Velocity(Immediately)**
    Syntax: void setGoalRotVelImm(double rotationalVelocity)
    Description:
    This function sets and updates the goal rotational velocity that the robot will attempt to achieve when it is following a path.

12. **Get Rotational Velocity**
    Syntax: double getGoalRotVel(void)
    Description:
    This function retrieves the current goal rotational velocity that the robot is following.

13. **Set Linear Acceleration(Immediately)**
    Syntax: void setGoalLinAccImm(double linearAcceleration)
    Description:
This function sets and updates the goal linear acceleration that the robot will attempt to achieve when it is following a path.

14. Get Linear Acceleration
   Syntax: double getGoalLinVel(void)
   Description:
   This function retrieves the current goal linear acceleration that the robot is following.

15. Set Rotational Acceleration (Immediately)
   Syntax: void setGoalRotAcclmm(double rotationalAcceleration)
   Description:
   This function sets and updates the goal rotational acceleration that the robot will attempt to achieve when it is following a path.

16. Get Rotational Acceleration
   Syntax: double getGoalRotAcc(void)
   Description:
   This function retrieves the current goal rotational acceleration that the robot is following.

17. Set Size Constant (Immediately)
   Syntax: void setSizeConstantImm(double SizeConstant)
   Description:
   This function sets the size constant which is used, among other things, to influence the sensitivity of the steering function.

18. Get Size Constant
   Syntax: double getSizeConstant(void)
   Description:
This function retrieves the current size constant that is being used in motion control.

19. **Set Total Distance (Immediately)**
   
   Syntax: `void setTotalDistanceImm(double distance)`
   
   Description:
   
   This function sets the total distance travelled by the robot to the value passed as a parameter.

20. **Get Total Distance**
   
   Syntax: `double getTotalDistance(void)`
   
   Description:
   
   This function returns the total distance travelled by the robot.

21. **Halt Motion (Immediately)**
   
   Syntax: `void haltMotionImm(void)`
   
   Description:
   
   This function brings the robot to a rest. It is different from the stop functions in that it’s purpose is a temporary halt with the assumption that you will continue or resume the motion. Accordingly, the original goal velocity is saved to be later used by the resume motion command to allow the robot to continue travelling at the same speed as it was travelling before it halted.

22. **Resume Motion (Immediately)**
   
   Syntax: `void resumeMotionImm(void)`
   
   Description:
   
   This function is to be called only after a halt velocity command. It allows the robot to resume the speed it was travelling before the `haltMotionImm()` was given.

23. **Parabola (Immediately)**
   
   Syntax: `void parabolaImm(PARA newParabola)`
Description:
This is the immediate function that commands the robot to follow the parabola configuration passed in the parameter.

24. Euclidean Distance
Syntax: double euDis(double x1, double y1, double x2 double y2)
Description:
This function computes the Euclidean distance between two given points.

25. Normalize
Syntax: double norm(double angle)
Description:
This function, when given an angle in radian, returns a normalized angle between -π and π. This is the most common normalizing function used in the system.

26. Positive Normalize
Syntax: double positiveNorm(double angle)
Description:
This function, when given an angle in radian, returns a normalized angle between 0 and 2π.

27. Negative Normalize
Syntax: double negativeNorm(double angle)
Description:
This function, when given an angle in radian, returns a normalized angle between -2π and 0.

28. Normalize PI/2
Syntax: double normPlover2(double angle)
Description:
This function normalizes the input angle between -\(\pi/2\) and \(\pi/2\). This was specifically designed for parabola tracking calculations.

29. Signed Difference

Syntax: double signedDiff(CONFIGURATION config, POINT pt)

Description:
The signed difference function calculates the size distance between a point and a configuration. If the value returned by the function is positive, that means that the point is to the left of the configuration. If the value returned is negative, then the point is to the right of the configuration.

30. Define Configuration

Syntax: CONFIGURATION defineConfig(double x, double y, double theta, double kappa)

Description:
When passed the values that define a configuration (x,y,theta, and kappa), this function allocates and assigns a configuration. It returns a configuration.

31. Define parabola

Syntax: PARA defineParabola(double xf,double yf, double xd, double yd, double td)

Description:
When passed the values that define a parabola (xf, yf, (the focal point), xd, yd, td (the directrix), this function allocates and assigns a parabola. It returns a pointer to a parabola.

32. Reverse orientation

Syntax: CONFIGURATION reverseOrientation(CONFIGURATION original)

Description:
The purpose of this function is to reverse the orientation of a given configuration by 180 degrees. You pass in the original configuration and then the reversed configuration is returned.

33. **Find symmetric configuration**

Syntax: CONFIGURATION findSymConfig(double a, double alpha)

Description:

This function finds the symmetric configuration of an original configuration. The parameter -- a -- is the distance from either configuration to the intersection of both lines determined by the two configurations. The parameter -- alpha -- is the angular difference between both orientations. One drawback to this function is that it is not possible to represent a symmetric configuration whose alpha is equal to. FindSymConfig1() is used to cover these situations.

