**ABSTRACT (Maximum 200 words)**

This thesis focuses on the design and implementation of a new interface editor for the Computer-Aided Prototyping System (CAPS), which decouples the user interface from the real-time prototype. Using this design, a CAPS user creates a prototype with an interface development tool and a Prototyping System Description Language (PSDL) editor. This real-time prototype executes on two processors using a client/server architecture; the user interface executes on a client, and the real-time PSDL application executes on a server. In addition, this thesis includes demonstrations, with source code, which implement the design. The demonstrations show that Java development tools can be used to create a high-quality user interface for a PSDL application. A socket connection was used to implement the client/server communication. The demonstrations were successful, but the socket programming model is too primitive for the new design. Therefore, a high-level client/server architecture, such as the Common Object Resource Broker Architecture (CORBA), is required for future development of the design.

ABSTRACT

This thesis focuses on the design and implementation of a new interface editor for the Computer-Aided Prototyping System (CAPS), which de-couples the user interface from the real-time prototype. Using this design, a CAPS user creates a prototype with an interface development tool and a Prototyping System Description Language (PSDL) editor. This real-time prototype executes on two processors using a client/server architecture; the user interface executes on a client, and the real-time PSDL application executes on a server. In addition, this thesis includes demonstrations, with source code, which implement the design. The demonstrations show that Java development tools can be used to create a high-quality user interface for a PSDL application. A socket connection was used to implement the client/server communication. The demonstrations were successful, but the socket programming model is too primitive for the new design. Therefore, a high-level client/server architecture, such as the Common Object Resource Broker Architecture (CORBA), is required for future development of the design.

ACKNOWLEDGMENT

The author wants to thank Prof. Luqi and Prof. Berzins for their help and guidance in preparing this work. I would also like to thank Lori, Diana, and Kyle for their support.
I. INTRODUCTION

A. GENERAL

In the development of software applications, the user interface software is often complex, large, and difficult to design. The user interface is the aspect of a computer program that has the most direct contact with the user. Likewise, the design of user interfaces has become an important part of the Computer-Aided Prototyping System (CAPS). CAPS is a collection of engineering tools, which are used to design real-time systems. A CAPS user enters specifications using the Prototyping System Description Language (PSDL). To complete the prototype, the user designs a user interface with the CAPS interface editor. Finally, the PSDL is translated into Ada; the Ada is linked with the user interface; and the prototype application is executed.

CAPS is an evolving research project, and many of its components are still under development. The user interface development tools of CAPS need to be revised. For instance, the current version of CAPS is only fully functional on a Sun Microsystems workstation running SunOS UNIX. Currently, the CAPS interface editor is Century Computing’s Transportable Applications Environment (TAE). TAE is only available for a few platforms, and it has limited capabilities. In addition, the CAPS user interface, written in Motif, is not easily ported to other platforms.

B. PROBLEM STATEMENT

A CAPS designer uses the prototyping process to create an application. PSDL is used to express the specifications of the application. Next, the CAPS interface editor can be used to create a prototype user interface. Unfortunately, the current interface editor does have the support and functionality that is required. This thesis focuses on creating a new design for linking a user interface with a PSDL application. In addition, this thesis
evaluates user interface development tools, which could be used to increase the functionality, portability, and versatility of CAPS.

C. SCOPE

The scope of this work was originally intended to integrate a commercial user interface development tool into CAPS. As work on this thesis progressed, it became clear that a new design for linking the user interface with the prototype was required. This design is based upon a client/server architecture. In addition, two demonstrations that use the new design are included.

D. ORGANIZATION OF THESIS

Chapter II contains background information about CAPS, user interface development tools, and supporting documentation. Chapter III presents the design process and results. Chapter IV presents the implementation of the new design. Chapter V contains demonstrations of the new design. Chapter VI provides the conclusion and a discussion of future research. Appendix A contains evaluations of user interface development tools.
II. BACKGROUND

A. COMPUTER-AIDED PROTOTYPING SYSTEM

The Computer-Aided Prototyping System (CAPS) is a software engineering tool for developing prototypes of real-time systems [Ref. 1]. CAPS was designed to allow a user to build software specifications and make them executable. In addition, CAPS can be used for requirements analysis, evaluation of models, and designing large-embedded systems. CAPS promotes the rapid prototyping life cycle (Figure 1). Rapid prototyping is an alternative paradigm for software development. By using the prototyping process, a user can validate system requirements early in the project's life cycle. In addition, CAPS includes tools for software reuse and evolution. [Ref. 2]

![Diagram showing the Rapid Prototyping Life Cycle](from Ref. [7])

A CAPS user specifies relationships, data flow, and constraints between software objects. These specifications are expressed in the Prototyping System Description Language (PSDL). The user initially works at a high level of abstraction, breaking down the objects into lower levels of abstraction. At the lowest levels, existing
code from a software library is used to implement the object. Alternatively, a high-level language, such as Ada, can be used to implement the object. The papers [Ref. 3], [Ref. 4], [Ref. 5], [Ref. 6], and [Ref. 7] provide more information about CAPS.

