DESIGNING OF A NONLINEAR OPTIMAL TERMINAL GUIDANCE LAW
FOR SPACE INTERCEPTION

Abstract: This article concerns a nonlinear kinematics model of space interception. Nonlinear optimal control is sought through use of inverse systematic methods. A theoretical nonlinear terminal guidance law of global state feedback is advanced. In addition, a simulation test is carried out and a comparison is made with proportional guidance. Results show that this guidance law performs satisfactorily.

Key words: nonlinear guidance law, inverse system methods, nonlinear optimal control, pseudolinear system.
GRAPHICS DISCLAIMER

All figures, graphics, tables, equations, etc. merged into this translation were extracted from the best quality copy available.
I. FORWARD

Conventional proportional guidance is simple and easy to carry out. However, precision is relatively low. Moreover, line of sight angular velocity divergence phenomena [4] exist. For this reason, there is a need to search out various types of optimal guidance laws. Due to actual interception kinematics models being nonlinear, as a result, one has only to solve optimal control problems associated with nonlinear systems and only then is it possible to obtain relatively high precision terminal guidance laws. With regard to general nonlinear optimal control problems, people still have not found a unified method of solution. However, we use inverse system methods, and it is possible to solve this concrete nonlinear optimal control problem encountered in terminal guidance.

II. NONLINEAR OPTIMAL CONTROL INVERSE SYSTEM METHODS

Assume the general form of nonlinear systems to be

\[ \sum: \begin{cases} \dot{X} = F(X, U) & X(t_0) = X_s \\ Y = G(X, U) \end{cases} \] (2-1-a)

(2-1-b)

In this, \( U \) is an \( m \) dimension input vector. \( Y \) is an \( r \) dimension output vector. \( X \) is an \( n \) dimension state vector.

* Numbers in margins indicate foreign pagination. Commas in numbers indicate decimals.
The output equation (2-1-b) is also capable of being written as

\[
\begin{align*}
  y_1 &= g_1(X,U) \\
  
  \vdots \\
  y_r &= g_r(X,U)
\end{align*}
\]

(2-2)

First, carry out derivation and transformations of equation (2-2), that is, in sequence, solve for the relevant \(a_1, a_2, \ldots \) order derivatives associated with time period \(t\) for \(y_1, y_2, \ldots, y_r\), constructing the new equation

\[
\begin{align*}
  y_1^{(\ast_1)} &= h_1(X,U) \\
  \vdots \\
  y_r^{(\ast_1)} &= h_r(X,U)
\end{align*}
\]

(2-3)

In this, numerical values for \(a_i (1 \leq i \leq r)\) are defined in accordance with the forms below

(2-4-a)

\[
\begin{align*}
  \frac{\partial}{\partial U} (F^k g_i) &= 0 \quad k = 0, 1, 2, \ldots, a_i - 1 \\
  \frac{\partial}{\partial U} (F^k g_i) &\neq 0 \quad k = a_i
\end{align*}
\]

(2-4-b)
In this, \( Fg_t \triangle \left( \frac{\partial}{\partial X} g_t \right)^F \), \( F^* g_t \triangle F \left( F^{* -1} g_t \right) \), and, when \( k = 0 \), one has \( F^* g_t \triangle g_t \).

Assuming that, during the process of the derivatives described above, with regard to \( 1 \leq i \leq r \), one has \( a_i < \infty \), in the equation set (2-3), if \( U \) can act as a function of \( x \) and \( y \), then, it is possible to solve for the explicit representation as

\[
U = H^{-1}(X, Y^*)
\]

(2-5)

In this, \( \hat{Y}^* \triangle \left( y, \cdots, y, \right)^T \). Then, it is conveniently possible, from equation (2-1), to construct a new system equation. The state equations can be obtained from substituting equation (2-5) into equation (2-1-a). The output equation is then form (2-5). As a result, system \( \pi: YU \) equations can be expressed as

\[
\begin{align*}
  \dot{X} &= F(X, H^{-1}(X, Y^*)), \quad X(t_0) = X_0 \\
  \pi: U &= H^{-1}(X, Y^*)
\end{align*}
\]

(2-6-a)

(2-6-b)
It can be demonstrated [8] that the system expressed by the equations described above is the inverse systems to system (2-1).

