Preface

This manual documents the two-dimensional, laterally averaged, hydrodynamic and water quality model CE-QUAL-W2. This manual was prepared in the Environmental Laboratory (EL), U.S. Army Engineer Waterways Experiment Station (WES), Vicksburg, MS. Funding for Version 2.0 of the manual was provided by Headquarters, U.S. Army Corps of Engineers (HQUSACE), under the Numerical Model Maintenance Program.

The Principal Investigator for Version 2.0 of CE-QUAL-W2 and the User Manual was Mr. Thomas M. Cole of the Water Quality and Contaminant Modeling Branch (WQCMB), Environmental Processes and Effects Division (EPED), EL. This report was prepared by Mr. Cole and Mr. Edward M. Buchak, J. E. Edinger Associates, Inc., Wayne, PA, under the direct supervision of Dr. Mark S. Dortch, Chief, WQCMB, and under the general supervision of Mr. Donald L. Robey, Chief, EPED, and Dr. John W. Keeley, Director, EL. Technical reviews by Dr. Dortch, Dr. Billy Johnson, and Mr. Ross Hall are gratefully acknowledged.

At the time of publication of this manual, Director of WES was Dr. Robert W. Whalin. Commander of WES was COL Bruce K. Howard, EN.

This report should be cited as follows:

The contents of this report are not to be used for advertising, publication, or promotional purposes. Citation of trade names does not constitute an official endorsement or approval of the use of such commercial products.
Model Package

All files on the CE-QUAL-W2 distribution disk are archived in self-extracting files. To install CE-QUAL-W2 from the distribution disk to a hard disk, copy over the compressed file "W2.EXE" on a PC’s hard disk. To decompress the files, enter "W2" at the DOS prompt. The "read_me.1st" file contains an explanation of the subdirectory structure and files which will be setup on the PC.

Several example applications are included in the subdirectory “EXAMPLES”. The Degrage application is a reservoir with a single branch and a complete water quality application. The J. Strom Thurmond (JST) application modeled 10km of JST reservoir below Richard B. Russell Dam on the Savannah River between Georgia and South Carolina. A downstream boundary head was applied since the entire reservoir was not modeled. Three branches were included and withdrawals were used to simulate pump-storage. Only DO and temperature were modeled. DO was treated as conservative except for atmospheric reaeration since the modeling period was only 2 days.

The Raritan river application modeled an east coast estuary for temperature, salinity, velocities, and water surface elevations. The Cheatham Reservoir application modeled a stretch of the Cumberland River near Nashville, TN for water quality and included the effects of BOD loadings on dissolved oxygen.

Programs

The following FORTRAN files are located in the SOURCE subdirectory:

- W2.FOR - CE-QUAL-W2 generic version
- W2_LAH.FOR - CE-QUAL-W2 Lahey FORTRAN version
- W2_FTN.FOR - CE-QUAL-W2 FTN77 FORTRAN version
- W2_UNIX.FOR - CE-QUAL-W2 unix workstation version
- PRE.FOR - Generic preprocessor
- PRE_LAH.FOR - Lahey FORTRAN preprocessor
- PRE_OTG.FOR - FTN77 FORTRAN preprocessor
- W2.INC - Include file containing the user modifiable code necessary to set up the model for a particular application
Input Files

The following input files come with each application:

- **W2_CON.NPT** - Control file for each application
- **BTH.NPT** - Bathymetry file
- **MET.NPT** - Meteorological file

A subset of the following input files comes with each application:

- **QIN_BR1.NPT** - Inflows
- **TIN_BR1.NPT** - Inflow temperatures
- **CIN_BR1.NPT** - Inflow constituent concentrations
- **QTR_TR1.NPT** - Tributary inflows
- **TTR_TR1.NPT** - Tributary inflow temperatures
- **CTR_TR1.NPT** - Tributary inflow constituent concentrations
- **EUH_BR1.NPT** - Upstream head elevations
- **TUH_BR1.NPT** - Upstream head boundary temperatures
- **CUH_BR1.NPT** - Upstream head boundary constituent concentrations
- **EDH_BR1.NPT** - Downstream head elevations
- **TDH_BR1.NPT** - Downstream head boundary temperatures
- **CDH_BR1.NPT** - Downstream head boundary constituent concentrations
- **QOT_BR1.NPT** - Outflows
- **QWD_BR1.NPT** - Withdrawals
- **VPR.NPT** - Vertical profile at dam for specifying initial conditions
- **LPR.NPT** - Longitudinal and vertical profiles specifying initial conditions for each cell

If more than one branch or tributary is modeled, then corresponding files using "BR2", "BR3", etc. (or "TR2", "TR3", etc.) in the filename will also be included.

Output Files

The following output files come with each application:

- **SNP.SAV** - Snapshot output file in ASCII with interpretation of FORTRAN carriage control characters
- **PRE.SAV** - Preprocessor output file

The snapshot files are from a short run of the application. Use these files to ensure you obtain the same answers. These files are setup to be printed on a LaserJet IV compatible printer. The FORTRAN compiler used to make these test runs was Lahey F77L3-EM/32 V5.10.
Computer Requirements

Hardware. The minimum configuration is an 80386 PC equipped with a math coprocessor. A minimum of four megabytes of memory is needed unless the user has an operating system or extender that uses virtual memory. A hard disk with a minimum available space of 25 Mb is also required.

Software. For an 80386 or greater PC operating under DOS, the user must have a 32 bit FORTRAN compiler with a DOS extender that will allow the model to utilize protected mode. The model has been tested on the following 32-bit PC compilers:

1. Lahey
2. FTN77
3. Microsoft PowerStation

If the user has either a Unix, OS/2, or Windows NT operating system, then a FORTRAN compiler that is compatible with the operating system is required. These operating systems remove the 640K memory limit and thus do not require an extender. The model has also been tested on Silicon Graphics, DEC Alpha, and Hewlett-Packard workstations, VAX minicomputers, and Cray supercomputers.
1 Introduction

Model Overview

CE-QUAL-W2 is a two-dimensional, longitudinal/vertical, hydrodynamic and water quality model. Because the model assumes lateral homogeneity, it is best suited for relatively long and narrow waterbodies exhibiting longitudinal and vertical water quality gradients. The model has been applied to rivers, lakes, reservoirs, and estuaries.

The application of CE-QUAL-W2 requires knowledge in the following areas:

1. Hydrodynamics
2. Aquatic biology
3. Aquatic chemistry
4. Numerical methods
5. Computers and FORTRAN coding
6. Statistics
7. Data assembly and reconstruction

Water quality modeling is in many ways an art requiring not only knowledge in these areas but experience in their integration. A word of caution to the first time user - model application is a complicated and time consuming task.

Model Background

Version 1.0. CE-QUAL-W2 has been under continuous development since 1975. The original model was known as LARM (Laterally Averaged Reservoir Model) developed by Edinger and Buchak (1975). The first LARM application was on a reservoir with no branches. Subsequent modifications to allow for multiple branches and estuarine boundary conditions resulted in the code known as GLVHT (Generalized Longitudinal-Vertical Hydrodynamics and Transport Model). Addition of the water quality algorithms by the Water Quality Modeling Group at the US Army Engineer Waterways Experiment Station (WES) resulted in CE-QUAL-W2 Version 1.0 (Environmental and Hydraulic Laboratories, 1986).

Version 2.0. Version 2.0 is a result of major modifications to the code to improve the mathematical description of the prototype and increase computa-
tional accuracy and efficiency. Numerous new capabilities have been included in Version 2.0. These are:

a. an algorithm that calculates the maximum allowable timestep and adjusts the timestep to ensure hydrodynamic stability requirements are not violated (autostepping)
b. a selective withdrawal algorithm that calculates a withdrawal zone based on outflow, outlet geometry, and upstream density gradients
c. a higher-order transport scheme (QUICKEST) that reduces numerical diffusion (Leonard, 1979)
d. time-weighted vertical advection and fully implicit vertical diffusion
e. step function or linear interpolation of inputs
f. improved ice-cover algorithm
g. internal calculation of equilibrium temperatures and coefficients of surface heat exchange or a term-by-term accounting of surface heat exchange
h. variable layer heights and segment lengths
i. surface layer extending through multiple layers
j. generalized time-varying data input subroutine with input data accepted at any frequency
k. volume and mass balances to machine accuracy
l. sediment/water heat exchange

Considerable effort has also been made to make the model easier to use. The input and output data have been reformatted and the user manual has been rewritten with this goal in mind.

Manual

Organization. The manual has been rewritten so the first time user is not initially hampered with the model’s burdensome details. It is intended to familiarize the user to the overall steps necessary in applying the model. It is organized into three chapters and four appendices. Chapter 1 consists of an introduction to the model and the user manual. Chapter 2 describes the model’s major capabilities and limitations. Chapter 3 provides an overview of the steps involved in applying the model including data preparation and model application.

The appendices provide the user with the information necessary to understand the model details. Appendix A describes the theoretical, numerical, and computational basis for the hydrodynamic portion of the model. Appendix B describes the theoretical and computational basis for the water quality portion of
INTRODUCTION

the model. Appendix C describes the preparation of input files. Appendix D describes the algorithms used in the code. References include a partial bibliography of CE-QUAL-W2 applications. An index is also included.

A major goal in rewriting the user manual was to allow easy access to the tremendous amount of information in the manual. The following concepts have been used to accomplish this goal:

1. Page headers are used to allow the user to easily find major areas in the manual.
2. Where applicable, paragraphs contain descriptive headings for easy reference.
3. Page references are used when related information is contained elsewhere.
4. An index is located at the end of the manual.

Conventions. References to FORTRAN variables in the manual are made in English and are followed by their FORTRAN name enclosed by brackets (eg., surface layer [KT]). The user need not first memorize the variable names to comprehend the manual. Potential problem areas in applying the model are emphasized with **bold italic** type.
2 Capabilities and Limitations

Capabilities

Hydrodynamic. The model predicts water surface elevations, velocities, and temperatures. Temperature is included in the hydrodynamic calculations because of its effect on water density.

Water quality. The water quality algorithms incorporate 21 constituents in addition to temperature including nutrient/phytoplankton/dissolved oxygen (DO) interactions during anoxic conditions. Any combination of constituents can be simulated. The effects of salinity or total dissolved solids/salinity on density and thus hydrodynamics are included only if they are simulated in the water quality module. The water quality algorithm is modular allowing constituents to be easily added as additional subroutines.

Long term simulations. The water surface elevation is solved implicitly which eliminates the surface gravity wave restriction on the timestep. This permits larger timesteps during a simulation resulting in decreased computational time. As a result, the model can easily simulate longterm water quality responses. Version 3.0 will eliminate the diffusion criteria from stability requirements allowing for even larger timesteps.

Head boundary conditions. The model can be applied to estuaries, rivers, or portions of a waterbody by specifying upstream or downstream head boundary conditions.

Multiple branches. The branching algorithm allows application to geometrically complex waterbodies such as dendritic reservoirs or estuaries.

Variable grid spacing. Variable segment lengths and layer thicknesses can be used allowing specification of higher resolution where needed.

Water quality independent of hydrodynamics. Water quality can be updated less frequently than hydrodynamics thus reducing computational requirements. However, water quality kinetics are not decoupled from the hydrodynamics (i.e., separate, standalone code for hydrodynamics and water quality where output from the hydrodynamic model is stored on disk and then used to specify advective fluxes for the water quality computations). Storage requirements for long-
term hydrodynamic output to drive the water quality model are prohibitive for anything except very small grids. Additionally, reduction in computer time is minimal when hydrodynamic data used to drive water quality are input every timestep.

**Autostepping.** The model includes a variable timestep algorithm ensuring numerical stability requirements for the hydrodynamics imposed by the solution scheme are not violated.

**Restart provision.** The user can output results during a simulation that can subsequently be used as input. Execution can then be resumed at that point.

**Layer/segment addition and subtraction.** The model will adjust surface layer and upstream segment locations for a rising or falling water surface during a simulation.

**Multiple inflows and outflows.** Provisions are made for inflows and inflow loadings from point/nonpoint sources, branches, and precipitation. Outflows are either specified as releases at a branch’s downstream segment or as lateral withdrawals. Although evaporation is not considered an outflow in the strictest sense, it can be included in the water budget.

**Ice cover calculations.** The model can calculate onset, growth, and breakup of ice cover.

**Selective withdrawal calculations.** The model can calculate the vertical extent of the withdrawal zone based on outlet geometry, outflow, and density.

**Time-varying boundary conditions.** The model accepts a given set of time-varying inputs at the frequency they occur independent of other sets of time-varying inputs.

**Outputs.** The model allows the user considerable flexibility in the type and frequency of outputs. Output is available for the screen, hard copy, plotting, and restarts. The user can specify what is output, when during the simulation output is to begin, and the output frequency. The present version requires the user to develop output plotting/visualization capabilities. Version 3.0 will include X-Windows based pre- and postprocessors for plotting/visualization.

Details of these capabilities are discussed in Appendix C.
Limitations

Theoretical

Hydrodynamics and transport. The governing equations are laterally and layer averaged. Lateral averaging assumes lateral variations in velocities, temperatures, and constituents are negligible. This assumption may be inappropriate for large waterbodies exhibiting significant lateral variations in water quality. Whether this assumption is met is often a judgement call on the user and depends in large part on the questions being addressed.

Eddy coefficients are used to model turbulence. The equations are written in the conservative form using the Boussinesq and hydrostatic approximations. Since vertical momentum is not included, the model may give inaccurate results where there is significant vertical acceleration.

Water quality. Water quality interactions are by necessity simplified descriptions of an aquatic ecosystem that is extremely complex. This is one area in which improvements will be made in the future as better means of describing the aquatic ecosystem in mathematical terms and time for incorporating the changes into the model become available. Many of these limitations will be addressed in Version 3.0. The following list describes the major assumptions in the water quality algorithms.

a. One algal compartment. The model includes only one algal compartment and thus cannot model algal succession. In particular, temperature dependency for different algal groups and nitrogen fixation for blue-greens is not modeled. Additional algal groups (diatoms, greens, and blue-greens) will be added in Version 3.0.

b. No zooplankton. The model does not explicitly include zooplankton and their effects on algae or recycling of nutrients.

c. No macrophytes. The model does not include the effects of macrophytes on water quality. In many cases, this is a good assumption.

d. Simplistic sediment oxygen demand. The model does not have a sediment compartment that models kinetics in the sediment and at the sediment-water interface. This places a limitation on long-term predictive capabilities of the water quality portion of the model. If sediments are modeled, then the model is more predictive; however, sediment oxygen demand is still modeled in a simplistic manner. A fully predictive
CAPABILITIES AND LIMITATIONS

sediment model that includes carbon diagenesis will be includ-
ed in Version 3.0.

Numerical

Solution scheme. The model provides two different numerical transport
schemes for temperature and constituents - upwind differencing and the higher-
order QUICKEST (Leonard, 1979). Upwind differencing introduces numerical
diffusion often greater than physical diffusion. The QUICKEST scheme reduc-
es numerical diffusion, but in areas of high gradients generates overshoots and
undershoots which may produce small negative concentrations. An option to
eliminate overshoots and undershoots will be included in Version 3.0. In
addition, discretization errors are introduced as the finite difference cell dimen-
sions or the timestep increase. This is an important point to keep in mind when
evaluating model predictions that are spatially and temporally averaged versus
observed data collected at discrete points in time and space. A more thorough
discussion of the numerical solution and its implementation is found in Appen-
dix A, beginning at page A14 and Appendix D, beginning at page D19.

Computer limits. A considerable effort has been invested in increasing model
efficiency. However, the model still places computational and storage burdens
on a computer when making long term simulations. In Version 2.0, most of
the computations are now performed using single precision (32 bits) but double
precision is still needed for some computations. A computer having a minimum
of 32 bits of accuracy for single precision arithmetic must be used. Year long
water quality simulations now typically take from one to three hours of CPU
time on a 66Mhz 80486 PC.

Input Data

The availability of input data is not a limitation of the model itself. However,
it is most often the limiting factor in the application or misapplication of the
model. This cannot be stressed enough. The user should always keep in mind
the adage "garbage in equals garbage out".
3 Model Application

This chapter is intended to present the user with a general overview of the steps involved in a model application. The initial user should read the chapter once to gain a general understanding of these steps setting aside questions which may arise upon initial reading. The user should then reread the chapter turning to the additional page references to clarify any questions which arose during the first reading. Filenames are referred to generically (i.e., inflow file, outflow file, withdrawal file). Actual filenames are specified by the user in the control file (see pages C107-C137).

Data Preparation

The following data are needed for model application:

a. geometric data  
b. initial conditions  
c. boundary conditions  
d. hydraulic parameters  
e. kinetic parameters  
f. calibration data

A detailed discussion of these data follows.

Geometric Data

The first input task involves assembling geometric data. These data will be used to define the finite difference representation of the waterbody. The following data are needed for setting up input geometry:

a. topographic map and/or sediment range surveys  
b. project volume-area-elevation table

The topographic map or sediment range surveys are used to generate bathymetric cross-sections that are input into the model. The project volume-area-elevation table is used for comparison with the volume-area-elevation table generated by the model.
Computational grid. The computational grid is the term used for the finite difference representation of the waterbody. Grid geometry is determined by three parameters:

a. longitudinal spacing  
   b. vertical spacing  
   c. average cross-sectional width

The longitudinal and vertical spacing may vary from segment to segment and layer to layer but should vary gradually from one segment or layer to the next to minimize discretization errors.

Factors affecting computational grid. A number of factors must be evaluated and weighed against each other when determining longitudinal and vertical spacing. These include:

a. Areas of strongest gradients. This factor applies particularly to the metalimnion in freshwater and the pycnocline in saltwater. If the model is not capturing water quality gradients in these regions, then vertical resolution may have to be increased. Similar reasoning applies to areas of longitudinal gradients.

b. Computational and memory requirements. The model penalizes the user in two ways when increasing grid resolution. As the number of grid cells goes up, so do computational and memory requirements. In addition, as the dimensions of a grid cell decrease, the timestep must also decrease to maintain numerical stability. As a rule of thumb, it is always desirable to err on the side of greater grid resolution, but at some point the user must give way to the reality of the available computer resources and the money and time available for completing the project.

c. Bottom slope. The waterbody bottom slope is more accurately modeled as the ratio of cell thickness to cell length [H]/[DLX] approaches the overall bottom slope.

Previous applications have used a horizontal grid spacing of 100 to 5,000 m and a vertical grid spacing of 0.2 to 5 m.

Bathymetric data. The next step after determining horizontal and vertical cell dimensions is to determine average cross-sectional widths for each cell. This is an iterative procedure whereby initial bathymetry is input into the preprocessor and the volume-area-elevation table is then generated by the preprocessor.
DATA PREPARATION

table is compared to the project table and widths are adjusted to better match the project table.

Several methods have been used for determining average widths. GEDA (Hydrologic Engineering Center, 1981) is a computer program that uses as input cross-sectional data taken at varying longitudinal distances and outputs widths as a function of elevation. The output can then be used to produce bathymetric data for input into CE-QUAL-W2.

Alternatively, transects along the waterbody centerline can be drawn on a topographic map. A contour at the elevation corresponding to the center of a grid cell is located and the area encompassed by the contour line and the upstream and downstream transect is determined by planimeter. This area divided by the segment length is the average width of the grid cell. The process is repeated for each grid cell.

When no topographic information is available, the user can determine average widths from sediment range surveys for existing waterbodies. However, this method is generally not as accurate as data obtained from topographic maps since the number of available transects are usually insufficient to adequately describe the complex shape of most waterbodies. If available, sediment range surveys should be used to refine the grid generated from topographic information - particularly where significant sedimentation has occurred.

Sample computational grid. A sample computational grid in the longitudinal/vertical plane with three branches is shown in Figure 1. The FORTRAN variables associated with the grid are also included. The grid consists of 20 longitudinal segments [IMP] and 22 vertical layers [KMP]. They constitute the total number of cells in the computational grid. This is exactly how the model sees the grid layout even though this is not the correct physical representation of the system. In reality, branch two and branch three join branch one. Branch setup is described in more detail below.

Grid cell types. Figure 1 contains two kinds of cells - ones with either a single or a double line border. Cells with a single line border represent cells that may contain water during the simulation. The active cells are defined in the bathymetry input as having non-zero widths. Cells with a double border represent boundary cells located at or beyond the waterbody boundaries. The boundary cells are defined in the bathymetry input as having zero widths.

Boundary cells. There are four types of boundary cells:

a. top
b. bottom
c. upstream
d. downstream
Figure 1. Schematic of three branch CE-QUAL-W2 grid.

Each segment must have a zero width for the cell in layer 1 and a zero width for every cell located below the bottom active cell. For example, cells 1 and 12-22 in segment five would have zero widths. In addition, each branch must have zero widths for upstream boundary and downstream boundary segments. Note this requirement results in two segments of boundary cells between each branch (segments 10-11 & 16-17).

Branches. CE-QUAL-W2 can simulate a waterbody with any number of branches. Figure 2 shows a plan view of the same three branch grid of Figure 1 along with the FORTRAN variables defining the geometry for each branch. For each branch, the upstream segment [US] and the downstream segment [DS] must be defined. The current upstream segment [CUS] is calculated by the model and may vary over time to meet restrictions imposed by the solution scheme (see a under Grid Restrictions).

A branch may connect to other branches at its upstream [UHS] or downstream segment [DHS]. In Figure 2, the downstream segment of branch 2 ([DS]=15) connects to branch 1 at segment 3 ([DHS]=3).
Figure 2. Planar view of CE-QUAL-W2 sample grid.

Grid restrictions. The grid must satisfy the following restrictions:

a. It must be at least two active cells deep at every segment. The model ensures this criterion is met during a simulation by adding or subtracting segments.

b. Cell widths cannot increase with depth.

c. A branch may connect to other branches at its upstream or downstream segment, but a branch may not enter or leave itself.

d. Two branches may not connect at the same segment of another branch.

The bathymetry input file contains the longitudinal grid spacing [DLX], initial water surface elevation [Z], segment orientations [PHI0], vertical grid spacing [H], and average cell widths [B] (see page C146).
After the bathymetry is generated, it should be checked to ensure the bottom elevation varies smoothly and represents the average slope over appropriate portions of the waterbody. Oftentimes, minimum bottom widths are set at from 10-30m. This helps increase timesteps with minimal impact on the volume-area-elevation curves. However, increasing widths in the bottom layers can affect water quality since sediment oxygen demand and nutrient fluxes are dependent on bottom surface areas. Refer to the bathymetry files and preprocessor output in the sample applications for additional guidance in setting up the bathymetry.

**Initial Conditions**

Initial conditions are specified in the control, bathymetry, and vertical and/or longitudinal profile input files. The control file specifies the following initial conditions:

a. **Time.** Starting [TMSTRT] and ending time [TMEND] of the simulation (see page C3).

b. **Temperatures and concentrations.** The initial temperature [IT2] (see page C11) and constituent concentrations [IC2] (see page C73). If the grid is not initialized to a single value, then a grid-wide vertical profile can be specified in the vertical profile input file [VPRFN]. The option is also available to specify a longitudinally and vertically varying initial concentration for temperature and constituents via the longitudinal profile file [LPRFN].

c. **Inflows/outflows.** The number and location of inflows and outflows (see pages C24-C34).

d. **Restart.** If a previous run with the model was made specifying restart conditions were to be written [RSOC] to an output file, then the user can specify the model read the file [RSIC] and continue the simulation from that point (see pages C66-C68).

e. **Waterbody type.** The waterbody can be specified as either saltwater or freshwater [WTYPE] (see page C11).

f. **Ice thickness.** The initial ice thickness [IICETH] (see page C11).
DATA PREPARATION

BOUNDARY CONDITIONS

Boundary Conditions

Inflows. The model recognizes the following inflows:

a. **Upstream inflows** (optional). Upstream inflows occur only at a branch's current upstream segment [CUS] which may vary during a simulation. The model provides the option to distribute inflows evenly throughout the inflow segment or place inflows according to density [PQC] (see page C12). If the upstream inflow option is used, then a separate file for inflow [QIN], a separate file for temperature [TIN], and, if constituents are modeled, a separate file containing constituent concentrations [CIN] for each branch is required (see page C152).

b. **Tributary inflows** (optional). Tributary inflows or point source loadings [QTRIB] may enter any segment of the computational grid. If the current upstream segment [CUS] number is greater than the segment the tributary enters, then the tributary inflows are added into the current upstream segment to maintain the waterbody water balance. As in upstream inflows, the model provides the option to distribute tributary inflows evenly throughout the inflow segment or place inflows according to their density [PQTR] (see page C12). The number of tributaries [NTRIB] and their segment location [ITRIB] are specified in the control file (see pages C35-C37). If this option is used, then file requirements for each tributary are the same as for upstream inflows (see pages C155-C157).

c. **Distributed tributary inflows** (optional). Distributed tributary inflows or nonpoint source loadings [DTRC] may be specified for any branch. The flow is distributed throughout a branch weighted by segment surface areas. If this option is used, then file requirements for each distributed tributary are the same as for upstream inflows (see pages C158-C160).

d. **Precipitation** (optional). Precipitation [PRC] can be specified for each branch and is distributed according to the segment surface areas (see page C12). If this option is used, then file requirements for each branch are the same as for upstream inflows (see pages C161-C163).
Outflows. The model recognizes the following outflows:

a. **Downstream outflows** (optional). Downstream outflows [QOUT] occur only at the downstream segment [DS] of a branch. There are two options for specifying downstream outflows. The first is the selective withdrawal option [SWC] where the vertical extent of and flow distribution in the withdrawal zone is calculated by the model (see pages C24-C29). The second allows the user to specify outlet layers where outflow occurs. The number of outlets [NOUT] for each branch and the layer location [KOUT] for each outlet are specified in the control file (see pages C30-C31). For both options, no outflow is allowed to occur if the outlet location is above the current water surface layer [KT]. **If** this option is used, then a separate file for each branch is required (see page C153).

b. **Lateral withdrawals** (optional). Lateral withdrawals [QWD] may be specified for any active cell. The number of withdrawals [NWD], their segment location [IWD], and their layer location [KWD] must be specified in the control file (see pages C32-C34). **If** this option is used, a separate file for each withdrawal is required (see page C154). Version 3.0 will compute selective withdrawal for lateral withdrawals.

c. **Evaporation** (optional). Evaporation is calculated by the model from air [TAIR] and dewpoint [TDEW] temperature and wind speed [WIND]. If a waterbody loses a significant amount of water from evaporation which is not accounted for in the inflows, then the user should include evaporation. Evaporative heat loss is **always** included in the heat budget.

**Head Boundary Conditions** (optional). The model recognizes the following head boundary conditions:

a. **External**. The user may specify an external upstream and/or downstream head boundary condition for each branch (see page C8). This boundary specification is intended primarily for estuarine simulations although it has also been used for river and reservoir applications. **If** this option is used, a separate file for time-varying elevations, [EUH] and/or [EDH], a separate file for vertical temperature profiles, [TUH] and/or [TDH], and, if constituents are modeled, a separate file containing vertical profiles for each constituent modeled, [CUH]
and/or [CDH], **must** be specified for each external head boundary condition (see pages C164-C167).

b. **Internal.** Internal head boundary conditions are specified wherever one branch connects with another branch (see page C8). The boundary surface elevation, temperatures, and constituent concentrations are calculated internally by the model.

**Surface Boundary Conditions (required).** The model requires the following surface boundary conditions:

a. **Surface heat exchange.** Surface heat exchange is calculated by either of two methods using the input variable [HEATC] in the control file (see page A21, C17). The first method uses equilibrium temperatures [ET] and coefficients of surface heat exchange [CSHE] to calculate surface heat exchange (Brady and Edinger, 1975). The second method uses a term-by-term accounting for calculating surface heat exchange. For both methods, latitude [LAT] and longitude [LONG] are specified in the control file (see page C10) and values for air temperature [TAIR], dew point temperature [TDEW], wind speed [WIND] and direction [PHI], and cloud cover [CLOUD] **must** be included in the meteorologic file (see page C149).

b. **Solar radiation absorption.** Distribution of solar radiation in the water column is controlled by the fraction of solar radiation absorbed in the surface layer [BETA] and the attenuation rate due to water [EXH2O], inorganic suspended solids [EXINOR], and organic suspended solids [EXORG]. Values for [EXINOR] and [EXORG] affect solar radiation only if constituents are modeled. These values are specified in the control file (see page C79).

c. **Wind stress.** Wind speed [WIND] and direction [PHI] must be supplied in the meteorologic file [METFN]. Wind stress is an extremely important physical process and should be included in all applications. The model allows the user to specify a wind sheltering coefficient [WSC] which, when multiplied with the wind speed, reduces effects of the wind. The sheltering coefficient is specified in the control file (see pages C20-C22).

d. **Gas exchange.** The wind speed [WIND] supplied in the meteorologic file is also used for computing gas exchange at the water surface if dissolved oxygen and/or total inorganic carbon are simulated (see page C149). Gas exchange is also affected by the wind sheltering coefficient [WSC].
DATA PREPARATION

Temperature transport cannot be turned off in the model. Temperature can be treated conservatively by turning off heat exchange computations [HEATC] (see page C16).

HYDRAULIC PARAMETERS (REQUIRED)

Dispersion coefficients. The horizontal dispersion coefficients for momentum [AX] and temperature/constituents [DX] are specified in the control file. They are presently time and space invariant. Sensitivity analyses on numerous applications have shown the model is insensitive to variations in the default values. The vertical dispersion coefficients for momentum [AZ] and temperature/constituents [DZ] vary in space and time and are computed by the model.

Chezy coefficient. The Chezy coefficient [CHEZY] is specified in the control file. It is used in calculating boundary friction which varies spatially as a function of exposed bottom area and temporally as a function of the flow field (see page C23). The model does not presently allow for spatially varying Chezy coefficients although Version 3.0 will include this capability.

KINETIC PARAMETERS (OPTIONAL)

There are approximately 60 coefficients affecting constituent kinetics. The values are specified in the control file. If simulations include water quality, then the user should see Appendix C (pages C79-C106) for a detailed discussion of these coefficients.

CALIBRATION DATA (REQUIRED)

Calibration data are used to provide boundary conditions and assess model performance during calibration. A great deal of thought should go into assessing the amount and type of data necessary to adequately characterize and understand the limnology of a waterbody and to develop the database required to support a water quality modeling effort. Gaugush (1986; 1987; 1993) provides detailed information on sampling design and frequency. Determining the availability of adequate calibration data should be done as early in the study as possible. If the user determines calibration data are inadequate, then immediate steps should be taken to collect sufficient data. Results will be suspect at best and will not withstand scrutiny at worst if the model is applied with insufficient and/or inadequate calibration data. The following discussion provides an overview of data required for the proper application of CE-QUAL-W2.

IN-POOL. Proper application of mechanistic water quality models requires at least one set of in-pool observed data. The preferred method is at least two sets of data encompassing different extremes in the prototype (i.e., high and low
flow years, warm and cold years, spring algal bloom and no spring algal bloom, etc.). In-pool data is used to set initial conditions and assess the model’s ability to reproduce observed conditions.

**Time-Varying Boundary Conditions.** It cannot be overemphasized that data used to drive the model needs to be as accurate as possible. For temperature calibration, this typically means developing regression relationships for inflow temperatures based on flow and air or equilibrium temperature to generate at least daily inflow temperatures (see Ford & Stein, 1984). Equilibrium temperature is preferred since it includes more of the mechanisms affecting water temperature.

For meteorologic data, use the most frequent data available. Previously, daily average values were used to drive the model because earlier 1-D models used daily timesteps. Many modelers still take hourly or three-hourly data and generate daily averages for model input. Any time data is averaged, information is lost. For most reservoirs, thermocline depth and shape are a function of two physical mechanisms - wind mixing and convective cooling. Using daily average air temperatures eliminates nighttime convective mixing which can be a very important physical process affecting epilimnetic depths and thermocline shapes for reservoirs. As another example, applying a daily average wind speed and direction can generate an artificial water surface slope which incorrectly drives hydrodynamics.

For water quality simulations, it is imperative the user provide accurate initial and time-varying boundary conditions. If nutrient loadings are not adequately characterized, then it will be impossible for the model to accurately reproduce algal/nutrient/DO dynamics. It is a waste of time and effort to collect in-pool data in support of water quality modeling when loadings have not been adequately characterized since they often drive the system. As in the development of inflow temperatures, regressions relating loadings with flow and possibly season should be developed for inflowing tributaries. Ideally, several storm events should be intensively sampled since this is when loadings are generally highest to a waterbody. Also, point source loadings should be identified and loading estimates obtained. Some estimate of non-point source loadings should also be made. In some cases, meteorologic loading estimates should be obtained. A software package, FLUX (Walker, 1986), is useful for generating loadings over time from intermittent samples. Table 1 gives general guidelines for data collection.

**Kinetic Rates.** Because water quality modeling is still very much an art with numerous rate coefficients available for adjustment during calibration, it is highly preferable to obtain actual measurements of these coefficients used in the water quality formulations. If all of the rate coefficients have been determined
for a waterbody, then any discrepancies between computed and observed data highlight the model’s shortcomings, help to identify the bounds of the model’s predictive capabilities, and provide direction for efficient use of resources to provide a better understanding of the system’s water quality dynamics.

Ideally, a model should be used as a starting point for limnological investigations of a waterbody, with the data and formulations continuously refined to reflect the increased understanding of the system and processes gained over time. Unfortunately, this approach is rarely taken in practice due in large part to the expense involved, but also, even more unfortunately, due to the inability of aquatic biologists/limnologists and engineers to collaborate together.

This cooperative approach between experimentalists and theoreticians is the main impetus behind the tremendous advances in physics, chemistry, and, to some extent, biology (e.g., genetic research) during the last century, but is seldom seen in the field of water quality modeling. A notable exception is the Chesapeake Bay Modeling Study (Cerco and Cole, 1994). Researchers in the Chesapeake Bay region (both biologists and engineers) were actively involved in data acquisition and water quality formulations and provided invaluable knowledge and feedback during the course of the study. This cooperative arrangement is continuing and should be a model for all future water quality model development.

1. enough samples to correlate to conductivity - important for density effects
2. used to characterize decay rates of organic matter
3. suspended solids affect phosphorus partitioning, light penetration, and density
4. can be limiting for diatom growth
5. preferably bi-weekly - samples should be taken at 1m intervals
6. 1m intervals
7. minimum number of samples includes one each in epilimnion, metalimnion, and hypolimnion
8. - preferred number of samples (depending on depth) would be at 3m intervals with more frequent metalimnetic sampling
9. when concerned about sediment release during anoxic periods

**Simulations**

Once the necessary data have been assembled into proper input format, then simulations can begin. This section describes the recommended steps for obtaining meaningful model results.
Model Preparation

The amount of application specific modifications to CE-QUAL-W2 have been kept to a minimum. Nonetheless, because of limitations imposed by FORTRAN, certain modifications must be made to the program. They are located in the file "W2.INC" and are identified by an exclamation point (!) in column 73 along with a description of what needs to be changed. They include the following:

a. **Control file specification.** The control file [CONFN] may be renamed if the user does not want to use the default - W2_CON.NPT. All other input files are specified in the control file and can be changed without recompiling the program.

b. **PARAMETER statement.** The following parameters may need to be changed:

   1) Number of segments [IMP]
   2) Number of layers [KMP]
   3) Number of constituents segments [IMC]
   4) Number of constituent layers [KMC]
   5) Number of branches [NBP]
   6) Number of outlet structures [NSP]
   7) Number of tributaries [NTP]
   8) Number of withdrawals [NWP]
   9) Number of output dates [NDP]

The number of segments [IMP] and layers [KMP] must always match the maximum number of segments and layers in the bathymetry file (including boundary layers and segments). The number of constituent segments [IMC] and layers [KMC] are set equal to [IMP] and [KMP] if water quality constituents are being simulated. Otherwise, the user should save memory by setting these values to one.

If modifications are made to the include file, then the code must be recompiled.

**Input checks.** Version 2.0 includes a preprocessor program, PRE.FOR, which performs checks of the control file for many errors that can be detected by the preprocessor. Errors are written to the file PRE.OPT and warnings are written to the file PRE.WRN. If no errors are detected, then input from the control file is written to an output file (PRE.OPT). The user should check preprocessor output against inputs to ensure they are correct. Further evaluation of control file input data must be performed by the user to ensure data the user thinks he has input into the model is what the model is actually receiving.
Additionally, all time-varying input data should be plotted and screened for errors.

**Calibration**

The next step is to begin calibration runs. Much of the literature refers to this step as calibration and verification in which model coefficients are adjusted to match an observed data set (calibration) and then the model is run on another data set without adjusting model coefficients to see if the model reproduces observed data in the prototype (verification, confirmation, validation, substantiation, etc.).

This separation is artificial and wrong. If a model does not reproduce observed data (and, more importantly, trends in data) for the "verification" data, then any good modeler will adjust coefficients, review model assumptions, include new processes, or collect additional data to adequately match both sets of data. Often, application to additional sets of data improves the fit to the first. The artificiality of this concept has led to applications in which modelers have used May, June, and July data for "calibration" and August, September, and October data of the same year for "verification" so they can state the model has been "calibrated/verified".

Ideally, calibration should involve multiple data sets encompassing as many variations and extremes as possible in the prototype. A model’s ability to reproduce prototype behavior under a variety of conditions gives the modeler more confidence in the model’s ability to make predictions under future conditions. To put it very simply, a model is a theory about behavior in the real world. A theory is continuously tested against experimental and/or observed data, and, if it does not match the data, then the theory should either be modified or a new one developed that more closely agrees with observed data.

**Model data/comparison.** At this stage, the user should have developed some means of displaying output from the model along with observed data. This is a recognized shortcoming of the present version. An X-windows based pre- and postprocessor is presently under development and will be available in Version 3.0. Plotted output is used to interpret model output. Output files available for plotting along with a brief description of their use are given below.

a. **Profile file** [PRFFN]. This file is used to plot observed versus predicted vertical profiles for temperature and constituents at a given segment (see pages C49-C51).

b. **Time series file** [TSRFN]. This file is used to plot time histories of temperature and constituents for inflows, outflows, and withdrawals. This file also contains information to plot out the
time history of the variable timestep and average timestep (see pages C57-C59).

c. **Contour plot file** [CPLFN]. This file is used to plot contours of temperature and constituents along the waterbody length (see pages C63-C65).

d. **Vector plot file** [VPLFN]. This file is used to plot velocity vectors determined from horizontal and vertical velocities. The output is useful in analyzing flow patterns in the waterbody (see pages C60-C62).

e. **Spreadsheet file** [SPRFN]. This file is similar to the profile except the output is suitable for importing into a spreadsheet type database for subsequent plotting (see page C138).