1. **CAPS Components**

   CAPS is a development environment consisting of tools linked by a user interface (Figure 2). The main sections of CAPS include: editors, execution support, software database, and project control. The editors are used to implement the software design. Execution support is for software translation, real-time scheduling, and compilation. The software database is intended for software storage and reuse. Project control contains tools for software evolution, such as revision control, merging of software versions, and project planning. [Ref. 8]

2. **Prototyping System Description Language**

   A CAPS user can input software specifications via the Prototyping System Description Language (PSDL). PSDL is a text-based language designed to express specifications of real-time systems. PSDL has only two kinds of components: operators and types. PSDL is based on a graph model of edges and vertices (Figure 3). The edges represent streams of data flow from one operator to another. The streams are instances of types. The vertices represent software operators. The operators can either be sporadic or periodic. The operators may have associated timing constraints. An example timing constraint is Maximum Execution Time (MET). In PSDL, the MET of an operator must not be exceeded, otherwise a timing error will be displayed. In addition, the operators may also have control constraints. Control constraints for a periodic operator include: Finish Within (FW) and Period. [Ref. 3]

   PSDL supports the concept of program abstraction. The PSDL operators can either be composite or atomic. An atomic operator is implemented in a standard programming
language such as Ada. A composite operator can be decomposed into a sub-layer containing operators and streams. [Ref. 3]

Figure 2. CAPS and Graph Editor
3. Monitoring PSDL Execution

By using PSDL, a CAPS user can create a prototype application. In most cases, a CAPS user must be able to monitor the prototype's execution. Even if the prototype is destined to be an embedded application without a Graphical User Interface (GUI), the user may require a GUI to evaluate the prototype. Alternatively, a user may also require a GUI to emulate an external environment.

CAPS has built-in diagnostics, which monitor a prototype's execution. Additionally, CAPS monitors the execution times of the operators. The user will be notified if timing constraints are violated. CAPS prints data-stream errors and exceptions during the execution of the prototype.

In addition to diagnostic output, a CAPS user may wish to observe data values, provide input, and observe simulations. A user can add simple print statements to monitor execution of a PSDL application. This is traditionally done by adding Ada print statements to the atomic operator's implementation.

4. Interface Editor

The interface editor is a GUI development tool designed to help the developer create high-quality user interfaces in a short period of time. If a CAPS user requires more
than just simple print statements in the prototype application, he/she can use the CAPS interface editor to design a graphical user interface prototype (GUI-prototype). The GUI-prototype allows a user to display and input information in a window-based environment. In many real-time embedded applications, the GUI-prototype is only required for analysis. In most cases, the GUI-prototype does not have timing constraints. It is important that the GUI-prototype not interfere with the real-time execution of the prototype application. [Ref. 8][Ref. 9]

5. **CAPS Release 1.1 Interface Editor: TAE**

CAPS Version 1.1 currently incorporates Century Computing’s TAE as the interface editor [Ref. 8][Ref. 10]. TAE allows a user to quickly create X-Widows/Motif based GUI-prototypes. TAE generates C or Ada program code. To create a prototype application, the TAE-Ada code is linked with translated PSDL.

TAE has some very useful features, including a GUI builder. In addition, the TAE resource file allows widgets to be interchanged without recompiling the entire application. Also, TAE allows the building of high-level reusable components. TAE has been successfully integrated, documented, tested, and demonstrated with the CAPS system.

However, TAE has drawbacks with respect to CAPS. TAE is expensive to support, license, and to include in the release of CAPS. In addition, TAE is not platform independent. Also, TAE does not work with all versions of UNIX. Most importantly, the current integration of TAE alters the TAE event manager. TAE is linked with a prototype application by removing the infinite loop from the TAE event manager. As a result, the prototype application is responsible for polling the TAE widgets. This design can make the prototype application sluggish to user input and slow when displaying data.

For information on how to link in TAE and PSDL consult [Ref. 8]. For information on how to use TAE, consult [Ref. 10].
B. GUI DEVELOPMENT TOOLS

Graphical User Interface (GUI) design is a field in computer science that has been changing rapidly in the last ten years. Window-based operating systems have allowed applications to have sophisticated user interfaces. Unfortunately, user interface software is often complex, large, and difficult to program. Traditionally, programmers have used toolkits to develop GUIs. The toolkits use the functionality of the platform's windowing and operating system. Fortunately, new software development tools are now available to aid the software designer. A GUI development tool is defined as software to aid in the creation of graphical user interfaces. Most GUI development tools are based on toolkits to achieve their look-and-feel. A few development tools do not make direct calls to the standard toolkits, but emulate the look-and-feel of the toolkits. Figure 4 shows the layering of GUI software.

<table>
<thead>
<tr>
<th>Application</th>
<th>GUI Development Tools</th>
<th>GUI Toolkits</th>
<th>Windowing System</th>
<th>Operating System</th>
</tr>
</thead>
</table>

Figure 4. Components of GUI Software "After Ref. [11]"

The software designer must decide whether to use a GUI development tool or program manually with just the toolkit libraries. The decision to program with GUI development tools is better than manual coding in several ways. For instance, most tools support prototyping, reuse, and code consistency. In contrast, the drawbacks of tools could include: added complexity, a higher learning curve, added expense, and performance penalties. [Ref. 12]

Object oriented design and coding has become a fundamental part of most GUI development tools. Most GUI development tools incorporate abstraction and
encapsulation in their design. For example, a software developer may not care to understand the inner functionality of a widget, but he/she may just need to know the available methods for the widget.