34. **Find symmetric configuration 1**

Syntax: CONFIGURATION findSymConfig1(double a, double alpha)

Description:

This function performs the same operation as findSymConfig(), except that it overcomes the drawback of not being able to handle the situation when alpha equals.

35. **Inverse**

Syntax: CONFIGURATION inverse(CONFIGURATION original)

Description:

The purpose of this function is to calculate the inverse of a given configuration such that: original * inversed = Identity. The parameter --original-- is the original configuration in global coordinates. This function returns the inversed configuration.

36. **Compose**

Syntax: CONFIGURATION compose(CONFIGURATION *first, CONFIGURATION *second)
Description:

The purpose of this function is to calculate the composition of two configurations. Specifically, the function takes parameter --first-- and composes it with parameter --second-- to calculate and return the composed value. A typical example of the usage of this function is to determine the goal position of a configuration in global coordinates. In such an example, the first argument would be the original configuration and the second argument would be the goal configuration in the original configuration's local coordinate system. The returned value would then be the goal configuration in global coordinates.

37. **Circular arc**

Syntax: `CONFIGURATION *circularArc(double l, double alpha)`

Description: Given alpha and the arc length l, this function calculates the final configuration (see figure below). The main purpose of this function is to be used in conjunction with compose function to form the new localization function. In this case, length would actually be delta-s and alpha would be delta-theta. CircularArc() would determine the configuration after the incremental move in the local coordinate system of the original configuration. Then compose() would then take the original configuration (in
global coordinates) and the incremental configuration (in local coordinates) to determine the incremental configuration in global coordinates.

![Circular arc diagram](image)

**Figure 14: Circular arc after (Kanayama, 94)**

B. SYSTEM FUNCTIONS

1. **Initialize the Motion Control System**

   Syntax: `void InitMotion(void)`

   Description:

   This function initializes the motion control system. Specifically, `InitMotion()` initializes all of the variables local to motion control module to their default values. Also in this initializing function, `SetMotionIntMechanism()` is called which establishes the synchronous interrupt mechanism for motion control. Next, the wheels subsystem is...
initialized with the `InitializeWheels()` function call. Finally, the wheels of the robot are enabled with the `MotionOn()` function call.

2. **Motion Control Interrupt**

   Syntax: `void MotionSysControl(void)`

   Description:

   Function `MotionSysControl(void)` is the interrupt handler workhorse and is called from the assembly interrupt handler shell. Its first task is to update the change in position and orientation through calls to the module responsible for movement. It then uses this information in the motion control laws to derive the commanded linear and rotational velocities required for this motion control cycle. Finally, it passes these computed velocities back to the movement module for execution.

3. **Set Path Element**

   Syntax: `void setPathElement(PATH_ELEMENT newPath)`

   Description:

   The function `setPathElement()` is one of several functions that act as an interface for modules outside of `MotionSysControl()` to access variables that are within `MotionSysControl()`. Specifically, `setPathElement()` sets the value of the current path element in motion control to the path element passed in as a parameter.

4. **Get Path Element**

   Syntax: `PATH_ELEMENT getPathElement(void)`

   Description:

   Similar to `setPathElement`, `getPathElement` acts an interface for functions outside of the motion control module. The function returns the current path element in the motion control module.

5. **Get Current Image**

   Syntax: `CONFIGURATION getCurrentImage(void)`
Description:
This function is also an interface for functions outside of the motion control module. This function returns that current image that is in the motion control module.

6. **Initialize Motion Support Commands**
   Syntax: `void InitMotionSpt(void)`
   Description:
   This function initializes the variables used in motionsupport.c.

7. **Update Total Distance**
   Syntax: `void updateTotalDistance(double deltaDistance)`
   Description:
   This function adds the value of the parameter to the running total distance.

8. **Get Parabola Configuration(Immediately)**
   Syntax: `PARA getParabolImm(void)`
   Description:
   This function retrieves the latest parabola that has been processed by the robot. It was developed for the paraRule() function in motion control.

9. **Motion On**
   Syntax: `void MotionOn(void)`
   Description:
   This function enables the wheels on the robot. It is called in InitMotion().

10. **Motion Off**
    Syntax: `void MotionOff(void)`
    Description:
    This function disables the wheels on the robot. It is called in main.c after user().
11. **Blink the LED**

Syntax: void blinkLED(void)

Description:

This function controls the output from the interrupt driven motion control system. Specifically, this function turns a LED on for a second and off for a second, repeatedly while the motion control interrupt is being called. This is helpful for debugging purposes. If the light stops blinking, you know that the motion control system is not being called.