With regard to the initially given system expressed by equation (2-1), take Ya in the inverse system (2-6) and replace it to be \( j \varphi = [\varphi_1, \varphi_2, \ldots, \varphi_r]^T \). It is then conveniently possible to obtain the a order integral inverse system.

\[
(2-7-a) \\
\dot{X} = F(X, H^{-1}(X, \varphi)) \quad X(\xi_0) = X_s \\
U = H^{-1}(X, \varphi)
\]

\[
(2-7-b)
\]

After that, before taking the a order integral inverse system obtained and connecting it with the original system, combined systems which are further obtained are then corresponding pseudo linear systems. The transmission relationship can be expressed as

\[
(2-8) \quad \text{diag}(D^s_1, D^s_2, \ldots, D^s_r).Y = \varphi
\]

In this, Dai is the ai order operator. \( i = 1, 2, \ldots, r \).
Pseudo linear systems can also be expressed as state spacial forms

\begin{align}
(2-9-a) \\
\begin{align*}
\dot{Z} &= AZ + B\phi \\
U &= CZ
\end{align*}
\end{align}

(2-9-b)

Assuming that optimal performance indicators corresponding to system (2-1) are

\begin{align}
J'(X,U) &= \frac{1}{2}X^T(t_f)R'X(t_i) \\
&\quad + \frac{1}{2}\int_{t_i}^{t_f} (X^T(t)Q'X(t) + U^T(t)S'U(t))dt
\end{align}

(2-10)

Choosing pseudo linear system (2-9)'s optimal performance index to be

\begin{align}
J(Z,\phi) &= \frac{1}{2}Z^T(t_f)RZ(t_i) \\
&\quad + \frac{1}{2}\int_{t_i}^{t_f} (Z^T(t)QZ(t) + \phi^T(t)S\phi(t))dt
\end{align}

(2-11)

If, at the same time that \( J(Z,\phi) \) min, one also has \( J'(X,U) \) min', then it is possible to first, with regard to pseudo linear (2-9) and in accordance with solution methods
for linear second order type optimal regulator devices, get pseudo linear system optimal control

\[ \phi^* = \phi^*(Z^*, t) \]

Assuming the relationship between state vectors \( X \) and \( Z \)

\[ Z = T(X) \]

comprehensive consideration of forms (2-7-b), (2-12), as well as (2-13), it is finally possible to obtain nonlinear system (2-1) optimum controls which are

\[ U^*(X^*, t) = H^{-1}(X^*, \phi^*(T(X^*), t)) \]

III. THE SETTING UP OF INTERCEPTION DEVICE AND TARGET RELATIVE MOTION EQUATIONS

Assuming that targets move along elliptical orbits, in studying instants with targets at point \( M \) and interception devices at point \( D \), the relative distance between the two is \( \rho \). Introducing line of sight coordinate system \( D\hat{\eta} \), the relationship between it and the interception device
three dimensional coordinate system $Dxlylz$ is determined by altitude angles $\theta$ and azimuth angles $\psi$ as shown in Fig.1. The mathematical relationship between the two coordinate systems is

\[
\begin{bmatrix}
\dot{x} \\
\dot{y} \\
\dot{z}
\end{bmatrix} =
\begin{bmatrix}
\cos \theta \cos \psi & \sin \theta & -\cos \theta \sin \psi \\
-\sin \theta \cos \psi & \cos \theta & \sin \theta \sin \psi \\
\sin \psi & 0 & \cos \psi
\end{bmatrix}
\begin{bmatrix}
\dot{X} \\
\dot{Y} \\
\dot{Z}
\end{bmatrix}
\]

(3-1)

Assuming that angular velocities of rotation of line of sight coordinate systems with respect to inertial coordinate systems are:

\[
\dot{\omega} = \dot{\omega}_t + \dot{\omega}_v + \dot{\omega}_i
\]

(3-2)