The GUI development tools can be grouped by the languages supported. Alternatively, the tools can also be grouped by the platforms supported. The following paragraphs divide the tools based on functionality. However, many of the commercial tools do not fit into just one category. [Ref. 12]

1. **GUI Toolkits**

A GUI toolkit is a library of widgets that can be used to develop user interfaces. Typical widgets include: buttons, sliders, text-fields, and canvases. Some toolkits contain high-level widgets, such as pop-up dialog boxes, which aid the developer in creating common interfaces. The use of high-level widgets maintains a consistent look-and-feel across different applications. Motif and OpenLook are examples of X-Windows toolkits. An example of a platform independent toolkit is Artificial Intelligence Applications Institute’s wxWindows [Ref. 13]. It is a free-of-charge library for C++.

2. **GUI Builders**

Usually a GUI development product contains a GUI builder to construct and edit the interface. Most GUI builders allow the designer to quickly create an interface in a *What You See Is What You Get* (WYSIWYG) mode. A GUI builder allows the user to easily add, delete, and replace widgets. In many cases, a GUI builder can be used by a person with little programming experience. In the prototyping process, the ability to create GUIs in a short period of time is very important. The GUI builders available today vary in quality, ease of use, and training required.
3. **User Interface Management Systems**

A User Interface Management System (UIMS) adds functionality to the GUI, without the user having to program in a high-level language. To achieve this functionality, some UIMS include high-level scripting languages, which add behavior to the GUI. [Ref. 14]. Open Software Associates’ OpenUI [Ref. 15] and Aonix’s Teleuse [Ref. 16] are examples of UIMSs.

4. **Analysis, Plotting, Graphics, and Visualization**

Some GUI tools contain graphics and 2D-3D visualization tools. Other tools may allow the user to analyze and plot technical data in generic formats. Visual Numerics PV-WAVE [Ref. 17] and Mathworks’ Matlab [Ref. 18] are examples. Some tools support real-time analysis of data. DataViews Corporation’s DataViews is an example of this kind of tool [Ref. 19].

5. **Application Development Environments**

Application development environments contain a wide range of tools, in addition to the GUI tools. These products contain tools to aid in the full range of software development. These tools could include: groupware, code-analysis, debugging, evolution control, and real-time control. Visix’s Galaxy [Ref. 20] and Sun Microsystem’s Visual Workshop [Ref. 21] are examples of application development environments.

6. **Platform Independent Graphical User Interface**

A Platform Independent Graphical User Interface (PIGUI) is defined as a software library that supports at least two different operating systems. [Ref. 22] A PIGUI allows a developer to create one version of code that runs on multiple platforms. A PIGUI will
hopefully decrease the amount of total development time for a project supporting multiple platforms. The PIGUI can either preserve the native look-and-feel of the target platform or maintain a consistent look-and-feel across platforms.

There are two types of PIGUIs. The PIGUI can link to the windowing toolkit on the target machine. XVT Softwares's XVT is an example of this kind of PIGUI. [Ref. 23] Secondly, a PIGUI can re-implement the widgets for each target platform. Visix's Galaxy is an example of this type. [Ref. 20] The extra overhead of PIGUIs will generally slow down the execution of the application. The supported languages for PIGUIs include C, C++, Ada, Java, and others, but the most predominate is C++. [Ref. 22]

C. DE-COUPLING OF THE GUI

GUI complexity has increased rapidly in the last few years. Users are requiring well-planned and sophisticated GUIs. The computer applications of the 1960's and 1970's had simple user interfaces with very little operator involvement. These early computer programs were mostly one-tier applications. A tier is a component of an application that is bound through external interfaces to other modules of the application [Ref. 24]. One-tier applications include all the functionality in one program. This functionality can include: presentation management, program rules code, and database access (Figure 5). One-tier applications have the advantage of being easy to design, setup, and maintain. On the other hand, one-tier applications are not easily scaleable and have inadequate performance at high volume. [Ref. 25]
The recent development of client/server middleware and Database Management Systems (DBMSs) allowed the developer to separate the database code from the rest of the application. Usually, client/server computing involves two or more computers distributing tasks appropriate to each computer to complete the application. Client/Server computing has been widely used in database systems. Figure 6 shows a DMBS task communicating with a database. The DBMS is de-coupled from the rest of the application. [Ref. 15]

Figure 6. Two-tier Client/Server Application

The separation of the GUI from the application code has mirrored the de-coupling of DBMSs [Ref. 15]. In recent years, the GUI has become the most complex part of many applications. A 1992 study found that an average of 48% of an application code is devoted to the user interface, and about 50% of the implementation time is devoted to the user interface [Ref. 12]. In many software designs the GUI is de-coupled from the rest of the application. Figure 7 shows a three-tier application; the GUI controls the display, handles user input, and requests services from other tiers of the application.