12. **Limit Robot Movement**

Syntax: double limit(double ystar)

Description:

This function is used by the steering function to keep the robot from doing loops when the distance between the robot’s position and the path that the robot is following is very large.
VII. RESULTS

With the new version of MML, many significant improvements are achieved. First, global variables are reduced from 152 to zero. Using the global variable and cali hierarchy trace, we limit all variable visibility to a module or function level scope. This directly enhances coupling because dependencies between modules caused by global variables is eliminated. Any function from an outside module has to access these variables through function interfaces. Also, data flow is further controlled by statically declaring variables and functions. Modifiability is improved because a developer needs only to be concerned with variables in the module he or she is working in. Finally, functional cohesion is improved because data are encapsulated and functions are structured logically. For example, in MML10, there are several occasions where code that supports a motion command is found in various modules. One in particular is the rotate command. Some of its code is in the motion control module and the rest is in the instruction buffer module. In MML11, all of the rotate command related code is located in the motion control module.

Recent work on the new MML provide testimony to MML improvements. For example, members of the Yamabico group read and understood the new code without having the implementor available. They attribute this high degree of understanding and readability to the extensively documented code in the form of comments. Also, members have already began adding new functionality to the new MML. For example, one member is adding parabola tracking logic to motion control. Instead of having to study the entire motion control module, we simply define the interfaces needed. He is only concerned with the interfaces--receiving the information he needs for his function, and providing the data needed in the calling path tracking function. Finally, the new MML is stable. It runs correctly consistently, and does what is expected. Furthermore, since little or no adjustments to already tested code is necessary, new functions and modules are running quickly with fewer initial run-time errors.
A major focus throughout the design and implementation of MML11 has been the grouping of data. As a result, most data is encapsulated with the same module as the functions that use them. For example, motion control related data is located with motion control related functions in the motion control module. This is true throughout the entire Yamabico subsystem. As a consequence, it is an object oriented designed system. Although ANSI is not an Object Oriented Language (OOL), our design has followed this methodology through the grouping of data. This makes it easy to move MML to an OOL in its next upgrade.
VIII. CONCLUSIONS

A. SUMMARY

Our initial goal was to construct a software system for a real-time mobile robot that was stable, readable, and easily modifiable. We first examined those attributes that were desirable in any software system. Then we analyzed MML10 using global variable and call-hierarchy tracing. Considering the desired software attributes, the structural challenges of MML10, and the design assumptions for the MML end users, we developed design goals for MML11. Following from the results of the previous chapter, we achieved our goal. The new system was more stable, easier to read and understand, and simpler to modify.

B. FUTURE RESEARCH

There are two areas of recommend future research. First, a graphical simulator for Yamabico based on MML11, would be a possible area of research. Considering the modular design of MML, this would not be a monumental task.

With the completion of this thesis, MML is now completely written in ANSI C. In restructuring the code, data has been encapsulated providing a object designed software system. Yamabico lends itself to this type of design methodology, because its subsystems, such as wheels, sonar, etc., provide a modular structure in which to design the software. The next logical step would be to write MML in an Object Oriented Language (OOL) such as C++.

*****************************************************************************

Routine main is required when using the 'gcc' compiler. This is because the
compiler inserts a call to this routine at the beginning of the main function
defined for the program. This is normally taken care of by linking in the
bootstrap object modules, however these are not added to a program that
operates without an operating system such as the mml program. Therefore, since
this routine is called, the only requirement is for this routine to simply
return back to the main program.

void Unexpected(void)
{ /* empty */ }

C. MOTION.H

File Name: motion.h
Description: This file contains the prototypes/interface for the functions available in the motion control module.

#ifndef MOTION_H
#include "definitions.h"

Function: InitMotion()
Purpose: initializes the motion subsystem by assigning default values to the local variables and establishing the interrupt handling mechanism.
Parameters: none
Returns: void
Comments:

void InitMotion(void);

Function: MotionSysControl()
Purpose: the interrupt handler workhorse and is called from the assembly interrupt handler shell.
Parameters: none
Returns: void
Comments:

void MotionSysControl(void);

INTERFACE FUNCTIONS SECTION

The following section defines the functions that provide an interface to values within in the motion control modules by functions in other modules. These routines are public.
Function: setPathElementO
Purpose: Sets the value of the current path element in motion control to
the path element passed in as a parameter.
Parameters: PATH_ELEMENT newPath
Returns: void
Comments:
void setPathElement(PATH_ELEMENT newPath);

Function: getPathElementO
Purpose: retrieves the current path element in the motion control module
Parameters: void
Returns: PATH_ELEMENT
Comments:
PATH_ELEMENT getPathElement(void);

Function: getCurrentlmageO
Purpose: retrieves the current image that is in the motion control module
Parameters: void
Returns: CONFIGURATION -- the current image
Comments:
CONFIGURATION getCurrentImage(void);

Function: setRobotConfiglmmO
Purpose: To set and update the robot configurations
Parameters: CONFIGURATION NewConfig
Returns: void
Comments:
void setRobotConfiglmm(CONFIGURATION NewConfig);

Function: getRobotConfigO
Purpose: Retrieves the current robot configuration
Parameters: Pointer the a variable where the current values for the robot's
configuration will be placed.
Returns: void
Comments:
*************************************************************************
CONFIGURATION getRobotConfig(void):

*************************************************************************
Function: setConfigImm()
Purpose: To set and update the robot's position and theta but not
it's kappa
Parameters: CONFIGURATION NewConfig
Returns: void
Comments:
*************************************************************************
void setConfigImm(CONFIGURATION NewConfig);

#endif

MOTION CONTROL SECTION

The following section defines the functions that provide access to the motion control system. These routines are public.