Calibration is an iterative process whereby model coefficients are adjusted until an adequate fit of observed versus predicted data is obtained. Unfortunately, there are no hard and fast guidelines for determining when an adequate fit is obtained. The user must continually ask himself "is the model giving reasonable results based on model formulations, assumptions and input data?". If it is not, then the user must determine if the inability of the model to produce reasonable results is due to the use of the model in an inappropriate manner (ie, hydrostatic approximation is invalid, one algal group is not sufficient to capture algal/nutrient/DO interactions, wind speed function for evaporation is inappropriate for the waterbody, etc.), model formulations are insufficient to describe known prototype behavior, or if input data are insufficient to describe the system dynamics.

Another important point to keep in mind during calibration is that a model may give inadequate results for a given spatial and/or temporal scale, but at another scale may reasonably represent the dynamics of the prototype. For example, the model may fail to predict a shortterm algal bloom but may adequately represent algal production over the summer stratification period. The model may thus be useful in determining a waterbody’s longterm response to nutrient loading reductions but be inadequate in addressing shortterm responses to a nutrient reduction strategy. In summary, it is not always necessary for model output to match all of the observed data for the model to provide meaningful results.

The usual sequence for calibration is to check the water budget first, then calibrate temperature (preferably salinity for estuarine applications), and finally water quality. Keep in mind water quality calibration can affect temperature/salinity calibration (see page 25). A description of each follows.
**Water budget.** The water budget is checked by comparing predicted reservoir elevations with observed elevations. Errors in the water budget are generated by the following:

a. **Incorrect bathymetry.** The user should carefully check the volume-area-elevation table produced by the model to ensure it closely matches the project volume-area-elevation table. If it does not, then bathymetry should be checked carefully to ensure there are no errors (see page C146). In some cases, additional sediment range surveys may be necessary to adequately define the bathymetry. It may also be necessary to include branches that were not included in the initial bathymetry.

b. **Storm events.** Errors in the water budget due to storm events can be determined by comparing predicted with observed elevations using output from the time series plots. If the error is generated during storm events, then the user should check to see if precipitation must be included and/or if more tributaries need to be included than were originally specified. The user may need to use a hydrologic model to determine inflows during storm events for ungaged tributaries. An alternative method is to apportion inflows for ungaged tributaries based on their watershed areas.

c. **Incomplete inflow data.** A substantial amount of inflow is often unaccounted for when using gaged inflows. The unaccounted inflows can include minor tributary, precipitation, stormwater, and wastewater treatment plant contributions. The distributed tributary option provides the user with a means to account for these contributions. This option distributes inflows into every branch segment weighted by the segment surface area (see page C40).

d. **Evaporation.** If evaporation in the region is significant and is not accounted for in inflows, then it should be included using the evaporation option [EVC] (see page C12).

e. **Seepage.** Seepage gains or losses can be significant for some waterbodies. The model does not explicitly handle seepage at present, but the coding is such that seepage can be readily included in the calculations as an additional rate term in the flow source/sink array [QSS].

Typically, the user will plot observed versus predicted water surface elevations for the simulation period. If discrepancies are found, then they should be
analyzed for the cause of error and adjusted for by using one or more of the above options. Remember to always check assumptions used during the gathering of input data to ensure they do not deviate too far from reality.

**Hydrodynamics and temperature/salinity.** The earliest mechanistic freshwater models (1D) modeled only temperature. As a result, temperature was the only model prediction that could be used for calibration. Since temperature is affected by surface and bottom heat exchange and is therefore nonconservative, it is not the best parameter for calibrating hydrodynamics. The ideal parameter is salinity which is conservative. However, this is generally feasible only for estuarine applications where salinity is routinely monitored. Dissolved solids are not conservative and are generally not a good substitute for salinity during calibration except in waterbodies where the conservative assumption is appropriate.

Coefficients affecting temperature and their default values are given in Table 2. The eddy viscosities, Chezy coefficient, and wind sheltering coefficient directly affect hydrodynamics which affect heat transport (and constituents). The remaining coefficients directly affect temperature which affects hydrodynamics. Of these, the last two coefficients affect temperature only if constituents are modeled. See pages C20-C23 and C79 in Appendix C for a more detailed description of these coefficients and their effects.

In addition to the above coefficients, temperature predictions are also affected by mainstem and tributary inflows and inflow temperatures and their placement, outlet and withdrawal specifications, the solution scheme, and bathymetry and meteorologic data. Again, always try to represent the prototype as accurately as possible.
SIMULATIONS

Applications on numerous reservoirs under a wide variety of conditions have shown the model generates remarkably accurate temperature predictions using default values when provided accurate geometry and boundary conditions. The wind sheltering coefficient [WSC] has the most effect on temperature during calibration and should be adjusted first. Previous applications with Version 2.0 varied the wind sheltering coefficient from 0.85 for mountainous terrain to 1.0 for open land. The user should also run sensitivity analyses on the other coefficients to gain a "feel" for how they affect temperature predictions.

Difficulties during temperature calibration can often be traced to the following:

a. **Inflows and Inflow temperatures.** Accurate inflows and inflow temperatures are desirable for all applications, but they are critical for waterbodies with short residence times or during high inflow periods. Temperature calibration will be difficult using monthly inflow temperatures for a waterbody with a one week residence time. Methods exist for generating more frequent inflow temperatures based on flow and meteorologic data (Ford and Stein, 1986), but there is no substitute for actual measurements.

b. **Meteorologic data.** Many difficulties are associated with extrapolating weather station meteorologic data to a waterbody site. Weather stations are typically located in different terrain and at large distances from the prototype. Wind data are often measured at 10m above the ground but in the model are applied at the air/water interface. Frontal movements can occur at different times over the waterbody and meteorologic station resulting in model predictions that are in closer agreement either earlier or later than the actual comparison date. Methods for addressing these problems include adjustment of the wind sheltering coefficient [WSC], use of an alternative meteorologic station, averaging data from several meteorologic stations, separating a waterbody into regions applying data from different meteorologic stations, and comparison of observed data using model output either before or after the observed date. If the user has the luxury of obtaining calibration data before applying the model, portable weather stations exist which can be deployed on the waterbody. Obviously, this is the preferred method.

c. **Outflow data.** The addition of the selective withdrawal algorithm in Version 2.0 has reduced many of the previous problems of accurately representing outflows. However, problems
still arise. In the application of CE-QUAL-W2 to Bluestone Reservoir, Tillman and Cole (1994) were unable to reproduce observed temperature stratification without limiting the lower withdrawal layer. Subsequent investigation showed that withdrawal was limited by trash accumulation which effectively acted as a submerged weir. This was a problem generated by inadequate knowledge of the prototype and not a problem with the model. Indeed, this is an example of a model giving insight into the behavior of the prototype. The current version of the model does not include the option of using the selective withdrawal algorithm for withdrawals. Version 3.0 will include this option.

d. **Bathymetry.** Several previous applications of the model encountered difficulties during temperature calibration until the bathymetry was revisited. Check the assumptions made during the development of the bathymetry to ensure they are not the source of the problem. Starting points include grid resolution which affects the models ability to define sharp thermal gradients and bottom slope, volume-area-elevation accuracy which can have a marked effect on hypolimnetic temperatures since the volumes are generally small near the bottom, and water surface areas which affect the area available for surface heat exchange. Branch definition has also been found have a pronounced effect on temperature predictions.

**Water quality.** Since water quality compartments are coupled, calibration of one compartment may affect other compartments making calibration difficult. *An understanding of the processes modeled as well as a knowledge of the system being simulated is an absolute must if the modeling effort is to succeed.* A complete description of water quality coefficients along with guidelines for appropriate values are given in Appendix C, pages C79-C106.

Constituents are grouped into three levels (Table 3). In level I, the tracer and total dissolved solids are conservative while coliform bacteria includes a decay rate. Level II includes constituents affecting algal/nutrient/DO dynamics. In level III, alkalinity and total inorganic carbon are transported by the model and are thus state variables. Carbonate species and pH are calculated from alkalinity and total inorganic carbon.

The user should spend time familiarizing himself with the water quality formulations in Appendix B taking note of the assumptions used. During water quality calibration, a process neglected in the formulations may need to be included. For example, carbonate precipitation is not included in the formulations. If phosphorus coprecipitation with calcium carbonate is known to be an important phosphorous removal mechanism, then it should be included. The water quality subroutines are formulated so that additional kinetic relationships can easily be incorporated into the model through additional coding.

Because the model was developed for application to a wide range of waterbodies for a variety of problems, recommending a general procedure for calibrating algal/nutrient/DO dynamics is not possible. Experience is the only way to become proficient at water quality calibration. However, as a starting point, particular care should be paid to the timing and duration of events involving algae and dissolved oxygen. If the onset, extent, and duration of anoxic conditions are not represented by the model, then nutrient dynamics will not be represented either. They in turn affect algal production which affects dissolved oxygen. Much of the art in water quality modeling is involved in calibrating algal/nutrient/DO dynamics.
A few final words about model calibration. For some applications, no amount of model adjustment or data reconstruction will provide acceptable calibration. For these cases, the model can still be used to provide information about the prototype. The model may point out data inadequacies, important mechanisms not included in the model but important in the prototype, or inappropriate assumptions used in the model.

CE-QUAL-W2 BIBLIOGRAPHY

CE-QUAL-W2 BIBLIOGRAPHY

Appendix A
Hydrodynamics and Transport

Fundamental Equations

CE-QUAL-W2 uses the laterally averaged equations of fluid motion derived from the three dimensional equations (Edinger and Buchak, 1975). They consist of six equations and six unknowns. The equations are:

**Horizontal Momentum**

\[
\frac{\partial U_B}{\partial t} + \frac{\partial U_B}{\partial x} + \frac{\partial W_B}{\partial z} = -\frac{1}{\rho} \frac{\partial P}{\partial x} + \frac{\partial}{\partial x} \left[ B A_x \frac{\partial U}{\partial x} \right] + \frac{\partial B \tau_x}{\partial z} \quad (A-1)
\]

where

- \( U \) = longitudinal, laterally averaged velocity, \( m \ sec^{-1} \)
- \( B \) = waterbody width, \( m \)
- \( t \) = time, \( sec \)
- \( x \) = longitudinal Cartesian coordinate: \( x \) is along the lake centerline at the water surface, positive to the right
- \( z \) = vertical Cartesian coordinate: \( z \) is positive downward
- \( W \) = vertical, laterally averaged velocity, \( m \ sec^{-1} \)
- \( \rho \) = density, \( kg \ m^{-3} \)
- \( P \) = pressure, \( N \ m^{-2} \)
- \( A_x \) = longitudinal momentum dispersion coefficient, \( m^2 \ sec^{-1} \)
- \( \tau_x \) = shear stress per unit mass resulting from the vertical gradient of the horizontal velocity, \( U \), \( m^2 \ sec^{-2} \)

The first term represents the time rate of change of horizontal momentum, and the second and third terms are the horizontal and vertical advection of momentum. The first term on the right-hand side (RHS) of equation (A-1) is the force imposed by the horizontal pressure gradient. The second term on the RHS is the horizontal dispersion of momentum, and the third term is the force due to shear stress.
Constituent Transport

\[
\frac{\partial B \Phi}{\partial t} + \frac{\partial U B \Phi}{\partial x} + \frac{\partial W B \Phi}{\partial z} - \frac{\partial}{\partial x} \left( B D_x \frac{\partial \Phi}{\partial x} \right) - \frac{\partial}{\partial z} \left( B D_z \frac{\partial \Phi}{\partial z} \right) = q_x B + S_x B \tag{A-2}
\]

where

\( \Phi \) = laterally averaged constituent concentration, \( g \ m^3 \)

\( D_x \) = longitudinal temperature and constituent dispersion coefficient, \( m^2 \ sec^{-1} \)

\( D_z \) = vertical temperature and constituent dispersion coefficient, \( m^2 \ sec^{-1} \)

\( q_x \) = lateral inflow or outflow mass flow rate of constituent per unit volume, \( g \ m^3 \ sec^{-1} \)

\( S_x \) = kinetics source/sink term for constituent concentrations, \( g \ m^3 \ sec^{-1} \)

Each constituent has a balance as in equation (A-2) with specific source and sink terms. The first term in equation (A-2) represents the time rate of change of constituent concentration and the second and third terms are the horizontal and vertical advection of constituents. The fourth and fifth terms are the horizontal and vertical diffusion of constituents. The first term on the RHS is the lateral inflow/outflow of constituents, and the second term represents kinetic source/sink rates for constituents.

Free Water Surface Elevation

\[
\frac{\partial B_\eta \eta}{\partial t} = \frac{\partial}{\partial x} \int_\eta^b UBdz - \int_\eta^b qBdz \tag{A-3}
\]

where

\( B_\eta \) = time and spatially varying surface width, \( m \)

\( \eta \) = free water surface location, \( m \)

\( h \) = total depth, \( m \)

\( q \) = lateral boundary inflow or outflow, \( m^1 \ sec^{-1} \)
HYDRODYNAMICS

Hydrostatic Pressure

\[ \frac{\partial P}{\partial z} = \rho g \]  
(A-4)

where

\[ g = \text{acceleration due to gravity, } m \text{ sec}^{-2} \]

Continuity

\[ \frac{\partial UB}{\partial x} + \frac{\partial WB}{\partial z} = qB \]  
(A-5)

Equation of State

\[ \rho = f(T_w, \Phi_{TDS}, \Phi_s) \]  
(A-6)

where

\[ f(T, \Phi_{TDS}, \Phi_s) = \text{density function dependent upon temperature, total dissolved solids or salinity, and suspended solids} \]

The six equations result in six unknowns:

1. free water surface elevation, \( \eta \)
2. pressure, \( P \)
3. horizontal velocity, \( U \)
4. vertical velocity, \( W \)
5. constituent concentration, \( \Phi \)
6. density, \( \rho \)

Lateral averaging eliminates the lateral momentum balance, lateral velocity, and Coriolis acceleration. The solution of the six equations for the six unknowns forms the basic model structure.

Horizontal Pressure Gradient Evaluation

The laterally averaged horizontal pressure gradient in the horizontal momentum balance includes the density driving force. It can be expanded to:
\[
\frac{\partial BP}{\partial x} = B \frac{\partial P}{\partial x} + P \frac{\partial B}{\partial x} \quad (A-7)
\]

The second term represents the static force of the fluid on the x projection of the lateral boundary, which in turn is cancelled by the force of the boundary on the fluid. Thus, this term represents the internal fluid horizontal pressure gradient. The horizontal pressure gradient is evaluated in combination with equation (A-4) to give:

\[
B \frac{\partial P}{\partial x} = -\rho_s B g \frac{\partial \eta}{\partial x} + B g \int_0^z \frac{\partial \rho}{\partial x} dz \quad (A-8)
\]

at any depth \(z\), where \(\rho_s\) is the density at the surface. The horizontal pressure gradient is divided into two components - the surface slope and the vertical integral of the horizontal density gradient. The first term is the barotropic gradient and the second is the baroclinic gradient. The horizontal pressure gradient is the major driving force for density circulation in many waterbodies.

**Free Water Surface Evaluation**

The basic characteristics of longitudinal and vertical free water surface hydrodynamics can be examined through evaluation of equation (A-3). The vertical integral of the horizontal flow can be determined from the algebraic forward-time difference of the local acceleration of horizontal momentum in equation (A-1). Formulation of the forward-time difference of UB, \(UB'\), is the first step in evaluating the numerical equations. It gives:

\[
UB' = UB - \frac{B \Delta t}{\rho} \frac{\partial P}{\partial x} + F_x \Delta t + \Delta t B \frac{\partial \tau_x}{\partial z} \quad (A-9)
\]

where

\[
F_x = \frac{\partial \left[ BA \frac{\partial U}{\partial x} \right]}{\partial x} - \frac{\partial WUB}{\partial x} - \frac{\partial WUB}{\partial z} \quad (A-10)
\]

The vertical integrals of the various terms in equations (A-9) and (A-10) can be further evaluated for insertion into the vertical integral of the flow required in the free water surface balance, equation (A-3). The vertical integral of the horizontal pressure gradient, the second term on the RHS of equation (A-9), can be evaluated from equation (A-8) to give:
\[ \frac{1}{\rho_{\eta}} \left[ B h \frac{\partial P}{\partial x} \right] dz = - \frac{\partial \eta}{\partial xg} \left[ B h \right] dz + \frac{g}{\rho_{\eta}} \left[ B \left\{ \int^z \frac{\partial \rho}{\partial x} dz \right\} \right] dz \]  

(A-11)

The first term on the RHS of equation (A-11) results from the fact that \( \partial \eta/\partial x \) is a function only of \( x \) and is constant over \( z \). The integral of width \( B \) over depth is the total cross-sectional area across which the surface slope contribution to the horizontal pressure gradient acts. The second term is the force due to the horizontal density gradient.

The vertical integral of the horizontal shear stress, the last term on the RHS of equation (A-9), can be expanded from the derivations of \( B \partial \tau / \partial z \) to give:

\[ \left[ B \left( \frac{\partial \tau_x}{\partial z} \right) \right] dz = \left( B h \right) \tau_h - B \left( \tau_x \frac{\partial B}{\partial z} \right) dz \]  

(A-12)

The first term on the RHS of equation (A-12) is column bottom shear evaluated at \( z = h \) and can be evaluated from bottom velocity friction relationships. The surface shear, \( B \left( \tau_x \right) \), is the surface wind shear component parallel to the \( x \) axis. The third term is wall or bottom shear due to the horizontal projection of the sloping sides of the waterbody. It is evaluated as bottom shear over the projected width at each elevation. The internal velocity shear cancels in the vertical integration.

Collecting the various terms of equation (A-9) into equation (A-3) gives the surface elevation equation of:

\[ \frac{\partial B \eta}{\partial t} - g \Delta t \frac{\partial}{\partial x} \left\{ \int^h \frac{\partial \eta}{\partial x} \left[ B dz \right] \right\} = \frac{\partial}{\partial x} \left\{ \int^h UB dz - \frac{g \Delta t}{\rho_{\eta}} \int^h \left\{ B \left( \int^z \frac{\partial \rho}{\partial x} dz \right) \right\} dz \right\} \]

\[ + \frac{\partial}{\partial x} \left[ \left( B h \right) \tau_h - B \left( \tau_x \frac{\partial B}{\partial z} \right) \right] \Delta t \]

\[ + \frac{\partial}{\partial x} \left[ \int^h F_x dz \right] \Delta t - \int^h qB dz \]  

(A-13)

With the water surface terms (\( \eta \)) collected on the left-hand side, equation (A-13) is the water surface equation of the integrated waterbody. Therefore, equation
(A-13) is a numerical form of the frictionally dampened, longwave equation for a stratified waterbody with an irregular geometry.

**Numerical Solution**

The first step in the numerical solution is to define the computational grid (Figure A-1). The grid is space-staggered since some variables are defined at one location and the remainder are displaced by $\Delta x/2$ or $\Delta z/2$. The grid discretizes a waterbody into computational cells whose locations are defined by their segment (i) and layer number (k), i.e., cell (k,i). Variables are located at either the center or boundary of a cell. Variables defined at the boundary include the velocities $U$ and $W$, dispersion coefficients $A_x$, $D_x$, $A_z$, and $D_z$, and internal shear stress $\tau_s$. The variables $\rho$, $\Phi$, $P$, and $B$ are defined at the cell center.

![Diagram](image)

Figure A-1. Variable locations in computational grid.
HYDRODYNAMICS               NUMERICAL SOLUTION

There is a rational basis for choosing variable locations. Since the constituent concentration is defined at the center and velocities are defined at the boundaries, spatial averaging of velocities is not required to determine changes in concentration over time. Also, the horizontal velocity is surrounded by a cell with water surface elevations and densities defined on either side. Thus, the horizontal velocity is computed from horizontal gradients of the surface slope and densities without requiring spatial averaging of these variables.

The geometry is specified in Figure A-1 by a cell width $B$, cell thickness $H$, and cell length $\Delta x$. Several additional geometric variables are used in the calculations. These include the average cross-sectional area between two cells $(k,i)$ and $(k,i+1)$

$$BH_{i,j} = \frac{B_{k,i}H_{k,i} + B_{k,i+1}H_{k,i+1}}{2} \quad (A-14)$$

the average widths between two cells $(k,i)$ and $(k+1,i)$

$$B_{b_{k,i}} = \frac{B_{k,i} + B_{k+1,i}}{2} \quad (A-15)$$

and the average layer thickness between layers $k$ and $k+1$

$$H_{k,i} = \frac{H_{k} + H_{k+1}}{2} \quad (A-16)$$

The numerical procedure for solving the six unknowns at each timestep is to first compute water surface elevations from equation (A-13). With the new surface elevations, new horizontal velocities can be computed from equation (A-9). With new horizontal velocities, the vertical velocities can be found from continuity, equation (A-5). New constituent concentrations are computed from the constituent balance, equation (A-2). Using new horizontal and vertical velocities, the water surface elevation equation, equation (A-13), can be solved for $\eta$ simultaneously. The solution for $\eta$ is thus spatially implicit at the same time level and eliminates the surface gravity wave speed criterion:

$$\Delta t < \frac{\Delta x}{\sqrt{gH_{\text{max}}}} \quad (A-17)$$

which can seriously limit timesteps in deep waterbodies.
SURFACE WAVE EQUATION

The numerical form of the surface elevation equation, equation (A-13), can be written in terms of the finite difference grid and its definitions given in Figure A-1. The vertically integrated momentum terms from the wave equation can be written in finite difference layer-averaged form as:

\[
F = -\frac{g}{\rho} \frac{\Delta \rho}{\Delta x} \int_0^z \frac{\partial \rho}{\partial x} \, dz - \frac{\partial (U^2 B H)}{\partial x} - (U B)_{r \downarrow} + (U B)_{r \uparrow} \\
+ \frac{\partial}{\partial x} \left[ B H A \frac{\partial U}{\partial x} \right] - (\tau_x B)_{r \downarrow} + (\tau_x B)_{r \uparrow}
\]  

(A-18)

When computing the new value of \( \eta \) at time \( n+1 \), terms in \( F \) are evaluated from values at timestep \( n \). The RHS terms in equation (A-18) are:

1. density gradient component of the horizontal pressure gradient
2. gradient of horizontally advected momentum
3,4. vertical advection of momentum into layer \( k \)
5. horizontal dispersion of momentum
6. horizontal shear stress on the bottom of layer \( k \)
7. horizontal shear stress on the top of layer \( k \)

Substitution of the vertically integrated momentum balance into the vertically integrated continuity balance results in the surface wave equation which can be written in time-backward, spatially implicit tridiagonal form as:

\[
A_{\eta} Z_{i-1} + V_{\eta} Z_i + C_{\eta} Z_{i+1} = D_{\eta}
\]  

(A-19)

where the tridiagonal matrix coefficients \( A_{\eta}, V_{\eta}, \) and \( C_{\eta} \) include reservoir geometry summed over a cross-section as:

\[
A_{\eta} = -g \frac{\Delta t^2}{\Delta x} \sum_k B H_{k,\eta}
\]  

(A-20)

\[
V_{\eta} = \Delta x B_{k,i} + g \frac{\Delta t^2}{\Delta x} \left[ \sum_k B H_{k,\eta} + \sum_k B H_{k,\nu} \right]
\]  

(A-21)

\[
C_{\eta} = -g \frac{\Delta t^2}{\Delta x} \sum_k B H_{k,\nu}
\]  

(A-22)
HYDRODYNAMICS

The $A_i$ geometry is the cross-sectional area between the i-1 and i segments, the $C_i$ geometry is the cross-sectional area between the i and i+1 segments, and the geometry in $V_i$ is the sum of the two cross-sections. The tridiagonal coefficient $D_i$ includes the overall dynamics, inflows, and outflows as:

$$D_{q,i} = \Delta x B_{k,i} Z_i + \Delta t^2 \sum_k \left[ F_{k,i} - F_{k,i-1} \right]$$

$$+ \Delta t \sum_k \left[ U_{k,i} BH_{u,i} - U_{k,i-1} BH_{u,i-1} \right] - \Delta t \sum_k Q_{k,i}$$

(A-23)

where $Q_{k,i}$ is lateral boundary inflow or outflows at cell k,i. Equation (A-18) is solved using the Thomas tridiagonal algorithm.

Equation (A-18) applies throughout the grid that represents the water body, including boundaries where there is zero flux. To incorporate longitudinal flow boundary conditions, $D_i$ is modified by subtracting total inflow or adding total outflow over a timestep for the left and right boundaries, respectively.

Head boundary conditions are incorporated into the solution by using the off-diagonal coefficients, $[A(CUS)]$ and/or $[C(ID)]$, with boundary elevations specified at the upstream and/or downstream ends of the computational grid. These terms are ordinarily ignored by the Thomas algorithm. However, here they are subtracted from $D_i$ in the solution for upstream and/or downstream surface elevations.

There are two cases in which head boundary conditions are used - open boundaries for which the external head or elevation is known, as in estuaries, and branch boundaries where the applied head is generated by solution of the surface wave equation in a joining branch, as in multistemmed reservoirs. In the latter, the numerical solution is applied to each branch in turn with internal boundary conditions joining the branches. Since branch computations are performed sequentially, calculation accuracy can be increased by numbering branches beginning with the mainstem. The remainder of the branches are numbered beginning with the most upstream branch then proceeding downstream.

**Evaluation of Forcing Function Terms**

The forcing function in the wave equation, $F$, in equation (A-18) must be evaluated before water surface elevations are computed at the new timestep. All terms in $F$ are therefore computed from values at the previous timestep. New timestep data entering the wave equation are boundary inflows, outflows, and surface heights. Many of the terms entering $F$, including the longitudinal
and vertical advection of momentum, longitudinal dispersion of momentum, and horizontal shear also enter the horizontal momentum balance for the U computations and are evaluated and saved as separate arrays.

Contribution of the horizontal density gradient to horizontal momentum is an integral over depth from a fixed reference surface of a horizontal density gradient. It applies at the i to i+1 boundary where U and F are located. The horizontal density gradient is first computed using the vertical integration of pressure as:

\[ P_{k,i} = P_{k-1,i} + g \rho_{k,i} H_{k,i} \]  \hspace{1cm} (A-24)

which is then used to calculate the horizontal pressure gradient, HPG:

\[ \text{HPG}_{k,i} = \frac{B_{k,i} + B_{k,i+1}}{\Delta x \rho} \left[ H_{k,i+1} P_{k-1,i+1} + P_{k,i+1} - H_{k,i} P_{k-1,i} - P_{k,i} \right] \]  \hspace{1cm} (A-25)

**Constituent Transport**

Version 1.0 used upwind differencing in the constituent transport advective terms in which the cell concentration immediately upstream of the velocity is used to calculate fluxes. A major problem with upwind differencing is the introduction of numerical diffusion given by (for longitudinal advection):

\[ \alpha_\varepsilon = \frac{u \Delta x}{2} (1 - c) \]  \hspace{1cm} (A-26)

where

- \( \alpha_\varepsilon = \) numerical diffusion
- \( c = \frac{U \Delta t}{\Delta x} \)

A similar condition holds for vertical advection. In many cases, numerical diffusion can overwhelm physical diffusion producing inaccurate results when strong gradients are present. The problem is particularly pronounced for stratified reservoirs and estuaries.

Numerical diffusion has been reduced by implementing an explicit, third-order accurate QUICKEST horizontal/vertical transport scheme (Leonard, 1979), and

QUICKEST uses an additional spatial term to estimate concentrations used in computing horizontal and vertical fluxes. A nonuniform grid QUICKEST scheme was developed using a three-point Lagrangian interpolation function to estimate constituent values at grid cell interfaces. Specifically, advective multipliers for each of three upstream weighted grid cells are derived in terms of cell lengths and the local cell interface velocity. Time invariant parts of the interpolation functions are calculated once thus minimizing computations for additional constituents.

Implicit vertical transport including variable layer heights has also been implemented. Vertical diffusion is fully implicit and advection employs a time-weighted, central difference, implicit scheme. A unique feature of vertical advection, in the explicit part of the time-weighted scheme, is QUICKEST which increases overall accuracy.

As implemented in the code, the new transport scheme is a two-part solution for constituent concentrations at the new timestep. First, horizontal advection is computed using QUICKEST and diffusion is computed using central differencing. This part also includes the explicit vertical advection contribution (which utilizes QUICKEST) and all sources and sinks.

Next, the implicit part of vertical advection and diffusion are included. Diffusion is always fully implicit. The user can time-weight advection by specifying a value for [THETA] which varies from 0 to 1. For [THETA] equal to 0, the solution is explicit in time and vertical advection is accounted for in the first part of the algorithm. For [THETA] equal to 1, the solution is fully implicit in time and vertical advection is accounted for in this part of the algorithm. A Crank-Nicholson scheme where vertical advection is time-weighted between the explicit (using QUICKEST) and implicit parts results if [THETA] is set to 0.55. The following is a description of the preferred transport scheme - QUICKEST.

**Non-Uniform Grid QUICKEST Formulation.** In one dimension, the conservative control volume advective transport of a constituent $\Phi$ integrated over a timestep is:

$$\Phi_{i,j}^{n+1} = \Phi_{i,j}^{n} - \frac{\Delta t}{\Delta x} (U_r \Phi_{i,j}^{n} - U_l \Phi_{i,j}^{n})$$  \hspace{1cm} (A-27)
where
\[ \Phi_i = \text{constituent concentration at a grid point} \]
\[ \Phi_{r,l} = \text{right and left cell face constituent concentrations} \]
\[ U_{r,l} = \text{right and left cell face velocity} \]
\[ t = \text{time} \]

The QUICKEST algorithm was originally derived using an upstream weighted quadratic interpolation function defined over three uniformly spaced grid points. This interpolation function estimates cell face concentrations required by the conservative control volume transport scheme. For example, the right cell face concentration estimate for a flow positive to the right is:

\[ \Phi_r = T_{i+1} \Phi_{i+1} + T_i \Phi_i + T_{i-1} \Phi_{i-1} \quad \text{(A-28)} \]

where \( T \) are advective multipliers which weight the contribution of three adjacent grid point concentrations.

The advective multipliers are obtained by collecting terms associated with each constituent defined by the QUICKEST advection operator. For a non-uniform grid, a combination of two and three point Lagrangian interpolation functions (Henrici, 1964) are used to compute the QUICKEST estimate for the right cell face concentration centered about cells \( i \) and \( i+1 \):

\[ \Phi_r = P_1(x) - \frac{U \Delta t}{2} P_2(x) + \left[ D_x \Delta t - \frac{1}{6} \left( \frac{\Delta x^2 - (U \Delta t)^2}{\Delta x} \right) \right] P_2^{\prime \prime}(x) \quad \text{(A-29)} \]

where
\[ x = \text{the local right cell face position} \]
\[ D_x = \text{diffusion coefficient} \]

Defining a local coordinate system of three non-uniformly spaced grid cells denoted by \( x_{i-1}, x_i, \) and \( x_{i+1} \) with corresponding constituent values, the interpolation functions required in equation (A-28) are:

\[ P_i(x) = \frac{(x-x_i)}{(x_{i+1}-x_i)} \Phi_{i+1} + \frac{(x_{i+1}-x)}{(x_{i+1}-x_i)} \Phi_i \quad \text{(A-30)} \]
and

$$P_i(x) = \frac{(x-x_i)(x-x_{i-1})}{(x_{i+1}-x_i)(x_{i+1}-x_{i-1})} \Phi_{i+1} + \frac{(x-x_{i+1})(x-x_{i-1})}{(x_i-x_{i+1})(x_i-x_{i-1})} \Phi_{i-1}$$

$$+ \frac{(x-x_{i+1})(x-x_i)}{(x_{i+1}-x_i)(x_{i+1}-x_{i-1})} \Phi_{i+1}$$

(A-31)

Taking the first derivative of $P_i(x)$ and the second derivative of $P_i(x)$ and substituting into equation (A-28), it is then possible to group terms and obtain the advective multipliers. For example, the $T_{i+1}$ multiplier is:

$$T_{i+1} = \frac{(x - x_i)}{(x_{i+1} - x_i)} - \frac{U \Delta t}{2} \left[ \frac{(x - x_i) + (x - x_{i-1})}{(x_{i+1} - x_i)(x_{i+1} - x_{i-1})} \right]$$

$$+ 2 \frac{D_x \Delta t - \frac{1}{6} \left[ \Delta x_i^2 - (U \Delta t)^2 \right]}{(x_{i+1} - x_i)(x_{i+1} - x_{i-1})}$$

(A-32)

Similar functions are obtained for $T_i$ and $T_{i-1}$ multipliers which completes the formulation for the QUICKEST algorithm.

From a computational standpoint, most geometric components of the multipliers are time-invariant and are computed once and stored in arrays. The time-varying part of the multipliers ($U$, $\Delta t$, $D_x$) are updated each timestep during computation of the $T$ arrays. However, when the QUICKEST scheme is applied vertically, the spatial part of the multipliers for layers $KT$ and $KT+1$ are updated each timestep to accommodate the surface elevation fluctuation.

**Vertical Implicit Transport.** Focusing on vertical advective and diffusive transport, constituent transport can be written:

$$\frac{\partial B \Phi}{\partial t} + \frac{\partial W B \Phi}{\partial z} - \frac{\partial}{\partial z} \left( B D_z \frac{\partial \Phi}{\partial z} \right) = \text{RHS}$$

(A-33)

where RHS represents horizontal transport, and all sources/sinks. Integrating the transport equation vertically and over time yields:

$$B \Phi^{n+1} + \theta \Delta t \delta_z \left( W B \Phi^{n+1} \right) - \Delta t \delta_z \left( B D_z \frac{\partial \Phi^{n+1}}{\partial z} \right) = B \Phi^*$$

(A-34)
where

\[ \Phi^* = \begin{aligned} &\text{all n-time level horizontal and explicit vertical transport and} \\ &\text{sources/sinks} \\
&\theta = \text{time-weighting for vertical advection, 0 if fully explicit, 0.55 if} \\ &\text{Crank-Nicholson, and 1 if fully implicit} \\
\end{aligned} \]

Expanding the differential operators in terms of central differences and collecting terms, equation (A-10) can be recast as:

\[ A_i \Phi_{i}^{n+1} + V_i \Phi_{i}^{n+1} + C_i \Phi_{i}^{n+1} = D_i \tag{A-35} \]

where

\[ A_i = \frac{\Delta t B_{b,i}}{BH_{k,i}} \left[ \theta \frac{W_{k,i}}{2} - \frac{D_{z,i}}{H_k} \right] \tag{A-36} \]

\[ V_i = 1 + \frac{\Delta t B_{b_{i-1,i}}}{BH_{k,i}} \left[ \theta \left( \frac{W_{k,i} B_{b,i} - W_{k-1,i} B_{b_{i-1,i}}}{2} \right) + \frac{B_{b_{i-1,i}} D_{z,i}}{H_{k-1}} + \frac{B_{b_{i,i}} D_{z_{i+1}}}{H_{k+1}} \right] \tag{A-37} \]

\[ C_i = -\frac{\Delta t B_{b_{i,i}}}{BH_{k,i}} \left[ \theta \frac{W_{k-1,i}}{2} + \frac{D_{z_{i-1}}}{H_{k-1}} \right] \tag{A-38} \]

The coefficients are computed once, stored in arrays, and used to update each constituent. This is accomplished by loading the explicit part of the solution, \( \Phi^* \), with each successive constituent and inverting the resulting matrix via a Thomas tridiagonal solver.

**Auxiliary Functions**

Auxiliary functions are relationships that describe processes independent of basic hydrodynamic and transport computational schemes in the model. Auxiliary functions include turbulent dispersion and wind shear processes, heat exchange (including ice cover), evaporation, density function, and selective withdrawal.

**Turbulence and Wind Shear**

In two-dimensional longitudinal-vertical models, wind shear enters the longitudinal momentum balance through the vertical transport of horizontal momentum written for the time averaged, instantaneous velocity as \( \partial <uw>/\partial z \). The instantaneous horizontal and vertical velocities can be written as:
\[ u = U + u' + u'' \]  
\[ w = W + w' + w'' \]  
(A-36a)  
(A-36b)

where

U and W = time averaged, mean velocity components  
u' and w' = turbulent velocity fluctuations about the mean generated by velocity shear  
u'' and w'' = velocity components of wind waves propagated downward from the water surface.

The time mean of the instantaneous velocity product becomes:

\[ <uw> = UW + <u'w'> + <u''w''> \]  
(A-37)

Turbulent transport is related to the mean velocity as:

\[ <u'w'> = -A_z \frac{\partial U}{\partial z} \]  
(A-38)

where \( A_z \) is the vertical eddy viscosity. Shear due to wind waves can be evaluated from the vertical decay of wind wave velocities given for simple sinusoidal waves as:

\[ u'' = A_\sigma e^{-kz} \sin(kx - \sigma t) \]  
(A-39a)

\[ w'' = A_\sigma e^{-kz} \sin(kx - \sigma_t + \phi) \]  
(A-39b)

where

\[ \sigma = \text{wave frequency} \ (2\pi/T \text{ where } T = \text{wave period}) \]
\[ \phi = \text{phase shift between vertical and horizontal components} \]
\[ \sigma = \text{ck, where } c \text{ is the wave speed and } k = 2\pi/L, \]
where L is the wave length.

Averaged over time, shear due to velocity fluctuations becomes:

\[ <u''w''> = \tau_{wx} e^{-2kz} \]  
(A-40)

where

\[ \tau_{wx} = \text{surface shear due to wind along the x-axis of the model} \]
The horizontal shear becomes:

\[ \tau_x = -A_z \frac{\partial U}{\partial z} + \tau_{wx} e^{-2kz} \]  \hspace{1cm} (A-41)

Thus, wind shear decays with depth and generates horizontal velocities directly through the horizontal momentum balance and momentum is dissipated through the vertical eddy viscosity.