Multiple-tiered computing has also distributed the tasks of an application to many remote sites. Distributed applications use client/server protocols to allow the client application to communicate with a server computer system. Distributed computing makes the sharing of data and processor resources possible.
Client/server computing has advantages and disadvantages. By separating an application into multiple tiers and incorporating the client/server model, it is modularized; reuse is promoted; and the computing load is distributed [Ref. 24]. Even if a client/server application is run on one CPU, it retains the benefits of modularity and reuse. On the other hand, a disadvantage of client/server computing is communication complexity. The communication protocols can add CPU load to the design. Also, client/server systems are harder to setup and design. [Ref. 26]

![Diagram of Three-Tier Software Design: Separation of GUI and DBMS]

Figure 7. Three-Tier Software Design: Separation of GUI and DBMS

D. EVALUATION OF GUI TOOLS

The number of commercial and public GUI development tools is large and is growing rapidly. The GUI tools vary in complexity, price, quality, programming language support, platform support, and adherence to standards. The following issues were considered in the evaluation of GUI development tools:

- Type of Tool: toolkit, GUI builder, UIMS, development environment, ...
- Toolkits supported: Openlook, Motif, Java, ...
- Platform independence
- Platform support
- Operating system support
- Cost: initial purchase, maintenance
- Level of vendor support
- Future support of tools
- Language Support - Ada, C, C++, Java, ..... 
- GUI builder availability
- Compliance to standards
- CAPS integration complexity
- Ease of use, learning curve
- Ease of installation
- Documentation
- Complexity
- Prototyping features
- Visualization tools
- Plotting and graphics
- Additional tools: maketool, evolution control, debugging, group-ware, ..... 

Appendix A contains evaluations of GUI development tools and toolkits. Additional information about these and other tools can be found in the papers [Ref. 22] and [Ref. 25].
III. DESIGN OF A CAPS INTERFACE EDITOR

A. DESIGN PROCESS

As mentioned in the introduction, this thesis focuses on the development of a new interface editor for CAPS. The first step is determining the purpose of the work. The next step is to evaluate the current CAPS' programming environment and determine the assumptions, goals, and constraints for a new design. Since CAPS is a group effort, this thesis must maintain consistency with the previously developed applications.

1. Purpose

The purpose of the CAPS interface editor is to allow a CAPS user to create a GUI-prototype for a prototype application. In addition, the GUI development tools could be used to port the CAPS tools, such as Graph Editor (GE), to other platforms.

2. Assumptions

1. The CAPS user will be familiar with the capabilities of the hardware/software platform.
2. The CAPS user will have knowledge of computer window systems.
3. The CAPS user will be familiar with CAPS, PSDL, and the chosen programming language.

3. Goals/Constraints

1. Goals for an Interface Editor

   1.1 The interface editor must integrate into the existing version of CAPS.
   1.2 The interface editor must run on a variety of platforms and operating systems besides SunOS UNIX.
   1.3 The GUI tools' licensing costs should be kept to a minimum.
   1.4 The execution of a CAPS prototype should not be adversely effected by the GUI repaint and input events.
1.5 The interface editor must be easy to use and be intuitive to a new user.
1.6 The interface editor should contain a variety of high-level widgets to aid in the development of user interfaces.
1.7 The interface editor should contain a GUI builder tool.
   1.6.1 Using the GUI builder, the interface widgets can be added, deleted, and replaced.
   1.6.2 The GUI builder should be able to create high-level widgets.
1.7 The interface editor should require little training.
1.8 The interface editor should be easy to use.
1.9 The GUI-prototype may or may not be part of the static schedule.

2. Constraints
2.1 The GUI integration will be incorporated into CAPS Version 1.1.
2.2 The GUI integration will be developed on a Sun Microsystems Sparc-10 running SunOS 4.1.4.

B. DESIGN RESULTS - GUI-CLIENT / PSDL-SERVER

When using CAPS, the GUI-prototype is for analysis of design, displaying data, and user interaction with the PSDL application. Alternatively, a CAPS designer may want the GUI-prototype to emulate an external environment. The GUI-prototype may not have real-time constraints or be required in a final embedded system, but it will require CPU resources. In this case, it is important that the GUI-prototype not interfere with the real-time execution of prototype application.

As a result, the new design de-couples the GUI-prototype from the rest of the prototype. The new design contains components from a multi-tier client/server architecture. The new design creates a GUI-client that communicates with a PSDL-server. A GUI-client is defined as a GUI-prototype, which is de-coupled from the PSDL and executes on a client processor. A PSDL-server is a PSDL application, without a GUI, which executes on a server processor. With this design, a user can create the GUI-client with any programming language and GUI development tools. The client/server architecture allows the GUI-client to be located on a local CPU, while the PSDL-server is running on a remote CPU (Figure 8). The GUI-client event model can be retained by running the PSDL-server on a different CPU. Also, the real-time schedule of the PSDL-
server is not affected by the GUI-client. In addition, the design allows the GUI-client to be compatible with existing CAPS Version 1.1 software.

The client/server communication is possible with a variety of middleware solutions. The simplest middleware solution is sockets.

![Client/Server Communication Diagram]

Figure 8. Multiple CPUs CAPS Client/Server

Alternatively, the client/server design could be implemented on one CPU if the processing of the GUI-client is taken into account. For this purpose, a prototype application could be run on one CPU by using synchronous communications between the GUI-client and the PSDL-server as shown in Figure 9. As a result, the synchronous communications could prevent the GUI-client from taking CPU resources during the execution of the PSDL-server.

Threads could be used to implement the one-CPU design. The first thread could execute the PSDL-server, while the second thread handles the GUI-client during non-critical times. Also, a single workstation with multiple CPUs could be evaluated.

Problems with the client/server design include: increased overhead and network traffic. A dedicated network will minimize the amount of network traffic. Another
problem with a CAPS client/server design is the added complexity in the overall CAPS system.