Function InitMotion() initializes all of the private global variables in this module to the default values. It then calls SetTimer to program the 5th timer on serial board #1 (the second serial board) to generate synchronous interrupts every 10ms. After the timer has been set up, the interrupt handling routine is made available to the system by the call to SetMotionInterruptHandler().

```c
void InitMotion(void)
{

/* Initialize motion related systems */
InitMotionsupport();
InitSeqcmd();
InitWheels();

/* Initializes the distance. Updated every motion control cycle by deltaS */
setTotalDistanceImm(0.0);

/* Initialize the goal velocities */
setGoalLinVellImm(DEFAULT_GOAL_VEL_LIN);
setGoalRotVellImm(DEFAULT_GOAL_VEL_ROT);

/* Initialize the commanded velocities */
   Commanded.Linear = 0.0;
   Commanded.Rotational = 0.0;

/* Initialize the linear and rotational acceleration */
setGoalLinAcclmm(DEFAULT_LIN_ACC);
setGoalRotAcclmm(DEFAULT_ROT_ACC);

/* Initialize the size constant */
setSizeConstantlmm(DIST_CONSTANT);

```
/* Initialize the commanded kappa */
kappaCommanded = 0.0;

/* Initialize the vehicle configuration */
vehicle.Posit.X = 0.0;
vehicle.Posit.Y = 0.0;
vehicle.Theta = 0.0;
vehicle.Kappa = 0.0;

/* Initialize the current path configuration */
currentPath.config.Posit.X = 0.0;
currentPath.config.Posit.Y = 0.0;
currentPath.config.Theta = 0.0;

#endif

#ifndef TIMER
    TimerLog = IOpen(TIMER_FILE, TIMER_SIZE, TIMER_FREQUENCY);
#endif

}
Return: void
Comments: It is called from the assembly interrupt handler shell. Its first task is to update the change in position and orientation through calls to the module responsible for movement. It then uses this information in the motion control laws to derive the commanded linear and rotational velocities required for this motion control cycle. Finally, it passes these computed velocities back to the movement module for execution.

```c
void MotionSysControl(void)
{
    double deltaTheta;
    double deltaS;
    VELCITY Actual; /* variable used to hold the actual vehicle velocity */

    #ifdef TIMER
        int tick = getCount();
    #endif

    /* updates the distance traveled by both wheels--found wheels.c */
    UpdateMovement0();

    /*returns the linear distance the vehicle has travelled between the last two calls to UpdateMovement0--found in wheels.c */
    deltaS = GetDistanceTraveled0();

    /* returns the difference between the changes in the distance of the left and right wheels between the last two calls to UpdateMovement0. Found in wheels.c */
    deltaTheta = GetOrientationChange0();

    /* Keeps track of the total distance traveled by vehicle */
    updateTotalDistance(deltaS);

    /* update the vehicle's configuration based on the distance travelled during the last motion control cycle */;
    vehicle = localize(vehicle, deltaS, deltaTheta);

    /* next 2 lines calculate the actual velocity that robot maintained based on the distance travelled over the last motion control cycle. */
    Actual.Linear = deltaS / MOTION_CONTROL_CYCLE;
    Actual.Rotational = deltaTheta / MOTION_CONTROL_CYCLE;

    /* logs the values of the vehicle configuration. Data is written to a buffer during each motion control cycle and then downloaded to a file when the program ends. LogMotion
```

54
Function: localize()
Purpose: Calculates the next configuration of the vehicle based on the
distance that the robot travelled during the last motion
control cycle
Parameters: CONFIGURATION robot --from the last motion control cycle
double deltaS -- linear distance travelled in last
motion control cycle
double deltaTheta --angular change in the last motion
control cycle
Returns: CONFIFURATION --of the vehicle based on the distance travelled
during the last motion control cycle

Comments:

CONFIGURATION localizeCONFIGURATION robot, double deltaS, double deltaTheta)
{
CONFIGURATION tempRobot;

tempRobot = circularArc(deltaS, deltaTheta);
robot = compose(&robot, &tempRobot);
robot.Kappa = kappaCommanded;

return robot;
}

Function GetLinearVelocity() calculates the linear component of the commanded velocity.