The vertical eddy viscosity for longitudinal-vertical dynamics can be formulated by analogy to the three-dimensional case:

\[ A_z = k \left( \frac{1}{2} \right) \sqrt{\left( \frac{\partial U}{\partial z} \right)^2 + \left( \frac{\partial V}{\partial z} \right)^2} e^{-CR_z} \]  \hspace{1cm} (A-42)

where

- \( k \) = von Karman constant, 0.4
- \( l \) = vertical length scale taken as \( \Delta z, \) m
- \( R_i \) = local Richardson number
- \( C \) = constant, taken as 1.5

In the longitudinal-vertical model, the lateral velocity, \( V, \) and its gradient, \( \partial V/\partial z, \) are due to the lateral component of wind wave motion and are assumed to be zero when averaged laterally, but not necessarily the square \( (\partial V/\partial z)^2. \) It is assumed that cross wind shear \( \tau_{wy} \) generates lateral wave components \( v'' \) such that \( \langle w'' v'' \rangle = \tau_{wy} e^{2kz}. \) Further, let

\[ A_z^2 \left( \frac{\partial V}{\partial z} \right)^2 = \left[ \tau_{wy} e^{-2kz} \right]^2 \]  \hspace{1cm} (A-43)

giving for cross wind shear:

\[ \left( \frac{\partial V}{\partial z} \right)^2 = \left[ \frac{\tau_{wy} e^{-2kz}}{A_z} \right]^2 \]  \hspace{1cm} (A-44)
AUXILLARY FUNCTIONS

TURBULENCE

Thus, eddy viscosity with cross wind shear becomes:

$$A_z = k \left( \frac{1}{2} \right) \left( \frac{\partial U}{\partial z} \right)^2 + \left( \frac{\tau_{xy} e^{-2kz}}{A_z} \right)^2 e^{-CR}$$  (A-45)

In numerical form, \( A_z \) can be iterated from equation (A-45) by using a value at the previous timestep to evaluate cross wind shear contribution. \( A_z \) should not be less than the molecular kinematic viscosity for water. For the present hydrodynamic solution, there is also the limit that \( A_z < \Delta z^3/\Delta t \). Version 3.0 will eliminate this restriction.

The above formulation of wind shear in horizontal momentum and evaluation of \( A_z \) leads to wind driven surface currents that are three to ten percent of the surface wind velocity with higher values appearing at higher wind speeds. This is in accordance with the few attempts to relate wind speed and surface current velocity from field data appearing in the literature. With the formulation, the surface current does not reach abnormal values as it does for the case of wind shear applied only to the surface and as the surface layer thickness decreases. The depth of the wind driven surface layer increases with wind speed, and mass transport due to wind appears to be insensitive to the finite difference layer thickness.

The wind wave formulation is based on the significant wave height and period. There is a whole spectrum of wind wave components, \( u' \) and \( v' \), equations (A-39) and (A-40), and hence a whole spectrum of wind wave decay rates producing a spectrum of wind shears. It is presently not known if the major portion of the wind shear is propagated by waves making up the significant wave height and period portion of the wind wave spectrum. The present formulation provides the basis for further theoretical investigations. A \( k-\epsilon \) turbulence model is presently undergoing testing and may be included as an option in Version 3.0.

Heat Budget

Surface Heat Exchange. Surface heat exchange can be formulated as a term-by-term process using the explicit adjacent cell transport computation as long as the integration timestep is shorter than or equal to the frequency of the meteorological data. Surface heat exchange processes depending on water surface temperatures are computed using previous timestep data and are therefore lagged from transport processes by the integration timestep.
AUXILLARY FUNCTIONS

HEAT BUDGET

Term-by-term surface heat exchange is computed as:

\[ H_n = H_s + H_a + H_r + H_e - (H_{sr} + H_{sr} + H_{br}) \]  \hspace{2cm} (A-46)

where

- \( H_n \) = the net rate of heat exchange across the water surface, \( W m^{-2} \)
- \( H_s \) = incident short wave solar radiation, \( W m^{-2} \)
- \( H_a \) = incident long wave radiation, \( W m^{-2} \)
- \( H_r \) = reflected short wave solar radiation, \( W m^{-2} \)
- \( H_{sr} \) = reflected long wave radiation, \( W m^{-2} \)
- \( H_{br} \) = back radiation from the water surface, \( W m^{-2} \)
- \( H_e \) = evaporative heat loss, \( W m^{-2} \)
- \( H_c \) = heat conduction, \( W m^{-2} \)

The short wave solar radiation is either measured directly or computed from sun angle relationships and cloud cover. The long wave atmospheric radiation is computed from air temperature and cloud cover or air vapor pressure using Brunts formula. The right-hand terms are all water surface temperature dependent.

Water surface back radiation is computed as:

\[ H_{br} = \varepsilon \sigma^* (T_s + 273.15)^4 \]  \hspace{2cm} (A-47)

where

- \( \varepsilon \) = emissivity of water, 0.97
- \( \sigma^* \) = Stephan-Boltzman constant, \( 5.67 \times 10^{-8} \ W m^{-2} °K^{-4} \)
- \( T_s \) = water surface temperature, °C

Like the remaining terms, it is computed for each surface layer cell on each iteration timestep.

Evaporative heat loss is computed as:

\[ H_e = f(W) (e_s - e_a) \]  \hspace{2cm} (A-48)

where

- \( f(W) \) = evaporative wind speed function, \( W m^{-2} mm Hg^{-1} \)
- \( e_s \) = saturation vapor pressure at the water surface, \( mm Hg \)
- \( e_a \) = atmospheric vapor pressure, \( mm Hg \)
Evaporative heat loss depends on air temperature and dew point temperature or relative humidity. Surface vapor pressure is computed from the surface temperature for each surface cell on each iteration.

Surface heat conduction is computed as:

\[ H_c = C_c \cdot f(W) \cdot (T_s - T_a) \]  \hspace{1cm} (A-49)

where

\[ C_c = \text{Bowen's coefficient}, \hspace{0.5cm} 0.47 \text{ mm Hg } ^\circ C^{-1} \]
\[ T_a = \text{air temperature, } ^\circ C \]

Short wave solar radiation penetrates the surface and decays exponentially with depth according to Bear's Law:

\[ H_s(z) = (1 - \beta) H_s e^{-\eta z} \]  \hspace{1cm} (A-50)

where

\[ H_s(z) = \text{short wave radiation at depth } z, \hspace{0.5cm} W m^{-2} \]
\[ \beta = \text{fraction absorbed at the water surface} \]
\[ \eta = \text{extinction coefficient, } m^{-1} \]
\[ H_s = \text{short wave radiation reaching the surface, } W m^{-2} \]

Aside from the problems of measuring meteorological data relative to a large waterbody and especially the problem of translating climatological data from distant weather stations, the most uncertain parameter in the surface heat exchange computations is the evaporative wind speed function, f(W). Various formulations of f(W) have been catalogued and examined in Edinger, et al. (1974). Unlike the use of wind speed in wind shear relations as discussed in the previous section, evaporative wind speed is thought to be a "ventilation speed" rather than a vector velocity. The different formulations result from the empirical determination of f(W) for different size and shape waterbodies with data from different locations and averaged over different periods of time.

Since certain of the terms in equation (A-46) are surface temperature dependent, and others are measurable or computable input variables, the most direct route is to define an equilibrium temperature, \( T_e \), as the temperature at which the net rate of surface heat exchange is zero. Equilibrium temperature is the fictitious water surface temperature at which incoming radiation heat rates are just balanced by outgoing water surface temperature dependent processes.
AUXILLARY FUNCTIONS

HEAT BUDGET

Linearization of equation (A-46) along with the definition of equilibrium temperature allows expressing the net rate of surface heat exchange, \( H_n \), as:

\[
H_n = -K_{aw}(T_w - T_e)
\]  
(A-51)

where

- \( H_n \) = rate of surface heat exchange, \( \text{W m}^{-2} \)
- \( K_{aw} \) = coefficient of surface heat exchange, \( \text{W m}^{-2} \text{C}^{-1} \)
- \( T_w \) = water surface temperature, \( \text{°C} \)
- \( T_e \) = equilibrium temperature, \( \text{°C} \)

Seven separate heat exchange processes are summarized in the coefficient of surface heat exchange and equilibrium temperature. The linearization used in obtaining equation (A-51) has been examined in detail by Brady, et al. (1968), and Edinger et al. (1974).

The definition of the coefficient of surface heat exchange can be shown to be the first term of a Taylor series expansion by considering equation (A-51) as:

\[
H_n = -\frac{dH_n}{dT_s}(T_s - T_e)
\]  
(A-52)

where the derivative of \( H_n \) with respect to surface temperature is evaluated from equation (A-46) to give \( K_{aw} \), the coefficient of surface heat exchange. All approximations of the individual surface heat exchange terms enter into the evaluation of the coefficient of surface heat exchange and the equilibrium temperature. Equations (A-47) and (A-48) are defined from equation (A-46). They have the same difficulties in evaluation as the individual terms in equation (A-46), but provide a simpler algebraic method for including surface heat exchange in temperature analyses.

The mass evaporation rate is computed by dividing evaporative heat loss by the latent heat of evaporation of water. Surface heat exchange \textit{always} includes evaporative heat loss in the heat budget, but the user may choose to exclude it in the water budget. For many reservoirs, inflow rates are determined from storage estimates that implicitly include evaporation.

\textbf{Sediment Heat Exchange.} Sediment heat exchange with water is generally small compared to surface heat exchange and many previous modelers have neglected it. Version 2.0 of the model now includes sediment/water heat exchange. Investigations on several reservoirs have shown the process must be included to accurately reproduce hypolimnetic temperatures primarily because
of the reduction in numerical diffusion. The formulation is similar to surface heat exchange:

\[ H_{sw} = -K_{sw}(T_w - T_s) \]  \hspace{1cm} (A-53)

where

- \( H_{sw} = \) rate of sediment/water heat exchange, W m\(^{-2}\)
- \( K_{sw} = \) coefficient of sediment/water heat exchange, W m\(^{-2}\) °C\(^{-1}\)
- \( T_w = \) water temperature, °C
- \( T_s = \) sediment temperature, °C

Previous applications used a value of 7 \times 10^8 W m\(^{-2}\) °C\(^{-1}\) for \( K_{sw} \) which is approximately 2 orders of magnitude smaller than the surface heat exchange coefficient. Average yearly air temperature is a good estimate of \( T_s \).

**Ice Cover**

Ice thickness and onset and loss of ice cover play an important role in the heat budget of northern waterbodies. At high latitudes, ice cover may remain until late spring or early summer and prevent warming due to absorption of short wave solar radiation.

The ice model is based on an ice cover with ice-to-air heat exchange, conduction through the ice, conduction between underlying water, and a "melt temperature" layer on the ice bottom (Ashton, 1979). The overall heat balance for the water-to-ice-to-air system is:

\[ \rho_i L_f \frac{\Delta h}{\Delta t} = h_{ai}(T_i - T_e) - h_{wi}(T_w - T_m) \]  \hspace{1cm} (A-54)

where

- \( \rho_i = \) density of ice, kg m\(^{-3}\)
- \( L_f = \) latent heat of fusion of ice, J kg\(^{-1}\)
- \( \Delta h/\Delta t = \) change in ice thickness (h) with time (t), m sec\(^{-1}\)
- \( h_{ai} = \) coefficient of ice-to-air heat exchange, W m\(^{-2}\) °C\(^{-1}\)
- \( h_{wi} = \) coefficient of water-to-ice heat exchange through the melt layer, W m\(^{-2}\) °C\(^{-1}\)
- \( T_i = \) ice temperature, °C
- \( T_e = \) equilibrium temperature of ice-to-air heat exchange, °C
- \( T_w = \) water temperature below ice, °C
- \( T_m = \) melt temperature, 0°C

The ice-to-air coefficient of surface heat exchange, \( h_{ai} \), and its equilibrium temperature, \( T_e \), are computed the same as for surface heat exchange in Edin-
ger, et al. (1974) because heat balance of the thin, ice surface water layer is the same as the net rate of surface heat exchange presented previously. The coefficient of water-to-ice exchange, $h_{wi}$, depends on turbulence and water movement under ice and their effect on melt layer thickness. It is a function of water velocity for rivers but must be empirically adjusted for reservoirs.

Ice temperature in the ice-heat balance is computed by equating the rate of surface heat transfer between ice and air to the rate of heat conduction through ice:

$$h_{si}(T_i - T_a) = -\frac{k_i(T_i - T_m)}{h}$$  
(A-55)

where

$$k_i = \text{molecular heat conductivity of ice, } W \text{ m}^{-1} \text{ °C}^{-1}$$

When solved for ice temperature, $T_i$, and inserted in the overall ice-heat balance, the ice thickness relationship becomes:

$$\frac{\rho_i L_i \Delta h}{\Delta t} = \frac{(T_m - T_a)}{h} + \frac{1}{k_i + \frac{1}{h_a}}$$  
(A-56)

from which ice thickness can be computed for each longitudinal segment. Heat from water to ice transferred by the last term is removed in the water temperature transport computations.

Variations in the onset of ice cover and seasonal growth and melt over the waterbody depend on locations and temperatures of inflows and outflows, evaporative wind variations over the ice surface, and effects of water movement on the ice-to-water exchange coefficient. Ice will often form in reservoir branches before forming in the main pool and remain longer due to these effects.

A second, more detailed algorithm for computing ice growth and decay has been developed for the model. The algorithm consists of a series of one-dimensional, quasi steady-state, thermodynamic calculations for each timestep. It is similar to those of Maykut and Untersteiner (1971), Wake (1977) and Patterson and Hamblin (1988). The detailed algorithm provides a more accurate representation of the upper part of the ice temperature profile resulting in a more accurate calculation of ice surface temperature and rate of ice freezing and melting.
The ice surface temperature, $T_s$, is iteratively computed at each timestep using the upper boundary condition as follows. Assuming linear thermal gradients and using finite difference approximations, heat fluxes through the ice, $q_i$, and at the ice-water interface, $q_{iw}$, are computed. Ice thickness at time $t$, $\theta(t)$, is determined by ice melt at the air-ice interface, $\Delta \theta_{ai}$, and ice growth and melt at the ice-water interface, $\Delta \theta_{iw}$. The computational sequence of ice cover is presented below.

**Initial ice formation.** Formation of ice requires lowering the surface water temperature to the freezing point by normal surface heat exchange processes. With further heat removal, ice begins to form on the water surface. This is indicated by a negative water surface temperature. The negative water surface temperature is then converted to equivalent ice thickness and equivalent heat is added to the heat source and sink term for water. The computation is done once for each segment beginning with the ice-free period:

$$\theta_0 = \frac{-T_w \rho_w C_p h}{\rho_i L_f}$$  \hspace{1cm} (A-57)

where

- $\theta_0$ = thickness of initial ice formation during a timestep, $m$
- $T_w$ = local temporary negative water temperature, $^\circ C$
- $h$ = layer thickness, $m$
- $\rho_w$ = density of water, $kg \ m^{-3}$
- $C_p$ = specific heat of water, $J \ kg^{-1} \ ^\circ C^{-1}$
- $\rho_i$ = density of ice, $kg \ m^{-3}$
- $L_f$ = latent heat of fusion, $J \ kg^{-1}$

**Upper air-ice interface flux boundary condition and ice surface temperature approximation:** The ice surface temperature, $T_s$, must be known to calculate the heat components, $H_m$, $H_r$, $H_c$, and the thermal gradient in the ice since the components and gradient all are either explicitly or implicitly a function of $T_s$. Except during the active thawing season when ice surface temperature is constant at $0 \ ^\circ C$, $T_s$ must be computed at each timestep using the upper boundary condition. The approximate value for $T_s$ is obtained by linearizing the ice thickness across the timestep and solving for $T_s$:

$$q_i = K_i \frac{T_r - T_r(t)}{\theta(t)}$$  \hspace{1cm} (A-58)

$$H_m + H_{an} - H_r - H_c - q_i = \rho_i L_f \frac{d \theta_{ai}}{dt}, \text{ for } T_s = 0^\circ C$$  \hspace{1cm} (A-59)
AUXILLARY FUNCTIONS

\[ T_s^n = \frac{\theta^{n-1}}{K_i} \left[ H_w^n + H_m^n - H_{br} T_s^n - H_{ec} T_s^n - H_{cs} T_s^n \right] \]  \hspace{1cm} \text{(A-60)}

where

- \( K_i \) = thermal conductivity of ice, \( W \ m^{-1} \ ^\circ C^{-1} \)
- \( T_f \) = freezing point temperature, \( ^\circ C \)
- \( n \) = time level

**Absorbed solar radiation by the water under the ice.** Although the amount of penetrated solar radiation is relatively small, it is an important component of the heat budget since it is the only heat source to the water column when ice is present and may contribute significantly to ice melting at the ice-water interface. The amount of solar radiation absorbed by water under the ice cover may be expressed as:

\[ H_{ps} = H_s (1 - \text{ALB}_i) (1 - \beta_i) e^{-\gamma_i \theta(t)} \]  \hspace{1cm} \text{(A-61)}

where

- \( H_{ps} \) = solar radiation absorbed by water under ice cover, \( W \ m^{-2} \)
- \( H_s \) = incident solar radiation, \( W \ m^{-2} \)
- \( \text{ALB}_i \) = ice albedo
- \( \beta_i \) = fraction of the incoming solar radiation absorbed in the ice surface
- \( \gamma_i \) = ice extinction coefficient, \( m^{-1} \)

**Ice melt at the air-ice interface.** The solution for \( T_s \) holds as long as net surface heat exchange, \( H_s(T_s) \), remains negative corresponding to surface cooling, and surface melting cannot occur. If \( H_n(T_s) \) becomes positive corresponding to a net gain of heat at the surface, \( q \) must become negative and an equilibrium solution can only exist if \( T_s > T_f \). This situation is not possible as melting will occur at the surface before equilibrium is reached (Patterson and Hamblin, 1988). As a result of quasi-steady approximation, heat, which in reality is used to melt ice at the surface, is stored internally producing an unrealistic temperature profile. Stored energy is used for melting at each timestep and since total energy input is the same, net error is small. Stored energy used for melting ice is expressed as:

\[ \rho_i C_p \frac{T_s(t)}{2} \theta(t) = \rho_i L_f \Delta \theta_{ai} \]  \hspace{1cm} \text{(A-62)}

where

- \( C_p \) = specific heat of ice, \( J \ kg^{-1} \ ^\circ C^{-1} \)
- \( \theta_{ai} \) = ice melt at the air-ice interface, \( m^{-1} \)
Formulation of lower ice-water interface flux boundary condition. Both ice growth and melt may occur at the ice-water interface. The interface temperature, $T_i$, is fixed by the water properties. Flux of heat in the ice at the interface therefore depends on $T_i$ and the surface temperature $T_s$ through the heat flux $q_i$. Independently, heat flux from the water to ice, $q_{iw}$, depends only on conditions beneath the ice. An imbalance between these fluxes provides a mechanism for freezing or melting. Thus,

$$q_i - q_{iw} = \rho_i L \frac{d\theta_{iw}}{dt}$$ \hspace{1cm} (A-63)

where

$\theta_{iw} = \text{ice growth/melt at the ice-water interface}$

The coefficient of water-to-ice exchange, $K_{wi}$, depends on turbulence and water movement under the ice and their effect on melt layer thickness. It is known to be a function of water velocity for rivers and streams but must be empirically adjusted for reservoirs. The heat flux at the ice-water interface is:

$$q_{iw} = h_{wi} (T_w(t) - T_i)$$ \hspace{1cm} (A-64)

where

$T_w = \text{water temperature in the uppermost layer under the ice, °C}$

Finally, ice growth or melt at the ice-water interface is:

$$\Delta \theta_{iw}^n = \frac{1}{\rho_i L} \left[ K_i \frac{T_i - T_s^n}{\theta^n - 1} - h_{wi} (T_i^n - T_i) \right]$$ \hspace{1cm} (A-65)

Density

Accurate hydrodynamic calculations require accurate water densities. Water densities are affected by variations in temperature and solids concentrations given by:

$$\rho = \rho_T + \Delta \rho_S$$ \hspace{1cm} (A-66)

where

$\rho = \text{density, kg m}^{-3}$

$\rho_T = \text{water density as a function of temperature, kg m}^{-3}$

$\Delta \rho_S = \text{density increment due to solids, kg m}^{-3}$
AUXILLARY FUNCTIONS

DENSITY

A variety of formulations have been proposed to describe water density variations due to temperatures. The following relationship is used in the model (Gill, 1982):

\[
\rho_{T_w} = 999.8452594 + 6.793952 \times 10^{-2} T_w \\
- 9.095290 \times 10^{-3} T_w^2 + 1.001685 \times 10^{-4} T_w^3 \\
- 1.120083 \times 10^{-6} T_w^4 + 6.536332 \times 10^{-9} T_w^5
\] (A-67)

Suspended and dissolved solids also affect density. For most applications, dissolved solids will be in the form of total dissolved solids (TDS). For estuarine applications, salinity should be specified. The effect of dissolved solids on density is calculated using either of these variables with the choice specified by the variable [WTYPE] (see page C11). Density effects due to TDS are given by Ford and Johnson (1983):

\[
\Delta \rho_{TDS} = (8.221 \times 10^{-4} - 3.87 \times 10^{-6} T_w + 4.99 \times 10^{-8} T_w^2) \Phi_{TDS}
\] (A-68)

where

\[
\Phi_{TDS} = \text{TDS concentration, g m}^{-3}
\]

and for salinity (Gill, 1982):

\[
\Delta \rho_{sal} = (0.824493 - 4.0899 \times 10^{-3} T_w + 7.6438 \times 10^{-5} T_w^2 \\
- 8.2467 \times 10^{-7} T_w^3 + 5.3875 \times 10^{-9} T_w^4) \Phi_{sal}
\] + (-5.72466 \times 10^{-3} + 1.0227 \times 10^{-4} T_w \\
- 1.6546 \times 10^{-6} T_w^2 ) \Phi_{sal}^{1.5} + 4.8314 \times 10^{-4} \Phi_{sal}^2
\] (A-69)

where

\[
\Phi_{sal} = \text{salinity, kg m}^{-3}
\]

The suspended solids effects are given by Ford and Johnson (1983):

\[
\Delta \rho_{ss} = \Phi_{ss} \left[ 1 - \frac{1}{SG} \right] \times 10^{-3}
\] (A-70)
AUXILLARY FUNCTIONS

where

$$\Phi_{ss} = \text{suspended solids concentration, g m}^{-3}$$

$$\text{SG} = \text{specific gravity of suspended solids}$$

Assuming a specific gravity of 2.65, the above relationship is simplified to:

$$\Delta \rho_{ss} = 0.00062 \Phi_{ss} \quad \text{(A-71)}$$

The total effect of solids is then:

$$\Delta \rho_s = (\Delta \rho_{sal} \text{ or } \Delta \rho_{ss}) + \Delta \rho_{ss} \quad \text{(A-72)}$$

Selective Withdrawal

Outflows from reservoirs are usually from outlets on the order of a model layer in thickness. The code provides an option to either specify flows from particular layers at downstream segments or a selective withdrawal algorithm where outflows and layer locations are calculated based on the total outflow [QOUT], structure type [SINK] and elevation [ELSTR], and computed upstream density gradients. The selective withdrawal computation uses these values to compute vertical withdrawal zone limits and outflows. It also sums the outflows for multiple structures.

Outflow distribution is calculated in the subroutine SELECTIVE_WITHDRAWAL. This routine first calculates limits of withdrawal based on either a user specified point or line sink approximation for outlet geometry [SINK]. The empirical expression for point sink withdrawal limits is:

$$d = (c_{bi}Q/N)^{0.3333} \quad \text{(A-73)}$$

and for a line sink:

$$d = (c_{bi}2q/N)^{0.5} \quad \text{(A-74)}$$

where

- $$d = \text{withdrawal zone half height, m}$$
- $$Q = \text{total outflow, m}^3 \text{s}^{-1}$$
- $$N = \text{internal buoyancy frequency, Hz}$$
- $$q = \text{outflow per unit width, m}^2 \text{s}^{-1}$$
- $$c_{bi} = \text{boundary interference coefficient}$$
AUXILIARY FUNCTIONS

The width is the outlet width. The point sink approximation assumes approach flow is radial both longitudinally and vertically while the line sink approximation assumes flow approaches the outlet radially in the vertical. The boundary interference coefficient is two near a physical boundary and one elsewhere.

Velocities are determined using a quadratic shape function:

\[
V_k = 1 - \left[ \frac{(\rho_k - \rho_o)}{(\rho_i - \rho_o)} \right]^2
\]  

(A-75)

where

- \(V_k\) = normalized velocity in layer k
- \(\rho_k\) = density in layer k, \(kg \ m^3\)
- \(\rho_o\) = density in the outlet layer, \(kg \ m^3\)
- \(\rho_i\) = density of the withdrawal limit layer, \(kg \ m^3\)

The shape function generates a maximum velocity at the outlet level with velocities approaching zero at withdrawal limits. During non-stratified periods, outflow from top to bottom is uniform. Uniform flows also result from large outflows during periods of mild stratification. As stratification develops, withdrawal limits decrease and outflow is weighted towards the outlet elevation.

Withdrawal limits can be varied by specifying a line sink and changing the effective width. Small outlet widths result in nearly uniform outflows, while large widths limit outflows to the outlet layer.
Appendix B
Water Quality

The constituent transport relationships described in Appendix A compute the transport of constituents with their kinetic reaction rates expressed in source and sink terms. All sources/sinks (both internal and external) for water temperature are contained in the array [TSS]. The sources/sinks for constituents are separated into two arrays, [CSSB] and [CSSK]. [CSSB] contains boundary sources/sinks. [CSSK] contains internal sources/sinks due to kinetic reactions. The reactions are computed in subroutines for all nonconservative materials. The division of terms allows kinetic sources/sinks to be updated at different frequencies than boundary sources/sinks - consistent with coarser time scales associated with biological and chemical processes as opposed to hydrodynamics. Computational time is also reduced. The frequency at which kinetic sources/sinks [CSSK] are updated is specified by the parameter [FREQUK] (see page C69).

The source/sink term [CSSK] represents a mass rate of change (grams per second) of a constituent due to kinetic reactions where concentrations are expressed as grams per meter$^3$. The kinetic reactions can be depicted graphically by considering each constituent as a compartment. Mass transfer rates between compartments are represented by arrows, with a source represented by an arrow leading to the compartment and a sink by an arrow leading away. The rate equation for a particular constituent can be developed directly from the graphical representation. Both graphical and mathematical descriptions of the rate equation for each constituent are provided.

All rate terms used in the equations are in units of per second. These rates are converted internally from units of per day specified in the control file (see Appendix C).

Conservative Tracer

A conservative constituent is included to allow dye study simulations, movements of conservative materials through the waterbody, and as an aid in calibrating and testing flow regimes. As a conservative material, this constituent has no internal sources or sinks and the rate term [CSSK] is set to zero.
Inorganic Suspended Solids

Inorganic suspended solids are important in water quality simulations because of their influence on density, light penetration, and nutrient availability. Increased solids concentrations reduce light penetration in the water column thus affecting temperature which in turn affects biological and chemical reaction rates. Nutrient concentrations are also affected by solids through adsorption and settling. Light and nutrient availability largely control algal production.

![Diagram of suspended solids settling]

Figure B-1. Internal flux for inorganic suspended solids.

Referring to Figure B-1, the rate equation for inorganic suspended solids is:

$$\frac{\partial \Phi_{ss}}{\partial t} = -\frac{\omega_{ss} \Phi_{ss}}{\Delta z}$$  \hspace{1cm} (B-1)

where

- $\omega_{ss}$ = settling velocity, $m \ sec^{-1}$
- $\Phi_{ss}$ = suspended solids concentration, $g \ m^{-1}$
- $\Delta z$ = cell thickness, $m$

In the finite difference representation of suspended solids concentrations, solids settling from layer [K]-1 serve as a source for the layer below it [K]. No provision is made to accumulate inorganic solids or allow resuspension in the sediments. Version 3.0 of the model will include these processes in a sediment...
transport compartment. Lateral averaging results in homogeneous solids concentrations laterally. In reality, concentrations generally decrease with distance away from the dominant flow path. This effect is not included. The rate term for inorganic suspended solids is evaluated in the subroutine SUSPENDED_SOLIDS.

**Coliform Bacteria**

Coliform bacteria is commonly used as an indicator of pathogen contamination. Safety standards and criteria for drinking and recreational purposes are based upon coliform concentrations. Predictions of coliform bacteria are important because of their impact on recreation and water supply.

![Diagram](image)

**Figure B-2.** Internal flux for coliform bacteria.

Total coliforms, fecal coliforms, or fecal streptococci are simulated with this compartment and are independent of all other compartments except temperature. Referring to Figure B-2, the rate equation for coliforms is:

\[
\frac{\partial \Phi_{\text{col}}}{\partial t} = -K_{\text{col}} \theta^{(T-20)} \Phi_{\text{col}}
\]

(B-2)

where

- \( K_{\text{col}} \) = coliform mortality, \( \text{sec}^{-1} \)
- \( \theta \) = temperature factor (Q10)
- \( T \) = water temperature, \( ^{\circ}C \)
- \( \Phi_{\text{col}} \) = coliform concentration, \( g \text{ m}^{-3} \)

and the rate term is evaluated in the subroutine COLIFORM.
The Q10 formulation arises from a doubling of the reaction rate with each 10°C increase in temperature. This doubling rate has not been found at lower temperatures (Hargrave 1972b) and is quite variable for various reactions (Giese 1968). Modeling coliform bacteria is discussed in detail in Zison, et al. (1978).

Total Dissolved Solids or Salinity

Total dissolved solids (TDS) effect both water density and ionic strength, thereby affecting water movements, pH, and the distribution of carbonate species. Dissolved solids are normally expressed as total dissolved solids (TDS) in freshwater applications. Estuarine applications normally use salinity. Either TDS or salinity can be used with the choice indicated by the parameter [WTYPX] specified in the control file (see page C11). The choice is then reflected in the computation of density and ionic strength. If TDS is used, the units are grams per meter$^3$, while salinity is kilograms per meter$^3$. It is important to keep in mind TDS and salinity are not equivalent - salinity is conservative while TDS is not. In the model, however, both are treated conservatively with the rate term set to zero.

Labile DOM

Because of the importance of dissolved oxygen in aquatic systems, all constituents exerting an oxygen demand must be included in kinetic formulations. This demand is often measured in rivers as the biochemical oxygen demand (BOD), which includes microbial respiration and metabolism of various organic and inorganic compounds. However, production of these materials occurs as well as decomposition, requiring the major components of BOD be modeled individually. One of these constituents is dissolved organic matter (DOM), which is composed of labile and refractory components. DOM is modeled as two separate compartments because of the two groups’ different decomposition rates.

Referring to Figure B-3, the rate equation for labile DOM is:

$$\frac{d \Phi_{ldom}}{dt} = K_{se} \Phi_s + (1 - P_{am}) K_{am} \Phi_s - \gamma_{om} K_{ldom} \Phi_{ldom} - K_{ld} \Phi_{ldom} \quad (B-3)$$

where

$K_{se}$ = algal excretion rate, sec$^{-1}$ (see equation B-12)
$K_{am}$ = algal mortality rate, sec$^{-1}$ (see equation B-13)
$K_{ldom}$ = labile DOM decay rate, sec$^{-1}$
$K_{ld}$ = transfer rate from labile to refractory DOM, sec$^{-1}$
$P_{am}$ = pattern coefficient for algal mortality
$\gamma_{om}$ = temperature rate multiplier for organic matter decay
Figure B-3. Internal flux between labile DOM and other compartments

\[ \Phi_a = \text{algal concentration, } g \, m^{-3} \]
\[ \Phi_{\text{dom}} = \text{labile DOM concentration, } g \, m^{-3} \]

and the rate terms are evaluated in subroutine LABILE_DOM. Where applications only require simulation of dissolved oxygen and BOD, this compartment would be turned off and BOD would be included in the simulation. If organic loading rates are available as BOD and algal/nutrient interactions are modeled, then both compartments would be included in the simulation.

**Refractory DOM**

Refractory DOM is composed of compounds in the aquatic environment that slowly decompose exerting oxygen demand over long periods. Internally, refractory DOM is produced from the decomposition of labile DOM.
Figure B-4. Internal flux between refractory DOM and other compartments.

Referring to Figure B-4, the rate equation for refractory DOM is:

$$\frac{\partial \Phi_{\text{rdom}}}{\partial t} = K_{t,\text{r}} \Phi_{\text{ldom}} - \gamma_{\text{t,dom}} K_{\text{r,dom}} \Phi_{\text{rdom}} \quad (B-4)$$

where

- $K_{t,\text{r}}$ = transfer rate from labile DOM, sec$^{-1}$
- $C_{\text{ldom}}$ = concentration of labile DOM, g m$^{-3}$
- $\gamma_{\text{t,dom}}$ = temperature rate multiplier
- $K_{\text{r,dom}}$ = refractory DOM decay rate, sec$^{-1}$
- $\Phi_{\text{rdom}}$ = refractory DOM concentration, g m$^{-3}$

and the rate terms are evaluated in subroutine REFRACTORY Dome.

**Detritus**

Detritus represents particulate organic material in the water column. When decaying, detritus is a source of nitrogen, phosphorus, and carbon. A stoichiometric relationship is used to release ammonium-nitrogen, phosphorus, and carbon, and an oxygen demand is exerted as detritus decomposes. When detritus settles to the bottom, it accumulates and decays in the sediment compartment if the sediment compartment is included in the simulation (see page C71).
Figure B-5. Internal flux between detritus and other compartments.

Referring to Figure B-4, the rate equation for detritus is:

$$\frac{d\Phi_d}{dt} = P_{am} K_{am} \Phi_a - K_{dt} \gamma_{om} \Phi_d - \frac{\omega_{dt}}{\Delta z} \Phi_d$$  \hspace{1cm} (B-14)

where

- $P_{am}$ = partition coefficient for algal mortality
- $K_{am}$ = algal mortality rate, $sec^{-1}$ (see equation B-13)
- $\Phi_a$ = algal concentration, $g \, m^{-3}$
- $K_{dt}$ = detritus decay rate, $sec^{-1}$
- $\omega_{dt}$ = detritus settling rate, $m \, sec^{-1}$
- $\Phi_d$ = detritus concentration, $g \, m^{-3}$
- $\Delta z$ = model cell thickness, $m$
- $\gamma_{om}$ = temperature rate multiplier for organic matter

and the rate terms are evaluated in subroutine DETRITUS. Detritus settling and accumulation in the sediment compartment is handled identically to the algal compartment.

Appendix B Water Quality
Algae

CE-QUAL-W2 uses a single compartment to represent algae. This representation precludes modeling algal succession for diatoms, greens, and blue-greens. However, an algal compartment does allow simulating the interaction between nutrients, algae, and dissolved oxygen.

Figure B-6. Internal flux between algae and other compartments.

Referring to Figure B-6, the rate equation for algae is:

$$\frac{\partial \Phi_a}{\partial t} = K_{ag} \Phi_a - K_{ar} \Phi_a - K_{ec} \Phi_a - K_{am} \Phi_a - \frac{\omega_a}{\Delta z} \Phi_a$$  \hspace{1cm} (B-5)

where

- $\Delta z =$ cell thickness, $m$
- $K_{ag} =$ algal growth rate, $sec^{-1}$ (see equation B-6)
- $K_{ar} =$ algal dark respiration rate, $sec^{-1}$ (see equation B-11)
- $K_{ec} =$ algal excretion rate, $sec^{-1}$ (see equation B-12)
- $K_{am} =$ algal mortality rate, $sec^{-1}$ (see equation B-13)
- $\omega_a =$ algal settling rate, $m sec^{-1}$

Appendix B Water Quality
KINETICS

\[ \Phi_a = \text{algal concentration, } g \frac{C}{m^3} \]

and the rate terms are evaluated in subroutine PHYTOPLANKTON. Chlorophyll \( a \) is most commonly available as an estimate of algal biomass. To convert chlorophyll \( a \) to algal biomass, chlorophyll \( a \) is typically multiplied by 67. This value can vary widely depending on the makeup of the phytoplankton population. Some previous studies determined the conversion factor by regressing particulate organic matter with chlorophyll \( a \).

Algal growth rate is computed by modifying a maximum growth rate affected by temperature, light, and nutrient availability:

\[ K_{ag} = \gamma_{at} \gamma_{af} \lambda_{min} K_{agmax} \quad (B-6) \]

where

\[ \gamma_{at} = \text{temperature rate multiplier for rising limb of curve} \]
\[ \gamma_{af} = \text{temperature rate multiplier for falling limb of curve} \]
\[ \lambda_{min} = \text{multiplier for limiting growth factor (minimum of light, phosphorus, and nitrogen)} \]
\[ K_{ag} = \text{algal growth rate, } sec^{-1} \]
\[ K_{agmax} = \text{maximum algal growth rate, } sec^{-1} \]

Rate multipliers for algal growth are computed based upon available light (\( \lambda_i \)), phosphorus (\( \lambda_p \)), and nitrogen (\( \lambda_n \)). The rate multiplier for light is based upon the Steele (1962) function:

\[ \lambda_i = \frac{I}{I_s} e^{\left( \frac{I}{I_s} - 1 \right)} \quad (B-7) \]

where

\[ I = \text{available light, } W \frac{m^2}{m^2} \]
\[ I_s = \text{saturating light intensity at maximum photosynthetic rate, } W \frac{m^2}{m^2} \]
\[ \lambda_i = \text{light limiting factor} \]

The above expression allows for simulation of photoinhibition at light intensities greater than the saturation value. However, light penetration decreases with depth:

Appendix B Water Quality
KINETICS

\[ I = (1-\beta) I_0 e^{-\alpha z} \]  

(B-8)

where

\[ I_0 = \text{solar radiation at the water surface, } W \text{ m}^2 \]
\[ \alpha = \text{attenuation coefficient, } m^{-2} \]
\[ z = \text{depth, } m \]
\[ \beta = \text{fraction of solar radiation absorbed at the water surface} \]

The average effect of light on algal growth in a particular model cell can be obtained by combining the above two expressions and integrating over the cell depth to obtain (Chapra and Reckhow, 1983):

\[ \lambda_i = \frac{e}{\alpha \Delta z} \left[ e^{-\gamma_1} - e^{-\gamma_2} \right] \]  

(B-9)

where

\[ \gamma_1 = \frac{(1-\beta)I_0}{I_0} e^{-\alpha d} \]
\[ \gamma_2 = \frac{(1-\beta)I_0}{I_0} e^{\alpha (d+\Delta z)} \]

\[ d = \text{depth at top of model cell, } m \]

Units used for solar radiation in computing algal growth, Watts per square meter, differ from those used in heat exchange computations, degrees Celsius per meter per second. The model makes this conversion internally.

The fraction of solar radiation, \( \beta I_0 \), is added directly to the surface layer. The attenuation coefficient, \( \alpha \), consists of a baseline value [EXH2O] to which the effects of inorganic [EXINOR] and organic [EXORG] suspended solids are added (see page C79).