Figure 9. One CPU CAPS Client/Server
IV. IMPLEMENTATION CONSIDERATIONS

A. SELECTION OF GUI TOOLS

I spent approximately six months evaluating and selecting GUI development tools. There are over a hundred commercial tools available. In addition, many universities have departments that are doing GUI research, and they offer their GUI development tools free-of-charge. Appendix A describes the evaluated tools. The following tools are considered as possible choices for integration in CAPS.

1. Fresco

Fresco is an object-oriented development toolkit for the development of user interfaces[Ref. 27]. Fresco is a design evolution from Stanford University’s Interviews toolkit. Fresco was developed at Fujitsu’s Faslab in conjunction with the X-Consortium. The OpenGroup’s X-Windows11-V6 (Broadway) contains a sample implementation of Fresco. [Ref. 28]

Unfortunately, Faslab discontinued support and development work on Fresco in late 1996. Also, the software community has failed to widely use Fresco. For these reasons Fresco was not integrated into CAPS.

2. Java Development Kit

The Java programming language, developed by Sun Microsystems, is being hyped as a replacement for C and C++. The Java programming language is becoming the programming language of choice for many internet and standalone applications [Ref. 29][Ref. 30]. Java is not a GUI development tool, but only a language and toolkit. Fortunately, many vendors are now selling complete GUI development environments for Java. Additionally, many traditional Motif development tools are now supporting Java.
Java is an object-oriented, distributed, interpreted, secure, platform-independent, and multithreaded programming language. Unlike most languages, Java has automatic garbage collection. Java has client/server protocols included in the language's API. In addition, Java has a built-in Abstract Window Toolkit (AWT). The AWT can be considered a PIGUI because it runs on multiple platforms without program modification. The Java AWT also supports the native look-and-feel of the target platform.

Consequently, many universities are now offering Java as the introductory programming language instead of C++. Appendix A contains more information about the Java programming language and development tools.

A GUI-client written in Java would allow the interface to run on almost any platform and communicate with a PSDL-server. Java was selected to test integration with CAPS.

3. Visual Workshop / X-Designer

Sun Microsystems' Visual Workshop and Imperial Software Technology's (IST) X-Designer are X-Windows/Motif tools for UNIX platforms. Visual Workshop incorporates IST's GUI builder (X-Designer) into its product. Both tools provide about the same functionality. The tools create Motif X-Windows code written in C and C++. Ada95 can be generated with OC-Systems' XDA attachment. Visual Workshop was also selected to test integration with CAPS. [Ref. 21][Ref. 31]

B. SELECTION OF CLIENT/SERVER MIDDLEWARE

The number of techniques for implementing client/server middleware is very large. Many vendors are trying to sell their products and create standards. The products include: Sockets, CORBA, CGI, Netscape's Caffeine, Java-RMI, and Microsoft's DCOM.
1. Sockets

A socket is the basic protocol for client/server communication over TCP/IP stacks. Sockets were originally introduced in 1981 for UNIX BSD 4.2. Sockets are available on almost every operating system. Sockets are available in several forms: datagram, stream, and raw. The most common socket API is the Berkley UNIX C protocol. Sockets can also be used for communication on a single computer. Figure 10 shows a typical sequence for establishing a client/server connection. Sockets are the basis for most higher level client/server middleware. The socket programming model is quite primitive, but it is very fast and a well-known standard. Sockets were implemented and evaluated as a possible middleware between the PSDL-server and the GUI-client. [Ref. 32][Ref. 33]

![Client/Server Scenario Diagram]

**Figure 10.** Client/Server Scenario

2. Common Object Request Broker Architecture (CORBA)

CORBA is a middleware project being developed by the Object Management Group (OMG) consortium, consisting of over 700 companies. The notable exception to
this group of companies is Microsoft, which has a competing product called the Distributed Component Object Model (DCOM). CORBA could replace all other implementations of client/server middleware. In CORBA client/server computing, objects cooperate over the network as opposed to cooperating processes. [Ref. 32] Specifications for CORBA objects are written with the Interface Definition Language (IDL). IDL provides operating system and programming language interfaces to other services on the CORBA bus. CORBA allows almost any programming language to communicate over a network as shown in Figure 11.

![Diagram of CORBA](image)

**Figure 11.** CORBA

C. **PSDL-SERVER – SOCKET – GUI-CLIENT**

In this implementation, a GUI-client, written in Java or Motif, communicates with a PSDL-server by using TCP/IP sockets. Figure 12 shows the implementation of the design. Demonstrations of the implementation are described in the next chapter. The source code for the demonstrations is in Appendix B.

The PSDL Ada atomic operators bind to a C module that implements the server side of the socket connection. The server socket is written in C because of the difficulty in implementing sockets with the VADS Ada83 compiler.
A protocol is established for passing a data structure between the GUI-client and the PSDL-server. An example communication data structure is shown below:

```c
struct CapsData {
    char command_number;
    int i1
    int i2;
    char buffer[SIZE];
}
```

At present, the communications data structure is modified for each new application. A more generic data structure should be designed to work with all prototype applications. The client/server communications in the demonstrations are synchronous. Asynchronous communication may also be used, but care must be taken to avoid data-loss or deadlocks. The implementations are multithreaded. One thread in the GUI-client is devoted to the socket communication.