In this, $\dot{\omega}_t, \dot{\omega}_v, \dot{\omega}_i$ are projections of absolute angular velocities $\dot{\omega}$, the three line of sight coordinate system axes. When target orbit altitudes are between 300km - 2500km, considerations of terminal guidance laws can ignore differences in gravity. Then, in studying three axis stability plans, and, assuming conditions where attitude controls guarantee
(3-3) \[ \bar{\omega}_t = \bar{\delta} \]

relative motion equations for targets and interception devices can be written as:

(3-4-a)

(3-4-b)
\[
\begin{aligned}
\bar{b} - \rho (\omega_1 + \omega_2) &= a_t \\
2\dot{\rho} \omega_1 + \rho \dot{\omega}_1 &= a_t \\
-2\dot{\rho} \omega_2 - \rho \dot{\omega}_2 &= a_t
\end{aligned}
\]

(3-4-c)

In these, \( a_t, a_\chi, a_\zeta \) are thrust acceleration orthogonal projections on the three line of sight coordinate system axes. Due to the forms above implicitly containing target movements, this article, therefore, hypothesizes that targets are a type of special case. Assume that, on interception devices, there are installed four normal thrust engines along the periphery of the center of mass as shown in Fig.2. That is, \( a_\chi = \bar{\delta} \). From Fig.1, it can be known that:
Fig. 1 Line of Sight Coordinate System and Three Dimensional Coordinate System

Fig. 2 Interception Device Thrust Engine Installation Diagram

\[
\begin{bmatrix}
\hat{a}_x \\
\hat{a}_y \\
\hat{a}_z
\end{bmatrix}
= \begin{bmatrix}
\cos \theta \cos \psi & \sin \theta & -\cos \theta \sin \psi \\
-\sin \theta \cos \psi & \cos \theta & \sin \theta \sin \psi \\
\sin \phi & 0 & \cos \phi
\end{bmatrix}
\begin{bmatrix}
\bar{v} \\
\bar{a}_x \\
\bar{a}_y \\
\bar{a}_z
\end{bmatrix}
\]
Assume that attitude control systems guarantee $\theta \to 0$, $\varphi \to 0$.
Then, one has

\begin{align*}
(3-6-a) \\
\begin{aligned}
a_t &= 0 \\
a_x &= a_{\gamma_1} \\
a_z &= a_{\gamma_1}
\end{aligned}
\end{align*}

(3-6-b)

Moreover, equation (3-4) changes to become

\begin{align*}
(3-7-a) \\
\begin{aligned}
\dot{\theta} - \rho (\omega_l + \omega_i) &= 0 \\
2\dot{\rho} \omega_l + \rho \dot{\omega}_l &= a_{\gamma_1} \\
-2\dot{\rho} \omega_l - \rho \dot{\omega}_l &= a_{\gamma_1}
\end{aligned}
\end{align*}

(3-7-b)

(3-7-c)

The equations above are nothing else than target and interception device relative motion equations in three
dimensional space. Attitude control system engine fuel combustion will give rise to changes in interception device centers of mass. Moreover, once four normal thrust engines are installed, the locations are not easy to change. Therefore, in the process of interception, interception device centers of mass will deviate by small amounts the planes determined by the centers of mass of the four normal direction thrust motors. Assuming that the errors given rise to from this factor as well as the errors given rise to by coupling of attitude and center of mass movements can be ignored in engineering terms, then kinematics model (3-7) is reasonable. From this, it can be seen that model (3-7) is one type of approximation model. This type of approximation causes the model to be very greatly simplified. As a result, the carrying out of guidance law design is facilitated.

If one lets \( x_1 = \rho, x_2 = \dot{\rho}, x_3 = \omega_i, x_4 = \dot{\omega}_i, u_1 = d_{\rho_1}, u_2 = d_{\omega_1} \),

then, equation (3-7) can be written as the state equations

(3-8-a) \[
\dot{x}_1 = x_2 \\
\dot{x}_2 = x_1 (x_1^2 + x_2^2) \\
\dot{x}_3 = -\frac{2x_1x_3}{x_1} - \frac{u_1}{x_1} \\
\dot{x}_4 = -\frac{2x_1x_4}{x_1} + \frac{u_2}{x_1}
\]

In these, \( x_1 \) is the relative distance between interception devices and targets. \( x_2 \) is their relative velocity. \( x_3 \) is their longitudinal planar
angular line of sight velocity. $x_4$ is transverse planar angular line of sight velocity. $u_1$ and $u_2$ are, respectively, accelerations produced in association with interception device thrusts on axes $Z_1$ and $Y_1$.