Rate multipliers limiting algal growth due to concentrations of phosphorus and nitrogen are computed using the Monod relationship:
\[
\lambda_i = \frac{\Phi_i}{P_i + \Phi_i}
\]  \hspace{1cm} (B-10)

where

\[
\begin{align*}
\Phi_i &= \text{phosphorus or nitrate + ammonia-nitrogen concentration, } g \ m^{-3} \\
P_i &= \text{half-saturation coefficient for phosphorus or nitrate + ammonia-nitrogen, } g \ m^{-3}
\end{align*}
\]

Algal dark respiration is computed using the rising limb of the temperature function:

\[
K_{ar} = \gamma_{ar} K_{ar\text{max}}
\]  \hspace{1cm} (B-11)

where

\[
K_{ar\text{max}} = \text{maximum dark respiration rate, sec}^{-1}
\]

Algal photorespiration (excretion) is evaluated using an inverse relation to the light rate multiplier:

\[
K_{ae} = (1 - \lambda_i) K_{ae\text{max}}
\]  \hspace{1cm} (B-12)

where

\[
\begin{align*}
K_{ae\text{max}} &= \text{maximum excretion rate constant, sec}^{-1} \\
\lambda_i &= \text{light limiting factor}
\end{align*}
\]

Excretion rates increase at both low and high light intensities, with excretion products contributing to labile DOM.

Algal mortality is defined as:

\[
K_{am} = \gamma_{ar} K_{am\text{max}}
\]  \hspace{1cm} (B-13)

where

\[
K_{am\text{max}} = \text{maximum mortality rate, sec}^{-1}
\]

This mortality rate represents both natural and predator mortality. Algal growth does not occur in the absence of light. Algal growth is not allowed to
exceed the limit imposed by nutrient supply over a given timestep. Algal excretion is not allowed to exceed algal growth rates.

Similar to inorganic solids, settling algae serve as a source for the layer below. Unlike inorganic solids, algae passing to the sediments accumulate within the sediment compartment. Detritus is also accumulated.

**Phosphorus**

Phosphorus is an important element in aquatic ecosystems since it serves as one of the primary nutrients for phytoplankton growth. In many fresh waters, phosphorus is considered to be the nutrient limiting maximum production of phytoplankton biomass (Schindler, 1971; Schindler et al., 1973; Vollenweider, 1968, 1976).

Phosphorus is assumed to be completely available as orthophosphate (PO₄) for uptake by phytoplankton. Measurements of soluble reactive phosphorus are closest to the form used in the model.

![Diagram showing the internal flux between phosphorus and other compartments](image)

**Figure B-7. Internal flux between phosphorus and other compartments.**
KINETICS

PHOSPHORUS

Referring to Figure B-7, the rate equation for phosphorus is:

\[
\frac{\partial \Phi_p}{\partial t} = (K_{ar} - K_{ag}) \delta_p \Phi_a + K_{dom} \delta_p \gamma_{om} \Phi_{dom} + K_{dt} \delta_p \gamma_{om} \Phi_{dt}
\]

\[
+ K_{rdom} \delta_p \gamma_{om} \Phi_{rdom} + K_s \delta_p \gamma_{om} \Phi_s + S_{ad} \gamma_{om} \gamma_{om} A_s
\]

\[
-B-15
\]

\[
- \frac{P_p (\omega_{ss} \Phi_{ss} + \omega_{dt} \Phi_{dt} + \omega_{FE} \Phi_{FE})}{\Delta z} \Phi_p
\]

where

- \Delta z = \text{model cell thickness, m}
- A_s = \text{sediment area, m}^2
- P_p = \text{adsorption coefficient, m}^3 \text{ g}^{-1}
- \delta_p = \text{stoichiometric coefficient for phosphorus}
- \gamma_{om} = \text{temperature rate multiplier for organic matter decay}
- \omega_i = \text{settling velocities, m sec}^{-1}
- K_{ar} = \text{algal dark respiration rate, sec}^{-1} (\text{see equation B-11})
- K_{ag} = \text{algal growth rate, sec}^{-1} (\text{see equation B-6})
- K_{dom} = \text{labile DOM decay rate, sec}^{-1}
- K_{dt} = \text{detritus decay rate, sec}^{-1}
- K_s = \text{sediment decay rate, sec}^{-1}
- S_{ad} = \text{anaerobic sediment release rate, g m}^{-3}
- K_{rdom} = \text{refractory DOM decay rate, sec}^{-1}
- \Phi_{dom} = \text{refractory DOM concentration, g m}^{-3}
- \Phi_s = \text{algal concentration, g m}^{-3}
- \Phi_{dom} = \text{labile DOM concentration, g m}^{-3}
- \Phi_{dt} = \text{detritus concentration, g m}^{-3}
- \Phi_s = \text{organic sediment mass, g}
- \Phi_{ss} = \text{inorganic suspended solids concentration, g m}^{-3}
- \Phi_p = \text{phosphorus concentration, g m}^{-3}
- \Phi_{FE} = \text{total iron concentration, g m}^{-3}

and the rate terms are evaluated in subroutine PHOSPHORUS.

The contribution of algae, detritus, and DOM to phosphorus is given in the rate equations and Figure B-7. However, effects due to settling and contribution from sediments require some additional explanation.

Phosphorus adsorbs onto particulates under oxic conditions and is lost when these materials settle. Loss may be rapid in the upper end of reservoirs (riverine and transition zones) due to greater concentrations of allochthonous particu-
lates. Loss occurs at a slower rate in the lacustrine zone as phosphorus adsorbs onto authochthonous particulates which may settle at a slower rate. A Langmuir isotherm describes this process. Since phosphorus concentrations are generally small, only the isotherm's linear region is utilized and is represented by the product $P_p \Phi_p$. The adsorbed solids settle at a rate equal to the solids' settling velocity. Adsorption is not allowed to occur if dissolved oxygen concentrations are less than a minimum value [O2LIM] (see page C106).

Sediment contribution of phosphorus to overlying waters can be simulated in three ways. In the first, the sediment compartment accumulates detritus and algae which then decay. This is modeled as a first-order process. However, sediment phosphorus release depends upon sediment age, chemistry, overlying phosphorus concentrations, and other factors not included in the sediment compartment. In the second, sediments can be assigned a release rate for phosphorus that is independent of sediment concentrations. Sediments are modeled as a "black box" using a zero-order rate. Phosphorus release is only allowed to occur if the overlying water dissolved oxygen concentration is less than a minimum value [O2LIM] (see page C106). The third method is a combination of the first two where organic materials accumulate and decay in the sediments along with a background decay rate independent of organic matter accumulation in the sediments.

**Ammonia-Nitrogen**

Ammonia-nitrogen is used by algae during photosynthesis to form proteins. In many estuarine applications, nitrogen is the limiting nutrient for algal growth.

Referring to Figure B-8, the rate equation for ammonia-nitrogen is:

$$
\frac{\partial \Phi_{\text{NH4}}}{\partial t} = K_{az} \delta_N \Phi_s - K_{az} \delta_N \Phi_s \frac{\Phi_{\text{NH4}}}{\Phi_{\text{NH4}} + \Phi_{\text{NO3}}} + K_{\text{dom}} \delta_N \gamma_{\text{om}} \Phi_{\text{dom}} \\
+ K_{\text{dom}} \delta_N \gamma_{\text{om}} \Phi_{\text{dom}} + K_{di} \delta_N \gamma_{\text{om}} \Phi_{di} + K_s \delta_N \gamma_{\text{om}} \Phi_s \\
+ S_{\text{NH4}} \gamma_{\text{om}} A_s + K_{\text{NO3}} \gamma_{\text{NO3}} \Phi_{\text{NO3}} - K_{\text{NH4}} \gamma_{\text{NH4}} \Phi_{\text{NH4}} \tag{B-16}
$$

where

- $A_s$ = sediment area, $m^2$
- $\Delta z$ = cell thickness, $m$
- $\delta_N$ = stoichiometric coefficient for nitrogen
- $\gamma_{\text{om}}$ = temperature rate multipliers for organic matter decay
- $\gamma_{\text{NH4}}$ = temperature rate multiplier for nitrification
- $\gamma_{\text{NO3}}$ = temperature rate multiplier for denitrification
Figure B-8. Internal flux between ammonia-nitrogen and other compartments.

\[ K_{ar} = \text{algal dark respiration rate, sec}^{-1} \text{ (see equation B-11)} \]
\[ K_{ag} = \text{algal growth rate, sec}^{-1} \text{ (see equation B-6)} \]
\[ K_{ldom} = \text{labile DOM decay rate, sec}^{-1} \]
\[ K_{rdom} = \text{refractory DOM decay rate, sec}^{-1} \]
\[ K_{dt} = \text{detritus decay rate, sec}^{-1} \]
\[ K_s = \text{sediment decay rate, sec}^{-1} \]
\[ S_{NH_4} = \text{sediment ammonia release rate, g m}^{-2} \text{ sec}^{-1} \]
\[ K_{NO_3} = \text{nitrato-nitrogen decay rate, sec}^{-1} \]
\[ K_{NH_4} = \text{ammonia-nitrogen decay rate, sec}^{-1} \]
\[ \Phi_{ss} = \text{suspended solids concentration, g m}^{-3} \]
\[ \Phi_{ldom} = \text{labile DOM, g m}^{-3} \]
\[ \Phi_{rdom} = \text{refractory DOM, g m}^{-3} \]
\[ \Phi_a = \text{algal concentration, g m}^{-3} \]
\[ \Phi_{dt} = \text{detritus concentration, g m}^{-3} \]
\[ \Phi_{NH_4} = \text{ammonia-nitrogen concentration, g m}^{-3} \]
\[ \Phi_{NO_3} = \text{nitrato-nitrogen concentration, g m}^{-3} \]
\[ \Phi_s = \text{sediment mass, g} \]

and the rate terms are evaluated in subroutine AMMONIA. As with phosphorus, zero-order sediment release only occurs when dissolved oxygen is less than a minimum value [O2LIM] (see page C106). Either a zero- or first-order process or a combination of both may be used for sediment ammonia release.
Nitrate-Nitrogen

This compartment represents nitrate plus nitrite-nitrogen. Nitrite is an intermediate product in nitrification between ammonium and nitrate. Nitrate is used as a source of nitrogen for algae and macrophytes during photosynthesis.

Nitrogen may be the limiting nutrient for algae in systems with high phosphorus loadings or in estuaries. Some species of blue-green algae are capable of fixing atmospheric nitrogen for use in photosynthesis. Nitrogen fixation is not in the model, so simulations dominated by nitrogen-fixing blue-green algae should be interpreted cautiously.

Figure B-9. Internal flux between nitrate + nitrite-nitrogen and other compartments.

Referring to Figure B-9, the rate equation for nitrate-nitrogen is:

\[
\frac{d\Phi_{NO3}}{dt} = K_{NH4} \gamma_{NH4} \Phi_{NH4} - K_{NO3} \gamma_{NO3} \Phi_{NO3}
\]

\[
- K_{ag} \delta N \Phi_a \left(1 - \frac{\Phi_{NH4}}{\Phi_{NH4} + \Phi_{NO3}}\right)
\]

(B-17)
where

\[ \gamma_{\text{NH}_4} = \text{temperature rate multiplier for nitrification} \]
\[ \gamma_{\text{NO}_3} = \text{temperature rate multiplier for denitrification} \]
\[ \delta_n = \text{stoichiometric coefficient for nitrogen} \]
\[ K_{\text{NH}_4} = \text{nitrification rate, } sec^{-1} \]
\[ K_{\text{NO}_3} = \text{denitrification rate, } sec^{-1} \]
\[ K_g = \text{algal growth rate, } sec^{-1} \text{ (see equation B-6)} \]
\[ \Phi_a = \text{algal concentration, } g \text{ m}^3 \]
\[ \Phi_{\text{NH}_4} = \text{ammonia-nitrogen concentration, } g \text{ m}^3 \]
\[ \Phi_{\text{NO}_3} = \text{nitrate-nitrogen concentration, } g \text{ m}^3 \]

and the rate terms are evaluated in subroutine NITRATE. Nitrification is only allowed to occur if oxygen is present, and denitrification is allowed only if dissolved oxygen is less than a specified minimum value [O2LIM] (see page C106).

**Dissolved Oxygen**

Oxygen is one of the most important elements in aquatic ecosystems. It is essential for higher forms of life, controls many chemical reactions through oxidation, and is a surrogate variable indicating the general health of aquatic systems.

CE-QUAL-W2 includes both aerobic and anaerobic processes. The ability to model anaerobic periods is important since it provides information on potential problems with water quality. Simulations can be used to identify possibilities for both metalimnetic and hypolimnetic oxygen depletion and its impact on various water control management alternatives. If a single variable were to be measured in aquatic systems that would provide maximum information about the system state, it would be dissolved oxygen.
KINETICS

DISTRIBUTED OXYGEN

Referring to Figure B-10, the rate equation for dissolved oxygen is:

\[
\frac{\partial \Phi_{\text{DO}}}{\partial t} = K_{\text{ag}} \delta_{\text{om}} \Phi_a - K_{\text{ar}} \delta_{\text{om}} \Phi_a - K_{\text{N}+\text{NH}_4} \delta_{\text{NH}_4} \gamma_{\text{NH}_4} \Phi_{\text{NH}_4}
\]

\[
- K_{\text{AS}} \delta_{\text{om}} \gamma_{\text{om}} \Phi_{\text{AS}} - K_{\text{DS}} \gamma_{\text{om}} \Phi_{\text{DS}} - S_{\text{OD}} \gamma_{\text{om}} A_5
\]

\[
- K_{\text{Idom}} \delta_{\text{om}} \gamma_{\text{om}} \Phi_{\text{Idom}} - K_{\text{Rdom}} \gamma_{\text{om}} \Phi_{\text{Rdom}} + A_{\text{ki}} E_0 (\Phi_{\text{DO}} - \Phi_{\text{DO}})
\]

(B-18)

where

- \( A_5 \) = sediment surface area, \( m^2 \)
- \( A_{\text{St}} \) = water surface area, \( m^2 \)
- \( \delta_{\text{om}} \) = oxygen stoichiometric coefficient for organic matter
- \( \delta_{\text{NH}_4} \) = oxygen stoichiometric coefficient for nitrification
- \( \gamma_{\text{NH}_4} \) = temperature rate multiplier for nitrification
- \( \gamma_{\text{om}} \) = temperature rate multiplier for organic matter decay
- \( K_{\text{ag}} \) = algal growth rate, \( \text{sec}^{-1} \) (see equation B-6)
- \( K_{\text{ar}} \) = algal dark respiration rate, \( \text{sec}^{-1} \) (see equation B-11)
- \( K_{\text{AS}} \) = ammonia decay (nitrification) rate, \( \text{sec}^{-1} \)
- \( K_{\text{DS}} \) = detritus decay rate, \( \text{sec}^{-1} \)
- \( K_{\text{Idom}} \) = labile DOM decay rate, \( \text{sec}^{-1} \)
- \( K_{\text{Rdom}} \) = refractory DOM decay rate, \( \text{sec}^{-1} \)
- \( K_\gamma \) = sediment decay rate, \( \text{sec}^{-1} \)
- \( S_{\text{OD}} \) = sediment oxygen demand, \( g \ m^2 \ \text{sec}^{-1} \)
- \( E_0 \) = interfacial exchange rate for oxygen, \( m \ \text{sec}^{-1} \)
- \( C_\alpha \) = algal concentration, \( g \ m^3 \)
- \( \Phi_{\text{Idom}} \) = labile DOM concentration, \( g \ m^3 \)
- \( \Phi_{\text{Rdom}} \) = refractory DOM concentration, \( g \ m^3 \)
- \( \Phi_{\text{DS}} \) = detritus concentration, \( g \ m^3 \)
- \( \Phi_{\text{NH}_4} \) = ammonia-nitrogen concentration, \( g \ m^3 \)
- \( \Phi_{\text{DO}} \) = dissolved oxygen concentration, \( g \ m^3 \)
- \( \Phi_\gamma \) = sediment mass, \( g \)
- \( \Phi_{\text{DO}}^{-} \) = saturation DO concentration, \( g \ m^3 \) (see equation B-22)

and the rate terms are evaluated in subroutine DISSOLVED_OXYGEN. Decay is not allowed to occur when dissolved oxygen concentrations are zero. This is accomplished by setting temperature rate multipliers equal to zero.
Figure B-10. Internal flux between dissolved oxygen and other compartments.

The interfacial exchange rate is computed according to Kanwischer (1963):

$$E_o = \frac{D_o}{\left[200-60\sqrt{W_s}\right] \times 10^{-6}} \quad \text{(B-19)}$$

where

- $D_o = \text{molecular diffusivity of dissolved oxygen}$
- $W_s = \text{wind speed, m sec}^{-1}$

$W_s$ is limited to 11 m sec$^{-1}$ to avoid instabilities. An alternative expression from Mackay (1980, as reported in Chapra and Reckhow 1983) is:

$$E_o = 6.4185 \times 10^{-6} \frac{W_s^{1.5}}{\sqrt{M_{O2}}} \quad \text{(B-20)}$$

where

- $M_{O2} = \text{molecular weight of oxygen}$
KINETICS

The FORTRAN code must be changed in subroutine DISSOLVED_OXYGEN to use this formulation.

Saturation dissolved oxygen is calculated from Mortimer (1981)

\[ \Phi'_{DO} = e^{(7.7117 - 1.31403 \ln(T_i \cdot 45.93))} \]  \hspace{1cm} (B-21)

where

\[ T_i = \text{surface water temperature, } ^\circ \text{C} \]
\[ \Phi'_{DO} = \text{saturation dissolved oxygen concentration, g m}^{-3} \]

Saturation concentration is corrected for altitude by:

\[ \Phi'_{DO} = \Phi_{DO} \left(1 - \frac{H}{44.3}\right)^{5.25} \]  \hspace{1cm} (B-22)

where

\[ H = \text{reservoir altitude, km} \]

SEDIMENTS

Sediments

Organic sediment contributions to nutrients and dissolved oxygen demand is simulated in two ways in the model. The first method uses a constant, or zero-order, release and demand. This method has been frequently used to model sediment demands and release rates. It does not depend on sediment concentrations or require a separate sediment compartment. However, the formulation is not predictive. As a consequence, results should be interpreted cautiously when evaluating effects of different nutrient loadings on dissolved oxygen in a waterbody.

The second method uses a sediment compartment to accumulate organic sediments and allow their decay. Nutrient releases and oxygen demand are thus dependent upon sediment accumulation - a first-order process. However, there is no accumulation of phosphorus or other diagenesis products when overlying water is oxic. Version 3.0 will include a fully predictive sediment model. Either of these methods, or a combination, may be used to simulate effects of organic sediments upon water quality. Again, caution must be exercised to avoid errors if both pathways are used.

The zero-order process uses a specified sediment oxygen demand and release rates for phosphorus, ammonia-nitrogen, and iron which are temperature depen
Figure B-11. Internal flux between organic sediments and other compartments.

Decay and nutrient releases do not occur when dissolved oxygen concentrations are above a minimum value [O2LIM] (see page C106). The sediment contribution to inorganic carbon is computed as a fraction of the sediment oxygen demand.

The first-order process requires specifying inclusion of this compartment in the simulation, a decay rate, and initial conditions. The sediment compartment is not transported. Instead, a compartmental equation is written for the sediment compartment which is solved within the subroutine SEDIMENT.

Referring to Figure B-11, the compartment equation for organic sediment is:

\[
\frac{d\Phi_s}{dt} = \frac{\omega_{dt}}{\Delta z} \Phi_{dt} + \frac{\omega_a}{\Delta z} \Phi_a - \gamma_{om} K_s \Phi_s
\]

(B-23)

where

- \(\Delta z\) = model cell thickness, m
- \(\omega_{dt}\) = detritus settling velocity, m sec\(^{-1}\)
- \(\omega_a\) = algal settling velocity, m sec\(^{-1}\)
- \(\gamma_{om}\) = rate multiplier for organic matter
- \(K_s\) = sediment decay rate, sec\(^{-1}\)
- \(\Phi_a\) = algal concentration, g m\(^{-3}\)
- \(\Phi_{dt}\) = detritus concentration, g m\(^{-3}\)
- \(\Phi_s\) = sediment mass, g
Total Inorganic Carbon

Carbon, hydrogen, and oxygen are the most abundant elements in living matter and form the essential backbone of organic material. Inorganic carbon directly influences pH.

Referring to Figure Figure B-12, the rate equation for total inorganic carbon is:

$$\frac{\partial \Phi_{\text{inc}}}{\partial t} = (K_{\text{al}} - K_{\text{sg}}) \delta_c \Phi_s + K_{\text{dl}} \delta_c \gamma_{\text{om}} \Phi_{\text{dt}} + K_s \gamma_{\text{om}} \delta_c \Phi_s$$

$$+ K_{\text{dom}} \gamma_{\text{om}} \delta_c \Phi_{\text{dom}} + K_{\text{reom}} \gamma_{\text{om}} \delta_c \Phi_{\text{reom}}$$

$$+ S_{\text{od}} \gamma_{\text{om}} \delta_s A_s + A_{\text{kt}} E_c (\Phi_{\text{CO}_2} - \Phi_{\text{CO}_2}) \quad (B-24)$$

where

- $A_s = \text{sediment surface area, } m^2$
- $A_{\text{kt}} = \text{surface area of top cell, } m^2$
- $\gamma_{\text{om}} = \text{temperature rate multipliers}$
- $\delta_c = \text{stoichiometric coefficients for carbon}$
- $K_{\text{al}} = \text{algal dark respiration rate, } sec^{-1} \text{ (see equation B-11)}$
- $K_{\text{sg}} = \text{algal growth rate, } sec^{-1} \text{ (see equation B-6)}$
- $K_{\text{dl}} = \text{detritus decay rate, } sec^{-1}$
- $K_s = \text{sediment decay rate, } sec^{-1}$
- $K_{\text{dom}} = \text{labile DOM decay rate, } sec^{-1}$
- $K_{\text{reom}} = \text{refractory DOM decay rate, } sec^{-1}$
- $S_{\text{od}} = \text{sediment oxygen demand, } g \ m^{-2} \ sec^{-1}$
- $E_c = \text{inorganic carbon interfacial exchange rate, } m \ sec^{-1}$
- $\Phi_{\text{dom}} = \text{labile DOM concentration, } g \ m^{-3}$
- $\Phi_{\text{reom}} = \text{refractory DOM concentration, } g \ m^{-3}$
- $\Phi_s = \text{algal concentration, } g \ m^{-3}$
- $\Phi_{\text{dt}} = \text{detritus concentration, } g \ m^{-3}$
- $\Phi_s = \text{sediment mass, } g$
- $\Phi_{\text{bc}} = \text{inorganic carbon concentration, } g \ m^{-3}$
- $\Phi_{\text{CO}_2} = \text{carbon dioxide concentration, } g \ m^{-3}$
- $\Phi_{\text{CO}_2} = \text{carbon dioxide saturation concentration, } g \ m^{-3} \text{ (see equation B-27)}$

and the rate terms are evaluated in subroutine INORGANIC\_CARBON.
Figure B-12. Internal flux between inorganic carbon and other compartments.

Interfacial exchange is computed from Kanwischer (1963):

$$E_c = \frac{D_c}{200 - 60 \sqrt{W_a}} \times 10^{-6}$$  \hspace{1cm} (B-25)

where
- $D_c$ = molecular diffusivity of carbon dioxide
- $W_a$ = wind speed, $m \text{ sec}^{-1}$

An alternative expression from Mackay (1980, in Chapra and Reckhow 1983) can also be used:

$$E_c = 6.4185 \times 10^{-6} \frac{W_a^{1.5}}{\sqrt{M_{CO2}}}$$  \hspace{1cm} (B-26)

where
- $M_{CO2}$ = molecular weight of carbon dioxide
Appropriate coding must be substituted to use this or another formula.

Carbon dioxide concentration for the interfacial exchange rate is determined from total inorganic carbon and alkalinity in subroutine PH_CO2. The saturation concentration of carbon dioxide is determined from:

\[
\Phi_{\text{CO}_2} = 0.286 e^{(-0.0314 T) P_a}
\]  \hspace{1cm} (B-27)

where

\[ P_a = \text{altitude correction factor} \]
\[ T_i = \text{surface cell water temperature, } ^\circ\text{C} \]

Altitude correction is from Mortimer, 1981:

\[
P_a = \left(1 - \frac{H}{44.3}\right)^{5.25}
\]  \hspace{1cm} (B-28)

where

\[ H = \text{reservoir elevation from sea level, km} \]

Alkalinity

Alkalinity provides an indication of the buffering capacity of aquatic systems and their resistance to pH changes from acidic or alkaline loadings. Alkalinity is treated as conservative in the model and its internal rate term is set to zero. Alkalinity, along with total inorganic carbon, is used to determine pH and concentrations of carbonate species in subroutine PH_CO2.

In reality, alkalinity variations are common in most aquatic systems. Whitings, or large precipitations of carbonates, may occur. Sediment release of carbonates may increase alkalinity in the anoxic zones of many reservoirs. If these effects are important, a non-conservative model of alkalinity should be added. Version 3.0 will include a non-conservative algorithm for alkalinity.

**pH and Carbonate Species**

The pH and carbonate species are computed using water temperature, TDS or salinity, alkalinity, and total inorganic carbon concentrations using basic carbonate relationships. Computed carbonate species are carbon dioxide, bicarbonates, and carbonates. The pH and carbonate species are computed in subroutine
PH\_CO2. These materials are not subject to transport and are computed at each water quality update interval.

Calculations performed by subroutine PH\_CO2 are based on the carbonate--bicarbonate equilibrium reaction (Stumm and Morgan 1981):

\[
\begin{align*}
\text{CO}_2 + \text{H}_2\text{O} & \rightleftharpoons \text{H}_2\text{CO}_3 \rightleftharpoons \text{H}^+ + \text{HCO}_3^- \quad (\text{B-29}) \\
\text{HCO}_3^- & \rightleftharpoons \text{CO}_3^- + \text{H}_\text{2} \quad (\text{B-30}) \\
\text{H}_2\text{O} & \rightleftharpoons \text{H}^+ + \text{OH}^- \quad (\text{B-31})
\end{align*}
\]

These equilibria express the source of bicarbonate and carbonate ions, alkaline constituents, and dissolution of atmospheric CO\_2 in water. Contribution of calcium and magnesium carbonate to alkalinity is not included. The equilibrium state in terms of the equilibrium constants $K_i$ is:

\[
\begin{align*}
K_1 &= \frac{[\text{H}^+][\text{HCO}_3^-]}{[\text{H}_2\text{CO}_3]} \quad (\text{B-32}) \\
K_2 &= \frac{[\text{H}^+][\text{CO}_3^-]}{[\text{HCO}_3^{-}]} \quad (\text{B-33}) \\
K_w &= \frac{[\text{H}^+][\text{OH}^-]}{[\text{H}_2\text{O}]} \quad (\text{B-34})
\end{align*}
\]

where

- $[X]$ = molar concentration of X
- $[\text{H}_2\text{O}]$ = unity (by definition)

Alkalinity is defined as:
KINETICS  

pH AND CARBONATE SPECIES

\[ [\text{ALK}] = [\text{HCO}_3^-] + 2[\text{CO}_3^{2-}] + [\text{OH}^-] - [\text{H}^+] \quad (B-35) \]

The following condition prevails for the dissolution of carbonic acid:

\[ [\text{H}_2\text{CO}_3] + [\text{HCO}_3^-] + [\text{CO}_3^{2-}] = \text{CONSTANT} = C_T \quad (B-36) \]

By combining equations B-32, B-33, and B-36, the quantities \([\text{HCO}_3^-]\) and \([\text{CO}_3^{2-}]\) can be expressed in terms of \([\text{H}^+]\) and the constant \(C_T\). In addition, equation B-34 allows for \([\text{OH}^-]\) to be expressed in terms of \([\text{H}^+]\). When these expressions are included in equation B-35, the result is:

\[ [\text{ALK}] = \frac{C_T[\text{H}^+]K_1}{[\text{H}^+]K_1 + K_1K_2 + [\text{H}^+]^2} + \frac{K_w}{[\text{H}^+]^2} - [\text{H}^+] \quad (B-37) \]

The model interprets the constant \(C_T\) as moles per liter of total inorganic carbon and assumes \([\text{ALK}]\) is known. Equation B-37 is iteratively solved in subroutine PH_CO2 until the value of \([\text{H}^+]\) converges. The negative logarithm of \([\text{H}^+]\) is, by definition, \(pH\).

Once equation B-37 has been solved for \([\text{H}^+]\), then \([\text{H}_2\text{CO}_3]\) is given by:

\[ [\text{H}_2\text{CO}_3] = \frac{C_T}{1 + \frac{K_1}{[\text{H}^+] + \frac{K_1K_2}{[\text{H}^+]^2}}} \quad (B-38) \]

and is the same as \([\text{CO}_3^{2-}]\). Bicarbonate concentration is computed from:

\[ [\text{HCO}_3^-] = \frac{C_T}{1 + \frac{[\text{H}^+]}{K_1} + \frac{K_2}{[\text{H}^+]}} \quad (B-39) \]

and carbonate from:

B26  
Appendix B Water Quality
KINETICS

\[ [\text{CO}_3^{2-}] = \frac{C_T}{1 + \frac{[\text{H}^+]^2}{K_1K_2} + \frac{[\text{H}^+]}{K_2}} \]  

(B-40)

which are then converted to grams per cubic meter.

Equilibrium constants in the preceding equations are obtained by first expressing a thermodynamic temperature dependence for a related constant, \( K_i^* \):

\[ \log K_i^* = a + \frac{b}{T} + cT + d \log T \]  

(B-41)

The constants \( a, b, c, \) and \( d \) are:

<table>
<thead>
<tr>
<th>( K_i^* )</th>
<th>( a )</th>
<th>( b )</th>
<th>( c )</th>
<th>( d )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( K_{w}^* )</td>
<td>35.3944</td>
<td>-5242.39</td>
<td>-0.00835</td>
<td>11.8261</td>
</tr>
<tr>
<td>( K_1^* )</td>
<td>14.8435</td>
<td>-3404.71</td>
<td>-0.03278</td>
<td>0</td>

<tr>
<td>( K_2^* )</td>
<td>6.4980</td>
<td>-2902.39</td>
<td>-0.02379</td>
<td>0</td>
</tr>
</tbody>
</table>

The relation between \( K_i \) and \( K_i^* \) is obtained from the definition of the activity of a chemical species:

\[ \{X\} = \gamma [X] \]  

(B-42)

where

\[ \{X\} = \text{activity of species } X, \text{ moles liter}^{-1} \]

\[ \gamma = \text{dimensionless activity coefficient} \]

\[ [X] = \text{concentration, moles litre}^{-1} \]
KINETICS

pH AND CARBONATE SPECIES

For the reaction:

\[ A + B \rightleftharpoons C + D \]  \hspace{1cm} (B-43)

the equilibrium constant \( K^* \) is:

\[ K^* = \frac{\{C\} \{D\}}{\{A\} \{B\}} \]  \hspace{1cm} (B-44)

thus:

\[ K^* = \frac{\gamma_c \{C\} \gamma_D \{D\}}{\gamma_A \{A\} \gamma_B \{B\}} = \frac{\gamma_c \gamma_D}{\gamma_A \gamma_B} K \]  \hspace{1cm} (B-45)

\[ K = \frac{\gamma_A \gamma_B}{\gamma_c \gamma_D} K^* \]  \hspace{1cm} (B-46)

Activity coefficients are obtained from an extension of Debye-Huckel theory as:

\[ \log \gamma = \frac{-AZ^2\sqrt{I}}{1 + 0.33a\sqrt{I}} + k_1 + k_2I + k_3I^2 \]  \hspace{1cm} (B-47)

where

- \( I \) = ionic strength
- \( Z \) = ionic charge
- \( A \) = approximately 0.5 for water at 25° C
- \( a \) = ionic size parameter
- \( k_i \) = empirical coefficients

Ionic strength is approximated as (Sawyer and McCarty 1967):
KINETICS

pH AND CARBONATE SPECIES

\[ I = 2.5 \times 10^{-3} \times \Phi_{\text{TDS}} \quad (B-48) \]

or for salinity:

\[ I = 0.00147 + 0.019885 \Phi_{\text{sal}} + 0.000038 \Phi_{\text{sal}}^2 \quad (B-49) \]

where

\( \Phi_{\text{TDS}} \) = total dissolved solids, g \( m^3 \)
\( \Phi_{\text{sal}} \) = salinity, kg \( m^3 \)

Values of the other parameters are:

<table>
<thead>
<tr>
<th></th>
<th>Z</th>
<th>a</th>
<th>( k_1 )</th>
<th>( k_2 )</th>
<th>( k_3 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>HCO(_3)</td>
<td>1</td>
<td>4</td>
<td>0.0047</td>
<td>0.042</td>
<td>-0.0093</td>
</tr>
<tr>
<td>CO(_2) (_3)</td>
<td>2</td>
<td>4.5</td>
<td>0.0121</td>
<td>0.0972</td>
<td>-0.0207</td>
</tr>
</tbody>
</table>

Activity coefficients for \([H^+]\), \([OH^-]\), \([H_2CO_3]\), and \([H_2O]\) are treated as special cases:

\[ [H^+] \gamma = [H_2O] \gamma = 1 \]
\[ [H_2CO_3] \gamma = [OH^-] \gamma = 0.07551 \]

**Total Iron**

Total iron is included in the model primarily because of its effect on nutrient concentrations through adsorption and settling. Iron is commonly released from anoxic sediments and may influence nutrient dynamics in many reservoirs. Iron may also contribute to dissolved oxygen depletions, but the model does not presently include these effects. Iron sediment release is modeled as a zero-order process.
Referring to Figure B-13, the rate equation for total iron is:

\[
\frac{\partial \Phi_{FE}}{\partial t} = S_{FE} \gamma_{om} A_s - \frac{\omega_{FE}}{\Delta z} \Phi_{FE}
\]  

(B-50)

where

- \( A_s \) = sediment area, \( m^2 \)
- \( \Delta z \) = cell thickness, \( m \)
- \( \gamma_{om} \) = temperature rate multiplier
- \( \omega_{FE} \) = settling velocity, \( m \ sec^{-1} \)
- \( S_{FE} \) = sediment release rate, \( g \ m^2 \ sec^{-1} \)
- \( \Phi_{FE} \) = total iron concentration, \( g \ m^3 \)

and the rate terms are evaluated in subroutine TOTAL_IRON.

![Figure B-13. Internal flux between total iron and other compartments.](image)

**Temperature Rate Multipliers**

Most biological and chemical rates are temperature dependent. Subroutine RATE_MULTIPLIERS calculates the temperature dependence for all rates. It is called after the temperature solution so the temperature of the current computational interval is used.
A representative rate multiplier function is shown in Figure B-14 with its $K$ and $T$ parameters. The curve shape represents how biological process rates exhibit an optimum range and diminish (asymmetrically) at higher and lower temperatures (Thornton and Lessem 1978).

\[
\lambda_{ii} = 0 \quad \text{when } T \leq T_1
\]

\[
\lambda_{ii} = \frac{K_i e^{\gamma_1(T-T_i)}}{1 + K_i e^{\gamma_1(T-T_i)}} \quad \text{when } T_1 < T < T_4 \quad (B-51)
\]

\[
\lambda_{ii} = 0 \quad \text{when } T \geq T_4
\]

where

\[
\gamma_1 = \frac{1}{T_2 - T_1} \ln \frac{K_2(1-K_1)}{K_1(1-K_2)}
\]

\[
\gamma_2 = \frac{1}{T_4 - T_3} \ln \frac{K_3(1-K_2)}{K_2(1-K_3)}
\]

The user supplies temperatures $T_1$ to $T_4$ and multiplier factors $K_1$ to $K_4$. Temperatures $T_1$ and $T_4$ represent mortality limits, and $T_2$ and $T_3$ are used to define the optimum range. Maximum reaction rates supplied by the user are multiplied by $\lambda_{ii}$ to determine rates corresponding to the water temperature of a model cell.

![Figure B-14. Temperature rate multiplier function.](image)
Appendix C
Input Data Description

Input file format has been developed for a full-screen text editor. Each input file begins with two lines used for file identification which are ignored by the program. The rest of the input file consists of groups of three lines - the first line is blank serving as a separator, the second line contains the card identification and the FORTRAN variable names associated with the input card, and the third line contains the input values. The identifier card is only checked by the pre-processor code. FORTRAN names are right justified according to the field widths associated with the input variable. There are 10 input fields associated with each card although the first field is not used in several of the input files. Each field has a length of eight characters.

Control File

The control file [CONFN] contains the variables used to run the model. There are no optional cards in the control file - each card is required although there may be either zero or no values associated with the card. The following pages contain a description of each card. All character inputs must be capitalized except the TITLE cards or the variable will take on the default value. An example of a portion of the control file for the DeGray Lake case (or in some instances, another application to illustrate features not used in the DeGray Lake application) is given with each card description.
Title (TITLE C)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>TITLE</td>
<td>Character</td>
<td>Text for identification of simulation</td>
</tr>
</tbody>
</table>

There are six title cards that can be used to identify various types of output. Each line may contain up to 72 characters of text. Title cards appear in every output file except for the restart file. Uses for the title cards include identifying the simulation, the simulation time frame, the date the simulation was run, and other information specific to the simulation. A few words of wisdom - the user should be conscientious in updating the title cards for each simulation.

Example

TITLE C                        TITLE
J. Strom Thurmond Lake - scenario run 1
Proposed summer power generation schedule
No pumpback or channel improvement
High Pool Elevation
Stations @ 0.25, 1.25, 2.25, 3.25, 5,75, and 6.75 km from RBR dam
Test run

C2 Appendix C Input Data Description
# Time Control (TIME CON)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2</td>
<td>TMSTRT</td>
<td>Real</td>
<td>Starting time, Julian day</td>
</tr>
<tr>
<td>3</td>
<td>TMEND</td>
<td>Real</td>
<td>Ending time, Julian day</td>
</tr>
<tr>
<td>4</td>
<td>YEAR</td>
<td>Real</td>
<td>Starting year</td>
</tr>
</tbody>
</table>

The simulation starting and ending times are specified with this card. When making a simulation extending into another year, the ending time is calculated as 364 (or 365 for a leap year) + Julian date of ending time. January 1 starts at Julian day 0.0 in the model. This is a different concept than what is usually employed for Julian dates. For example, 12 noon on January 1 would correspond to Julian day 0.5 in the model. Twelve midnight on January 1 would correspond to Julian day 1.0. This is necessary since fractions of Julian days exist in the model.

