ABSTRACT
A dynamic link library (DLL) is developed to perform interpolation/table lookup functions from within 20-SIM by Controllab Products B.V. (Netherlands). The use of these functions, implemented in the C programming language, provides a multi-platform modeling and simulation environment through 20-SIM’s C code generation capability. Externally developed interpolation/table lookup functions are necessary since 20-SIM’s internal table lookup functions are not allowed with its C code generation process.

1.0 INTRODUCTION
The modeling and simulation software 20-SIM (www.20sim.com) has been developed at the Control Laboratory of the University of Twente (the Netherlands). It fully supports graphical and rapid modeling through iconic diagrams, block diagrams, bond graphs and equations in an unlimited hierarchical model structure—allowing the design and analysis of dynamic systems in an intuitive and user friendly way. While 20-SIM is based mainly on the Microsoft Windows PC platform, it provides a tool for C code generation. This capability provides a means by which a model can be run on another platform as long as that platform supports the C programming language. Some of 20-SIM’s built-in functions, such as table lookups, are not supported by the code generation process. The use of calls to dynamic link libraries (DLL’s) is supported and these calls are included in the C code generated. By writing needed interpolation/table lookup functions in C, these functions can be used on any platform—by calls to a DLL (Windows) or calls directly to a C function compiled and linked with the model source code. To enable this multi-platform capability, a dynamic link library of interpolation/table lookup functions has been written in C.

2.0 DESCRIPTION
While 20-SIM does not allow some of its built-in lookup functions to be used in the C code generation process it does allow calls to DLL’s (subroutines). Two types of data need to be handled through this process: Internal arrays and external arrays. Internal arrays are declared directly within 20-SIM. External arrays are usually large sets of data that are stored in files outside 20-SIM (such as road profiles, etc.). They are read in during the initialization process and kept in temporary memory for access during the simulation. This requires some internal static storage space within the DLL to hold the external arrays values. The internal and external arrays described here are limited to two dimensions.

2.1 20-SIM Model
In 20-SIM every model or submodel has an implementation. This can be a composition of lower level submodels, which themselves are composed of lower level submodels etc. At the bottom of this hierarchy the submodels consist of a set of mathematical equations (equation submodel). These submodels are therefore known as equation models. All equations used in 20-SIM are described in the language SIDOPS+.

The general layout of a SIDOPS+ equation model is:

```c
constants   //enter your constants here
parameters  //enter your parameters here
variables   //enter your variables here
initialequations  // enter your initial equations here
code       // enter your equations here
finalequations // enter your final equations here
```
Only the "equations" section is required. The other sections are optional. It is within this framework that the functions will be called. A call to a DLL function in 20-SIM is defined as

```c
out = dll('dll_func.dll','func_name',input);
```

and could appear in any of the sections that allow equations. This function call will be used to replace calls to the "data" and "table" functions.

### 2.2 DLL Function Prototype

The C function prototype required for DLL functions is

```c
int func_name(double *inarr, int inputs,
               double *outarr, int outputs, int major);
```

where

- `inarr`: pointer to an input array of doubles. The size of this array is given by the second argument.
- `inputs`: size of the input array of doubles.
- `outarr`: pointer to an output array of doubles. The size of this array is given by the fourth argument.
- `outputs`: size of the output array of doubles.
- `major`: boolean which is 1 if the integration method is performing a major integration step, and 0 in the other cases. For example Runge-Kutta 4 method only has one in four model evaluations a major step.

This call only passes a pointer and length to the input and output variables (and a flag to indicate a minor or major integration step) which does not pass enough information to call the interpolation/table lookup routine at one time. Because of this calling restriction, multiple DLL functions must be defined to set the necessary parameters before the interpolation/table lookup function call. This requires some internal static storage space (global) within the DLL to store these parameters (initial values).