Figure 12. CAPS-Socket-GUI
1. **Java GUI-client**

The GUI-client was implemented using the Java programming language. The Java GUI-client can be created with the Java development kit or designed with development tools, such as Symantec’s Visual Café [Ref. 34]. The Java GUI-client can either be a standalone application or run as an applet in a network browser. The Java implementation is multithreaded. Unfortunately, programming Java threads can be difficult. The *Thread Scheduling Model*, which is platform dependent, determines the thread that will be running at any given time. Some operating systems use *preemptive scheduling* and others use *time slicing*. Consequently, the programmer must carefully design the application so that it is still platform independent. The code for a Java implementation is in Appendix B.

2. **Motif GUI-client**

Another GUI-client was implemented in Motif using Visual Workshop (Version 3.) for a Sun Microsystems’ workstation. The GUI-client is also multithreaded. The code for a Motif implementation is included in Appendix B.

D. **PSDL-SERVER – CORBA – GUI-CLIENT**

CORBA has the potential of making middleware transparent to the application programmer. In this thesis, the CORBA middleware was not fully implemented. A CORBA interface is written in IDL. An example IDL interface between the PSDL-server and the GUI-client is as follows:

```idl
// IDL
interface Capsdata {
    attribute int ix;
    attribute int iy
```
int repaint()
int readdata()
int writedata();
}
V. DEMONSTRATIONS OF NEW DESIGN

A. ROBOT CONTROL SYSTEM

This demonstration reworks a CAPS project originally developed in CS4920 (Spring 1996). The project developed a software prototype for a robot control system. The prototype was developed using CAPS Version 1.1. This demonstration uses a socket to connect the GUI-client with the PSDL-server.

1. Requirements for Robot Control System

The robot moves on a friction-less table using air bearings, and is equipped four compressed air thrusters that are aligned with the directions of the coordinate axes (+x, -x, +y, -y). Opposing thrusters should never be both turned on at the same time. Thruster force can be continuously varied under computer control. The maximum thrust from each thruster produces an acceleration of 1 meter per second per second. The software is supposed to provide a “soft landing” capability for the robot. In the test bench for the robot control software, the initial positions (x and y coordinates of the robot) and initial velocities (x and y components of its speed) are specified as input. The controller is supposed to bring the robot to a stop at a position less than 2 cm from the origin of coordinate system. The robot must never get closer than 1 cm from the origin, and it must stay within the border of the table ( -1 meter <= x <= 1 meter and -1 meter <= y <= 1 meter). The initial position must be a legal position, and both components of the initial velocity must not exceed 1 meter per second.

2. Robot: PSDL-server

CAPS (Version 1.1), running on a Sun Microsystems’ Sparc10 (SUNOS 4.14), was used to implement the demonstration. The PSDL for this demonstration is simple, but
contains time-critical operations. Appendix B contains the source code for the PSDL-server. Figure 13 shows the Robot PSDL graph. The operators \textit{bop\_display} and \textit{bop\_input} are atomic operators implemented in Ada. These operators bind to a C program that implements the server connection. The atomic operator \textit{bop\_display} sends data to GUI-client while \textit{bop\_input} requests input from the GUI-client.

![Figure 13. Robot PSDL Graph](image)