**Example**

```
TIME CON TMSTRT TMEND YEAR
  63.5  64.5  1980
```
Timestep Control (DLT CON)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2</td>
<td>NDT</td>
<td>Integer</td>
<td>Number of timestep intervals</td>
</tr>
<tr>
<td>3</td>
<td>MINDLT</td>
<td>Real</td>
<td>Minimum timestep, sec</td>
</tr>
</tbody>
</table>

The number of timestep intervals and minimum timestep are specified on this card.

The autostepping algorithm calculates a maximum timestep based on hydrodynamic numerical stability requirements (see page D26) and then uses a fraction of this value for the actual timestep. The user can specify up to 50 intervals in which the maximum timestep and fraction of the timestep can vary. These values are specified in the next three cards. This option is useful during periods of very low flow where the timestep is very large. Under these conditions, small changes in flow will result in large timestep changes which can lead to an excessive number of timestep violations detected by the autostepping algorithm. Also, if any inputs are at hourly intervals, then the maximum timestep should never be more than an hour. For a more detailed description of autostepping, see Appendix D, pages D26-D28.

The minimum timestep is useful during periods of extremely high flows. In these instances, the timestep could become too small to economically run the model. Care should be taken when using this variable as the model may become unstable if the minimum value is set too high.

Example

```
DLT CON NDT MINDLT
  1  1.0
```

Branch Geometry (BRANCH G)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>US</td>
<td>Integer</td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2</td>
<td>DS</td>
<td>Integer</td>
<td>Branch downstream segment</td>
</tr>
<tr>
<td>3</td>
<td>UHS</td>
<td>Integer</td>
<td>Upstream boundary condition</td>
</tr>
<tr>
<td>5</td>
<td>DHS</td>
<td>Integer</td>
<td>Downstream boundary condition</td>
</tr>
</tbody>
</table>

This card specifies the branch location in the grid and branch boundary conditions. The mainstem of the waterbody is always branch 1. Other branches can be ordered in any fashion, but it is good practice to order the remaining branches starting with the most upstream branch and continuing downstream.

The branch upstream segment number [US] is the most upstream potentially active segment. For branch 1, this would always be segment 2. The branch downstream segment number [DS] is the most downstream active segment. The boundary segment is never included for either the upstream or downstream segment.

There are three upstream and downstream boundary conditions which can be specified. Boundary conditions along with the upstream head segment [UHS] and downstream head segment [DHS] value which specify these conditions are:

<table>
<thead>
<tr>
<th>Boundary type</th>
<th>[UHS] and/or [DHS]</th>
</tr>
</thead>
<tbody>
<tr>
<td>External head</td>
<td>-1</td>
</tr>
<tr>
<td>External flow</td>
<td>0</td>
</tr>
<tr>
<td>Internal head</td>
<td>&gt;0</td>
</tr>
</tbody>
</table>

For internal head boundary conditions, [UHS] and/or [DHS] correspond to the branch segment the branch attaches to. See Chapter 3, pages 10-11 for additional information on branch setup.

The user must ensure the number of branches parameter [NBP] in the PARAMETER statement in the file W2_INC.FOR is equal to the number of branches in the computational grid (Chapter 3, see page 21).

Example

```
BRANCH G US DS UHS DHS PHIO
2 31 0 0 5.14
```

<td>LONG</td>
<td>Real</td>
<td>Longitude, <em>degrees</em></td>
</tr>
<tr>
<td>4</td>
<td>ELBOT</td>
<td>Real</td>
<td></td>
</tr>
</tbody>
</table>

This card specifies the waterbody latitude and longitude and bottom reference elevation. The bottom elevation is used to tie computed water surface elevations to an external benchmark (e.g., m above sea level) and represents the elevation at the bottom of the bottommost active cell.

#### Example

```
LOCATION   LAT  LONG  ELBOT
34.2       93.3  66.35
```
## Initial Conditions (INIT CND)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>

<td>T2I</td>
<td>Real</td>
<td></td>
<td>Initial temperature, °C</td>
</tr>
<tr>
<td>3</td>
<td>ICETHI</td>
<td>Real</td>
<td></td>
<td>Initial ice thickness, m</td>
</tr>
<tr>
<td>4</td>
<td>WTYPEC</td>
<td>Character</td>
<td>FRESH</td>
<td>Waterbody type</td>
</tr>
</tbody>
</table>

This card specifies the initial temperature and ice thickness, and waterbody type. Initial temperature can be specified as either a single value, a single vertical profile used to initialize every segment, or a vertical profile for each segment.

#### Initial condition [IT2]

1. Isothermal
   - >0
2. Single vertical profile
   - -1.0
3. Vertical profile at each segment
   - -2.0

If option 2 or 3 is chosen, then the user must specify input files [VPRFN] or [LPRFN] containing the profile(s). See pages C174-C176 for more details on the file specifications.

Initial ice thickness [ICETHI] is ignored if ice computations are turned off (see page A21, C17).

The waterbody type [WTYPEC] is either FRESH or SALT. If [WTYPEC] is set to SALT, then constituent computations [CCC] (see page C69) should be turned on and salinity should be included in the computations.

### Example

```
INIT CND     T2I  ICETHI  WTYPEC
             -1.0  0.0    FRESH
```

<tr>
<td>6</td>
<td>PRC</td>
<td>Character</td>
<td>OFF</td>
<td>Precipitation included</td>
</tr>
</tbody>
</table>

This card specifies whether certain optional calculations are performed by the model. Calculations are turned on or off by *right justifying* ON or OFF in the input field.

Volume balance calculations are useful during initial runs as a check to ensure the model is preserving continuity and should always be used as a check if the user modifies the code. In order to reduce roundoff errors, the volume balance algorithm accumulates spatial and temporal *changes* in volume over time and uses these for comparison. Once the user is satisfied the model is running correctly, volume balance calculations should be turned off to reduce computational time.

Thermal energy and mass balance calculations are similar in use to volume balance calculations. They should be used initially to ensure the model is running properly and turned off for further calculations. When this option is used, mass balances are performed for each constituent if constituent computations are turned on. Mass balances are not computed if only temperature is modeled.

There are two options for distributing mainstem and branch inflows. The default is inflows distributed evenly into each layer from top to bottom. If [PQC] is turned on, then inflows are matched up with the layer(s) whose density most closely corresponds to inflow density.

If precipitation is specified, then the user must supply input files for precipitation and precipitation temperature. If constituents are being modeled, then the user must supply an input file for constituent concentrations included in the simulation. The *Precipitation Active Constituent Control* card specifies which concentrations are included (see page C78).
Evaporation rates are sometimes accounted for in estimating the inflow record. If so, then [EVC] should be set to OFF. Evaporation is always considered in the surface heat exchange calculations.

<td>Character</td>
<td>OFF</td>
<td>Interpolate meteorologic data</td>
</tr>
</tbody>
</table>

These options control whether time-varying data are input as a step function or linearly interpolated between data points. If interpolation is used, then the user must ensure it is appropriate and the input data supply correct information. Many reservoirs have periods of no releases. If outflow interpolation is turned on, then input data must be set up so no outflow occurs during these periods. This is accomplished by including extra dates in the outflow file with zero outflows to ensure the interpolation routine yields zero outflows. For example, given the following outflow time-series in the outflow file [QOTFN]:

```
JDAY QOT
100.00 50.0
110.00 0.0
120.00 50.0
```

If interpolation is not used, then outflow from Julian day 100 to 110 is 50 m$^3$ sec$^{-1}$, from Julian day 110 to 120 is 0.0 m$^3$ sec$^{-1}$, and 50 m$^3$ sec$^{-1}$ thereafter. If interpolation is turned on, then outflow linearly decreases from Julian day 100 to 110 and then increases from Julian day 110 to 120. To ensure no outflow occurs between day 110 and 120 with interpolation on, the outflow file should be setup as follows:

```
JDAY QOT
100.0000 50.0
109.9999 50.0
110.0000 0.0
119.9999 0.0
120.0000 50.0
```

</tbody>
</table>

This card has been used primarily during model development debugging. It is in the release version because it can be useful in evaluating relative effects of the hydrodynamic forcing functions and also as a debugging tool if the user decides to modify the code. Occasionally in estuarine applications, temperature is treated conservatively with the initial and boundary conditions set at a constant temperature with bottom and heat exchange turned off although it is not recommended.

**Example**

```
DEAD SEA WINDC QINC QOUTC HEATC
ON ON ON ON ON
```

Ice calculations are controlled with this card. The variable [ICEC] turns on/off ice calculations. Two different methods for computing ice cover are available. The first method ([SLICEC] = SIMPLE) was included in version 1.0 and is available for backwards compatibility (see page A21). The second method (DETAIL) is the preferred method (see page A22). The variable [SLHTC] specifies the type of heat exchange calculations used in determining surface heat exchange. This variable is used to select the method of determining surface heat exchange even if ice calculations are turned off. If [SLHTC] is set to TERM, then term-by-term calculations are used (see page A18). If [SLHTC] is set to ET, then equilibrium temperatures and coefficients of surface heat exchange are used to calculate surface heat exchange (see page A20).

The coefficient of water-ice heat exchange [HWI] is a user specified calibration parameter which determines the rate of heat exchange between water and ice. [BETAI] is the fraction of solar radiation absorbed at the ice surface and is similar to [BETA] in the surface heat exchange computations. [GAMMAI] is the solar radiation extinction coefficient through ice and is also similar to [GAMMA] in the surface heat exchange computations.
CONTROL FILE

INITIAL CONDITIONS

Albedo is the ratio of reflection to incident radiation. It is normally expressed by the albedo of a surface and varies widely depending on the solar altitude and the waterbody surface properties.

For free water surfaces, Anderson (1954), in his Lake Hefner studies, derived the following empirical formula for the water surface albedo, \( \text{ALB}_w \), as a function of average solar altitude:

\[
\text{ALB}_w = 1.18 \text{A}_s^{-0.77}
\]  

(B-52)

where \( \text{A}_s \) is average solar altitude in degrees. Anderson found the coefficient 1.18 and the exponent -0.77 to vary only slightly with cloud height and coverage.

For ice surface, a functional representation of albedo has not been established. Reported values for ice surface albedo vary greatly from about 10% for clear lake ice (Bolsenga, 1969) to almost 70% for snow free Arctic sea ice (Krutskikh, et al., 1970). Krutskikh, et al. suggest ice albedo is more dependent on air temperature than on solar altitude. Based on their extensive Arctic sea observations, ice surface albedo for solar radiation was determined as:

\[
\text{ALB}_i = \epsilon \quad \text{for} \ T_s \leq 0^\circ \text{C}
\]

\[
\text{ALB}_i = \xi + \omega e^{\Psi T_s} \quad \text{for} \ T_s > 0^\circ \text{C}
\]  

(B-53)

where \( \epsilon, \xi, \omega, \) and \( \Psi \) are empirical constants, and \( T_s \) is air temperature, \( ^\circ \text{C} \). Equation (B-53) is an empirical fit to the observed data given by Krutskikh, et al. for Arctic ice.

Example

| ICE COVER | ICEC SLICEC SLHCT ALBEDO | HMI BETAI GAMMA1 ICEMIN ICET2 |
|-----------|---------------------------|-----------------|-----------------|-----------------|-----------|
| OFF DETAIL | 0.25 | 10.0 | 0.6 | 0.07 | 0.05 | 3.0 |

<td>Transport solution scheme - either QUICKEST or UPWIND</td>
</tr>
<tr>
<td>3</td>
<td>THETA</td>
<td>Real</td>
<td></td>
<td>Time-weighting for vertical advection scheme</td>
</tr>
</tbody>
</table>

This card specifies the transport solution scheme used by the model. There are two options for [SLTRC] - 'UPWIND' or 'QUICKEST' with the latter being the recommended option. The old solution scheme is retained in this version of the model mainly as a means of comparing the two solution schemes. The 'QUICKEST' option employs a higher-order solution scheme to reduce numerical diffusion present in the original 'UPWIND' differencing scheme. [THETA] specifies the amount of time-weighting in the vertical advection scheme. A value of 0 specifies fully explicit vertical advection, 1 specifies fully implicit vertical advection, and 0.55 specifies a Crank-Nicholson scheme. Vertical diffusion is always fully implicit.

**Example**

```
TRANSPORT SLTRC THETA
QUICKEST 0.00
```
Number of Sheltering Coefficients (WSC NUMB)

Field | Name | Value | Description
--- | --- | --- | ---
1 | | | (Ignored by code)
2 | NWSC | Real | Number of time intervals the wind sheltering coefficient varies

This card specifies the number of intervals during which the wind sheltering coefficient [WSC] may vary over the simulation. The model, like the prototype, is *extremely sensitive to wind*, and this coefficient is used to adjust the effects of the wind. Its physical basis is that surrounding terrain often shelters the waterbody so that observed winds taken from meteorologic stations are not the effective winds reaching the waterbody. Since prevailing wind direction and vegetative cover vary with time, the user has the option to vary the wind sheltering coefficient with time. Intervals and values for [WSC] are specified in the next two cards. Version 3.0 will include the option to vary wind sheltering spatially.

Example

```
WSC NUMB  NWSC
  3
```

Wind Sheltering Coefficient Day, page C21
Wind Sheltering Coefficient, page C22
Wind Sheltering Coefficient Day (WSC DATE)

Field  Name  Value  Description
       1     (Ignored by code)
       2-10  WSCD  Real  Starting time for a given wind sheltering coefficient

This card specifies time intervals during which the wind sheltering coefficient [WSC] will vary. Time intervals should roughly correspond to different seasons in which prevailing winds or vegetative growth have changed sufficiently to physically justify using a different sheltering coefficient. If there are more dates than can be specified on one line, then they are continued on the next line without specifying another WIND DAY card.

Example

<table>
<thead>
<tr>
<th>WSC DATE</th>

<td>Coefficient of bottom heat exchange, $W m^2 \text{ sec}^{-1}$</td>
</tr>
<tr>
<td>6</td>
<td>TSED</td>
<td>Real</td>
<td>Sediment (ground) temperature, °C</td>
</tr>
</tbody>
</table>

This card specifies hydraulic and bottom heat exchange coefficients which can be varied during model calibration. The horizontal eddy viscosity [AX] specifies dispersion of momentum in the X-direction. The horizontal eddy diffusivity [DX] specifies dispersion of heat and constituents in the X-direction. Both values are presently time and space invariant. The Chezy coefficient is used in calculating effects of bottom friction. The coefficient of bottom heat exchange [CBHE] and the ground temperature [TSED] are used to compute heat exchange at the ground-water interface. Ground temperature can be estimated from average yearly temperature at the site. Recommended values are given in the example.

Previous experience has shown recommended values produce remarkably accurate rate predictions for a wide variety of systems. The horizontal eddy viscosities and diffusivities and Chezy coefficient may need additional tuning when calibrating for water quality portion since longitudinal temperature gradients in most applications are negligible. The Chezy coefficient is important in estuarine applications for calibrating tidal range and phase. Version 3.0 will allow the Chezy coefficient to vary spatially.

Example

```
HYD COEF  AX  DX  CHEZY  CBHE  TSED
1.0       1.0  70.0  7.0E-8 12.8
```
Selective Withdrawal (SEL WITH)

Field   Name  Value  Default  Description
        1    SWC    Character  OFF  (Ignored by code)
2-10    SWC    Character  OFF  Specifies if the selective withdrawal algorithm is used in calculating outflows

This card specifies whether selective withdrawal calculations are used to determine the outflow layers for each branch. If the selective withdrawal option for a given branch is turned on, then it overrides any options on the N OUTLET and O LAYER cards (see pages C30-C31).

Example

SEL WITH SWC SWC SWC SWC SWC SWC SWC SWC SWC
       ON  OFF  OFF

Bottom Layer Limit (K BOTTOM)

Field Name Value Description
1 (Ignored by code)
2-10 KBSW Integer Bottommost layer for outflows of each structure in the selective withdrawal algorithm

The selective withdrawal algorithm calculates vertical withdrawal zone limits based on outlet geometry, outflows, and in-pool densities. The algorithm then assigns flows for each layer within the withdrawal zone. This card specifies the bottom layer for which outflows are calculated in the selective withdrawal algorithm. This option is most commonly used when a submerged weir, trash accumulation, or some other structure is located upstream from the dam which limits the bottom of the withdrawal zone.

Example

<table>
<thead>
<tr>
<th>K BOTTOM</th>
<th>KBSW</th>
<th>KBSW</th>

Number of Outlets (N OUTLET)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>NOUT</td>
<td>Integer</td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2</td>
<td>NOUT</td>
<td>Integer</td>
<td>Total number of outlets in each branch</td>
</tr>
</tbody>
</table>

This card specifies the total number of outlets in the waterbody. For each outlet, a flow must be specified in the outflow file [QOTFN]. At least one outflow is required, although the flow may be set to zero. An outlet structure spanning multiple layers may be specified by breaking the single outlet into several and apportioning outflow among them. If selective withdrawal for a branch is turned on, then information on this card is ignored.

Outlets are always located at the most downstream segment [DS] for each branch. They are permitted only for a downstream flow boundary condition. The withdrawal option should be used for outlets not located at the downstream segment.

The user must ensure the number of structures parameter [NSP] in the PARAMETER statement in the file W2_INC.FOR is equal to the total number of outlets specified on this card (Chapter 3, see page 21).

Example

```
N OUTLET NOUT NOUT NOUT NOUT NOUT NOUT NOUT NOUT NOUT
8       3
```

<tbody>
<tr>
<td>1</td>
<td>NWD</td>
<td>Integer</td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td>Number of withdrawals</td>
</tr>
</tbody>
</table>

This card specifies the number of withdrawals for the waterbody. Withdrawals are associated with a layer and segment. Like outlets, withdrawal structures can span more than one layer by breaking the single withdrawal into several and apportioning outflow among them. If withdrawals are not used in the simulation, then **NWD must be set equal to zero**.

All withdrawals are considered lateral and thus are not considered in the momentum equation. The present model version cannot calculate a selective withdrawal zone for withdrawals. Version 3.0 will include this capability.

An example of a withdrawal is a water supply inlet structure. Withdrawals have also been used to simulate pumpback operations (see the JST example application supplied on the distribution disk).

The user must ensure the number of withdrawals parameter [NWP] in all the PARAMETER statement in the file W2_INC.FOR is **equal** to the total number of withdrawals specified on this card (Chapter 3, see page 21).

Example

```
N WDRWAL  NWD
  1
```

<tr>
<td>2</td>
<td>NTR</td>
<td>Integer</td>
<td>Number of tributaries</td>
</tr>
</tbody>
</table>

This card specifies the number of tributaries. Tributaries are used primarily to complete the water budget without having to include tributaries in the computational grid. They can also be used to represent point source loadings.

For each tributary, files containing inflows [QTRFN], inflow temperatures [TTRFN], and, if constituents are modeled, then concentrations [CTRFN] must be supplied to the model. If constituents are modeled, the user can select which constituents are included in the tributary concentrations input file (see Tributary Active Constituent Control card, page C76).

The user must ensure the number of tributaries parameter [NTP] in the PARAMETER statement in the file W2_INC.FOR is greater than or equal to the number of tributaries [NTR] specified on this card (Chapter 3, see page 21).

Example

```
N TRIBS      NTR
8
```

</tbody>
</table>

This card specifies how tributary inflows are distributed into the model layers. There are three options. Inflows can be distributed evenly from top to bottom ([TRC] = DISTR), placed according to density ([TRC] = DENSITY), or the user may specify a range of layer elevations in which the tributary inflows are distributed evenly ([TRC] = SPECIFY). This is similar to the branch inflows, but the additional option allowing the user to specify the range of layer elevations in which to distribute the inflows. This option is particularly useful when trying to model discharges from a pipe such as wastewater treatment effluent.

If there are more tributaries than can be specified on one line, then they are continued on the next line without another TRIB PLACE card being specified.

Example

```
TRIB PLACE TRC TRC TRC TRC TRC TRC TRC TRC TRC
DENSITY DISTR SPECIFY DENSITY DENSITY DENSITY DENSITY DENSITY

Distributed Tributaries (DST TRIB)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>DTRC</td>
<td>Character</td>
<td>OFF</td>
<td>Distributed tributary option</td>
</tr>
</tbody>
</table>

This card specifies whether or not a branch contains a distributed tributary. A distributed tributary is equivalent to a non-point source loading. This option may be turned ON or OFF for each branch and is useful in accounting for ungaged flows for the water budget. The flow is distributed among the segments in each branch proportional to their surface areas. There is one value of [DTRC] for each branch.

For each distributed tributary specified, the user must supply an inflow file [QDTFN], an inflow temperature file [TDTFN], and, if constituents are modeled, an inflow constituent concentration file [CDTFN].

If constituents are modeled, the user can select which constituents are included in the distributed tributary concentrations input file (see Distributed Tributary Active Constituent Control card, page C77).

If there are more distributed tributaries than can be specified on one line, then they are continued on the next line without another DST TRIB card being specified.

Example

```
DST TRIB DTRC DTRC DTRC DTRC DTRC DTRC DTRC DTRC
OFF    OFF    OFF    OFF    OFF    OFF    OFF    OFF
```

Screen Print (SCR PRNT)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2</td>
<td>SCRC</td>
<td>Character</td>
<td>OFF</td>
<td>Specifies if information is written to the screen</td>
</tr>
<tr>
<td>3</td>
<td>NSCR</td>
<td>Integer</td>
<td></td>
<td>Number of screen update intervals</td>
</tr>
</tbody>
</table>

This card specifies if information is output to the screen during the run and the number of intervals during which the frequency of updating the screen can change. The frequency at which the screen is updated should be large (at least 0.1 days). Experience has shown that updating the screen every timestep can easily double the runtime.

Example

```
SCR PRNT  SCRC  NSCR
ON      2
```

<td>Output vertical velocities</td>
</tr>
<tr>
<td>5</td>
<td>TPRNC</td>
<td>Character</td>
<td>OFF</td>
<td>Output temperatures</td>
</tr>
<tr>
<td>6</td>
<td>DTPRNC</td>
<td>Character</td>
<td>OFF</td>
<td>Output limiting timestep frequencies</td>
</tr>
</tbody>
</table>

This card specifies the laserjet model and hydrodynamic terms written to the snapshot file [SNPFN]. [LJPC] can be specified as either "OFF", "II", "III", or "IV". The model will output the appropriate codes so that the preprocessor output and snapshot will print on a laserjet compatible hardcopy device. If [LJPC] is set to "OFF", then no codes are output and the user must then have an output device, such as a line printer, that supports 132 column output.

The velocities, temperatures, and limiting timestep frequencies can be turned off in the snapshot file by specifying OFF in the appropriate position on the input card. The printing of constituents is specified in the Constituent Output card (see page C74).

**Example**

```plaintext
SNAPSHOT LJPC UPRNC WPRNC TPRNC
      IV OFF OFF ON
```

<td>OFF</td>
<td>Specifies if information is written to snapshot file</td>
</tr>
<tr>
<td>3</td>
<td>NSNP</td>
<td>Integer</td>
<td></td>
<td>Number of snapshot dates</td>
</tr>
</tbody>
</table>

This card specifies if information is output to the snapshot file [SNPFN] and the number of snapshot intervals for specifying output dates and frequencies.

Snapshot file output provides the user with a hard copy of computed values for hydrodynamic and constituent variables for user assigned segments. Output from this file can take up a tremendous amount of disk space and when printed can use up large quantities of computer paper in a short time. This option is generally used during initial runs and then turned off before the user becomes buried in computer output.

The number of snapshot dates [NSNP] refers to the option of writing information to the snapshot file for different dates and frequencies. For example, the user may specify output is to begin on Julian day 224.4 and output every 0.1 days until day 225.5. Information is then output every day until the end of the simulation. In this case, [NSNP] would be set to 2.

Example

```
SNP PRNT  SNPC  NSNP
ON       2
```

<td>-</td>
<td>Number of profile dates</td>
</tr>
<tr>
<td>4</td>
<td>NIPRF</td>
<td>Integer</td>
<td>-</td>
<td>Number of segments to be included in output</td>
</tr>
</tbody>
</table>

This card specifies if information is output to the profile output file [PRFFN], the number of profile intervals for specifying output dates and frequencies, and the number of segments included in the output.

The profile file [PRFFN] is used to plot vertical profiles of temperature and constituents at a specified model segment. This option is normally turned off during initial runs while the user is verifying the model is performing correctly. It is turned on to compare observed data with simulated data during calibration runs.

This file is in a form suitable for FORTRAN postprocessing. The spreadsheet output file can be used for processing output data in a spreadsheet (see page C53).

The Constituent Output card (see page C74) controls which constituents are output to the profile file. Temperature is always output to the profile file.

Example

PRF PLOT PRFC NPRF NIPRF
ON 4 12

<td>Number of segments to be included in output</td>
</tr>
</tbody>
</table>

This card specifies if information is output to the spreadsheet output file (SPRFN), the number of intervals for specifying output dates and frequencies, and the number of segments included in the output.

The spreadsheet file [SPRFN] is used to plot vertical profiles of temperature and constituents at a specified model segment and is suitable as ASCII input into a spreadsheet type database. This option is normally turned off during initial runs while the user is verifying the model is performing correctly. It is turned on to compare observed data with simulated data during calibration.

The **Constituent Output** card (see page C74) controls which constituents are output to the spreadsheet file. Temperature is always output to the spreadsheet file.

**Example**

```
SPR PLOT SPRC NSPR NISPR
  ON     4     12

<td>Integer</td>
<td></td>
<td>Number of contour plot dates</td>
</tr>
</tbody>
</table>

This card specifies if information is output to the contour plot file [CPLFN] and the number of contour plot intervals for specifying output dates and frequencies. Version 2.0 requires the user to develop his own means of postprocessing data for contour plots. Version 3.0 will include an X-windows postprocessor capable of producing contour plots.

Example

CPL PLOT CPLC NCPL
ON 7

Related cards and files

<td>Output algal limiting growth factor</td>
</tr>
<tr>
<td>5</td>
<td></td>
<td></td>
<td></td>
<td>Frequency which constituent kinetics are updated</td>
</tr>
</tbody>
</table>

This card starts the specification of constituent computations. [CCC] determines if constituent computations are performed. If this variable is turned off, then constituent computations are not performed and all information specified on the remaining constituent control cards is ignored. Individual constituent computations are controlled on the Active Constituents card (see page C71). During the initial calibration runs for freshwater systems, constituent computations are usually turned off until temperature, water surface elevations, and velocities are calibrated.

The [SDC] variable specifies whether longitudinally varying sediment oxygen demand is adjusted upstream or downstream when segments are added or subtracted. This applies only to the zero-order oxygen demand specified on the Sediment Oxygen Demand card (see page C93). Oxygen demand exerted by the accumulation of algae and detritus in the sediment compartment is not affected.

The model calculates the limiting factor affecting algal growth - either nitrogen, phosphorus, or light. [LIMC] specifies if the limiting factor is output to the snapshot file.

The model allows the user to update constituent kinetics at a different frequency than constituent transport. The variable [FREQUK] specifies how many transport iterations are performed before constituent kinetics are updated. This option is included primarily to reduce computation time. This variable should initially be set to one during initial calibration. If computation time is of concern, [KFREQ] can be increased until water quality results begin to deviate significantly.

</tbody>
</table>

If alkalinity calculations are included, then carbon dioxide, bicarbonate, carbonate, and pH are always calculated even if the user specifies they not be included.

The user must be certain of what he is doing if he leaves out one or more constituents in level II. For example, total inorganic carbon must be simulated to determine the remaining constituents in level III. However, total inorganic
CONTROL FILE

carbon is also a function of constituents in level II. As stated previously, the constituent kinetics are strongly coupled and failure to include one or more constituents can have far reaching effects that are hard to determine.

<td>Extinction due to organic suspended solids, m⁻³ m⁻¹ g⁻¹</td>
</tr>
<tr>
<td>5</td>
<td>BETA</td>
<td>Real</td>
<td>Fraction of incident solar radiation absorbed at the water surface</td>
</tr>
</tbody>
</table>

This card specifies the extinction coefficients and amount of solar radiation, β, absorbed in the surface layer. Extinction coefficients are used to calculate a net extinction coefficient, γ, which is determined from the following equation:

\[
γ = ε_{H2O} + ε_{is}Φ_{is} + ε_{os}Φ_{os}
\]  

(B-54)

where:

- \(γ\) = net extinction coefficient
- \(ε_{H2O}\) = light extinction exclusive of suspended solids
- \(ε_{is}\) = light extinction due to inorganic suspended solids
- \(ε_{os}\) = light extinction due to organic suspended solids (algae + detritus)
- \(Φ_{is}\) = inorganic suspended solids concentration, g m⁻³
- \(Φ_{os}\) = organic suspended solids (algae + detritus) concentration, g m⁻³

\(ε_{H2O}\) varies greatly depending upon the dissolved substances in the water. Table 4, Table C-2 gives values reported in the literature which can be used as rudimentary guidelines for selecting a value of \(ε_{H2O}\).

Megard et al. (1980) and Smith and Baker (1978) determined each gram per cubic meter of chlorophyll increased \(ε_{os}\) by 22 and 16 m⁻¹, respectively. Averaging the two values and assuming a carbon to algal biomass ratio of 0.45 and a carbon to chlorophyll ratio of 50, then each gram per cubic meter of algal biomass should increase \(ε_{os}\) by about 0.17 m⁻¹. However, the carbon to chlorophyll ratios vary from 25 to 150. Values for \(ε_{is}\) should be of the same order of magnitude as \(ε_{os}\).

If any constituents included in equation (B-54) are not included in the simulation, then the value for \(ε_{H2O}\) should be increased to account for the constituent left out. Equation (B-55) can be used to estimate the extinction coefficient.

</tbody>
</table>

\[
\gamma = 1.11 Z_s^{-0.73} \quad (B-55)
\]

where
\[\gamma\] = net extinction coefficient
\[Z_s\] = secchi disk depth, \(m\)

Equation (B-55) includes the effects of \(\epsilon_{ss}\) and \(\epsilon_{os}\) and should be used only when inorganic and organic suspended solids are not included in the simulation.

The fraction of incident solar radiation absorbed at the water surface, \(\beta\), represents solar radiation absorbed in a 0.6 m surface layer. Once \(\gamma\) has been determined, Equation (B-56) can be used to determine \(\beta\).

\[
\beta = 0.27 \ln(\gamma) + 0.61 \quad (B-56)
\]

Appendix C Input Data Description
Coliform (COLIFORM)

Field | Name | Value | Description
--- | --- | --- | ---
1 | COLQ10 | Real | (Ignored by code)
2 | COLQ10 | Real | Coliform Q₁₀ coefficient
3 | COLDK | Real | Coliform decay rate, day⁻¹

This card specifies the Q₁₀ coefficient and decay rate for coliform. The model uses a Q₁₀ formulation to modify the coliform decay rate as a function of temperature. The Q₁₀ coefficient is usually 1.04. A range of values can be found in Zison et al. (1978).

Coliform decay rate is a function of sedimentation, solar radiation, nutrient availability, predation, algae, bacterial toxins, and physicochemical factors. For studies in which bacterial contamination is of important concern, efforts should be made to obtain in situ decay rate measurements. Methods for obtaining decay rates can be found in Frost and Streeter (1924), Marais (1974), and Zison et al. (1978). Table C-3 gives reported literature values for coliform decay rates.

</tr>
<tr>
<td>2</td>
<td>SSETL</td>
<td>Real</td>
<td>Suspended solids settling rate, m day⁻¹</td>
</tr>
</tbody>
</table>

This card specifies the suspended solids settling rate. Settling rate is a function of particle type, grain size, density, viscosity, and turbulence. The model uses a net settling velocity which does not explicitly account for these factors and it is up to the user to choose an appropriate value. For waterbodies with high suspended sediment loads, selection of appropriate values for the settling velocity is critical for a successful application. For most large waterbodies, the larger particles settle very quickly and should not be included in the inflow. Lane (1938) gives values of 0.86 to 860.0 m day⁻¹ for particle diameters of 0.002 to 0.1 mm. Particles found in the main body of a reservoir are usually at the lower end of this range.

</tbody>
</table>

This card specifies rates for algal growth, mortality, excretion, respiration, and settling, fraction of algal biomass lost by mortality to detritus, and algal light saturation intensity at maximum photosynthetic rate.

[AGROW] is the maximum gross production rate which is not corrected for respiration, mortality, excretion, or sinking. Most literature values report net production rates which take into account respiration so care must be taken when using reported literature values. The user must evaluate the experimental design to determine if reported values represent gross or net production rates. Also, [AGROW] is temperature dependent. If the expected temperature in the photic zone is 25°C, then the user should select rates measured near this temperature.

Maximum algal mortality rate [AMORT] is also temperature dependent. A general rule of thumb is [AMORT] should be less than 10% of [AGROW]. Values ranging from 0.01 to 0.03 have been used in previous modeling studies.

[AEXCR] is the maximum algal excretion (or photorespiration) rate which goes directly to the labile DOM compartment. Literature values are reported in Table C-4.

[ARESP] is the maximum dark algal respiration rate. Respiration rates are often expressed as millilitres of oxygen consumed per milligram of organism dry weight per hour. To convert to model units (mg O₂ mg⁻¹ organism dry weight day⁻¹), multiply dark respiration rates by 0.74 mg dry weight/1 ml O₂. Table C-5 gives literature values for respiration rates.

[ALGS] is a representative settling velocity for algal assemblages. Literature values are given in table C-6, but care must be taken in their use. Laboratory and in situ methods for determining settling velocities each have their drawbacks when attempting to measure net settling velocities.

Algae, page C83
Dissolved Organic Matter (DOM)

Field  Name   Value  Description
1       (Ignored by code)
2       LDOMDK  Real  Labile DOM decay rate, \( \text{day}^{-1} \)
3       LRDK    Real  Labile to refractory decay rate, \( \text{day}^{-1} \)
4       RDOMDK  Real  Maximum refractory decay rate, \( \text{day}^{-1} \)

This card specifies decay rates associated with dissolved organic matter. Dissolved organic matter in the model is divided into labile and refractory partitions. The labile partition has a higher decay rate and generally consists of autochthonous inputs such as early products of algal decay. Table 8 gives literature values for various organic compounds. The refractory decay rate, \([\text{RDOMDK}]\), is generally two orders of magnitude smaller than the labile decay rate \([\text{LDOMDK}]\). If BOD decay rates are available, then they should be used as a starting point for \([\text{LDOMDK}]\).

Example

\[ \begin{align*}
\text{DOM} & \quad \text{LDOMDK} & \quad \text{LRDK} & \quad \text{RDOMDK} \\
0.12 & 0.001 & 0.001
\end{align*} \]
Particulate Organic Matter (POM)

Field | Name   | Value | Description
--- | ------ | ----- | --------------
1    |        |       | (Ignored by code)
2    | LPOMDK | Real  | Detritus decay rate, day$^{-1}$
3    | LPOMS  | Real  | Detritus settling rate, day$^{-1}$

Detritus in the model consists of autochthonous and allochthonous particulate organic matter (POM). The model uses a single decay rate [LPOMDK], but in reality, detritus is a heterogeneous mixture in various stages of decay. Allochthonous inputs are usually refractory while autochthonous inputs are initially labile becoming refractory over time. The present model formulation does not allow for spatially and temporally varying detritus decay rates. Literature values for detritus decay rates are given in Table C-9.

<td>Sediment decay rate, $day^{-1}$</td>
</tr>
<tr>
<td>3</td>
<td>FSOD</td>
<td>Real</td>
<td>Fraction of SOD</td>
</tr>
</tbody>
</table>

This card specifies the sediment decay rate which should be of comparable magnitude as the labile decay rate. If the sediment compartment is included during simulations, then the following equation can be used to compare oxygen consumption rates with reported literature values. [SEDDK] can then be adjusted accordingly.

$$O_{2\;\text{demand}} = [\text{SEDDK}] \Phi_{\text{sed}} \sigma$$  \hspace{1cm} (B-57)

where

$$O_{2\;\text{demand}} = \text{oxygen consumption rate at the sediment/water interface,}$$

$$g \; C \; m^2 \; day^{-1}$$

$$\Phi_{\text{sed}} = \text{value of sediments in the sediment compartment,} \; g \; m^2$$

$$\sigma = \text{carbon to oxygen stoichiometric equivalent}$$

The fraction of SOD [FSOD] is used to rapidly adjust the values of [SOD] during calibration. The value for [SOD] is multiplied by [FSOD] at each segment to adjust values.

Example

SEDIMENT  SEDDK  FSOD
0.06  0.9

<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>SOD</td>
<td>Real</td>
<td>Sediment oxygen demand for each segment, g C m² day⁻¹</td>
</tr>
</tbody>
</table>

This card specifies the zero-order sediment oxygen demand for each segment (including boundary segments) in the computational grid. If there are more values than can be specified on one line, then they are continued on the next line without another S DEMAND card being specified.

Sediment oxygen demand is known to vary spatially in reservoirs due to differences in sedimentation patterns and algal production (Cole & Hannan, 1989). In the model, the user can specify a separate value of [SOD] for each model segment. Sediment oxygen demand typically ranges from 0.1 to 1.0 g O₂ m² day⁻¹ but can be higher (Newbold and Liggett, 1974). Additional information can be found in Gunnison, Chen, and Brannon (1983) and Chen, Brannon, and Gunnison (1984). Additional values are given in Table C-11.

<td>TBOD</td>
<td>Real</td>
<td>Temperature coefficient</td>
</tr>
<tr>
<td>4</td>
<td>RBOD</td>
<td>Real</td>
<td>Ratio of BOD5 to ultimate BOD</td>
</tr>
</tbody>
</table>

BOD has been added to Version 2.0. [KBOD] is the first-order reaction constant. [TBOD] is used to adjust the decay rate for temperature effects according to the following equation:

\[
KBOD = KBOD_{20} \times TBOD^{(T-20)}
\]

where T is the temperature and KBOD_{20} is the decay rate at 20°C. [RBOD] is used to convert 5-day BOD values to ultimate BOD.

The present formulation accounts only for BOD effects on dissolved oxygen and does not recycle nutrients to the water column. It is intended primarily for applications which involve determining the effects of waste effluents on dissolved oxygen in which loadings are typically expressed in terms of BOD.