IV. NONLINEAR OPTIMUM GUIDANCE LAW DESIGN

For the sake of convenience in the study of guidance laws, it is possible to take equation (3-8) and divide it into two dimensional models, that is, longitudinal planar relative motion equations

\begin{align}
(4-1-a) \\
\dot{x}_1 &= x_1 \\
\dot{z}_1 &= x_1 z_1 \\
\dot{x}_2 &= -\frac{2x_1 x_2}{x_1} - \frac{u_1}{x_1}
\end{align}

(4-1-c)

as well as transverse planar relative motion equations
(4-2-a)

\[
\begin{aligned}
\dot{x}_1 &= x_1 \\
\dot{z}_1 &= x_1 x_1 \\
\dot{z}_1 &= -\frac{2x_1 x_2}{x_1} + \frac{u_1}{x_1}
\end{aligned}
\]

(4-2-b)

(4-2-c)

Now, taking the transverse planar case in order to design guidance laws, assume system (4-1)'s output equation is

\[y_1 = x_1\]

(4-3)

With regard to equation (4-3), carry out derivation and transformation to obtain

\[
\begin{aligned}
\dot{y}_1 = \dot{x}_1 &= -\frac{2x_1 x_1}{x_1} - \frac{u_1}{x_1}
\end{aligned}
\]

(4-4)

After transformation, one has:
\[(4-5)\quad u_i = -x_i y_i - 2x_i x_i \]

Let \( \varphi = y_i \), then, pseudo linear system numerical models are:

\[(4-6)\quad \dot{y}_i = \varphi \]

Assume that pseudo linear system state variables are

\[(4-7)\quad z = y_i \]

Then, pseudo linear system \((4-6)\) can also be written as state controls forms:

\[(4-8-a)\quad \begin{cases} \dot{z} = \varphi \\ y_i = z \end{cases} \]

\[(4-8-b)\]
If one takes equation (4-6) and substitutes into equation (4-5), then, one has:

\[ u_i = -x_i\varphi - 2x_{i1}x_i \]  \hspace{1cm} (4-9)

After considering equations (4-3) and (4-7), equation (4,9) is changed to be:

\[ u_i = -x_i\varphi - 2x_{i2}z \]  \hspace{1cm} (4-10)

From equation (4-10), it is possible to write pseudo linear system characteristic indices as

\[ J(x,\varphi) = \frac{1}{2}rs^2(t_b) + \frac{1}{2}\int_{t_s}^{t_b} [qs^2(t) + s\varphi^2(t)]dt \]  \hspace{1cm} (4-11)

In the equation, \( r, q, \) and \( s \) are weighting coefficients. \( t_b \) is time of entry into terminal guidance origination time. From equation (4-10) and equation (4-11), it is possible to see that one has only to appropriately select weighting coefficients. Then, when equation (4-11) reaches a minimum, it is possible to make the absolute values of line of sight angular
velocity \( x_3 \) and control \( u_1 \) diminish. That is, it is possible to make equation (2-11), which corresponds to a matrix associated with a certain set of weighting coefficients \( R', Q', S' \), reach minimums. As a result, making connections, it is possible to carry on in accordance with methods described in Section II.

\[
\varphi^*(t) = -\frac{1}{s} p(t) z^*(t)
\]

(4-12)

In this, \( p(t) \) satisfies Riccati scalar quantity integral equations [7]:

\[
\begin{cases}
\dot{p}(t) = \frac{1}{s} p(t) - q \\
p(t_0) = r
\end{cases}
\]

(4-13-a)

\[
(4-13-b)
\]

Through solving Riccati equations, it is finally possible to obtain pseudo linear system optimum control as:

\[
\varphi^*(t) = \frac{(r + \sqrt{s}q) + (r - \sqrt{s}q) \exp \left[ 2 \sqrt{\frac{s}{q}} (t - t_0) \right]}{(r + \sqrt{s}q) - (r - \sqrt{s}q) \exp \left[ 2 \sqrt{\frac{s}{q}} (t - t_0) \right]} x^*(t).
\]