Code fragments for the PSDL-server are shown below. The file \textit{ada.h} contains the data structure that is passed between the GUI-client and PSDL-server. The file "\textit{bop\_display.a}" is source code for the atomic operator \textit{bop\_display}. This atomic operator passes display data to GUI-client. Inside "\textit{bop\_display.a}", the function call \textit{socket( )} passes the data structure to the GUI-client. The file "\textit{socket.a}" contains the source code.
for `socket()`, which binds to the C program “server.c” which performs the actual socket connection, socket binding, and data transfer.

```ada
-- FILE : ada.h

typedef struct {
    int ix;
    int iy;
    int ir;
} Rec, *Rec_Ptr;

-- FILE : socket.a

--pkg
package body socket_PKG is
    a1 : FLOAT;
    b1 : FLOAT;
    type Rec is record
        ix: Integer ;
        iy: Integer ;
        ir: Integer ;
    end record;
    type Rec_Ptr is access Rec;
    I : Rec_Ptr := new Rec;
    pragma LINK_WITH ("server.o");
    procedure server(I : in Rec_Ptr);
    pragma Interface (C, server);

    procedure Socket(xx: in out Float; yy: in out Float;
        ireq: in out INTEGER) is
    begin
        .
        server(I);
        .
        end Socket;
end socket_PKG;
```

```ada
--FILE : bop_display.a

with pva_data_Pkg;
with socket_Pkg;
use socket_Pkg;

procedure bop_display(bnss_pva_data: in pva_data_Pkg.pva_data) is
    begin

29
socket(fb,fy,ix);  -- Send the x,y position to the GUI-client.

end bop_display;

3. Robot: GUI-Client

The GUI-client can be written with almost any language and GUI development tools. A GUI-client communicates with the PSDL-server.

a. Java

The Java GUI-client was developed on a Sun Microsystems' UltraSparc (Solaris 2.5) and a Windows95 PC, using the Java Developers Kit (Version 1.1). In addition, Symantec's Visual Café (Version 1.0) was used to develop the GUI-client. The Java program can be designed for a browser or as a standalone application. Figure 14 shows a Java-applet version of the GUI-client. The source code for the applet version is in Appendix B. The Java applet is being displayed in a Netscape browser. The Java program is multithreaded. One thread responds to read/write data via the socket, while the other thread waits for user input and paints the screen.

The Java program has various controls. The "Restart" button reinitializes the socket connection. The "Zoom" button changes the aspect of the view. The user can enter the initial x, y, x-velocity, y-velocity. The user can also drag the robot to a new starting location.

b. Visual Workshop

The GUI-client was also implemented using Sun Microsystems' Visual Workshop version 3.0. running on a Sun Microsystems' Sparcstation-20 (Solaris 2.5). The GUI-client is very simple, but it does contain a thread to read/write data from the
PSDL-server. Figure 15 shows the Visual Workshop GUI builder, with the GUI-client loaded. Figure 16 shows the Visual Workshop version of the GUI-client.

Figure 14. Java GUI-Client
Figure 15. Visual Workshop GUI builder
Figure 16. Visual Workshop GUI-Client
B. SMARTSHIP PROJECT

The Smartship Project commenced in December 1995 in response to the CNO’s review of the 1995 Summer NRAC study which focused on reduced manning. The study concluded that major reductions in manning could be achieved by design in new construction ships. Commander Naval Sea Systems Command responded to the CNO’s desire to focus on existing operational ships. The overall goal is to reduce workload, improve mission readiness, and maintain safety at minimum cost to the government. A Naval Postgraduate School thesis “Smartship Project Modeling”, by Nolan Ruiz, is trying to determine if an effective modeling approach for the Smartship project can be found. In addition, it tries to determine if the current Productivity Allowance is valid. [Ref. 35]

This thesis will look at possible user interfaces, using the GUI-client/PSDL-server design, that could be used with the Smartship project. A socket is used to connect the GUI-client with the PSDL-server. This demonstration will contain only preliminary results, but Nolan Ruiz’s thesis will contain a complete prototype.

1. Smartship PSDL-server

The Manpower/Workload profile of a ship’s Communications Division was evaluated. Tasks can either be periodic or sporadic. Periodic tasks include: Station Watch, PMS Actions, and Field Day. Sporadic tasks include: Underway Replenishment, Vertical Replenishment, General Quarters Drills, Fire Drills, Security Drills and Training.

CAPS (Version 1.1), running on a Sun Microsystems’ Sparc10 (SUNOS 4.14), was used to implement the CAPS demonstration. The top-level PSDL graph contains the following composite operators: SHIP, NAVSEA, and USER. The SHIP composite operator can be broken down into periodic and sporadic tasks. Figure 17 is the PSDL graph for the SHIP composite operator. The data flow between the operators (the periodic and sporadic tasks) is in man-hours.
2. Smartship GUI-client

The Java GUI-client was developed on a Sun Microsystems' UltraSparc (Solaris 2.5) and a Windows95 PC, using the Java Developers Kit (Version 1.1). In addition, Symantec's Visual Cafe (Version 1.0) was used to develop was used to develop the GUI-client. Figure 18 is a Java version of a GUI-client for the Smartship prototype.

Figure 18. Smartship GUI-client (Java)
VI. CONCLUSION

A. SUMMARY OF DESIGN AND IMPLEMENTATION

The client/server design allows a PSDL-server to communicate with a GUI-client. The design is successful in decreasing the coupling between the GUI-client and the real-time prototype application. The GUI-client can be created with almost any GUI development tools. In addition, the design allows the GUI-client to be located on a local or remote CPU. The GUI-client can be unbound or bound to the real-time schedule of the PSDL server.

The demonstrations, using a variety of commercial products, show the successful implementation of the design. In addition, the proper use of threads and GUI-client/PSDL-server communications (synchronous/asynchronous) is very important. If implemented properly, the client/server middleware does not effect the performance of the prototype.

Although this thesis did not finish the integration of a new interface editor in CAPS, many GUI development tools were evaluated for possible integration. The client/server design increases the number of GUI development tools that can be used in the CAPS environment. The Java development tools were determined to be the best tools available to use with CAPS. The reasons to use Java include: low cost, abundance of tools, popularity, language features, and platform independence.

The largest obstacle for implementation of the design is the client/server middleware. For a first implementation, sockets were able to provide the required functionality, but the socket programming model is very primitive. Therefore, a higher level product must be chosen. CORBA, with Ada, C, C++, and Java interfaces, could be used to implement the client/server middleware.
B. FUTURE RESEARCH

In the course of work on this thesis, many ideas came forward, but were not implemented. A great deal of time was spent on the evaluation of GUI tools and middleware. The following is a list of ideas for future work.