**Example**

CBOD | KBOD | TBOD | RBOD |
-----|------|------|------|
0.25 | 1.047| 1.85 |
Phosphorus (PHOSPHOR)

</tbody>
</table>

[PO4REL] is the sediment release rate of phosphorous under anaerobic conditions specified as a fraction of the sediment oxygen demand. Values up to 0.3 have been used in previous studies. [PARTP] is the phosphorous partitioning coefficient for sorption onto suspended solids. [AHSP] is the algal half-saturation constant for phosphorous and is defined as the phosphorous concentration at which the uptake rate is one-half the maximum rate. This represents the upper concentration at which algal growth is directly proportional to phosphorous concentrations.

Example

```
PHOSPHOR  PO4REL  PARTP  AHSP
  0.015    1.2     0.009
```

[NH4REL] is the sediment release rate of ammonia anaerobic conditions specified as a fraction of the sediment oxygen demand. Values up to 0.4 have been used in previous studies.

[NH4DK] is the rate at which ammonia is oxidized to nitrate-nitrite. Since the model considers nitrate-nitrite as one compartment, the rate specified should be the rate for conversion of ammonia to nitrate. Literature values are given in Table C-13.

[PARTN] is the ammonia partitioning coefficient for sorption onto suspended solids.

[AHSN] is the algal half-saturation constant for nitrogen and is defined as the nitrogen concentration (ammonia + nitrate/nitrite) at which the uptake rate is one-half the maximum rate. This represents the upper concentration at which algal growth is proportional to nitrogen. Table C-14 gives literature values for the nitrogen half-saturation constant.

<td>Real</td>
<td>Stoichiometric equivalent between organic matter and carbon</td>
</tr>
</tbody>
</table>

This card specifies the stoichiometric equivalents used in the model. These values should not be changed unless the user has data to support the new value.

### Example

```
STOICHMT O2NH3 O2ORG O2RESP O2ALG BIOP BION BIOC
        4.57  1.4  1.4  1.4  0.011  0.08  0.45
```
Oxygen Limit (O2 LIMIT)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2</td>
<td>O2LIM</td>
<td>Real</td>
<td>Dissolved oxygen concentration at which anaerobic processes begin, $g , m^3$</td>
</tr>
</tbody>
</table>

This card specifies the dissolved oxygen concentration below which anaerobic processes such as nitrification and sediment nutrient releases take place.

Example

```
O2 LIMIT  O2LIM  0.2
```
Bathymetry Filename (BTH FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>BTHFN</td>
<td>Character</td>
<td>Bathymetry filename</td>
</tr>
</tbody>
</table>

This card specifies the filename containing the waterbody bathymetry.

**Example**

```
BTH FILE..............................................BTHFN..............................................
    bth.npt
```
Vertical Profile Filename (VPR FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>VPRFN</td>
<td>Character</td>
<td>Temperature and constituent vertical profile filename used for specifying initial conditions for the grid</td>
</tr>
</tbody>
</table>

This card specifies the filename used to specify vertically varying initial temperatures and concentrations for the grid. See page C174 for more information on data setup.

Example

```
VPR FILE.....................................VPRFN..................................
  vpr.npt
```
## Longitudinal Profile Filename (LPR FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>LPRFN</td>
<td>Character</td>
<td>Temperature and constituent longitudinal profile filename used for specifying initial conditions for the grid</td>
</tr>
</tbody>
</table>

This card specifies the filename used to specify vertically and longitudinally varying initial temperatures and concentrations for the grid. See page C176 for more information on data setup.

### Example

```
LPR FILE....................LPRFN......................
  lpr.mpt
```
## Restart Input Filename (RSI FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>RSIFN</td>
<td>Character</td>
<td>Restart input data filename</td>
</tr>
</tbody>
</table>

This card specifies the filename used as input for restarts.

### Example

```
RSI FILE........................................RSIFN.........................................
rsi.npt
```
Meteorologic Data Filename (MET FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>METFN</td>
<td>Character</td>
<td>Meteorologic input data filename</td>
</tr>
</tbody>
</table>

This card specifies the filename for time-varying meteorologic data. See page C149 for more information on data setup.

Example

```
MET FILE..........................METFN.................................
met.npt
```
Withdrawal Filename (QWD FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>QWDFN</td>
<td>Character</td>
<td>Withdrawal filename</td>
</tr>
</tbody>
</table>

This card specifies the filename for withdrawal outflows. See page C154 for more information on data setup.

Example

```
QWD FILE..................QWDFN.................................
qwd.rpt
```
**Branch Inflow Filename (QIN FILE)**

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>QINFN</td>
<td>Character</td>
<td>Inflow filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch inflows. See page C150 for more information on data setup.

**Example**

```
QIN FILE.........................QINFN.........................
Br 1  qin_br1.npt
Br 2  qin_br2.npt
Br 3  qin_br3.npt
```
Branch Inflow Temperature Filename (TIN FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>TINFN</td>
<td>Character</td>
<td>Inflow temperature filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch inflow temperatures. See page C151 for more information on data setup.

Example

```
TIN FILE.............................................TINFN.............................................
Br 1  tin_br1.npt
Br 2  tin_br2.npt
Br 3  tin_br3.npt
```
Branch Inflow Constituent Filename (CIN FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>CINFN</td>
<td>Character</td>
<td>Inflow constituent filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch inflow concentrations. See page C152 for more information on data setup.

Example

```
CIN FILE..........................CINFN........................................
Br 1  cin_br1.npt
Br 2  cin_br2.npt
Br 3  cin_br3.npt
```
Branch Outflow Filename (QOT FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>QOTFN</td>
<td>Character</td>
<td>Outflow filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch outflows. See page C153 for more information on data setup.

Example

```
QOT FILE..............................QOTFN.................................
Br 1  qot_br1.npt
Br 2  qot_br2.npt
```
Tributary Inflow Filename (QTR FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>QTRFN</td>
<td>Character</td>
<td>Tributary inflow filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for tributary inflows. There must be a separate file for each tributary. See page C155 for more information on data setup.

Example

QTR FILE........................................QTRFN...........................................
Tr 1  qtr_tr1.npt
Tr 2  qtr_tr2.npt
**Tributary Inflow Temperature Filename (TTR FILE)**

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>TTRFN</td>
<td>Character</td>
<td>Tributary temperature filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for tributary inflow temperatures. There must be a separate file for *each* tributary. See page C156 for more information on data setup.

**Example**

```
TTR FILE ................................................ TTRFN  ...........................................
Tr 1   ttr_tr1.npt
Tr 2   ttr_tr2.npt
```
Tributary Inflow Concentration Filename (CTR FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>CTRFN</td>
<td>Character</td>
<td>Tributary inflow concentration filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for tributary inflow concentrations. There must be a separate file for each tributary. See page C157 for more information on data setup.

Example

CTR_FILE...........................................CTRFN...........................................
Tr 1  ctr_tr1.npt
Tr 2  ctr_tr2.npt
Distributed Tributary Inflow Filename (QDT FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>QDTFN</td>
<td>Character</td>
<td>Distributed tributary inflow filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for distributed tributary inflow. There must be a separate file for each branch. See page C158 for more information on data setup.

Example

```
QDT FILE............................QDTFN....................................
Br 1  qdt_tr1.npt
Br 2  qdt_tr2.npt
```
### Distributed Tributary Inflow Temperature Filename (TDT FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>TDTFN</td>
<td>Character</td>
<td>Distributed tributary temperature filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for distributed tributary inflow temperatures. There must be a separate file for *each* branch. See page C159 for more information on data setup.

**Example**

```
TDT FILE........................................TDTFN....................................
Br 1  tdt_tr1.npt
Br 2  tdt_tr2.npt
```
Distributed Tributary Inflow Concentration
Filename (CDT FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>CDTFN</td>
<td>Character</td>
<td>Distributed tributary inflow concentration filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for distributed tributary inflow concentrations. There must be a separate file for each branch. See page C160 for more information on data setup.

Example

CDT_FILE....................................CDTFN........................................
Br 1  cdt_tr1.npt
Br 2  cdt_tr2.npt
## Precipitation Filename (PRE FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>PREFN</td>
<td>Character</td>
<td>Precipitation filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for each branch precipitation. There must be a separate file for each branch. See page C161 for more information on data setup.

### Example

```
PRE FILE..............................PREFN..............................
Br 1    pre_br1.npt
Br 2    pre_br2.npt
```
Precipitation Temperature Filename (TPR FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>TPRFN</td>
<td>Character</td>
<td>Precipitation temperature filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch precipitation temperatures. There must be a separate file for each branch. See page C162 for more information on data setup.

Example

```
TPR FILE..............................................TPRFN............................................
Br 1   tpr_br1.npt
Br 2   tpr_br2.npt
```
Precipitation Concentration Filename (CPR FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>CPRFN</td>
<td>Character</td>
<td>Precipitation concentration filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch precipitation constituent concentrations. There must be a separate file for each branch. See page C163 for more information on data setup.

Example

CPR FILE........................................CPRFN........................................
Br 1  cpr_br1.npt
Br 2  cpr_br2.npt
External Upstream Head Filename (EUH FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>EUHFN</td>
<td>Character</td>
<td>External upstream head filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch external upstream heads. There must be a separate file for each branch. See page C164 for more information on data setup.

Example

```
EUH FILE.......................................................EUHFN........................................
Br 1  euh_br1.npt
Br 2  euh_br2.npt
```
External Upstream Head Temperature Filename
(TUH FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>TUHFN</td>
<td>Character</td>
<td>External upstream head temperature filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch external upstream head vertical temperatures. There must be a separate file for each branch. See page C165 for more information on data setup.

Example

```
TUH FILE........................................TUHFN........................................
Br 1  tuh_br1.npt
Br 2  tuh_br2.npt
```
External Upstream Head Concentration Filename
(CUH FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>CUHFN</td>
<td>Character</td>
<td>External upstream head concentration filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch external upstream head constituent concentrations. There must be a separate file for each branch. See page C167 for more information on data setup.

Example

CUH FILE...........................................CUHFN...........................................
Br 1   cuh_br1.npt
Br 2   cuh_br1.npt
External Downstream Head Filename (EDH FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>EDHFN</td>
<td>Character</td>
<td>External downstream head filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch external downstream heads. There must be a separate file for each branch. See page C169 for more information on data setup.

Example

```
EDH FILE.............................................EDHFN.............................................
Br 1  edh_br1.npt
Br 2  edh_br2.npt
```
## External Downstream Head Temperature Filename (TDH FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>TDHFN</td>
<td>Character</td>
<td>External downstream head temperature filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch external downstream head vertical temperatures. There must be a separate file for each branch. See page C170 for more information on data setup.

### Example

```
TDH FILE........................................TDHFN........................................
Br 1  tdh_br1.npt
Br 2  tdh_br2.npt
```
# External Downstream Head Concentration Filename (CDH FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>CDHFN</td>
<td>Character</td>
<td>External downstream had concentration filename</td>
</tr>
</tbody>
</table>

This card specifies the filename(s) for branch external downstream head constituent concentrations. There must be a separate file for each branch. See page C172 for more information on data setup.

**Example**

```
CDH FILE..................................................CDHFN..................................................
Br 1   cdh_br1.npt
Br 2   cdh_br2.npt
```
**Snapshot Filename (SNP FILE)**

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>SNPFN</td>
<td>Character</td>
<td>Snapshot filename</td>
</tr>
</tbody>
</table>

This card specifies the snapshot filename.

**Example**

```
SNP FILE.................................SNPFN...................................
snp.opt
```
### Restart Output Filename (RSO FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>RSOFN</td>
<td>Character</td>
<td>Restart output filename</td>
</tr>
</tbody>
</table>

This card specifies the restart output filename.

#### Example

```
RSO FILE..........................RSOFN................................
   rso.opt
```
**Time Series Plot Filename (TSR FILE)**

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>TSRFN</td>
<td>Character</td>
<td>Time series plot filename</td>
</tr>
</tbody>
</table>

This card specifies the time series plot filename.

**Example**

```
TSR FILE............................TSRFN..................................tsr.opt
```
Profile Plot Filename (PRF FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>PRFFN</td>
<td>Character</td>
<td>Profile plot filename</td>
</tr>
</tbody>
</table>

This card specifies the vertical profile plot filename.

Example

```
PRF FILE..................................................PRFFN...........................................

prf.opt
```
Vector Plot Filename (VPL FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>VPLFN</td>
<td>Character</td>
<td>Vector plot filename</td>
</tr>
</tbody>
</table>

This card specifies the velocity vector plot filename.

Example

```
VPL_FILE........................................VPLFN........................................vpl.opt
```
## Contour Plot Filename (CPL FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>1</td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>CPLFN</td>
<td>Character</td>
<td>Contour plot filename</td>
</tr>
</tbody>
</table>

This card specifies the contour plot filename.

**Example**

```
CPL FILE...CPLFN...cpl.opt
```
Spreadsheet Plot Filename (SPR FILE)

<table>
<thead>
<tr>
<th>Field</th>
<th>Name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>(Ignored by code)</td>
</tr>
<tr>
<td>2-10</td>
<td>SPRFN</td>
<td>Character</td>
<td>Spreadsheet plot filename</td>
</tr>
</tbody>
</table>

This card specifies the spreadsheet output filename. Output from this file is suitable for import into a spreadsheet or graphics package which uses a spreadsheet format for data management.

Example

```plaintext
SPR FILE......................SPRFN........................................
spr.opt
```
Sample Control Input File

Bathymetry File

The bathymetry file contains information specifying the segment lengths, water surface elevations, segment orientations, layer heights, and average widths for each grid cell. The following is a list of guidelines for file preparation.

1. The first three lines are ignored and can be used to comment the input file.
2. Segment lengths, water surface elevations, segment orientations, layer heights, and cell widths at each segment are preceded by two lines which are ignored. They can be used to comment each individual segment’s bathymetry.
3. Input format for each cell width is F8.0 with 10 cell widths per line.
4. It is recommended the user number the branches starting with the mainstem as branch 1. The remaining branch numbers should be numbered consecutively starting with the most upstream branch followed by the remaining branches as one moves downstream.
5. Each branch is surrounded by a segment of boundary cells (cells with zero widths) on both the upstream and downstream ends. Note this requirement results in two segments of zero widths between each branch.
6. Boundary cells must also be included at the top and bottom of each segment.
7. If there are more cell widths than can fit on one line, then they are continued immediately on the next line.
8. The number of segments must agree with the value of [IMP] in the file W2.INC.
9. Cell widths start at layer 1 and continue to the maximum number of layers [KMP]. The number of layers specified in this file must match the value of [KMP] in the file W2.INC.
10. Only cells that are potentially active have non-zero widths. The first layer, boundary segment cells, and cells below the reservoir bottom elevation at a given segment have zero widths.

The following bathymetry file gives an example for a three branch case involving a mainstem and two branches for a total number of 20 segments [IMP] and 22 layers [KMP].
# INPUT FILES

## BATHYMETRY

**Example**

CE-QUAL-W2 sample bathymetry file - 3 branches, [IMP] = 20, [KMP] = 22

C148

Appendix C Input Data Description
Meteorologic File

The meteorologic input file contains the following data:

<table>
<thead>
<tr>
<th>Variable Description</th>
<th>Name</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Julian date</td>
<td>[JDAY]</td>
<td>F8.0</td>
</tr>
<tr>
<td>Air temperature, °C</td>
<td>[TAIR]</td>
<td>F8.0</td>
</tr>
<tr>
<td>Dewpoint temperature, °C</td>
<td>[TDEW]</td>
<td>F8.0</td>
</tr>
<tr>
<td>Wind speed, m sec⁻¹</td>
<td>[WIND]</td>
<td>F8.0</td>
</tr>
<tr>
<td>Wind direction, rad</td>
<td>[PHI]</td>
<td>F8.0</td>
</tr>
<tr>
<td>Cloud cover</td>
<td>[CLOUD]</td>
<td>F8.0</td>
</tr>
</tbody>
</table>

The following is a list of guidelines for file preparation:

1. Data is read in according to an F8.0 format which allows the user to override the decimal point location according to the location specified in the input file. The field widths must be the same as specified above.
2. The first two lines are ignored and can be used to comment the file.
3. The third line contains the variable names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
4. Data can be input at any frequency and may vary during the simulation. The user need only specify the Julian date corresponding to the data.

Example

Sample meteorologic input file

<table>
<thead>
<tr>
<th>JDAY</th>
<th>TAIR</th>
<th>TDEW</th>
<th>WIND</th>
<th>PHI</th>
<th>CLOUD</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0</td>
<td>7.8</td>
<td>-0.9</td>
<td>2.19</td>
<td>2.0</td>
<td>8.0</td>
</tr>
<tr>
<td>2.0</td>
<td>3.3</td>
<td>1.3</td>
<td>4.75</td>
<td>2.0</td>
<td>6.0</td>
</tr>
<tr>
<td>3.0</td>
<td>3.3</td>
<td>1.3</td>
<td>4.75</td>
<td>2.0</td>
<td>3.0</td>
</tr>
<tr>
<td>4.0</td>
<td>2.2</td>
<td>-3.5</td>
<td>3.33</td>
<td>2.0</td>
<td>4.0</td>
</tr>
<tr>
<td>5.0</td>
<td>6.4</td>
<td>-2.4</td>
<td>1.86</td>
<td>2.0</td>
<td>4.0</td>
</tr>
<tr>
<td>6.0</td>
<td>7.5</td>

<td>4.00</td>
<td>2.0</td>
<td>10.0</td>
</tr>
<tr>
<td>7.0</td>
<td>1.9</td>
<td>-4.9</td>
<td>4.83</td>
<td>2.0</td>
<td>2.0</td>
</tr>
<tr>
<td>8.0</td>
<td>1.7</td>
<td>-6.6</td>
<td>4.00</td>
<td>2.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>
Branch Inflow File

This file contains the inflow for a branch with an upstream flow boundary condition (see page C8). The following is a list of guidelines for file preparation:

1. A separate file is required for each branch with an upstream flow boundary condition (see page C8). This allows the user to update inflows for one branch independent of another branch.
2. Input format for each field is F8.0 which allows the user to specify the decimal point location.
3. The first two lines are ignored and can be used to comment the file.
4. The third line contains the variable names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.
6. The second field is the inflow rate, $m^3/sec^1$.

Note the following example takes advantage of the algorithm's capability to use data at varying frequencies.

Example

```
CE-QUAL-W2 sample inflow file

<table>
<thead>
<tr>
<th>JDAY</th>
<th>QIN</th>
</tr>
</thead>
<tbody>
<tr>
<td>182.0000</td>
<td>0.</td>
</tr>
<tr>
<td>182.5416</td>
<td>283.</td>
</tr>
<tr>
<td>182.6250</td>
<td>566.</td>
</tr>
<tr>
<td>182.6666</td>
<td>1699.</td>
</tr>
<tr>
<td>182.7916</td>
<td>566.</td>
</tr>
<tr>
<td>182.8333</td>
<td>283.</td>
</tr>
<tr>
<td>182.9166</td>
<td>0.</td>
</tr>
<tr>
<td>185.5416</td>
<td>283.</td>
</tr>
<tr>
<td>185.6250</td>
<td>566.</td>
</tr>
<tr>
<td>185.6666</td>
<td>1699.</td>
</tr>
<tr>
<td>185.7916</td>
<td>566.</td>
</tr>
<tr>
<td>185.8333</td>
<td>283.</td>
</tr>
<tr>
<td>185.9166</td>
<td>0.</td>
</tr>
<tr>
<td>186.5416</td>
<td>283.</td>
</tr>
</tbody>
</table>
```
Branch Inflow Temperature File

This file contains the inflow temperatures for a branch with an upstream flow boundary condition (see page C8). The following is a list of guidelines for file preparation:

1. A separate file is required for each branch with an upstream flow boundary condition (see page C8). This allows the user to update temperatures for one branch independent of another branch.
2. Input format for each field is F8.0 which allows the user to specify the decimal point location.
3. The first two lines are ignored and can be used to comment the file.
4. The third line contains the variable names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.
6. The second field is the inflow temperature, °C.

Example

CE-QUAL-W2 sample inflow temperature file

<table>
<thead>
<tr>
<th>JDAY</th>
<th>TIN</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.00</td>
<td>6.80</td>
</tr>
<tr>
<td>2.00</td>
<td>6.70</td>
</tr>
<tr>
<td>3.00</td>
<td>7.00</td>
</tr>
<tr>
<td>4.00</td>
<td>6.30</td>
</tr>
<tr>
<td>5.00</td>
<td>6.40</td>
</tr>
<tr>
<td>6.00</td>
<td>6.10</td>

<td>6.60</td>
</tr>
<tr>
<td>13.00</td>
<td>5.50</td>
</tr>
<tr>
<td>14.00</td>
<td>5.60</td>
</tr>
<tr>
<td>15.00</td>
<td>7.30</td>
</tr>
<tr>
<td>16.00</td>
<td>9.50</td>
</tr>
</tbody>
</table>
Branch Inflow Constituent Concentration File

This file contains the inflow concentrations for a branch with an upstream flow boundary condition (see page C8). The following is a list of guidelines for file preparation:

1. If constituents are being modeled, a separate file is required for each branch with an upstream flow boundary condition (see page C8). This allows the user to update constituent concentrations for one branch independent of another branch.

2. Input format for all fields is F8.0 which allows the user to specify the decimal point location. The number of fields is determined by (6) below and are always located on one line.

3. The first two lines are ignored and can be used to comment the file.

4. The next line contains the abbreviations for the constituent names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.

5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.

6. The remaining fields contain the concentration for each constituent specified on the Inflow Active Constituent Control card (see page C75). Only those constituents specified as active on the Inflow Active Constituent control card are included in the constituent inflow concentration file. In the following example, only coliform bacteria has been included in level I while level III has been left out entirely.

Example

<table>
<thead>

Branch Outflow File

This file contains the outflow for a branch with a downstream flow boundary condition (see page C8). The following is a list of guidelines for file preparation:

1. A separate file is required for each branch with a downstream flow boundary condition. This allows the user to update outflows for one branch independent of another branch.
2. Input format for each field is F8.0 which allows the user to specify the decimal point location. There are a maximum of 10 fields to a line. If there are more outflows than can be specified on one line, then they are continued on the next line with blanks inserted in the Julian date field.
3. The first two lines are ignored and can be used to comment the file.
4. The next line contains the variable names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.
6. The remaining fields are the outflow rate, \( m^3/sec \).
7. If the selective withdrawal option is used, then a separate column of outflow values must be specified for each outlet structure (see page C24).
8. If the selective withdrawal option is not used, then outflows from a single outlet structure spanning more than one layer in the computational grid can be divided up into several outflows and the total outflow apportioned among them.

Withdrawal File

This contains the outflow for each withdrawal specified on the **Number of Withdrawals** card (see page C32). The following is a list of guidelines for file preparation:

1. The order in which withdrawal outflows appear in the file **must** correspond with the order specified on the Withdrawal Segment and the **Withdrawal Layer** cards (see pages C33-C34).
2. Input format for each field is F8.0 with 10 fields to a line. The F8.0 input field allows the user to specify the decimal point location.
3. The first two lines are ignored and can be used to comment the file.
4. The third line contains the variable names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.
6. The remaining fields are the withdrawal outflow rate, \( m^3 \text{ sec}^{-1} \).
7. Outflows from a single withdrawal structure spanning more than one layer in the computational grid can be divided up into several outflows and the total outflow apportioned among them.
8. If there are more withdrawals than can be specified on one line, then they are continued on the next line with blanks inserted under the JDAY field.

Tributary Inflow Concentration File

This file contains the inflow constituent concentrations for each tributary specified on the Tributary Segment card (see page C37). The following is a list of guidelines for file preparation:

1. If constituents are being modeled, a separate file is required for each tributary. This allows the user to update constituent inflow concentrations for one tributary independent of another tributary.
2. Input format for all fields is F8.0 which allows the user to specify the decimal point location. The number of fields is determined by (6) below and are always located on one line.
3. The first two lines are ignored and can be used to comment the file.
4. The next line contains the abbreviations for the constituent names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.
6. The remaining fields contain the concentration for each constituent specified on the Tributary Active Constituent Control card (see page C76). Only those constituents specified as active on the control card may be included in the tributary inflow concentration file. In the following example, only coliform bacteria has been included in level I while level III has been left out entirely.

Branch External Upstream Head Elevation File

This file contains the elevations for a branch with an external upstream head boundary condition (see page C8). The following is a list of guidelines for file preparation:

1. A separate file is required for each branch with an external upstream head boundary condition. This allows the user to update elevations for one branch independent of another branch.
2. Input format for each field is F8.0 which allows the user to specify the decimal point location.
3. The first two lines are ignored and can be used to comment the file.
4. The next line contains the variable names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.
6. The next field is the external head elevation (m above datum specified on the Initial Condition card, page C11).

Example

```
CE-QUAL-W2 sample external head elevation file

JDAY   ELHN
180.000 431.12
180.050 431.15
180.100 431.20
180.150 431.25
180.200 431.30
```
Branch External Upstream Head Temperature File

This file contains the upstream temperature profiles for a branch with an external upstream head boundary condition (see page C8). The following is a list of guidelines for file preparation:

1. A separate file is required for each branch. This allows the user to update temperatures for one branch independent of another branch.
2. Input format for each field is F8.0 which allows the user to specify the decimal point location.
3. The first two lines are ignored and can be used to comment the file.
4. The third line contains the variable names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.
6. The next fields are the upstream boundary temperatures, °C
7. Temperature values must be specified for each cell starting from layer two and extending to the bottom active layer at the upstream segment. If the values do not all fit on one line, then they are continued on the next line with the first field (corresponding to the Julian date field) left blank. The reason why the temperatures must start at layer two is the water surface may vary over many layers during the simulation and it is impossible to know beforehand exactly what time layers will be added or subtracted. When preparing the boundary temperature profiles, it is best to assign boundary temperatures starting from the bottom layer. Once the surface layer has been reached, then use this value to assign values up to layer two. In the following example, the surface layer [KT] starts out at layer six and the bottom is at layer 22. The first four values correspond to layers two through five and must be defined even if they are never used.
### Example

**CE-QUAL-W2 sample external upstream boundary temperature file**

Branch External Upstream Head Constituent Concentration File

This file contains the upstream constituent concentration profiles for a branch with an external upstream head boundary condition (see page C8). The following is a list of guidelines for file preparation:

1. **If** constituents are being modeled, then a separate file is required for each branch. This allows the user to update temperatures for one branch independent of another branch.
2. Input format for each field is F8.0 which allows the user to specify the decimal point location.
3. The first two lines are ignored and can be used to comment the file.
4. The third line contains the variable names which are right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.
5. The first field is the Julian date which can be entered at any frequency. The frequency between updates may vary during the simulation.
6. The next fields are the upstream boundary constituent concentrations.
7. Constituents must appear in the same order as they are turned on in the **Active Constituent** card (see page C71). A boundary concentration is **required for each** active constituent.
8. Concentration values must be specified for each cell starting from layer two and extending to the bottom active layer at the upstream segment. If the values do not all fit on one line, then they are continued on the next line with the first field (corresponding to the Julian date field) left blank. The reason why the concentrations must start at layer two is the water surface may vary over many layers during the simulation and it is impossible to know beforehand exactly what time layers will be added or subtracted. When preparing the boundary concentration profiles, it is best to assign concentrations starting from the bottom layer. Once the surface layer has been reached, then use this value to assign values up to layer two. In the following example, the surface layer [KT] starts out at layer six and and the bottom is at layer 22. The first four values correspond to layers two through five and must be defined even if they are never used. Salinity and dissolved oxygen are the only values specified as active.

Vertical Profile File

This file contains a single vertical profile used to specify initial conditions for temperatures and/or constituent concentrations. The vertically varying profile is then used to initialize all segments in the computational grid. This file is most commonly used for vertically stratified waterbodies with no longitudinal gradients. The following is a list of guidelines for file preparation:

1. An initial vertical profile is specified by inputting -1.0 for the initial temperature on the Initial Conditions card or a constituent’s initial concentration on the Initial Concentration card (see pages C11 and C73). If temperature is included, then it must be the first profile in the file. Constituent profiles must be input in the same order as they are specified on the Initial Concentration card.

2. Input format for each field is F8.0 which allows the user to specify the decimal point location.

3. The first two lines are ignored and can be used to comment the file.

4. The third line contains in the first field a constituent identifier name to aid in creating and editing the file. The remaining fields contain the variable name which is right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.

5. The first field is left blank or can be used for comments since it is ignored on input. The remaining fields are used for specifying the temperature or concentration at a given layer. If there are more values than can be specified on one line, then they are continued on the next line leaving the first field blank or using it for comments.

6. Values for the vertical profile start at the water surface layer [KT] and stop at the bottom layer. Boundary segments are not included in the file.

The following sample input file contains vertically varying initial temperature and dissolved oxygen profiles which correspond to the sample input bathymetry. The surface layer [KT] is located at layer five.

Longitudinal Profile File

This file contains vertical profiles for each segment used to initialize temperature and/or constituent concentrations for each computational grid cell. It is useful when temperature or a constituent is both vertically and longitudinally stratified where a single value or profile is not representative of the initial conditions. The following is a list of guidelines for file preparation:

1. An initial longitudinal profile input is specified by inputting -2.0 for the initial temperature on the Initial Conditions card or a constituent’s initial concentration on the Initial Concentration card (see pages C11 and C73). If temperature is included, then it must be the first series of profiles in the file. Constituent profiles must be input in the same order as they are specified on the Initial Concentration card.

2. Input format for each field is F8.0 which allows the user to specify the decimal point location.

3. The first two lines are ignored and can be used to comment the file.

4. The third line contains in the first field a constituent identifier name to aid in creating and editing the file. The remaining fields contain the variable name which is right justified according to the input field. This line is also ignored although the preprocessor checks to ensure the fields are aligned correctly.

5. The first field is left blank or can be used for comments since it is ignored on input. The remaining fields are used for specifying the temperature or concentration at a given layer. If there are more values than can be specified on one line, then they are continued on the next line leaving the first field blank or using it for comments.

6. Values for the vertical profile at each segment start at the water surface layer [KT] and stop at the bottom layer. Boundary segments are not included in the file.

The following sample input file includes vertically and longitudinally varying initial conditions for temperature and dissolved oxygen which corresponds to the sample input bathymetry. The surface layer [KT] is located at layer 5.

Appendix D
Description of Algorithms

Introduction

*Programming Philosophy.* The basic philosophy behind the coding of CE-QUAL-W2 is that the present code is not the end of the model's development. Any good code recognizes this and facilitates future improvements. Code should not be static and should accommodate, with minimal effort, advances in the state-of-the-art in hydrodynamics, numerical solutions, water quality interactions, and computer software and hardware.

Unfortunately, most water quality models were written for mainframe computers oriented towards card deck inputs by people with little formal training in computer programming. Many models were written by engineers whose goal during code development was to have the code give correct answers on their computers for the problem being addressed. Little thought was given to the fact that if the program was to be useful, then it should be applicable to different problems and by other people using different computers. The code that can be applied to only one problem by only one person on only one type of computer should probably have never been written in the first place.

Many water quality modelers also ardently believe the only people who should apply water quality models should be experts. This philosophy has its merit. Many criticisms aimed at water quality modeling (much of it deserved) are due to the misapplication of a model by a person only vaguely familiar with water quality modeling and even less familiar with the model he heard about through a colleague or at a scientific meeting. To keep the model out of the hands of novices, many code developers knowingly made a model hard to use, or at least resisted improving the model to make it easier to use, so only very determined people would use the model. Unfortunately, a person who is bound and determined to misapply a model will discover a way to do so regardless of the best efforts of the code developer. Putting obstacles up to deter an unqualified user also hinders the qualified user. Even more unfortunately, models are not being used to give cost effective guidance to decision makers because they are too difficult, time consuming, and expensive to use.
APPENDIX D  DESCRIPTION OF ALGORITHMS

One of the major goals in revising the model was to make it easier to understand and thus more maintainable, and easier to use and thus more widely used. The code has been revised according to the following principles:

1. Easily understandable code. For a code to evolve, it must be easily understood. People responsible for maintaining codes come and go and it should not involve man-years of effort for a new person to thoroughly understand 6,000 lines of code. FORTRAN is called a language for a good reason. Its primary reason for coming into being was not to communicate with the computer. A computer is much happier being given binary instructions. Indeed, this is the only language a computer understands. Rather, FORTRAN was devised to communicate among people - either the person writing the program or someone who comes along after the program is written. CE-QUAL-W2 has been rewritten with this in mind.

The coding has been extensively reformatted to make the program visually easier to read. A person uses his eyes first in the process of understanding a written language before the thinking portion of the brain is ever engaged. It is easier and faster to discern the logic of a code if the logical structure stands out to the eye. The user should not have to expend more brainpower just to see an algorithm than to understand it. Imagine how much more difficult this manual would be to read and understand if it were not broken down into parts, sections, paragraphs, and sentences - yet a great deal of code is still written this way.

The code has been rewritten according to top-down programming principles. The code logic structure starts at the program beginning and proceeds downwards. The autostepping algorithm is the only place in the code using a GO TO statement to jump around code. The algorithm could have been coded without the statement, but this is one of the few instances where the code is actually clearer with it.

The code has been reorganized into logical units that, for the most part, are self-contained. For example, inputs occur only in the input section. The model does not read in a portion of the input data, process it, and then read in more data. If the user needs to modify the input data, he knows exactly where to go in the code.
APPENDIX D

DESCRIPTION OF ALGORITHMS

Unlike many large programs, CE-QUAL-W2 does not have a main program that is essentially a driver for a series of subroutines. The reasoning is the basic model consists of solving the hydrodynamic and then the transport equations. This is what the program does and this is what the user sees when investigating the code. If changes are made to this portion of the code, they can have far reaching effects because the coding in the main program is intimately tied together. The organization reflects this. The model does have subroutines but their coding does not directly affect the main program. For example, changes to the water quality subroutines have no effect on how the main program solves the hydrodynamic and transport equations. Another benefit of this programming approach is the model runs faster when not burdened with the overhead of many subroutine calls.

Logical variables are used extensively throughout the code resulting in self-documenting and easier to understand code. There is a reason why they are called LOGICAL variables. They improve the understanding of the code logic.

It is recognized the code is still incomplete and improvements will be made in the future. In addition, experience has shown almost every application has some unique aspect requiring coding changes. A usable piece of code recognizes these facts and is constructed so changes to the code, although daunting, are not impossible. It is hoped users will make changes to the code to increase the model’s utility. However, a word of warning is appropriate. If you make changes, make certain they are consistent with the programming style in the code. It is extremely difficult to read reports written by several authors each using a different style of writing. It is almost impossible to understand FORTRAN code pieced together by many different programmers each with their own widely varying style (or in many cases, lack of it).

A few additional comments regarding nomenclature in the code. A large effort was put into making the nomenclature as consistent as possible to make the code understandable. The following list describes conventions for much of the nomenclature in the code. Note these are general guidelines and exceptions do exist.

1. variables beginning with I and K refer to variables associated with segments and layers, respectively - variables beginning with I may also refer to initial conditions
2. variables ending with a 1 or 2 refer to variables occurring at two different time levels

Appendix D Description of Algorithms
APPENDIX D

DESCRIPTION OF ALGORITHMS

3. variables beginning with S refer to variables whose values are saved - most of these variables are used in the autosteping algorithm
4. variables ending with a T refer to variables whose value changes temporarily and then is reset, or variables that refer to longitudinal or vertical transport
5. variables starting with Q refer to flow associated variables
6. variables ending in C refer to control variables that turn on/off or select various computations to be performed in the code
7. variables beginning with C refer to variables associated with constituents
8. variables ending in BR refer to branch related variables
9. variables beginning with VOL refer to volume related variables
10. variables ending in P refer to pointers to arrays
11. variables ending in PR refer to print related variables

Outline of CE-QUAL-W2

An outline of the code listing the major algorithms is given below. Parts of this outline are direct implementations of the hydrodynamic and transport computations (Tasks 2.2 and 2.3) and their accompanying initial and boundary conditions (Task 1.4.4 and Task 2.2.1) presented in Appendix A. The remaining tasks are related to algorithms described in this Appendix.

Task 1: Initialization
   Task 1.1: Common Block
   Task 1.2: Program
   Task 1.3: Inputs
   Task 1.4: Variables
      Task 1.4.1: Zero Variables
      Task 1.4.2: Miscellaneous Variables
      Task 1.4.3: Geometry
      Task 1.4.4: Initial Conditions
   Task 1.5: Outputs
Task 2: Calculations
   Task 2.1: Hydrodynamic Sources/Sinks
   Task 2.2: Hydrodynamic Calculations
      Task 2.2.1: Boundary Concentrations, Temperatures, and Densities
      Task 2.2.2: Momentum Terms
      Task 2.2.3: Water Surface Elevation
      Task 2.2.4: Longitudinal Velocities
      Task 2.2.5: Vertical Velocities
      Task 2.2.6: Autostepping
APPENDIX D  DESCRIPTION OF ALGORITHMS

Task 2.3: Temporal Balance Terms and Temperatures
Task 2.4: Constituents
Task 2.5: Layer - Segment Addition and Subtraction
Task 2.6: Balances
Task 2.7: Update Variables for Next Timestep
Task 2.8: Output Results
Task 3: End Simulation

The reader should refer to the code and Appendix C, Input Data Description, while studying the following description of the model code.

Task 1: Initialization

All of the code dealing with setting up the model for a simulation is located in this task. This includes variable declarations and initializations, initial conditions input and grid setup, and output initialization.

Task 1.1: Common Block

This section of code contains the data statements for variables in named common areas. ANSI standard Fortran restricts data initialization of common blocks to block data subprograms.

Task 1.2: Program

Type declarations
Dimension statements
Common declarations
Data statements

The separate include file, W2.INC, contains the PARAMETER, DIMENSION, and EQUIVALENCE statements, and type declarations global to the code. It also establishes a common area for the constituent concentrations and their sources/sinks. The PARAMETER statements in the include file specify the name of the control file and the array dimensions that depend on the grid size used to represent the waterbody being modeled.

The equivalence statements allow the kinetics subroutines to be written using easily understandable variable names (e.g., [ALGAE] instead of [C2]) while still allowing simple DO loops in the main code.
APPENDIX D

DESCRIPTION OF ALGORITHMS

Following the include statement are type declarations, dimension statements and specification of common areas. An attempt has been made to logically group the variables according to their usage in the code.