(4-14)
Take equation (4-14) and substitute into equation (4-9). One then obtains the longitudinal planar nonlinear optimum guidance law:

\[
u^* = \sqrt{\frac{q}{s}} \frac{(r + \sqrt{s}q) + (r - \sqrt{s}q)\exp\left[2\sqrt{\frac{q}{s}}(t-t_s)\right]}{(r + \sqrt{s}q) - (r - \sqrt{s}q)\exp\left[2\sqrt{\frac{q}{s}}(t-t_s)\right]} x^*_i x^*_i - 2x^*_i x^*_i.
\]

(4-15)

By the same reasoning, it is possible to obtain the transverse planar nonlinear optimal guidance law:

\[
u^* = -\sqrt{\frac{q}{s}} \frac{(r + \sqrt{s}q) + (r - \sqrt{s}q)\exp\left[2\sqrt{\frac{q}{s}}(t-t_s)\right]}{(r + \sqrt{s}q) - (r - \sqrt{s}q)\exp\left[2\sqrt{\frac{q}{s}}(t-t_s)\right]} x^*_i x^*_i + 2x^*_i x^*_i.
\]

(4-16)

Looking at the two equations above, this type of nonlinear optimal guidance law requires the carrying out of global state feedback on systems. This then brings with it certain difficulties in realizing guidance laws. In
particular, it requires the measurement of distances. However, we are capable of using reconstructed state methods in order to solve this problem. In summary, although the guidance laws we put forward are a bit complicated, guidance performance will, however, be very greatly increased.

V. NUMERICAL VALUE SIMULATION

Using longitudinal planar nonlinear guidance laws as an example, simulation tests were carried out. When

\[ x_i(t_0) = 100 \text{km}, x_i(0) = -10 \text{km/sec}, \quad x_i(t_0) = 5 \times 10^{-4} \text{rad/sec}, \]

simulation results for guidance law (4-15) are as shown in Fig. 3, 4, and 5 (among these, selections are made for \( r=10 \), \( q=60 \), \( s=110 \), \( t_0 = 0 \) sec, and \( t_b = 10 \) sec). Moreover, proportional guidance law simulation results are seen in Fig. 6 and 7. In accordance with calculation formulae for the amounts by which targets are missed [9],

\[
\rho_k = \frac{x_k \sqrt{x_k^2 + x_k^2}}{\sqrt{x_k^2 + x_k^2 + (x_k^2 + x_k^2)}}
\]

(5-1)

it is possible to solve for the amounts by which targets are missed as associated with nonlinear guidance law (4-15) and conventional proportional guidance laws to be, respectively, 5.4x10\(^{-7}\) m and 10.32 m, assuming the aiming blind area range is 2000m. In nonlinear guidance laws, the values of weighting coefficients \( r, q, \) and \( s \) influence
guidance characteristics. Through simulations, it is possible to know that, the larger the value of q/s is, the better guidance performance is. Moreover, the influence of the value of r on guidance characteristics is very tiny. Simulation results also tell us that the absolute values of control signals associated with nonlinear guidance law (4-15) are monotonic reduction functions of time. Moreover, they will not exceed maximum thrust ranges associated with interception device motors. Besides this, conventional proportional guidance indeed has line of sight angular velocity divergence phenomena. Moreover, as far as the nonlinear guidance laws discussed above are concerned, the line of sight angular velocities drop monotonically and converge to zero. In summary, the performance of the nonlinear guidance laws given in this article are indeed very good.

VI. CONCLUSIONS

This article makes use of inverse system methods and studies nonlinear optimal control problems. In conjunction with that, it puts forward nonlinear optimal guidance laws. The guidance laws in question furnish a theoretical foundation for increasing space intercept terminal guidance performance. Of course, during actual realization, there still exist a number of problems—for instance, problems with obtaining relative distance signals $x_1(t)$ in it. Please see reference [6]. This article will not provide superfluous details.