### 2.3 DLL Internal Storage

Although this is not needed for external arrays—since the complete array information is contained within the static array structure when it is read in and allocated into static memory (see `AllocateArray` in section 2.4)—the same mechanism is used to avoid more than one interpolation/table lookup function for both types of arrays. Therefore, for both external and internal arrays, multiple function calls are made to initialize these parameters before the interpolation/table lookup function call.

The necessary internal static storage needed to access external array information during the simulation and to accommodate this parameter initialization is defined by the following global structure/variables at the beginning of the DLL.

```c
#define FLEN 512 // filename length
#define NARR 10  // max # of arrays
#define ALEN 30000 // max array length
typedef struct {
    char filename[FLEN];
    double mem[ALEN];
    int size;
    int dimy;
    int dimx;
} arrstruct; // external array struct

// external array structure
static arrstruct arr[NARR]; // external arrays
static int arrnum; // external array # to work on

// interpolation/table lookup parameters space
static double *arrx; // pointer to x array
static double *arry; // pointer to y array
static double *arrxy; // pointer to xy array
static int size; // dimension of array (1 or 2)
static int dimy; // length of y dimension
static int dimx; // length of x dimension
```

This structure is defined so that pointers to the arrays (external or internal), array size, and array dimension are set before the interpolation/table lookup function is called. A description for the set of function calls that implement this multi-call scheme is given first for external arrays (section 2.4) and then internal arrays (section 2.5).

### 2.4 External Array Functions

The external array functions are described below and each operates on the global structure. All have the same prototype for DLL’s as described in section 2.2:

- **SetArrNum**
  
  Sets "arrnum" to the number in the first location of the input pointer passed (inarr). Defines what array in “arr[]” to work on.

- **SetFileName**
  
  Copies the string pointed to by the input pointer into “arr[arrnum].filename” Prerequisite: Must call SetArrNum to define array number to work on.

- **AllocateArray**
  
  Reads into “arr[arrnum].mem” the data contained in “arr[arrnum].filename” and sets “arr[arrnum].size”, “arr[arrnum].dimy”, and “arr[arrnum].dimx”. Prerequisite: Must call SetArrNum to define array number to work on.
The data file must be in the following format ("%" denotes comments and "%%" denotes a command—both can appear only in the header):

---BOF---
%%NDIM:# defines the number of dimensions (1 or 2)
%%DIMS:# defines the length of each dimension (or %%DIMS:# # if 2 dimension)
 file name
%%NDIM:1
%%DIMS:10
0.000000
3.000000
.
.
---EOF---

SetXdll
Copies the pointer to "arr[arrnum].mem" to the x array pointer "arrx". Prerequisite: Must call SetArrNum to define array number to work on.

SetYdll
Copies the pointer to "arr[arrnum].mem" to the y array pointer "arry". Prerequisite: Must call SetArrNum to define array number to work on.

SetXYdll
Copies the pointer to "arr[arrnum].mem" to the xy array pointer "arrxy". Prerequisite: Must call SetArrNum to define array number to work on.

InterpDll
Uses the pointers in "arrx", "arry", "arraxy", "size", "dimy", and "dimx" to perform an interpolation using the first location of the input pointer as lookup value "x" and the second location (if size = 2) of the input pointer as lookup value "y". The value obtained is passed back to the first location pointed to by the output pointer (outarr).

2.6 DLL Support Functions
Several other miscellaneous functions are described below:

Initialize
Used to perform necessary initialization tasks when the DLL is loaded.

Terminate
Used to perform necessary termination tasks when the DLL is unloaded.

printnum
Searches through "in1[]" for each name in "list1[]" and prints out the array index of the location where the name is found. This function is used to identify the array location number for parameters, variables, etc. for direct modification of values in the generated C code. The prototype of this function is

```
int printnum(char *in1[], int inl, char *list1[], int listl)
```

where

```
in1[]: list of names to search for.
inl: size of "in1[]" input array of names.
list1[]: list of defined names to search in.
listl: size of "list1[]" search array of names.
```