**Task 1.3: Inputs**

Open control file
  Read title cards
  Read time control cards
  Read grid definition cards
  Read initial condition cards
  Read inflow-outflow cards
  Read output control cards (excluding constituents)
  Read constituent control cards
  Read kinetics coefficients
  Read input filenames
  Read output filenames
Read bathymetry file
Initialize logical control variables
Initialize temperature and constituents
Read restart data
Close files
Input FORMATs

This code section reads data from the control file [CONFN], the bathymetry file [BTHFN], the vertical profile file [VPRFN] and/or the longitudinal-vertical profile file [LPRFN], and the restart file [RSIFN]. These files contain all of the inputs necessary for a simulation except for time-varying boundary condition data used during the simulation. In general, the control file sets up initial conditions for the simulation. The inputs are broken into sections that are as similar as possible.

The bathymetry file contains geometric information to initialize the computational grid. The information includes the segment lengths [DLX], the layer heights [H], the water surface elevation for each segment [Z1], the orientation for each segment [PHI0], and the average widths for each cell in the grid [B].

A preliminary section of logical variables are initialized in this section because of their necessity when the code evaluates whether or not to read initial conditions for temperature and/or constituents from a file containing a single vertical profile [VPRFN] and/or a file containing a vertical profile **for each segment** [LPRFN]. The next piece of code runs through the logic necessary for deter-
mining if either of these two files are used to set initial conditions and proceeds as follows:

The variables [IT2] and [IC2] which were input in the control file are used to determine if initial temperatures and/or concentrations will be obtained from information in these files. If either [IT2] for temperature or [IC2] for any constituent is set to -1, then the logical variable [VERT_TEMP] and/or [VERT_CONC] is set to true and the code then knows information is to be read from the vertical profile file. This file specifies a single vertically varying profile used to initialize temperature and/or constituent concentrations for each segment. If either [IT2] or [IC2] is set to -2, then the logical variable [LONG_TEMP] and/or [LONG_CONC] is set to true and the code then knows information is to be read from the longitudinal-vertical profile file. This file specifies a vertically varying profile for each segment used to initialize the grid. The logical variable [OPEN_VPR] is set to true if either [VERT_TEMP] or any of the [VERT_CONC] variables are true. This variable is used in the next section to open the vertical profile file [VPRFN] where the single vertical profile is read into either the array [TVP] and/or [CVP].

Similar logic is used with the [OPEN_LPR] variable except the information is not read in until the initialization section. There are two reasons for doing this. If the information is read in at this point, then the user would have to specify a vertical profile for every segment in the grid starting at segment two. By waiting until the grid geometry is defined, the user need only specify vertical profiles starting at the upstream active segment [IUC]. The second reason is to eliminate the need for temporary storage array dimensioned (KMP,IMP,NCP) thus reducing memory requirements.

The restart capability of the code permits previous simulations to be continued. The code reads an unformatted file output by a previous run containing all the necessary variables to reproduce exactly the internal state of the code at the end of the previous run. The logical variable RESTART_IN is used to control how the code is initialized for restarts. The reader may trace the use of this variable in the code beginning with the variable [RSIC] which specifies whether input is read in from the restart file (see page C110).

Internally, the file names and corresponding FORTRAN unit numbers are consistently named with the unit numbers corresponding to the input filenames (i.e., BTH for unit number, BTHFN for the filename). Unit numbers 10-19 are reserved for input files.
APPENDIX D
DESCRIPTION OF ALGORITHMS

Task 1.4: Variables

This section initializes variables based on the information available from reading the control, bathymetry, vertical profile, and restart files.

Task 1.4.1: Zero Variables

Task 1.4.1 initializes to zero variables used in the code before they are initialized (i.e., appear on the right hand side of an assignment statement before being assigned a value). These include source and sink arrays, vertical and horizontal velocities and volume balance variables. Note the logical variable used for restarting the computation [RESTART_IN] to prevent values read in from the restart file from being overwritten:

```fortran
IF (.NOT.RESTART_IN) THEN
  Z1(I) = 0.0
  DO K=1,KMP
    U(K,I) = 0.0
    W(K,I) = 0.0
  END DO
END IF
```

The character array [CONV] is initialized to a series of blanks. This array is used to print water surface elevations, ice cover, velocities, temperatures, vertical eddy viscosities, constituent concentrations and limiting factors for the growth of algae. It permits computed values for these variables to be printed for active cells and blanks to be printed for inactive cells thus improving the readability of the snapshot output.

Task 1.4.2: Miscellaneous Variables

Logical controls
Convert rates from per-day to per-second
Time and printout control variables
Active constituents

This code section converts logic control variables specified in the control file to LOGICAL variables. LOGICAL variables are used extensively throughout the code to make the code more readable. For the most part, the logic associated with setting these variables is inconsequential to understanding what is going on in the code. The user may examine these statements to determine the relationship of the control file inputs (see Appendix C) to the LOGICAL variables.

The logic for identifying winter is used to prevent ice formation after Julian day 40 and before Julian day 300. The logical array [TRANSPORT] is used to
APPENDIX D  DESCRIPTION OF ALGORITHMS

prevent the transport of certain constituents that are not state variables but are secondarily calculated (i.e., bicarbonate calculated from alkalinity and total inorganic carbon). Rates are converted from their input values which have units of day$^{-1}$ to the internal units of second$^{-1}$.

Time variables are initialized next. The variable [JDAY] is used to keep track of the fractional Julian day of the year (i.e., 12 noon on January 1 being day 0.5). It is initialized to the starting time [TMSTRT] specified by the user (see page C3). The simulation starting year [YEAR] is an integer value and is read from the control file directly (see page C3). The simulation elapsed time [ELTM] is the time since the start of the simulation, measured in seconds.

A number of other variables depend on these basic time variables. For example, the code allows the user to specify the snapshot output frequency depends on keeping arrays of snapshot dates [SNPD] and frequencies [SNPF] (see pages C47 and C48). This logic requires a pointer [SNPDP] to the current snapshot date and frequency which is initialized in Task 1.4.2. Since the algorithm that locates a particular frequency requires both a beginning and ending date, a final end date must be assigned. This end date is computed as the simulation ending time [TMEND] plus one day:

\[
\text{DO J=NSNP+1, NDP} \\
\quad \text{SNPD(J) = TMEND + 1.0} \\
\text{END DO}
\]

This logic is necessary to prevent the possibility of the snapshot date pointer [SNPDP] pointing to a value past the last specified date in the array. For example, given the following values for the [SNPD] array:

<table>
<thead>
<tr>
<th>SNP DATE</th>
<th>SNPD</th>
<th>SNPD</th>
<th>SNPD</th>
<th>SNPD</th>
<th>SNPD</th>
<th>SNPD</th>
<th>SNPD</th>
<th>SNPD</th>
</tr>
</thead>
<tbody>
<tr>
<td>100.5</td>
<td>130.5</td>
<td>160.5</td>
<td>190.5</td>
<td>220.5</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If the simulation extended past Julian day 220.5, then the logic for determining when the next snapshot will be output increments [SNPDP] to the next value in the array. Without the preceding initialization, the pointer would be incremented to 6 and the value of [SNPD] would be zero. Since the model's Julian date would be greater than 0.0, a snapshot would be output at every timestep after 220.5. This is eliminated by setting [SNPD(6)] to [TMEND] + 1.0. The variables determining when data will be sent to an output file (i.e., [NXTMSN]) are also initialized here. Refer to a description of Task 2.8, page D37 for a more detailed description of the algorithm controlling model output.

The user selects which of the 21 water quality constituents are to be included for a particular application. The next section of code makes a list of the selected constituents:
APPENDIX D

DESCRIPTION OF ALGORITHMS

IF (CONSTITUENTS) THEN
  DO JC=1,NCP
    IF (ACC(JC).EQ.'ON') THEN
      NAC = NAC+1
      CN(NAC) = JC
    END IF
    IF (INACC(JC).EQ.'ON') THEN
      NACIN = NACIN+1
      INCN(NACIN) = JC
    END IF
    .
    .
    IF (PRACC(JC).EQ.'ON') THEN
      NACPR = NACPR+1
      PRCN(NACPR) = JC
    END IF
  END DO
END IF

The constituent list is [CN]. If the user specified "ON" for a tracer and coliform bacteria on the Active Constituent Control card, then [CN] would have the values 1 and 2 only.

This code segment also makes a list of the boundary inputs the user has specified. The boundary inputs consist of inflows, tributaries, distributed tributaries and precipitation. For example, the user may wish to simulate all 21 water quality constituents but may feel comfortable only specifying inflow constituent concentrations for four of them (based on the importance of the boundary inflow or the availability of data). The Inflow Active Constituent Control card (see page C75) allows the user to specify which four inflow constituent concentrations will be available. The logic for this procedure is exactly the same as for the active constituents. These arrays are used in the subroutine TIME_VARYING_DATA which is discussed in more detail on page D38.

Task 1.4.3: Geometry

Layer elevations
Bottom layers
Upstream active cell
Boundary bottom layers
Minimum bottom layers
Boundary widths
Areas and bottom widths
Initial water surface and derived geometry
Branch numbers corresponding to tributaries, withdrawals, and head
Branch layer area
Wind fetch lengths
Segment heights
APPENDIX D DESCRIPTION OF ALGORITHMS

Layer elevations
Beginning and ending segment and bottom layer for snapshots
Transport interpolation multipliers
Positive flows
Negative flows

The variables needed to initialize the waterbody geometry are read in previously in Task 1.3. These variables are the segment length [DLX], the water surface deviation from the top of the initial layer [Z1], the segment orientations [PHI0], and the layer thicknesses [H], all taken from the bathymetry file [BTHFN] (see page C107). Two additional values, the water surface initial layer location [KT] and the elevation at the bottom of the deepest active layer [DATUM] are read from the control file (see page C8).

Task 1.4.3 takes these data and computes variables necessary for the computation. These variables include:

1. layer elevations [EL]
2. deepest active cell for each segment [KB]
3. upstream active cell for each branch [CUS]
4. minimum bottom layer between segment i and i + 1 [KBMIN]
5. areas [BHKT2]
6. average bottom widths [BH]
7. average right-hand side widths [BB]
8. branch numbers corresponding to:
   a. tributaries [JBTR]
   b. withdrawals [JBWD]
   c. upstream head [JBUH]
   d. downstream head [JBDH]
9. surface layer thickness [HKT2]
10. average layer thickness [AVHKT2]
11. adjusted surface widths [AVH]
12. branch layer area [BKT]
13. segment heights [AKBR]
14. layer in which the water surface resides [IKT]

The derived geometry variables are computed once in this section of code and, except for surface related variables which must be updated as the water surface elevation changes, are never recomputed. Most computations are straightforward. However, the algorithm allowing the water surface elevation to extend through multiple layers is described in more detail.
APPENDIX D

DESCRIPTION OF ALGORITHMS

Version 2.0 allows the water surface to extend through multiple layers, whereas in the previous version it was restricted to a maximum of two layers. The variable [IKT] keeps track of which layer the water surface resides in for each segment and is calculated as follows:

```
DO WHILE (EL(IKT)-Z1(I).GT.EL(IKT(I)))
  IKT(I) = IKT(I)-1
END DO
```

This section of code takes the elevation [EL] of the user specified surface layer location [KT] and subtracts the deviation from the water surface [Z1]. Remember the deviation upward from the surface layer is defined as negative and the deviation downward is defined as positive, hence [Z1] is subtracted from [EL] to give the actual water surface elevation at a given segment. This value is compared to the layer elevation that [IKT] points to. If the elevation that [IKT] points to is less than the actual water surface elevation, then [IKT] is decremented and the loop is continued until the water surface elevation pointed to by [IKT] is greater than the actual water surface elevation at that segment. After the loop is finished, [IKT] will point to the layer in which the water surface elevation resides. This algorithm requires [EL] be defined beforehand and is the reason why the calculation of [EL] appears first in this section. More details of the variable water surface elevation algorithm are given on page D20.

The bottom active cell [KB] for the internal head boundary segments which attach to branches are assigned the values of [KB] for the segment they attach to. For external heads, [KB] is assigned the value of [KB] at either the upstream or downstream active segment. The same logic is used later in this section to assign the boundary widths [B] for internal head boundary segments.

The assignment of branch numbers where tributaries [JBTRIB], withdrawals [JBWD], and upstream [JBUH] and downstream [JBDH] heads are located is included in this section. Branch layer areas [AKBR], upstream [FETCHU] and downstream [FETCHD] fetch lengths, segment heights [HSEG], and ending [IEPR] segments and bottom layer [KEPR] for printing are also included here. The code is straightforward.

This task is complete with the computation of the transport interpolation multipliers for both positive and negative flow directions. Refer to page A10 for a description of how the multipliers were derived.
APPENDIX D

DESCRIPTION OF ALGORITHMS

Task 1.4.4: Initial Conditions

Temperature
Constituents
Constituent mass
Ice cover
Vertical eddy viscosity
Saved concentrations
Density
Horizontal diffusion
Open output files

This task illustrates some of the typical index sweeps used throughout the remainder of the program. These sweeps are made possible because of variables defined in Task 1.4.3 that identify the current upstream segment for a particular branch [CUS] and the bottom layer number for each segment [KB]. Keep in mind the extent of the sweeps depends on whether a particular variable is defined on the computational grid. Variables defined at the center of a cell sweep from the upstream [ID] to the downstream [ID] segments and the surface layer [KT] to the bottom layer [KB]. If the variables are defined at the bottom or right side of a computational cell, then the sweeps are decreased by one.

DO JB=1,NBP
   IU = CUS(JB)
   ID = DS(JB)
   IF (.NOT.RESTART_IN) THEN

********* Temperature

   DO I=IU,ID
      IF (LONG_TEMP) READ (LPR,1190) (T1(K,1),K=KT,KB(1))
      DO K=KT,KB(1)
         IF (ISO_TEMP) T1(K,1) = T12
         IF (VERT_TEMP) T1(K,1) = TVP(K)
         T2(K,1) = T1(K,1)
      END DO
   END DO

********* Horizontal diffusion

   DO I=I1,ID-1
      DO K=KT,KMIN(1)
         DX(K,1) = IDX
      END DO
   END DO
END DO

Appendix D  Description of Algorithms  D13
The variables ISO_TEMP, VERT_TEMP, and LONG_TEMP are used in the code that initializes the temperature field [T1]. Not only does this section of code demonstrate the use of the logical variables described earlier, but it also shows the use of the segment indices [IU] and [ID]. These indices are stored in arrays by branch number - the current upstream segment [IU] stored in [CUS] and the downstream segment [ID] stored in [DS]. Since temperatures are located at the cell center, their initialization can proceed from the upstream segment [IU] to the downstream segment [ID] and from the top layer [KT] to the bottom layer number for a particular segment [KB].

For horizontal diffusion [DX], which is located at the right-hand side of a cell, use is made of some of the geometric variables computed in Task 1.4.3. The segment loop index [I] extends only to ID-1, since the horizontal diffusion must be maintained at zero along the boundary. The use of the minimum bottom layer number [KBMIN], computed in Task 1.4.3 as KBMIN(I) = MIN(KB(I),KB(I+1)) permits horizontal diffusion to be maintained at zero when the waterbody bottom stairsteps upward.

The saved concentration array [C1S] is initialized here. The array is necessary because the QUICKEST transport algorithm can produce negative values in areas of sharp gradients. The array stores concentrations after they are transported and before negative values are eliminated from the constituent concentrations passed to the kinetic subroutines [C2]. The use of this dual-array system permits perfect mass balances while eliminating negative constituent concentrations from either being displayed or used in the kinetics subroutines.

**Task 1.5: Outputs**

Open output files
Plot files

This section opens the snapshot [SNPFN], times series [TSRFN], profile [PRFFN], vector plot [VPLFN], and contour plot [CPLFN] files if the user specified output for these files (see pages C46, C57, C52, C60 and C63). The error and warning files (err.opt and wrn.opt) are opened elsewhere when necessary by the code. The restart output file [R SofN], an unformatted file, is also opened near the end of the main code in the output section. Initial information for the plot file is also written at this time.
Task 2: Calculations

Task 2 integrates the hydrodynamic and transport equations over time. This task is repeated until the simulation is completed. The simulation is initialized at the starting time [TMSTRT] and is completed when the time loop reaches the ending time [TMEND]. The short bit of code under this heading includes the DO WHILE statement that repeats the large number of statements in its range until the ending time is reached. The calls to the subroutines TIME_VARYING_DATA and INTERPULSE_INPUTS are used to fetch and interpolate time-varying boundary condition data for use in the computations. TIME_VARYING_DATA supplies the boundary data at the correct time. INTERPULSE_INPUTS linearly interpolates the data which otherwise is supplied to the main code as a step function.

Task 2.1: Hydrodynamic Sources/Sinks

This task incorporates the calculations necessary at the beginning of each time-step before the individual branch calculations are done - distribute outflows using an empirical selective withdrawal algorithm located in the subroutine SELECTIVE_WITHDRAWAL (see page A27), and include various inflows and outflows by assigning them to source and sink arrays. These computations are done for the waterbody as a whole and will be contrasted to similar computations done on a branch-by-branch basis in Task 2.2.1.

The boundary inflows and outflows considered in Task 2.1 are evaporation, precipitation, tributaries, distributed tributaries, withdrawals, and flows to and from other branches.

The following code segment illustrates a typical computation in which a boundary inflow or outflow is added to the hydrodynamic source and sink array [QSS]. This example is the outflow for a user-specified withdrawal. Withdrawals are flows removed from the side of a waterbody, for example, by a generating station's cooling water intake, and are not to be confused with dam releases at a downstream segment.

```plaintext
IF (WITHDRAWALS) THEN
  DO JW=1,NWP
    IF (JB.EQ.JBW(JW)) THEN
      IF (KWD(JW).GE.KT) THEN
        QSS(KWD(JW),IWD(JW)) = QSS(KWD(JW),IWD(JW))-QWD(JW)
      END IF
    END IF
  END DO
END IF
```
APPENDIX D  DESCRIPTION OF ALGORITHMS

The withdrawal rates are supplied by the user through the withdrawal file [QWDFN] (see page C112) and to the model through the subroutine TIME_VARYING_DATA as the array [QWD]. The segment and layer at which the withdrawal occurs are also specified by the user in the control file as the variables [IWD] and [KWD] (see pages C33 and C34). In the code segment, each withdrawal is accessed (JW=1,NWP) by the branch in which it is located. If the withdrawal is at or beneath the current top layer [KT], then the source and sink array is decremented by the withdrawal rate. Note the minus sign for [QWD] representing a sink of water.

This section of code is accessed only if the user has specified at least one withdrawal, which causes the logical variable [WITHDRAWALS] to be set to "true". The branch number for the withdrawal [JBWD] was computed in the initialization section (Task 1.4.3).

Task 2.1 also includes the entry point for restarting the timestep iteration in case the computed timestep [DLT] was too large for the current iteration.

Task 2.2: Hydrodynamic Calculations

The hydrodynamic computations are direct FORTRAN implementations of the finite difference solution described in Appendix A. The reader is encouraged to review this Appendix before studying the code and the following narrative, which concentrates on the FORTRAN structures implied in the finite difference solution as well as the code required for the linking of branches.

The hydrodynamic calculations are completed on a branch by branch basis. Thus, the segment of code in Task 2.2 begins a DO loop over each branch (DO JB=1,NBP) and extracts the upstream [IU] and downstream [ID] segment locations from their respective lists, [CUS] and [DS], for use in the following tasks.

Task 2.2.1: Boundary Concentrations, Temperatures, and Densities

The computations done in this task provide additional boundary condition data to the computation on a branch-by-branch basis. Remember some of the boundary source/sinks were included in the source/sink array [QSS] in Task 2.1. The remaining source/sinks are included in this task and also Task 2.2.3, including upstream and downstream flows and upstream and downstream internal and external heads. These flows enter the computation as momentum sources and need to be included in the water surface elevation computation.
APPENDIX D  DESCRIPTION OF ALGORITHMS

These computations are done on a branch-by-branch basis because the internal head computations depend on having the latest solution to the water surface elevation, especially the elevation for segments at junctions. For example, if branch 2 is connected with the main stem (branch 1) of a reservoir at segment 37, then the hydrodynamic solution for branch 2 needs the boundary head and temperature/constituent profiles at segment 37. Placing these computations in Task 2.2.1 permits the latest available information to be used for each succeeding branch computation.

The computations for external heads or flow boundary conditions could be placed earlier in Task 1.2.1 since the current timestep information comes from user-supplied data files. However, these computations are similar to the internal head computations in that they are branch-specific calculations and are placed here for consistency.

The following code segment illustrates the typical computations in Task 2.2.1:

```plaintext
IF (UP_HEAD(JB)) THEN
  IUT = IU-1
  IF (UH_INTERNAL(JB)) THEN
    DO K=KT,K8(IU-1)
      DO JC=1,NAC
        C1(K,IUT,CN(JC)) = C2(K,UHS(JB),CN(JC))
        C2(K,IUT,CN(JC)) = C2(K,UHS(JB),CN(JC))
      END DO
      T1(K,IUT) = T2(K,UHS(JB))
      T2(K,IUT) = T2(K,UHS(JB))
      RHO(K,IUT) = RHO(K,UHS(JB))
    END DO
  ELSE IF (UH_EXTERNAL(JB)) THEN
    DO K=KT,K8(IU-1)
      DO JC=1,NAC
        C1(K,IUT,CN(JC)) = CUH(K,CN(JC),JB)
        C2(K,IUT,CN(JC)) = CUH(K,CN(JC),JB)
      END DO
      T1(K,IUT) = TUH(K,JB)
      T2(K,IUT) = TUH(K,JB)
      RHO(K,IUT) = DENSITY (T2(K,IUT),SS(K,IUT),DISS(K,IUT))
    END DO
  END IF
END IF
```

Remembering this computation is done within a branch loop, the branch upstream head list [UP_HEAD] is checked to determine if this branch has an upstream head boundary. Assuming it does, it can be either an external (user-supplied head, as for an estuary case) or internal (linked to another branch in the waterbody) head boundary. For the internal case, constituents [C1] and [C2], temperature [T1] and [T2] and density [RHO] profiles at the upstream boundary for the branch are obtained from the junction segment. If it is an external head boundary, the same data are obtained from the arrays [TUH] and [CUH] supplied by the subroutine TIME_VARYING_DATA. In either case,
these boundary profiles are used in the development of momentum terms for the water surface elevation and horizontal velocity calculations.

The following statement

\[
\text{IF (\text{NOT\_VIOLATION}) THEN}
\]

ensures these calculations are done only if the timestep did not violate numerical stability requirements and are not repeated if the timestep did.

**Task 2.2.2: Momentum Terms**

Densities
Density pressures
Horizontal density gradients
Vertical eddy viscosity
Check for density inversions
Shear stresses
Horizontal momentum
Vertical momentum

The computation of the momentum terms follows very closely the finite-difference forms of the momentum equation given in Appendix A. These terms are used both in the water surface elevation solution and in the horizontal velocity field solution. These terms appear in both computations since the solution for the water surface elevation in CE-QUAL-W2 is the continuity equation with the momentum equation substituted for the horizontal velocity terms in that equation. This substitution gives rise to three water surface elevations (central, forward and back) in the equation which is then solved using the tridiagonal algorithm. Thus, the water surface is solved simultaneously with the horizontal velocity field. When the horizontal velocities are later solved algebraically, the solution makes use of the same momentum terms computed in Task 2.2.2.

The computation of densities, density pressures, horizontal density gradients, and vertical eddy viscosities is preparatory to the computation of the terms shown in Appendix A on the right-hand side of Equation (A-13), page A5. Note certain DO loops for [I] are done for [IU] and [ID], and others are done for [IUT] and [IDT]. [IU] and [ID] are the current beginning segment and ending segment for a branch respectively. [IUT] and [IDT] are temporary indices that move the [I] sweep further upstream by a segment or downstream by a segment, respectively, for the case of an internal or external head boundary condition. The presence of a -1 in the terminating index of the sweep indicates a computation is being done at the interface of segments. For example, the computation of densities
Appendix D  Description of Algorithms

************ Densities

DO I=IUT,IDT
   DO K=KT+1,KBMIN(I)
      RHO(K,I) = DENSITY(T2(K,I),SS(K,I),DISS(K,I))
   END DO
END DO

is done only for the segments formally included in the branch. If the branch has an open boundary, the densities in the open boundary segment were computed earlier in Task 2.2.1.

The computation of density pressures (pressures computed without the water surface elevation deviation) needs to include segments that are part of an open boundary specification:

************ Density pressures

DO I=IUT,IDT
   P(KT,I) = RHO(KT,I)*G*H(KT)
   DO K=KT+1,KBMIN(I)
      P(K,I) = P(K-1,I)+RHO(K,I)*G*H(K)
   END DO
END DO

Contrast the segment indices for this computation with the indices for the previous computation of [RHO(K,I)]. The latter are available at I=IUT and I=IDT for the density pressure computations because they were computed earlier in Task 2.2.1.

Finally, the computation of horizontal density gradients

************ Horizontal density gradients

DO I=IUT,IDT-1
   DLXRHO = 1.0/((DLX(I)+DLX(I+1))*RHO(I))
   HPG(KT,I) = DLXRHO*(BK(I)+BK(I+1)+0.5*(HKT(I)+1)*P(KT+1)*P(KT+2))
   DO K=KT+1,KBMIN(I)
      HPG(K,I) = DLXRHO*BHR(K,I)*((P(K-1,I)+1)-P(K-1,I))
   END DO
END DO

are done at interfaces at the right hand side of a cell and therefore the computation stops at [IDT]-1.

The vertical eddy viscosity calculation follows the discussion in Appendix A, in which the vertical eddy viscosity has a component due to lateral wind stress, a stress which otherwise would not be included in the longitudinal-vertical computations. The computation also limits the value of the vertical eddy viscosity

Appendix D  Description of Algorithms  D19
to prevent stability violations due to dispersion, $\Delta t < \Delta z^2 / A_z$ (see the variables [AZMXKT(I)] and [AZMAX(K-1)]).

The computation of the top [ST] and bottom [SB] shear stresses, the advection of x-direction momentum [ADMX], the diffusion of momentum [DM], and vertical momentum [ADMZ] are computed next and used in the water surface elevation computation and later in the horizontal velocity computation.

Note that [ADMX], [DM], and [ADMZ] are not functions of the timestep [DLT] and need only be computed once. Other variables are timestep dependent and must be recalculated if a timestep violation occurs. As mentioned previously, the logical variable [VIOLATION] controls this process. At the beginning of the hydrodynamic computations, [VIOLATION] has the value "false". If, after the water surface and velocities are updated for the new timestep, the timestep was found to be too large to theoretically maintain numerical stability, then [VIOLATION] is set to "true.". The water surface elevations and velocities are then recalculated using a smaller timestep. Since [VIOLATION] is now true, then only the code that is timestep dependent is re-executed. See the discussion of Task 2.2.6 (page D26) for more details of the autostepping algorithm.

**Task 2.2.3: Water Surface Elevation**

- Tridiagonal coefficients (D and F)
- Boundary tridiagonal coefficients (D and F)
- Set boundary surface elevations
- Tridiagonal coefficients (A, C, D, and V)
- Thomas algorithm for water surface elevation solution
- Update surface layer and related variables

The water surface elevation calculation for a given branch uses the longitudinal momentum terms computed in Task 2.2.2. This calculation follows directly from the equations shown in Appendix A.

The first half of this section of code prepares the coefficients necessary for the tridiagonal solution for the water surface elevation. The second half of this section performs the solution and then updates variables related to the new water surface elevation.

The coefficients that need to be prepared are the left-hand side sub-, main- and super-diagonals [A], [V] and [C] and the right-hand side [D]. These terms are identified in Equations (A-20) through (A-22) of Appendix A, page A8.
APPENDIX D  DESCRIPTION OF ALGORITHMS

A common term in these equations is the variable [BHRHO] which is a vertical integral appearing in [A], [C], and [V]. [BHRHO] is calculated at the interfaces between the branch's internal segments as the integral from [KT] to [KBMIN]-1.

At the same time [BHRHO] is being calculated, other vertical integrals are also summed, also at the interfaces but to the layer limit [KB] so any sources/sinks below the [KBMIN] limit can be included. These are [D] and [F], which can also be examined directly in Equations (A-18) and (A-22), in Appendix A, pages A8-A9.

The next code segment augments [D] and [F] to include the boundary data not incorporated in the computation through the hydrodynamic source and sink array [QSS]. These data include upstream inflows [QIN], downstream outflows [QOUT], and upstream and downstream heads, whether internal or external. Note for upstream and downstream heads, an abbreviated set of longitudinal momentum terms [SB], [ST], and [HPG] are included. A more complete expression of the longitudinal momentum terms is not currently in the code. Thus, there is no momentum transfer between branches.

The last head-related task before the final set of coefficients are assembled is to gather the boundary elevations and place them in the appropriate locations for the solution:

********** Set boundary surface elevations

IF (UH_INTERNAL(JB)) Z1(ID-1) = Z1(UHND(JB))
IF (UH_EXTERNAL(JB)) Z1(ID-1) = EL(KT)-ELUH(JB)
IF (DH_INTERNAL(JB)) Z1(ID+1) = Z1(DHND(JB))
IF (DH_EXTERNAL(JB)) Z1(ID+1) = EL(KT)-ELDH(JB)

These boundary elevations will then be referenced when solving for the water surface, which is then performed using the Thomas algorithm for the solution of a tridiagonal matrix.

Once the new water surface elevation is computed and placed in [Z1], the surface dependent geometry is updated. This algorithm is similar to the one described in Task 1.4.3 in that the layer in which the water surface resides is computed and water surface elevation dependent geometry is updated.

For each segment in the branch being computed, the new water surface elevation deviation [EL] at [KT]-[Z1] is examined to determine if the elevation is above or below the elevation of the [IKT] layer. Recall the [IKT] layer is the layer in which the water surface elevation for that particular segment actually resides. If the new elevation exceeds the elevation at the top of the [IKT]
APPENDIX D

DESCRIPTION OF ALGORITHMS

layer, [Z1] is modified by spreading the water contained over the [IKT] and [IKT]-1 layers:

\[
\begin{align*}
\text{IF } & (\text{EL}(K) - Z1(I), GT, EL(\text{IKT}(I))) \text{ THEN} \\
& \text{DO WHILE } (\text{EL}(K) - Z1(I), GT, EL(\text{IKT}(I))) \\
& \qquad Z1(I) = EL(K) - EL(\text{IKT}(I)) - (EL(K) - EL(\text{IKT}(I))) - Z1(I) \\
& \qquad \cdot (B(\text{IKT}(I), 1, 1)/B(\text{IKT}(I)-1, 1)) \\
& \qquad \text{IKT}(I) = \text{IKT}(I)-1 \\
& \text{END DO}
\end{align*}
\]

If the new elevation is less than the elevation at the top of the [IKT] layer, a similar computation is done using geometric data for the [IKT] and [IKT]+1 layers:

\[
\begin{align*}
\text{ELSE IF } & (\text{EL}(K) - Z1(I), LT, EL(\text{IKT}(I)+1)) \text{ THEN} \\
& \text{DO WHILE } (\text{EL}(K) - Z1(I), LT, EL(\text{IKT}(I)+1)) \\
& \qquad Z1(I) = EL(K) - EL(\text{IKT}(I)+1) - (EL(K) - EL(\text{IKT}(I)+1)) \\
& \qquad \cdot (Z1(I)+1)/B(\text{IKT}(I)+1, 1) \\
& \qquad \text{IKT}(I) = \text{IKT}(I)+1 \\
& \text{END DO}
\end{align*}
\]

Once the modified water surface deviations [Z1] are updated, the geometric terms dependent on the water surface elevation are then computed.

**Task 2.2.4: Longitudinal Velocities**

Pressures  
Horizontal pressure gradients  
Boundary horizontal velocities  
Place inflow according to density  
Place inflows according to weighted cell volumes  
Horizontal velocities  
Corrected horizontal velocities  
Head boundary flows

After updating the water surface elevation, horizontal velocities can then be updated. The first step is to compute the pressures and horizontal pressure gradients, which now include the contribution of the newly computed water surface elevation through the surface layer thickness [HKT1] - one of the terms updated at the end of the previous task.

The next step is to compute the boundary horizontal velocities [U]. There are two options for computing upstream flow boundary velocities - place the inflows according to densities or distribute the inflows over the entire upstream segment. For inflows placed according to density, the inflow density is calculated based on temperature and dissolved and suspended solids if the latter two
constituents are modeled. This density is then compared to the density of each cell in the upstream segment until a cell is found with a density greater than the inflow density. A pointer is saved [K] which identifies this layer for the remainder of this computation. Next, the volume of inflow is computed. If the volume of inflow is greater than nine-tenths of the upstream cell volume receiving the inflow, then nine-tenths of the inflow volume is assigned to layer [K] and the remainder is assigned to the layer immediately above. If the computed inflow layer is the surface layer [KT] then the remainder of the inflow is assigned to the layer immediately below [KT]. For inflows distributed over the entire water column, a fraction of the inflow [QINF] is calculated for each upstream cell based on flow weighting and the inflows are apportioned according to the fraction calculated for each cell.

Setting the boundary velocities for the case of downstream flows is done simply on the basis of the outflow specified by layer [QOUT] and [KOUT]. The outflow layer may have been specified by the user or computed by the model using the selective withdrawal routine [SELECTIVE_WITHDRAWAL].

The computation for the head-type boundary velocities is made from the limited set of longitudinal momentum terms computed prior to the surface elevations. Once the boundary horizontal velocities are computed from these terms, e.g.,

\[ U(K, ID) = (BHR(K, ID) \times U(K, ID) \times DLT \times (-SB(K, ID) \times ST(K, ID) \times HPG(K, ID))) / BHR(K, ID) \]

the velocities for the entire branch can be computed, based on Equation (A-9) in Appendix A, page A4:

\[ U(K, I) = U(K, I) \times DLT / BHR(K, I) \times (-SB(K, I) \times ST(K, I) \times ADM2(K, I) \times ADMZ(K, I) \times ADMX(K, I) \times DM(K, I) \times HPG(K, I)) \]

In order to perfectly satisfy continuity, the horizontal velocities [U] are then adjusted based on an overall volume balance for the branch. The overall volume balance is based on the previously completed water surface elevation computations.

The problem to be addressed is the over determination of the basic volume balance in the computation - the volume balance is complete when the water surface elevation computation is finished. However, the code goes on to compute horizontal velocities explicitly for each cell based on the same information used to compute the water surface elevation. This is possible since the hydrodynamic computation is a simultaneous solution of the elevation and velocity computation. The code then computes the vertical velocities from the continuity equation, integrating at each segment from the bottom up.
APPENDIX D  DESCRIPTION OF ALGORITHMS

This single pass through all the equations inevitably results in some inconsistencies. In Version 1.0, these inconsistencies showed up in the vertical velocities at the bottom of the surface cells. The inconsistency was these velocities did not perfectly balance the change in storage in the top cells (since the water surface lies within these top cells, their volume changes). This problem was addressed by maintaining a separate vertical velocity [WKT] for these cells computed from the top cell volume balance rather than from integrating the continuity equation from the bottom up, as is done for the ordinary vertical velocities. This approach did not solve the problem, however, since the constituent equation continued to have a slight volume error.

The approach taken here, which results in volume balances to machine accuracy, is to adjust the horizontal flows after they have been explicitly computed using a volume balance based on the water surface elevation. This algorithm is discussed in detail below.

There is yet another approach to the volume balance problem. One should recognize that although the computation for elevations and velocities is simultaneous, certain terms in the elevation solution depend on the magnitude of the velocities, which are not known until the water surface elevation is computed. In fact, the theoretically correct approach is to iterate through the [Z]-[U]-[W] computation until a perfect water balance is attained. This balance can be achieved in about four iterations. However, the cost is to increase the time devoted to the hydrodynamic computation. The compromise adopted here results in both perfect mass and constituent balances.

The velocity adjustment procedure is based on computing vertically integrated flows at each segment [Q(I)], which are based on the recently solved horizontal velocities:

\[ Q(IU-1) = U(KT,IU-1)*BHRKT1(IU-1) \]
\[ DO K=KB(IU),KT+1,-1 \]
\[ Q(IU-1) = Q(IU-1)+U(K,IU-1)*BHR(K,IU-1) \]
\[ END DO \]
\[ QC(IU-1) = Q(IU-1) \]
\[ DO I=IU,1 \]
\[ BHRSUM = 0.0 \]
\[ IF (I.EQ.ID.AND.DN_FLOW(JB)) THEN \]
\[ Q(I) = 0.0 \]
\[ QSSUM(I) = 0.0 \]
\[ DO K=KT,KB(I) \]
\[ QSSUM(I) = QSSUM(I)+QSS(K,I) \]
\[ END DO \]
\[ DO J0=1,NOUT(JB) \]
\[ K = KOUT(J0,JB) \]
\[ IF (K.GE.KT) THEN \]
\[ BHR = BHR(K,I) \]
\[ IF (K.EQ.KT) BHR = BHRKT1(I) \]
\[ IF (U(K,I).NE.0.0) BHRSUM = BHRSUM+BHR \]
\[ Q(I) = Q(I)+U(K,I)*BHR \]

D24  Appendix D Description of Algorithms
APPENDIX D

DESCRIPTION OF ALGORITHMS

END IF
END DO
ELSE
BHRSUM = BHRKT1(I)
Q(I) = U(KT,I)*BHRKT1(I)
QSUM(I) = QSS(KT,I)
DO K=KBMIN(I),KT+1,-1
BHRSUM = BHRSUM+BHR(K,I)
Q(I) = Q(I)+U(K,I)*BHR(K,I)
QSUM(I) = QSUM(I)+QSS(K,I)
END DO
END IF

The variable [Q] is initialized at the upstream segment [IU]-1 and then vertically and longitudinally integrated. At the same time, any sources/sinks [QSS(K,I)] are accounted for. The logic within the DO loop allows the computation to account for either downstream flow or downstream head conditions.

A similar computation is done for the corrected vertically integrated flows [QC(I)]. These differ from the vertically integrated flows [Q] in that the change in storage over the timestep, [BHKT2] - [BHKT1], is added. This permits the adjustment of the horizontal flows [U] by adding or subtracting to them the amount necessary for perfect volume balances through the entire [Z]-[U]-[W] pass:

QC(I) = QC(I-1)+DLX(I)/DLT*(BHKT2(I)-BHKT1(I))+QSUM(I)
IF (I.EQ.ID.AND.DN_FLOW(JB)) THEN
DO JO=1,NOUT(JB)
K = KOUT(JO,JB)
IF (K.GE.KT.AND.U(K,I).LE.0.0) THEN
U(K,I) = U(K,I)+(QC(I)-Q(I))/BHRSUM
END IF
END DO
ELSE
DO K=KBMIN(I),KT,-1
U(K,I) = U(K,I)+(QC(I)-Q(I))/BHRSUM
END DO
END IF
END DO

Task 2.2.5: Vertical Velocities

Calculation of the vertical velocities [W] completes the hydrodynamic calculations and, as shown in the previous section, completes the perfect volume balance. They are computed from continuity, beginning at the bottom cell of each segment using the known (and adjusted) horizontal velocities [U] and bottom vertical velocities [W] (always zero for the bottom cell) to compute the vertical velocity at the top of each cell. At the end of this task, hydrodynamics have been computed for each branch pending the autostepping algorithm that determines if there has been a timestep violation.
APPENDIX D

DESCRIPTION OF ALGORITHMS

Task 2.2.6: Autostepping

Task 2.2.6 was referred to when discussing the logical variable VIOLATION. The purpose of this task is to examine the current timestep [DLT] to determine if it violates the hydrodynamic numerical stability criteria in the finite difference solution.