static double GetLinearVelocity(double ActualVelocity, double CommandedVelocity)
{
    double stopDistance;
double deceleration;
double VelocityChange;

    if (currentPath.pathType.class == BLINECLASS &&
        needsToDecelerate(ActualVelocity))
    {
        stopDistance = restOfPath();
        if (stopDistance <= 0.0) {
            CommandedVelocity = 0;
            currentPath.pathType.mode = STOPMODE;
        }
        else {
            deceleration = (ActualVelocity * ActualVelocity)/(2 * stopDistance);
            CommandedVelocity = Max(CommandedVelocity - deceleration * MOTION_CONTROL_CYCLE, 0);
        }
    }
    else {
        VelocityChange = getGoalLinAcc() * MOTION_CONTROL_CYCLE;

        if (ActualVelocity < getGoalLinVel())
            CommandedVelocity = Min(CommandedVelocity + VelocityChange, getGoalLinVel());
        else
            CommandedVelocity = Max(CommandedVelocity - VelocityChange, getGoalLinVel());
    }

    return CommandedVelocity;
}
Function restOfPath() calculates the remaining distance to the ending configuration for the BLINE class

```c
static double restOfPath(void)
{
    return ((currentPath.config.Posit.X -
             currentImage.Posit.X) * cos(currentImage.theta) +
             (currentPath.config.Posit.Y -
             currentImage.Posit.Y) * sin(currentImage.theta));
}
```

Function: needToDecelerate()
Purpose: To determine whether the robot needs to begin decelerating. Such as in a bline function.
Parameters: double actualVelocity (linear)
Returns: It returns 1 if it needs to decelerate. Otherwise, it returns 0.
Comments:

```c
static int needsToDecelerate(double actualVelocity)
{
    double decelerate = 0.0;
    if (currentPath.pathType.class == BLINECLASS) {
        if (2.0 * getGoalLinAcc0 * restOfPath0 <= actualVelocity
            * actualVelocity)
            decelerate = 1;
    }
    return decelerate;
}
```

Function: transition()
Purpose: If the leaving point flag is true then read the next instruction
Parameters:
Returns: void
Comments:

```c
static void transition()
{
    switch(currentPath.pathType.mode) {
```
case STOPMODE:
    ProcessInstruction();
    break;

case PATHMODE:

Comments:  

void setSizeConstantlmmo(double SizeConstant);

Function: getSizeConstanto()  
Purpose: returns the current size constant being used in motion control  
Parameters: void  
Returns: double size constant  
Comments:  

double getSizeConstant(void);

Function: setTotalDistancelmm0()  
Purpose: sets the total distance travelled by the rc value passed as a parameter  
Parameters: double distance
void setTotalDistanceImm(double distance);

Function: updateTotalDistance()
Purpose: adds the value of the parameter to the running total distance
Parameters: double deltaDistance
Returns: void
Comments:

void updateTotalDistance(double deltaDistance);

Function: getTotalDistance()
Purpose: returns the total distance travelled by the robot
Parameters: void
Returns: double totalDistance
Comments:
double getTotalDistance(void);

Function: getTotalDistanceImm()
Purpose: returns the total distance travelled by the robot
Parameters: void
Returns: double totalDistance
Comments:
double getTotalDistanceImm(void);

Function: haltMotionImm()
Purpose: brings the robot to a rest. Is different from stop in that it’s original goal velocity is saved to be later used by the resume command to allow the robot to continue travelling at the same speed.
Parameters: void
Returns: void
Comments:
void haltMotionImm(void);

Function: resumeMotionImm()
Purpose: Allows the robot to resume the speed it was travelling before the haltMotionImm() command was given.
Parameters: void
Returns: void
Comments:
*******************************************************************************/

void resumeMotionImm(void);

1. USER.C

File Name: user.c
Description: This file contains a sample user program that can be used with
the new MML system created using ANSI C.

#include "definitions.h"
#include "iosys.h"
#include "stiosys.h"
#include "serial.h"
#include "motion.h"
#include "sonar.h"
#include "trace.h"
#include "geometry.h"
#include "time.h"
#include "seqcmd.h"
#include "system.h"
#include "immcmd.h"
#include "motionsupport.h"
#include "motionlog.h"

#define ESC 0x1b

/* Function: user() */
Purpose:
Parameters: void
Returns: void
Comments: This user program commands the robot to follow a star path. It follows the path offsetting where the robot "thinks" it at by using the setConfig() command.

void
user(void)
{
    int segments = 5;
    CONFIGURATION start, justGo, currentPosit, jump;

    start = defineConfig(0.0, 0.0, 0.0, 0.0);
    justGo = defineConfig(0.0, 0.1, 0.0, 0.0);
    jump = defineConfig(0.0, 45.0, -1.5*HPI, 0.0);

    printf("This is the set_config star program.");

        currentPosit = getRobotConfig();
        printf("in current x position is : %f", currentPosit.Posit.X);
        printf("in current y position is : %f
", currentPosit.Posit.Y);
    }
setRobotConfigImm(compose(&currentPosit,&jump));
) while(--segments);
APPENDIX B. GEOMETRIC FUNCTIONS

A. GEOMETRY.H

/******************************************************************************/
File Name: geometry.h
Description: This file contains the standard geometry functions that are called by several functions.
/******************************************************************************/
#ifndef __GEOMETRY_H
#define __GEOMETRY_H
#include "definitions.h"