1. Selection of Middleware

In addition to sockets, other middleware should be investigated. CORBA was only partially investigated in this thesis, but it could be used to connect atomic operators written in Ada to a GUI-client. Other middleware to investigate include: Java’s RMI, Microsoft’s DCOM, Netscape’s Caffeine, RPC.

2. Selection of GUI Development Tools

A GUI development tool should be selected for full integration into CAPS. In addition, a PIGUI would aid in the porting of the other CAPS tools.

3. Further Demos

New applications using the new GUI-client/PSDL-server design should be demonstrated. Previous CAPS applications could be ported and their performance compared. Implementations using a single CPU could be evaluated.

4. Socket Communications

If sockets are used, the server-side and the client-side source code could be automatically generated. The data structure for passing data between the GUI-client and PSDL-server could be standardized.
Several protocols exist for socket communications. The socket protocols should be compared to find the most efficient method of communications.

This thesis implemented the PSDL-server by binding the Ada83 code to a C module. The C module implemented the socket communication. Ada95 should be able to implement a socket connection.

5. **JavaBeans**

A *bean* is a reusable and interchangeable Java component. Even though JavaBeans are a new technology, many vendors are now selling JavaBeans tools. It might be possible to create a Java-Bean GUI-client automatically in the CAPS Graphics Editor (GE).

</tr>
<tr>
<td>Comments:</td>
<td>Java is an object-orientated, multithreaded, and portable programming language. The Abstract Window Toolkit (AWT) is a built-in library for creating window components. Java has built-in garbage collection. A great deal of work is being on and with Java, but the language is in a state of flux. The class library is very comprehensive, but lacks the high level GUI object or dialog objects. Many third parties are developing these high level objects. Unfortunately, Java is currently slower in execution speed than other languages, but Sun Microsystems and other vendors are developing compilers that should bring the performance of Java close to other languages. The loading of the Java AWT software on a Sun Microsystems Sparcstation (Solaris 2.5) and Windows-95 was very easy. Linking directly with CAPS would be difficult. A client/server interface with CAPS was completed in this thesis. [Ref. 29] [Ref.30] [Ref. 36] [Ref. 37]</td>

| Cost:        | Free |
| Vendor Support: | None, the vendor has completed the research |
| Future Support: | The research on Fresco at FASLAB has been completed. No future work seems to be planned. |
| Languages Supported: | C++ |
| GUI builder available: | No |
| Comments:    | The Opengroup's X11-V6 (Broadway) contains a sample implementation of Fresco. Fresco is user interface system specified using CORBA IDL. Even though it is included in the latest version of X-Windows, Fresco is not yet a standard. Fresco is a PIGUI, but it does not support the native look and feel. Loading Fresco on Sun Microsystems Sparcstation (Solaris 2.5) was fairly simple. A tutorial walks a new user through examples. FrescoVFX is a fairly complete example of what Fresco can do. Fresco has very little low level documentation and the software library still seems buggy. There is no documentation on how to put the components together into a final product. Fresco could possibly connect to CAPS via a client/server approach. [Ref. 27] |

**Comments:**
Open Software Associates main office is in Australia, but there support of their product is very good. OpenUI (Figure 23) has built in client(GUI)/server(Logic) application development. A user one must learn their interface language (OPL) to complete a user interface. C, C++ is used to bind to application code. ADA is longer supported. OpenUI would be useful for large project.

<tr>
<td>Comments:</td>
<td>Galaxy (Figures 25, 26) is complete software engineering environment. Galaxy is an emulated API. An emulated API does not require high level toolkits to compile the program. For example, when Galaxy emulates Motif, Galaxy does not have to link in Motif libraries. A benefit of the emulated approach is that you can try out a Macintosh look-and-feel on a UNIX workstation. It also has a full range of other tools including: image and color editors. [Ref. 20]</td>

| **Vendor:**      | The MathWorks, Inc.  
24 Prime Park Way,  
Natick, Mass, 01760  
(508) 653-1415  
http://www.mathwork.com |
| **Type of Tool:** | Numeric Computation, Graphing, and Visualization |
| **PGUI:**        | Partially, many programs can be run on different platforms with no change. |
| **Supported Platforms:** | UNIX, Window95/NT, Macintosh |
| **Cost:**        | Varies on Platforms and options |
| **Vendor Support:** | Yes |
| **Future Support:** | Yes |
| **Languages Supported:** | Script Language, can be bound to C |
| **GUI builder available:** | Yes |
| **Comments:**    | Matlab (Figure 28) is a popular signal processing and visualization tool. Additional toolboxes can be added Matlab. GUIs can be easily created in MATLAB. The Matlab scripting language is easy to use and there are many example of source code available. [Ref. 18] |

-- This is the central operator of the robot "soft landing process".
-- On the first call to this operator, initial input is prompted for.
-- On subsequent calls, this operator calculates the robot's distance
-- from the origin and adjusts acceleration as necessary to bring
-- the robot to a soft landing within the required "doughnut". The
-- algorithm used is to continually adjust thruster acceleration
-- as follows:
--
-- Calculate the robot's distance from origin.
--
-- If the robot is too close to the center,
--     issue an error message.
-- Else if inside the doughnut,
--     set acceleration to force robot to stop in 2 periods.
--     if the robot is moving very, very slow,
--         issue a "DONE" message.
-- Else, the robot still has a ways to go, so
--     calculate thruster acceleration needed to reach origin
--     in 2 seconds (the robot may initially speed up, but it
--     should eventually experience continued slowdown as it
--     gets closer to the doughnut relative to it initial
--     distance from the doughnut).
--
-- If the robot is off the table,
--     issue an error message.
--
-- Calculate the distance moved since the last call to the this
-- operator based on this operator's calling period.
--
-- Calculate the robot's current velocity.
--
-- Write position, acceleration, velocity to outgoing data streams.
--
-- Save the operator's state.

Robot Visual Workshop (Motif) GUI-client: file: client.c

/***********************************************************/
* File: client.c

Client.c is used to start the socket connection for the GUI-client. It
communicates with the server. If communication is disrupted,
it is re-started. Data is sent and received. Communication is hard coded to
a predefined port number. The server name is also hard-wired.
This is just a prototype implementation. A better method for
doing for synchronizing the passing of data should be established.