The following computations are done for each active cell in the grid. The surface layer thickness for each cell is computed based on the newly computed water surface elevation deviation and a warning message is written if the height in any segment is less than zero. This is a severe error and typically arises when a large surface wave is generated which causes the water surface to extend into layer [KT] + 1 over one timestep. The solution to this problem is to add/subtract layers immediately after computing the new water surface elevations [Z1]. This will be fixed in Version 3.0.

Next, the stability limits based on the internal gravity wave speed [CELRTY], and the advection/diffusion criteria, [TAU1], [TAU2], and [QTOT], are calculated. The criteria are given in equation (D-1).

$$\Delta t \leq \frac{1}{2 \left( \frac{A_x}{\Delta x^2} + \frac{A_z}{\Delta z^2} \right) + \frac{Q}{V} + \sqrt{\frac{\Delta \rho \ g \ H}{\rho \ \Delta x} \ \frac{2}{\Delta x}}}$$  \hspace{1cm} (D-1)

where

- $\Delta t = \text{timestep, sec}$
- $A_x = \text{longitudinal eddy viscosity, } m^2 \text{ sec}^{-1}$
- $A_z = \text{vertical eddy viscosity, } m^2 \text{ sec}^{-1}$
- $Q = \text{total flow into or out of a cell, } m^3 \text{ sec}^{-1}$
- $V = \text{cell volume, } m^3$
- $g = \text{gravitational acceleration, } m \text{ sec}^{-2}$
- $H = \text{maximum waterbody depth, } m$
- $\rho = \text{water density, } kg \ m^{-3}$
- $\Delta \rho = \text{surface to bottom water density difference, } kg \ m^{-3}$

The calculated maximum timestep [DLTCAL] is compared to the current maximum calculated timestep [CURMAX]. If [DLTCAL] is less than [CURMAX], then [CURMAX] is assigned the value of [DLTCAL], the segment [ILOC] and layer [KLOC] pointers containing the limiting timestep location are updated, and the computations proceed for the remainder of the grid. After the computations for the entire grid are completed, then [CURMAX] will contain the maxi-
mum computed value of the timestep necessary to maintain hydrodynamic stability with [ILOC] and [KLOC] pointing to the cell which produced this value. Additional coding keeps track of the minimum timestep during a simulation [MINDLT] and its location [KMIN] and [IMIN].

The calculated maximum timestep [CURMAX] is then compared to the actual timestep used in the water surface elevation and velocity calculations. Also included is a comparison to the minimum timestep [MINDLT] specified in the control file (see page C4). [MINDLT] is included to prevent the timestep from becoming too small for the run to be economical, but care must be taken in its use. It is possible to violate hydrodynamic stability if [MINDLT] is set to high. A warning message is output to the warning file [WRNFN] if the timestep drops to the minimum value.

If the calculated maximum timestep [CURMAX] is less than the timestep used in the hydrodynamic calculations and greater than the user-specified minimum timestep, then the actual timestep to be used in the recalculation of the water surface and velocities is computed by multiplying [CURMAX] by the timestep fraction [DLTF] specified by the user (see page C7). There is a threefold reason for multiplying [CURMAX] by [DLTF]. First, [CURMAX] may be on the edge of numerical stability. Multiplying [CURMAX] by [DLTF] is a safety factor. Second, using only a fraction of [CURMAX] reduces the number of timestep violations as the computations proceed. For example, if [DLTF] is set to 0.9, then [CURMAX] calculated during the next iteration of the code can decrease by as much as 10% without causing a timestep violation. Finally, the criteria for numerical stability used in the autostepping algorithm ensure the hydrodynamic stability criteria are met. The model can still become unstable during the water quality transport calculations if more mass is removed from a cell over a timestep via the kinetic source/sink term [CSSK] than exists in the cell.

If the timestep [DLT] is less than the minimum timestep, then the date and timestep are sent to the warning output file [WRNFN] to alert the user the computations may be unstable at this point in the simulation, and the timestep is then set to [DLTMIN]. The current maximum timestep [CURMAX] is then reset to the maximum timestep [DLTMAX] specified on the Timestep Control Card (see page C4). Finally, saved values of the water surface elevation deviation [SZ1], minimum layer number [SIKT], and velocity fields, [SU] and [SW], are retrieved and placed in their corresponding arrays. The hydrodynamic source and sink array [QSS] is reinitialized to zero since the flows between branches are lagged in time and thus timestep dependent. The computation is then returned to the entry point (10010 CONTINUE) where only the timestep dependent calculations are repeated. This is one of the few places where a GO
APPENDIX D
DESCRIPTION OF ALGORITHMS

TO statement is used in the code because it is one of the few instances where the coding is simplified by using it.

**Task 2.3: Temporal Balance Terms and Temperatures**

Surface heat exchange
Ice present
Heat balance at air-ice interface
Solar radiation attenuation
Ice growth at ice-water interface
Ice melt at ice-water interface
Total ice thickness
External heat sources/sinks and total inflow/outflow
Horizontal advection and diffusion multipliers
Vertical advection multipliers
Transport heat
Vertical advection and implicit diffusion
Tridiagonal solution

After evaluation of the elevation and velocity fields and checks to ensure numerical stability, the program proceeds to the transport computations. The transport computations are identical for temperature and each constituent except for the differing sources/sinks. Sources/sinks are represented by the right-hand side of Equation (A-2) in Appendix A. An inefficient FORTRAN construction of the transport computations would repeat the entire sequence performed for the first computation for each successive computation. However, as noted in Appendix A, there are several parts of the transport computation that can be saved after temperature transport for use later in computing the transport of constituents. One of these parts was already noted in Task 1.4.3 when the spatially invariant transport interpolation multipliers were computed prior to the start of the model’s main time loop [SF2L...SF14L and SF2V...SF11V].

During the transport of heat, spatially invariant coefficients are computed and saved to be used later in constituent transport. These include the longitudinal [AD1L], [AD2L], and [AD3L] and vertical [AD1V], [AD2V], and [AD3V] advection multipliers.

The transport computation includes both the upwind and QUICKEST formulations. The QUICKEST formulation is the preferred option, but since the upwind form is a subset of QUICKEST, the old transport scheme is still retained for those who feel uncomfortable with change. An input switch [SLTC] on the Transport Scheme card allows the user to select either method (see page C19).
APPENDIX D   DESCRIPTION OF ALGORITHMS

The transport of heat also differs from the constituent computations in that the sources/sinks are, for the most part, evaluated in the main code, rather than in subroutines. Further, the computation of ice thickness, a parameter closely related to water temperature, is computed at the same time as the transport of heat.

The user may chose between the linearized surface heat computation, which uses the coefficient of surface heat exchange and equilibrium temperature, and the term by term heat budget, which computes the individual heat exchange terms. If the latter has been selected, two subroutines are called at the beginning of Task 2.3: HEAT_EXCHANGE, which computes incident solar radiation, surface heat exchange, and equilibrium temperature, and RADIATION which computes absorbed solar radiation and long-wave atmospheric radiation. Surface heat exchange and equilibrium temperature are always needed for ice computation.

Assuming surface heat exchange is to be included in the computation at all [NO_HEAT], the surface heat exchange computation consists of either the linearized surface heat exchange with attenuated through the water column. Note a third heat exchange subroutine is called for the term-by-term heat budget [SURFACE_TERMS]. This subroutine computes the three surface heat exchange components dependent on the water surface temperature. The presence of these three terms is the main difference between the two approaches. In either case, solar radiation is attenuated through the water column. Note neither of the surface heat exchange computations are done if ice cover is present.

The ice cover computation includes two input parameters used during calibration - the temperature at which ice is permitted to form [ICET2] and the minimum ice thickness [ICE_MIN]. The first part of the ice computation converts these parameters into the logic control variables [ALLOW_ICE] and [ICE_IN]. The ice calculation itself can be done either of two ways. The first option, [DETAILED_ICE], is based on individual heat balances and the air-ice-water interfaces and requires a separate computation of initial ice thickness which is triggered by a computed water temperature less than zero:

```fortran
IF (T2(KT,1).LT.0.0) THEN
  IF (INIT(I).EQ.0) THEN
    ICETH2 = -T2(KT,1)*RHO(KT,1)*CP*HKT2(I)/(RHOICE
    *RLT1)
  ELSE
    ICETH2 = 0.0
    INIT(I) = 0
  ENDIF
ELSE
  TSS(KT,1) = TSS(KT,1)-T2(KT,1)*RHO(KT,1)*CP
  *HKT2(I)*B(KT,1,I)/4.186E6/DLT
  *DLX(I)
  INIT(I) = 1
```

Appendix D  Description of Algorithms
APPENDIX D  DESCRIPTION OF ALGORITHMS

END IF
END IF

The ice thickness [ICETH2] is computed as the amount of heat that would have gone into ice formation. If this thickness is less than half a centimeter, it is ignored (assuming wind breakup and mixing of this thin ice). If it is thicker, then the temperature heat balance is corrected and the initial ice flag [INIT] is set to 1 for this segment.

On time iterations after ice formation, the ice logical variable [ICE] is true, and surface heat exchange for the air-ice interface is computed using the linearized surface heat exchange computations. This procedure is iterative, since the ice temperature must be computed and surface heat exchange recomputed until a solution is found:

```
ICOUNT = 0
TICE = TAIR
CONTINUE
ICOUNT = ICOUNT+1
IF (ICOUNT.GT.2000) GO TO 10050
CALL SURFACE_TERMS (TAIR,TDEW,WIND,TICE,RB,RE,RC)
RN(I) = RS*(1.0-ALBEDO)*BETA+RAN*RB-RE-RC

*************** Heat balance at air-ice interface

DEL = RN(I)*RK1*(RINT-TICE)/ICETH(I)
IF (ABS(DEL).GT.1.0) THEN
  TICE = TICE+DEL/500.0
  GO TO 10040
END IF
CONTINUE
```

Following this computation, solar radiation attenuation through the ice, ice growth and melt at the ice-water interface, and total ice thickness are then computed.

The alternate, simple ice computation is:

```
HIA  = 0.2367*CSHE/5.65E-8
ICETH(I) = ICETH(I)+DLT*((RINT-ET)/(ICETH(I)/RK1+1.0
    -HIA)-T2(KT,I)-RINT))/(RHOICE*RL1)
ICETH(I) = MAX(ICETH(I),0.0)
ICE(I)  = ICETH(I).GT.0.0
IF (ICE(I)) THEN
  TSS(KT,I) = TSS(KT,I)+2.392E-7*(RINT-T2(KT,I))
     *B1(KT(I),1)*DLX(I)
```

This computation is based on the heat balance over the entire ice thickness.

Similar to the boundary inflow and outflow computations, heat from inflows and outflows are included in the temperature source and sink array [TSS]. At
APPENDIX D
DESCRIPTION OF ALGORITHMS

this time, information is accumulated that is used in determining the computations overall volume balance. The variables [VOLEV], [VOLPR], [VOLTR], [VOLDT], [VOLWD], [VOLIN], [VOLUTION], [VOLUH], [VOLDH] keep track of the volume added or subtracted over the timestep by the evaporation, tributary, distributed tributary, withdrawal, inflow, outflow, and upstream and downstream head processes.

Furthermore, the temperature source and sink arrays [TSS] are updated for these same processes. The augmentation of [TSS] for the head boundary conditions notes that these interchanges between branches are not automatically calculated when flows leave a particular branch.

The last steps in this task are to calculate the horizontal and vertical advection and diffusion multipliers and the transport of heat. These advective multipliers are independent of the constituent being transported and are computed prior to the computation of the first constituent, temperature, so they are available for that computation as well as each succeeding computation. The reader should consult Appendix A, page A10 for an overview of the transport computation as well as the rationale for the preparation of the multipliers at this stage. The advective multipliers are shown as Equation (A-25).

The advective multipliers become part of the advective fluxes that must be done for each constituent. Since temperature is always computed, it is included in this task rather than in the constituent transport, Task 2.4. An examination of the temperature computation (marked "Transport heat" in the code) shows the general features of the QUICKEST computation.

The first part of the QUICKEST computation is completed with the solution for the new temperature [T1] based only on horizontal advective and dispersive fluxes and boundary fluxes (and vertical fluxes depending on the value of [THETA]):

```fortran
DO JB=1,NBP
   IU = CUS(JB)
   ID = DS(JB)
   DO I=IU,ID
      T1(KT, I) = (T2(KT, I)*BHKT(I)) / DL + (TADL(KT, I)*BHK(I))
      T1(KT, I) = T1(KT, I) / DL + (TSS(KT, I)/DLX(I)) * DL /
      ) / BHKT(I)
   END DO
   T1(K, I) = (T2(K, I)*BH(K, I)) / DL + (TADL(K, I)*BHK(K, I))
   T1(K, I) = T1(K, I) / DL + (TSS(K, I)/DLX(I)) * DL /
   ) / BH(K, I)
END DO
```

Appendix D Description of Algorithms
APPENDIX D

DESCRIPTON OF ALGORITHMS

Note there is a slightly different form of this equation for the top layer which
uses geometric terms based on water surface elevations that vary from iteration
to iteration and are stored separately.

In the second part of the transport scheme, vertical diffusion is calculated im-
licitly. The second part of the transport scheme is solved implicitly with the
vertical temperature dependent terms moved to the left-hand side of the equation
to provide the three tri-diagonal coefficients. Thus, a fully explicit, [THETA]=0, or fully implicit, [THETA]=1, vertical advection can be specified in
the solution. The Thomas algorithm is used for the final solution for tempera-
ture.

Task 2.4: Constituents

Internal sources/sinks
External sources/sinks
Transport constituents
Horizontal advection and diffusion terms
Vertical advection terms
Transport constituents
Crank-Nicholson vertical advection and implicit diffusion

The outline of this task is similar to Task 2.3, except kinetic sources/sinks for
the water quality parameters need to be computed via the kinetic subroutine
calls, and the computation proceeds over multiple constituents. Most transport
terms have already been computed during temperature transport (Task 2.3).

The logical variable [UPDATE_KINETICS] is used to control whether the
kinetics subroutines are called at a given timestep. This logic variable is deter-
nined from the frequency of kinetic updates [FREQUK] specified on the Constitu-
tent Computations card (see page C69). The subroutines RATE_MULTIPLIERS and DECAY_CONSTANTS are called first.
RATE_MULTIPLIERS computes the temperature dependent rate multipliers
and DECAY_CONSTANTS computes the water quality rate constants used in
the kinetic formulations.

Following these computations, sources/sinks due to boundary inflows and out-
flows are computed in a manner similar to those in heat transport. The actual
transport of constituents follows closely the transport of heat except many of the
coefficient arrays have already been computed. A comparison of the two com-
putations will readily show the differences.
Task 2.5: Layer - Segment Addition and Subtraction

Determine water surface minimum height
Initialize variables in new layer
Upstream active cell
Add segments
Initialize variables in subtracted layer
Initialize variables in new layer
Upstream active cell
Subtract segments

After the hydrodynamic and transport computations are performed for the entire grid, new values for water surface elevation, velocity, temperature, and constituent fields exist throughout the finite difference grid representation of the waterbody. At this point, water surface elevations are examined to determine if layers should be added or subtracted. The code calculates the minimum height of the water surface over the entire grid [ZMIN] which is then used to determine if layers need to be added or subtracted.

While [ZMIN] extends less then 0.8 of the way into the next higher layer [KT]-1 or extends less then 0.6 of the way into the current surface layer [KT], no action is taken. However, when the minimum water surface extends above the upper limit, a layer is added to better resolve the current top layer. Note the water surface position is not changed, but the surface layer is divided into two layers. This layer addition may in turn allow the addition of upstream segments to the active computational grid for a particular branch based on the requirement that there must be at least two active layers in an active segment. The active grid therefore expands upward and upstream in response to increasing water surface elevations.

Conversely, when the current surface layer is less than 40 percent full at the segment where the water surface elevation deviation is lowest [ZMIN], then the current surface layer is incorporated into the next lower layer. This requires the examination of the current upstream boundary segment [CUS] to determine whether segments need to be subtracted to fulfill the requirement of two active layers at each active segment.

[ZMIN] is then used in the setting of two logical variables for layer addition [ADD_LAYER] and subtraction [SUB_LAYER]. The evaluation of these logical variables express the rules noted earlier for layer additions and subtractions:

\[
\text{ADD} \_\text{LAYER} = \text{ZMIN} \_\text{LT} \_\text{-0.80}\_\text{H(KT-1)} \_\text{AND}\_\text{KT.NE.2} \\
\text{SUB} \_\text{LAYER} = \text{ZMIN} \_\text{GT} \_\text{0.60}\_\text{H(KT)}
\]
APPENDIX D

DESCRIPTION OF ALGORITHMS

The remainder of this task is divided into the code for adding a layer and the code for subtracting a layer. When adding a layer, the existing layer is divided into two layers - one completely full and the other (the new surface layer) partially full.

Geometric terms for the new layer are recomputed for each branch and each segment and the temperatures and constituent concentrations computed for the previous surface layer [KT]+1 are assigned to the new surface layer:

```plaintext
DO JB=1,NBP
   IU = CIS(JB)
   ID = DS(JB)
   DO I=IU-1,ID+1
      Z1(I) = H(KT)+Z1(I)
      U(KT,I) = U(KT+1,I)
      W(KT,I) = W(KT+1,I)*BB(KT+1,I)/BB(KT,I)
      MKTI(I) = H(KT)-Z1(I)
      BHKT(I) = BHKT(I)+BH(KT+1,I)
      BX(I) = BHKT(I)/MKTI(I)
      T1(KT,I) = T1(KT+1,I)
   DO JC=1,NAC
      C1(KT,1,CN(JC)) = C1(KT+1,1,CN(JC))
      CSSK(KT,1,CN(JC)) = CSSK(KT+1,1,CN(JC))
   END DO
   END DO
   DO I=IU-1,ID
      BHKT(I) = (BHKT(I)+BHKT(I+1))*0.5
   END DO
```

Since this procedure simply breaks an existing layer into two, the temperatures and constituent concentrations from the previous single layer are assigned to the new layer. Geometry updates are done for upstream and downstream head conditions and related variables. For an upstream head boundary, these include the total cross-section area at the head boundary [BHSUM], and flow [QUH1], temperature [TSSUH1], and constituent mass fluxes [CSSUH1]. Similar updates are done for the downstream head condition. With the resetting of the horizontal and vertical eddy viscosity [DX] and [AZ], the layer addition for the case of no upstream cell additions is complete for the given branch.

At this point in the layer addition algorithm, the upstream segments are examined to determine if the layer addition allows additional upstream segments to be incorporated into the active grid. This logic is accomplished by examining the number of layers in the candidate segments [KB]-[KT] based on the new surface layer location and setting a new, temporary upstream segment limit [IUT]:

```plaintext
I = US(JB)
DO WHILE (KB(I)-KT.LT.1.AND.1.LT.DS(JB))
   I = I+1
END DO
IUT = I
```

D34
Appendix D Description of Algorithms
If the new upstream segment [IUT] is not the same as the current upstream segment [IU], then the grid is expanded to incorporate the new segments which meet the two active layer minimum criteria. This procedure is straightforward. Note when the process of initializing the newly added segments is complete, the new upstream segment limit [IUT] is transferred to the current upstream segment array [CUS]. The temperature and constituent concentrations used to set values in the new segments come from the previous current upstream segment. This procedure is different from layer additions where the concentrations in the new layer are unambiguous since they come simply from the divided current layer. Here, upstream concentrations are estimated from the previous current upstream segment concentrations. An alternate procedure would be to initialize the new active segments to the inflow temperatures [TIN] and concentrations [CIN]. To complete the DO WHILE loop for layer addition, a new [ZMIN] is computed and the logical variable [ADD_LAYER] is reset. It is possible for the new water surface elevation to increase sufficiently that another layer needs to be added. This is rare, but possible.

When subtracting a layer, a similar process is followed. The main difference is temperatures and constituent concentrations from the old surface layer are mixed into the new surface layer based on volume-weighted concentrations thus maintaining mass balance.

\[
T1(KT,1) = (T1(KT-1,1) + \frac{BHKT1(1)-BH(KT,1)}{BH(KT,1)}) + T1(KT,1) * \frac{BH(KT,1)}{BHKT1(1)}
\]

When the subtraction of a layer causes the subtraction of one or more segments, the temperatures and concentrations in those segments are reset to zero.

The layer and segment subtraction DO WHILE loop ends with a recomputation of [ZMIN] and the resetting of the logical variable [SUB_LAYER]. Again, it is rare that more than one layer will need to be subtracted, but still possible.

**Task 2.6: Balances**

Water quality modeling is fundamentally a process of keeping track of mass through boundary sources/sinks and internal transformations. An absolute requirement of the solution is the finite difference representation of the waterbody, the transport solution technique, and the kinetic transformations conserve mass. Thus, any acceptable water quality model must be shown to be conservative - including water, heat, and constituents.

Volume balances are computed when the logical variable [VOL_BALANCE] is set to true via the [VBC] variable on the Calculations card in the control file (see page C12). The algorithm compares the spatial change in volume
APPENDIX D

DESCRIPTION OF ALGORITHMS

[VOLSBR] based on changes in the water surface elevation for each branch to the initial volumes plus the net inflow/outflow during the simulation [VOLTBR]. The spatial change is computed by summing the changes in volume in the surface layer for each timestep [DLVOL]. This spatial integral is thus dependent on the details of the computation as it directly reflects the solution to the surface elevation equation as well as any manipulations of the grid through layer and segment additions and subtractions. The change in the temporally integrated volume [VOLTBR] is a direct result of the boundary conditions which affect volume (i.e., inflows/outflows, branch exchanges, precipitation, and evaporation).

If the difference between the spatially and temporally integrated volumes exceeds the volume tolerance [VTOL] (set to 100 m$^3$ in the code) a warning is written to the warning file [WRNPN]. During the implementation of a new algorithm or some other extension of the coding, an error in the volume balance indicates an error in the algorithm. Errors are also produced if numerical stability requirements are violated. Diagnosing this error can be accomplished by monitoring the balance. Typical volume balance errors are 1 m$^3$ out of 1x10$^6$ m$^3$ on a 32 bit machine.

Similar balances are kept for each constituent under control of the logical variable MASS_BALANCE. Here, the spatial integral is determined by examining each cell in each branch and the temporal integral by accessing the constituent source and sink arrays. Typical mass balance errors are 1g out of 1x10$^6$g on a 32 bit machine.

Task 2.7: Update Variables for Next Timestep

The variables representing the water surface elevation and derived surface elevation geometry, temperature, and constituents exist at two time levels. At the start of the integration loop, current values (timestep n) are located in arrays suffixed with a "2". As new values (timestep n+1) are computed, they are placed in arrays suffixed with a "1". At the end of the integration loop, new values are placed in arrays suffixed with a "2" in preparation for the beginning of the next timestep integration.

The saved arrays are also updated here. These arrays keep track of the variables used on a second iteration through the time loop in the event of a timestep violation. Any negative concentrations in the constituent array [C2] are eliminated so negative concentrations are not passed into kinetics subroutines. The negative concentrations are placed in the saved constituent array [C1S] used in the transport computations. This ensures mass balances are maintained. For kinetics to act again upon a constituent whose concentration is negative, suffi-
APPENDIX D  

DESCRIPTION OF ALGORITHMS

cient mass must be transported into a cell or produced from kinetic interactions during the simulation.

Task 2.7 finishes by updating all timestep dependent variables. These include the number of iterations [NIT] and the simulation time [JDAY]. The logical variable signalling the end of the simulation [END_RUN] is also reset for use in the time loop (DO WHILE (.NOT.END_RUN)). Variables related to the variable timestep algorithm are also updated. In particular, the timestep [DLT] is reset as the maximum of the user specified minimum [DLTMIN] and as a user specified fraction of the current maximum [DLTMAX].

Task 2.8: Output Results

Snapshots
Vertical profiles
Velocity vectors
Contours
Time series
Restart

The final task before going to the next integration timestep is to write results to the various output files opened in Task 1.5 (see page D14). The results generated by CE-QUAL-W2 are longitudinal/vertical grids of velocities, temperatures, constituents, and longitudinal profiles of surface elevations produced at each timestep. In order to examine in detail portions of what would be an immense record for a year-long simulation, several types of summaries are available. The most widely used is the snapshot, which is a longitudinal/vertical grid for selected segments at some useful frequency (e.g., every two weeks for a simulation period of one year). Other summaries available are values over time of a particular parameter at a specific location. An example would be outlet release temperatures. Also, vertical profiles at user specified segments may be output for plotting. This output is used primarily to compare computed and observed values. Finally, grids of velocities at a given frequency may be output for vector plots of circulation fields and grids of constituent concentrations may be output for contour plots.

The snapshot date [SNPD] and frequency [SNPF] variables set in Task 1.4.2 are used to determine if it is time to print a new set of snapshots:

    IF (SNAPSHOT) THEN
    IF (JDAY.GE.NXMSN.OR.JDAY.GE.SNPD(SNPD+1)) THEN
        IF (JDAY.GE.SNPD(SNPD+1)) THEN
            SNPD = SNPD+1
            NXMSN = SNPD(SNPD)
        END IF
        NXMSN = NXMSN+SNPF(SNPD)
    END IF

Appendix D  Description of Algorithms
APPENDIX D  DESCRIPTION OF ALGORITHMS

If NXTMSN has been encountered, NXTMSN is updated and output is sent to the snapshot file [SNPFN]. Much of the code in this section involves writing information for the snapshot header. The elevations, velocities and constituent concentrations themselves are output by the subroutine PRINT_GRID.

The logic for determining when output is sent to the other output files is identical to that of the snapshot file. The reader can examine the specific information written to each file.

Logic for restart output is similar to the logic for snapshots. However, each restart output is saved to a separate file. The inability of FORTRAN to eliminate blanks in character names requires the logic shown here for concatenating a julian day to the file name "rso". The binary write to these files are identical to the reads shown in Task 1.3.

Task 3: End Simulation

Profile FORMATs
Snapshot FORMATs
Run time information FORMATs
Time series FORMAT’s
Run time warning FORMATs
Run time error FORMATs
Contour plot FORMATs

The computation is ended after the user-specified ending time is reached (see Task 1.3). All open files are closed.

Subroutine TIME_VARYING_DATA

Subroutine TIME_VARYING_DATA reads all time-varying boundary conditions required by the model during a simulation. The subroutine opens required input files and reads in boundary conditions at appropriate times. The system for reading these files is best explained by examining a particular boundary input in detail.

An upstream inflow and its temperature and constituent concentrations are the most commonly used time-varying boundary condition data. Variables associated with the input of these data are the logical variable [UPFLOW], the FORTRAN unit numbers [INQ], [INT] and [INC], and the filenames [QINFN], [TINFN] and [CINFN]. Each variable is dimensioned to the number of branches in the waterbody [NBP] so each branch can have a separate inflow file.
APPENDIX D

DESCRIPTION OF ALGORITHMS

The logical variable [UP_FLOW] is set to "true" if the upstream boundary condition variable [UHS] is set to 0, which specifies an external inflow boundary condition. [UP_FLOW] is then used to access the code that initializes the unit numbers and opens the associated files:

```
IF (UP_FLOW(JB)) THEN
  INQ(JB) = UNIT
  UNIT = UNIT+1
  INT(JB) = UNIT
  UNIT = UNIT+1
  OPEN (INQ(JB),FILE=QINFN(JB),STATUS='OLD')
  OPEN (INT(JB),FILE=TINFN(JB),STATUS='OLD')
  READ (INQ(JB),1000)
  READ (INT(JB),1000)
  IF (CONSTITUENTS) THEN
    INC(JB) = UNIT
    UNIT = UNIT+1
    OPEN (INC(JB),FILE=CINFN(JB),STATUS='OLD')
    READ (INC(JB),1000)
  END IF
END IF
```

Unit numbers corresponding to a particular inflow files are computed and stored in arrays (i.e., [INT] for the inflow temperature file for branch JB) and may vary from one application to the next depending upon which boundary conditions are included in the application. This code segment also illustrates the use of a related logical variable, CONSTITUENTS, that, when set to "true", reads in time-varying concentrations for each constituent being modeled.

The variable [UP_FLOW] is also used to read the opened file. In the following code segment, two sets of time-varying inflow data and the date associated with each is read and assigned to the inflow variable [QIN] used in the hydrodynamic computation:

```
IF (UP_FLOW(JB)) THEN
  IF (JDAY.GE.NXQIN1(JB)) THEN
    DO WHILE (JDAY.GE.NXQIN1(JB))
      NXQIN2(JB) = NXQIN1(JB)
      QIN(JB) = QINNX(JB)
      QINO(JB) = QINNX(JB)
      READ (INQ(JB),1020) NXQIN1(JB),QINNX(JB)
    END DO
  END IF
  NXTVD = MIN(NXTVD,NXQIN1(JB))
END IF
```

The algorithm is based on always having two sets of inflow data in memory. Dates for these two sets must straddle or fall on the current simulation time [JDAY]. [NXQIN2] is the time associated with the inflow data immediately prior to or on [JDAY], and [NXQIN1] is the time associated with the next inflow date. On the first call to TIME_VARYING_DATA, statements lying within the range IF (JDAY.GE.NXQIN1(JB)) THEN ... END IF are used to
read a set of time-varying inflow data up until [JDAY] is less than [NXQIN1] -
that is, until the end point for the straddle exceeds [JDAY]. This procedure
includes exchanging new data set for old so a chronological sequence is main-
tained - the beginning point for the straddle, [NXQIN2], is set to the previous
end point, the values for [QIN] and [QINO] are set to the previous end point
values and new end point values are read. The inflow array [QIN] is used
directly in the hydrodynamic solution. The old inflow value [QINO] is used by
the interpolation subroutine.

On every succeeding call to TIME_VARYING DATA, a check is made to see
if the current date [JDAY] exceeds the date for updating inflows. If it does,
data is exchanged and a new set is read, as described previously. If not, the
value of [QIN] is correct and nothing additional need be done.

The subroutine also keeps track of the time until the next time-varying data of
any kind is required to be read by use of the variable [NXTVD].
TIME_VARYING_DATA is only called by the main code when [JDAY] equals
or exceeds [NXTVD].

Another feature of TIME_VARYING_DATA is its ability to read only those
constituent concentrations the user has specified are available for a particular
type of inflow (upstream inflow, tributary, distributed tributary or precipita-
tion).

The list of constituents for which inflow concentrations are available [INCN] is
used to select which constituent concentrations are read from the inflow consti-
tuent file. Task 1.4.2 in the initialization section of the code previously deter-
mined the number of active inflow constituents and their numbers based on the
variable [INACC] located on the Inflow Active Constituent Control card (see page C75) card in the control file.

*************** inflow constituent concentrations

IF (CONSTITUENTS) THEN
  IF (JDAY,GE,NXCIN1(JB)) THEN
    DO WHILE (JDAY,GE,NXCIN1(JB))
      NXCIN2(JB) = NXCIN1(JB)
      JC=1,NACIN
      CIN(INCN(JC),JB) = CINN(NCNX(INCN(JC),JB)
      CINO(INCN(JC),JB) = CINN(NCNX(INCN(JC),JB)
    END DO
    READ (INC(JB),1030) NXCIN1(JB),(CINN(INCN(JC),JB),
                   JC=1,NACIN)
  END DO
END IF
NXTVD = MIN(NXTVD,NXCIN1(JB))
END IF
END IF

D40

Appendix D Description of Algorithms
The alternative to this procedure would be to ask for a constituent concentration for every constituent being simulated, regardless of whether these data were available. External head boundary data are handled differently. If an external head boundary has been specified, then the user must supply an external boundary profile for each active constituent.

The final section of code in TIME_VARYING_DATA allows the user to conveniently turn off any or all of the external forcing functions associated with the time-varying data. This procedure is useful in debugging problems due to incorrect or extreme values of, for example, wind or inflow rates. This section of code is activated by the variables [WINDC], [QINC], [QOUTC], and [HEATC] on the Dead Sea card. The case of turning all these forcing functions off is called the dead sea case because no motion results. Without this feature, the user would have to construct a debugging data set in which each time-varying input would be set to zero.

**Subroutine INTERPOLATE_INPUTS**

TIME_VARYING_DATA supplies boundary data at the correct time, and INTERPOLATE_INPUTS linearly interpolates the data which otherwise would be supplied as a step function. Each boundary condition data type may be individually interpolated. The Interpolation card (see page C14) may be examined to identify the time-varying boundary data which can be interpolated. Continuing with the example of the upstream inflows used in the discussion of TIME_VARYING_DATA, it can be seen from the following code fragment the interpolation is based on the fraction of time between the previous inflow value and the next inflow value [QRATIO]. Different ratios are used for the temperature and constituent values since these data can occur at different frequencies.

```fortran
IF (UP_FLOW(JB)) THEN
IF (INTERP_INFLOW) THEN
  QRATIO = (NXQIN1(JB) - JDAY)/(NXQIN1(JB) - NXQIN2(JB))
  TRATIO = (NXTIN1(JB) - JDAY)/(NXTIN1(JB) - NXTIN2(JB))
  IF (CONSTITUENTS) THEN
    CRATIO = (NXCIN1(JB) - JDAY)/(NXCIN1(JB) - NXCIN2(JB))
  END IF
  QIN(JB) = (1.0 - QRATIO)*QINNX(JB) + QRATIO*QINO(JB)
  TIN(JB) = (1.0 - TRATIO)*TINNX(JB) + TRATIO*TINO(JB)
  DO JC=1,NACIN
    CIN(INCN(JC),JB) = (1.0 - CRATIO)*CINNX(INCN(JC),JB) + CRATIO*CINO(INCN(JC),JB)
  END DO
END IF
END IF
END IF
```
Subroutine HEAT_EXCHANGE

This subroutine is used to compute the linearized surface heat exchange parameters - equilibrium temperature [ET] and coefficient of surface heat exchange [CSHE]. These terms are discussed fully in Appendix A, page A17-A21. Note these terms are required for the simplified ice computations as well as the equilibrium temperature approach to surface heat exchange.

Also required in either approach to computing surface heat exchange is the solar radiation rate. In this subroutine, it is computed from time, solar altitude and cloud cover (Ryan and Stolzenbach, 1972; Wunderlich, 1972).

Equilibrium temperature is computed iteratively using the methods in Edinger, et al. (1974). The calculations are done in British units and converted to SI units prior to the return.

Subroutine RADIATION

Subroutine RADIATION computes net solar radiation (incoming minus that reflected at the surface, usually 6%) and longwave atmospheric radiation (Wunderlich, 1972).

Subroutine SURFACE_TERMS

The two previously discussed subroutines compute surface heat exchange terms dependent only on the observed meteorological data and are called once for each timestep. These terms account for four of the seven terms involved in surface heat exchange: incident solar (shortwave) radiation, reflected shortwave radiation, and incoming atmospheric (longwave) radiation. The other three terms (back radiation from the water surface, evaporative heat flux and conductive heat flux) are dependent on the water surface temperature and need to be computed for each segment at each timestep. Note with the linear approximations to surface heat exchange (equilibrium temperature and the coefficient of surface heat exchange), the surface temperature dependent terms are approximated and this approach does not require reference to the water surface temperature. This feature was the prime reason for their use prior to generally available fast computers.

Subroutine PRINT_GRID

This subroutine is called under control of the snapshot logic (see Task 2.8). It prints snapshots over time of elevations, velocities, temperatures, and constitu-
ent concentrations. The coding is straightforward but several features are worth noting. First, the results are not directly written from their computational arrays (i.e., [U]), but instead to a character variable [CONV]. The latter variable contains blanks in the locations representing inactive cells. This permits only active cell information to be displayed in the snapshot file - writing the variables directly to the snapshot file would show zeros at locations of inactive cells. Also note the logic for long and short forms. Logical variables are also used to control which arrays are output. These may be traced from the user specification of them on the Constituent Output card (see page C74).

Subroutine SELECTIVE_WITHDRAWAL

The selective withdrawal algorithm calculates the vertical limits of the withdrawal zone based on the boundary outflows, outlet geometry, and in-pool densities. The algorithm then assigns flows for each layer within the calculated withdrawal zone.

The subroutine is called for each branch (assuming the user has selected this computation) in Task 2.1. The main computational loop computes, for each structure in the branch, the upper and lower withdrawal limits in terms of the model's layer numbers. The velocity and flow associated with each structure are then computed. Once this loop is completed, the flows for all structures are combined. Boundary horizontal velocities [U] and outflows [QOUT] previously computed but are now beyond the range of the withdrawal limits are reset to zero.

**Abstract (Maximum 200 words)**

This manual describes and provides guidance for the use of CE-QUAL-W2 V2.0, a two-dimensional, longitudinal/vertical, hydrodynamic and water quality model. The model was originally developed by the Environmental and Hydraulics laboratories, U.S. Army Engineer Waterways Experiment Station, and is suitable for applications to rivers, lakes, reservoirs, and estuaries. Version 2.0 is a result of major code modifications that have improved the mathematical description of the prototype, computational efficiency, and utility of the model.

The manual is organized into three chapters and four appendixes. Chapter 1 consists of an introduction to the model and the user manual. Chapter 2 describes the model's major capabilities and limitations. Chapter 3 provides an overview of the steps involved in applying the model including data preparation and model application. The appendixes provide the user with the information necessary to understand the model details. Appendix A describes the theoretical, numerical, and computational basis for the hydrodynamic portion of the model. Appendix B describes the theoretical and computational basis for the water quality portion of the model. Appendix C describes the preparation of input files. Appendix D describes the algorithms used in the code. An index is included in Appendix E. References include a partial bibliography of CE-QUAL-W2 applications.

**Subject Terms**

| CE-QUAL-W2 | Numerical model |
| Eutrophication | Surface water quality |
| Hydrodynamics | |