/******************************************************************************/
Function: euDis()
Purpose: Computes the Euclidean distance between two given points
Parameters: double x1, y1, x2, y2
Returns: double
Comments:
******************************************************************************/
double euDis(double x1, double y1, double x2, double y2);

/******************************************************************************/
FUNCTION: norm()
PARAMETERS: double angle ---- the angle to normalize
PURPOSE: normalize the input angle between -PI and PI
RETURNS: double.the normalized angle in radians
COMMENTS: This is the most common normalizing function used in the system
******************************************************************************/
double norm(double angle);

/******************************************************************************/
FUNCTION: positiveNorm()
PARAMETERS: double angle ---- the angle to normalize
PURPOSE: normalize the input angle between 0 and 2PI
RETURNS: double.the normalized angle in radians
COMMENTS: None
******************************************************************************/
double positiveNorm(double angle);

/******************************************************************************/
FUNCTION: negativeNorm()
PARAMETERS: double angle ---- the angle to normalize
PURPOSE: normalize the input angle between -2PI and 0
RETURNS: double.the normalized angle in radians
COMMENTS: None
******************************************************************************/
double negativeNorm(double angle);
/*****************************************************************************/

FUNCTION: normPlover2()
PARAMETERS: double angle      ---- the angle to normalize
PURPOSE: normalize the input angle between -PI/2 and PI/2
RETURNS: double: the normalized angle in radians
COMMENTS: This was designed specifically for parabola calculations
*****************************************************************************/

double
normPlover2(double angle);

*****************************************************************************/

FUNCTION: signedDiffO
PARAMETERS: CONFIGURATIONS directerix
POINT focus
PURPOSE: to calculate the size distance between a point and a configuration.
RETURNS: double: the signed difference
COMMENTS:
*****************************************************************************/

double
signedDiff (CONFIGURATION config , POINT pt);

*****************************************************************************/

FUNCTION: defineConfigO
PARAMETERS: double x,y,theta,kappa      --The values that define a configuration
PURPOSE: To allocate nad assign a configuration
RETURNS: CONFIGURATION:a pointer to a configuration
COMMENTS: Was called def_configuration() in MML10
*****************************************************************************/

CONFIGURATION defineConfig(double x,double y,double theta,double kappa);

*****************************************************************************/

FUNCTION: defineParabolaO
PARAMETERS: double xf,yf      --defines the focus
double xd, yd, thetad      --defines the directrix
PURPOSE: To allocate assign a parabola
RETURNS: PARA:a pointer to a parabola type
COMMENTS: Was called def_parabola() in MML1u
*****************************************************************************/

PARA defineParabola(double xf,double yf, double xd, double yd, double td);

*****************************************************************************/

FUNCTION: reverseOrientationO
PARAMETERS: CONFIGURATION original      --the original configuration
PURPOSE: To reverse the orientation of a given configuration
RETURNS: CONFIGURATION: the reversed configuration
COMMENTS: Was called negate() in MML10
*****************************************************************************/

CONFIGURATION reverseOrientation(CONFIGURATION original);
FUNCTION: findSymConfig()
PARAMETERS: double a -- distance from either point to the intersection of both lines determined by the two configurations
double alpha -- The angular difference between both orientations
PURPOSE: This function finds the symmetric configuration of a configuration described by alpha and a above.
RETURNS: CONFIGURATION: sym_config -- the symmetric configuration
COMMENTS: Was called deflsym0 in MML10
One drawback to this function is that it is not possible to represent a symmetric configuration whose alpha is equal to Pi.
find_sym_config0() is used to cover these situations
*******************************************************************************/
CONFIGURATION findSymConfig(double a, double alpha);

FUNCTION: findSymConfig1()
PARAMETERS: double d -- distance from the origin (base configuration) to the symmetric configuration.
double alpha -- The angular difference between both orientations
PURPOSE: This finds the symmetric configuration of a configuration described by alpha and a above.
RETURNS: CONFIGURATION: sym_config -- the symmetric configuration
COMMENTS: Was called def_sym1() in MML10
This function overcomes the drawback of the original find_sym_config0() of not being able to handle the situation when alpha equals Pi
*******************************************************************************/
CONFIGURATION findSymConfig1(double d, double alpha);

FUNCTION: inverse()
PARAMETERS: CONFIGURATION *original -- the original configuration in global coordinates
PURPOSE: To calculate the inverse of a given configuration
RETURNS: CONFIGURATION: the inversed configuration such that;
original * inversed = Identity
COMMENTS: None
*******************************************************************************/
CONFIGURATION inverse(CONFIGURATION original);