3.0 FUNCTION IMPLEMENTATION
During the actual implementation of these functions issues arise that should be noted. These are platform specific. This particular implementation was accomplished using Borland C++ Builder 6 for testing the DLL with 20-SIM on the PC platform, and then code was transferred to an SGI Irix (Unix) platform.
3.1 Creating the DLL Functions
For the PC platform (using Borland C++ Builder 6), the "extern "C" and "declspec(dllexport)" specifiers are required to export functions, data, and objects from a DLL. An example of this for the SetArrNum function is

```c
extern "C" __declspec(dllexport) int SetArrNum(double *inarr, int inputs, double *outarr, int outputs, int major);
```

See Appendix A for the particular DLL entry point subroutine. (Specific to the Borland C++ Builder is the inclusion of the ".LIB" file in the project which is made with the IMPLIB command.)

3.2 Modifying the 20-SIM Function Calls
The following illustrates the equation model sections and calling sequence needed to handle external arrays. (Notice the underscore ("_") prefix to the function name due to Borland C++ Builder)

```c
parameters
  // string filename;
  // integer column;
  string fnecyclex = 'fmtv_cycle_x.arr';
  string fnecley = 'fmtv_cycle_y.arr';

variables
  real parm[3];
  real tmp;

initial equations
if TRUE then
  parm[1] = 1.0;
  tmp = dll('dllinterp.dll','_SetArrNum',parm);
  tmp = dll('dllinterp.dll','_SetFileName',fnecyclex);
  parm[1] = 2.0;
  tmp = dll('dllinterp.dll','_AllocateArray',parm);
  parm[1] = 2.0;  // array number
  tmp = dll('dllinterp.dll','_SetYdll',parm);
  parm[1] = time;  // lookup value
  output = dll('dllinterp.dll','_InterpDll',parm);
end;

A summary of the process is as follows—during the simulation, a pointer to each array is copied into the global static parameters used by the interpolation function. Notice that two lookup indexes were passed (fuel and omega) in this case since the size of the array was specified to be two (see "SetSize").

3.3 Generating the C Code
The code generation process within 20-SIM should be capable of producing C code for the model or submodel once the 20-SIM functions have been replaced with the DLL calls. The files generated are named with a prefix of "xx" (eg. "xxmodel.c"). Modification of the "targets.ini" file allows the prefix "xx" to be changed to another desired prefix string.
3.4 Renaming/Recompiling the DLL functions
The calls to the DLL functions from the generated C code will have the following structure

dllinterp_Initialize ();
dllinterp__myGetFile ("eng_trq.dat", 1, &xx_V[263], 1, xx_major);

In the C code generation process, the name of the DLL being called, in this case “dllinterp”, has been added to the beginning of the DLL function name. This prefix will have to be added to the DLL function/subroutine names before compiling on another platform. It should be noted, as before, that some function names may also require a leading underscore (“_”) in the 20SIM environment. This is the case for the Borland C++ Builder since it automatically appends an underscore as a prefix to the function names. The use of “extern “C”” may also be required to avoid mangled function names in the C++ environment.

Once the DLL functions (used on the 20-SIM platform) have been renamed with the DLL name as a prefix, they can be recompiled on another platform and linked into the model executable. The DLL functions will now be called directly by the model executable.

3.5 FORTRAN Interface
Since the model/submodel from 20-SIM will be generated directly into C code, calling it from another C program should be trivial. Calling the model from FORTRAN presents a set of interface issues that will be discussed, but are implementation specific. For the particular version (MIPSProF77) and platform SGI Irix used here, calling C functions from FORTRAN requires the C functions to be declared “EXTERNAL”, “double” C variables be declared “DOUBLE PRECISION”, and “int” C variables to be declared “INTEGER”—such as

```
DOUBLE PRECISION u(5), y(5)
INTEGER maj
EXTERNAL XXInitializeSubmodel
EXTERNAL XXCalculateSubmodel
EXTERNAL XXTerminateSubmodel
```

The model call looks like