FUNCTION: compose()
PARAMETERS: CONFIGURATION *first -- pointer to the first configuration
   *second -- pointer to the second configuration
   *third -- pointer to the third configuration
PURPOSE: To calculate the composition of the first and second configurations
RETURNS: CONFIGURATION: pointer to third configuration which is the composition of the first and second configurations
COMMENTS: A typical example of the usage of this function is to determine the goal position of a configuration in global coordinates. In such an example, the first argument would be the original configuration and the second argument would be the goal configuration in the original configuration's local coordinate system. The resultant third argument would then be the goal configuration in global coordinates. Was called comp() in MML10

CONFIGURATION compose(CONFIGURATION *first, CONFIGURATION *second):

FUNCTION: circularArc()
PARAMETERS: CONFIGURATION length -- the arc length
    alpha -- the end orientation
    config -- pointer to the resultant configuration
PURPOSE: Given the arc length and alpha, to calculate the final configuration
RETURNS: CONFIGURATION: pointer to the final configuration
COMMENTS: The main purpose of this function is to be used in conjunction with compose() to form a new next(). In this case, length would actually be delta-s and alpha would be delta-theta. CircularArc() would determine the configuration after the incremental move in the local coordinate system of the original configuration. Then compose() would take the original configuration (in global coordinates) and the incremental configuration (in local coordinates) to determine the incremental configuration in global coordinates.

CONFIGURATION circularArc(double length, double alpha);

#endif

B. GEOMETRY.C

/*---------------------------------------------
   File Name: geometry.c
   Description: This file contains the standard geometry functions that are called by several functions.
   ---------------------------------------------*/

87
/*#include "math68881.h"
#include "definitions.h"
#include "geometry.h"

Function: euDis()
Purpose: Computes the Euclidean distance between two given points
Parameters: double x1,y1,x2,y2
Returns: double
Comments:

double euDis(double x1, double y1, double x2, double y2)
    return sqrt((x1 - x2) * (x1 - x2) + (y1 - y2) * (y1 - y2));

FUNCTION: norm()
PARAMETERS: double angle ---- the angle to normalize
PURPOSE: normalize the input angle between -PI and PI
RETURNS: double the normalized angle in radians
COMMENTS: This is the most common normalizing function used in the system
          This performs that same as norm() and normalize() in MML10.

double norm(double angle)
    { while ((angle >= PI) || (angle < -PI))
        { if (angle >= PI)
            angle -= DPI;
          else
            angle += DPI;
        } return angle;
    }

FUNCTION: positiveNorm()
PARAMETERS: double angle ---- the angle to normalize
PURPOSE: normalize the input angle between 0 and 2PI
RETURNS: double the normalized angle in radians
COMMENTS: Same functionality as norm() in MML10

double positiveNorm(double angle)
    { while ((angle >= DPI) || (angle < 0))
        { }
if (angle >= DPI)
    angle -= DPI;
else
    angle += DPI;
return angle;

FUNCTION: negativeNorm()
PARAMETERS: double angle ---- the angle to normalize
PURPOSE: normalize the input angle between -2PI and 0
RETURNS: double: the normalized angle in radians
COMMENTS: Same functionality as nnorm() in MML10

double negativeNorm(double angle)
{
    while ((angle > 0) || (angle <= -DPI))
    {
        if (angle > 0)
            angle -= DPI;
        else
            angle += DPI;
    }
    return angle;
}

FUNCTION: normPlover2()
PARAMETERS: double angle ---- the angle to normalize
PURPOSE: normalize the input angle between -PI/2 and PI/2
RETURNS: double: the normalized angle in radians
COMMENTS: This was designed specifically for parabola calculations

double normPlover2(double angle)
{
    while ((angle > PI/2) || (angle <= -PI/2))
    {
        if (angle > PI/2)
            angle -= PI;
        else
            angle += PI;
    }
    return angle;
}

FUNCTION: signedDiff()
PARAMETERS: CONFIGURATIONS directerix
            POINT focus
PURPOSE: to calculate the size distance between a point and a configuration.
RETURNS: double: the signed difference
COMMENTS:

double signedDiff(CONFIGURATION config, POINT pt)
{
    return -(pt.X - config.Posit.X) * sin(config.Theta) +
}

FUNCTION: defineConfig()
PARAMETERS: double x,y,theta,kappa -- The values that define a configuration
PURPOSE: To allocate and assign a configuration
RETURNS: CONFIGURATION: a configuration
COMMENTS: Was called def_configuration() in MML10

CONFIGURATION defineConfig(double x,double y,double theta,double kappa)
{
    CONFIGURATION newConfig;

    newConfig.Posit.X = x;
    newConfig.Posit.Y = y;
    newConfig.Theta = theta;
    newConfig.Kappa = kappa;
    return newConfig;
}

FUNCTION: defineParabola()
PARAMETERS: double xf,yf -- defines the focus
double xd, yd, thetad -- defines the directrix
PURPOSE: To allocate assign a parabola
RETURNS: PARA: a parabola type
COMMENTS: Was called def_parabola() in MML10

PARA defineParabola(double xf,double yf, double xd, double yd, double td)
{
    PARA newPara;

    newPara.Focus.X = xf;
    newPara.Focus.Y = yf;
    newPara.Directrix.Posit.X = xd;
    newPara.Directrix.Posit.Y = yd;
newPara.Directrix.Theta = td;
newPara.Directrix.Kappa = 0.0.
return newPara;
}

FUNCTION reverseOrientation()
PARAMETERS CONFIGURATION original -- the original configuration
orientation changed by 180 degrees
PURPOSE To reverse the orientation of a given configuration
RETURNS CONFIGURATION the reversed configuration
COMMENTS Was called negate() in MML10

CONFIGURATION reverseOrientation(CONFIGURATION original)
|
CONFIGURATION reversed.

reversed.Posit X = original.Posit X;
reversed.Posit Y = original.Posit Y;
reversed.Theta = norm(original.Theta + PI);
return reversed;

FUNCTION: findSymConfig()
PARAMETERS: double a -- distance from either point to the intersection of
both lines determined by the two configurations
double alpha -- The angular difference between both orientations
PURPOSE: This function finds the symmetric configuration of a configuration
described by alpha and a above.
RETURNS: CONFIGURATION: symConfig --the symmetric configuration
COMMENTS: Was called def sym() in MML10
One drawback to this function is that it is not possible to
represent a symmetric configuration whose alpha is equal to PI.
find_symConfig1() is used to cover these situations

CONFIGURATION
findSymConfig(double a, double alpha)
{
 return defineConfig(a * (1. + cos(alpha)), a * sin(alpha), alpha, 0.0);
}

FUNCTION: findSymConfig1()
PARAMETERS: double d -- distance from the origin (base configuration) to
the symmetric configuration.
double alpha -- The angular difference between both orientations
PURPOSE: This finds the symmetric configuration of a configuration
described by alpha and a above

RETURNS: CONFIGURATION sym_config -- the symmetric configuration

COMMENTS: Was called det_sym1() in MML10

This function overcomes the drawback of the original
find_sym_config() of not being able to handle the situation when
alpha equals PI

====================================================================

CONFIGURATION

findSymConfig1(double d, double alpha)
{
    double beta = alpha 2

    return defineConfig(d * cos(beta), d * sin(beta), alpha, 0.0);
}

====================================================================

FUNCTION inverse()  
PARAMETERS CONFIGURATION original -- the original configuration
in global coordinates

PURPOSE: To calculate the inverse of a given configuration

RETURNS: CONFIGURATION the inversed configuration
such that:
original * inversed = Identity

COMMENTS: None

====================================================================

CONFIGURATION

inverse(CONFIGURATION original)
{
    CONFIGURATION inversed;

    inversed.Posit.X = original.Posit.X * cos(original.Theta) - original.Posit.Y * sin(original.Theta);

    inversed.Posit.Y = original.Posit.X * sin(original.Theta) - original.Posit.Y * cos(original.Theta);

    inversed.Theta = -original.Theta;
    inversed.Kappa = -original.Kappa;

    return inversed;
}

====================================================================

FUNCTION: compose()  
PARAMETERS: CONFIGURATION *first -- pointer to the first configuration  
*second -- pointer to the second configuration

PURPOSE: To calculate the composition of the first and second configurations
RETURNS CONFIGURATION: configuration which is the composition of the first and second configurations

COMMENTS: A typical example of the usage of this function is to determine the goal position of a configuration in global coordinates. In such an example, the first argument would be the original configuration and the second argument would be the goal configuration in the original configuration's local coordinate system. The resultant third argument would then be the goal configuration in global coordinates. Was called comp() in MM1.

CONFIGURATION compose(CONFIGURATION * first, CONFIGURATION * second)

CONFIGURATION third
  double x, y, theta,
  double xx, yy, tt

  x = second->Posit.X;
  y = second->Posit.Y;
  theta = first->Theta;

  xx = cos(theta) * x + sin(theta) * y + first->Posit.X;
  yy = sin(theta) * x + cos(theta) * y + first->Posit.Y;
  tt = norm(first->Theta + second->Theta);

  third.Posit.X = xx;
  third.Posit.Y = yy;
  third Theta = tt;

  return third;

FUNCTION: circularArc()
PARAMETERS: CONFIGURATION length -- the arc length
            -- the end orientation
            config -- pointer to the resultant configuration
PURPOSE: Given the arc length and alpha, to calculate the final configuration
RETURNS: CONFIGURATION: pointer to the final configuration
COMMENTS: The main purpose of this function is to be used in conjunction with compose() to form a new next(). In this case, length would actually be delta-s and alpha would be delta-theta. Circular_arc() would determine the configuration after the incremental move in the local coordinate system of the original configuration. Then compose() would take the original configuration (in global coordinates) and the incremental configuration (in local coordinates) to determine the incremental configuration in global coordinates.
CONFIGURATION

circularArc(double length, double alpha)
{
    return defineConfig((1 - (alpha * alpha)/6) * length,
        (0.5 - (alpha * alpha)/24) * alpha * length,
        alpha, 0.0);
}