```
CALL XXCalculateSubmodel(%ref(u), %ref(y),
       &%val(time))
```

where "%ref()" passes the variable by reference and "%val" passes the variable by value. The variable "time" is passed by value (see the function prototype in "XXCalculateSubmodel"). If your implementation of FORTRAN does not allow passing by value, the model/submodel subroutines and their prototype will have to be modified to accept a reference to the variable and then use a temporary variable to get the value from the reference passed to the function.

Modification can also be made to the “XXCalculateSubmodel” subroutine to pass back more variables through modification of the calling prototype. Finally, the model functions (or any C function called)

```
XXInitializeSubmodel
XXCalculateSubmodel
XXTerminateSubmodel
```

should be renamed as lowercase with an "_" as a suffix to satisfy the FORTRAN calling interface to C functions.

3.6 Interface Issues
A mechanism must be implemented to ensure that the initialization “XXInitializeSubmodel” and termination “XXTerminateSubmodel” functions are called only once, at the beginning and end of the simulation, respectively.

The code generation process does include simple integrators (eg. Euler, Runge-Kutta (RK2)) as part of the model code. Consideration must be given as to how the integration of state variables will be handled. One method is to use the integrators included with the model and make sure its time steps are synced with the calling program’s, or the second method is to have the calling program’s integrator handle the state variables. The second method involves replacing calls to the built-in integrator with a process that will have the calling program update the state variables directly. This issue arises when calling “XXCalculateSubmodel”

While 20-SIM defines the function prototype required for DLL functions, it does not do type checking on them. The passing of a string to the "SetFileName" function in 20-SIM is permissible through the use of the “union” structure

```
cchar *NamePtr;
union
{
  double realval;
  char *strval;
} value;
value.realval = inarr[0];
NamePtr = value.strval;
```

However, when the C code is generated it will place a string variable (type "*char") as the first argument to the “SetFileName” function (as the input array). Compiling the code will result in a type mismatch. Outside of the 20-SIM environment, we are no longer restricted to use the DLL required prototype and should thus change the first argument of the prototype to this function to be “*char”.

3.7 Support Function Usage
The “printnum” function is used to identify the array location number for parameters, variables, etc. for direct modification of values in the generated C code.
Currently in 20-SIM, there are six arrays in which to search for names:

1. xx_constant_names[]
2. xx_parameter_names[]
3. xx_variable_names[]
4. xx_state_names[]
5. xx_rate_names[]
6. xx_matrix_names[]

A call to "printnum" for each one may be in order if you are not sure which array the name you are looking for is in. The file "xxmodel.c" defines the dimension of these name arrays. For each name array there is a corresponding value array:

1. xx_constants[]
2. xx_parameters[]
3. xx_variables[]
4. xx_states[]
5. xx_rates[]
6. xx_matrices[]

and a pointer to each of these value arrays

1. xx_C
2. xx_P
3. xx_V
4. xx_S
5. xx_R
6. xx_M

An example of using the "printnum" function is given below. The following code should be inserted into the generated C code "xxmain.c" to find the named variables/state array indexes.

```c
char *list[]={"cycle\output",
            "Submodel6\Accumulator\Function\output",
            "VehiclePitch\tire_rear2\X\output",
            "Driver\ms_mph\output",
            "Submodel6\Engine\omega_rpm\output",NULL};

printf("xx_variable_names\n");
printnum(&xx_variable_names[0],3033,&list[0],5);
printnum("xx_variable_names\n");
printnum(&xx_variable_names[0],3033,&list[0],5);
printnum("xx_variable_names\n");
printnum(&xx_variable_names[0],3033,&list[0],5);
printnum("xx_variable_names\n");
printnum(&xx_variable_names[0],3033,&list[0],5);

A summary of the process is as follows--here "*list[]" is an array of names you want to find an index for with length five. Two calls are made, one to search the variable name array, with length 3033, and one to search the state name array, with length 41. The output below indicates what index value you should look for in the generated C code ("xxmodel.c") to change or modify the named value. (Remember to remove the "exit(0)" command and comment out this section when finished.) Sample results of calling this function are below

xx_variable_names
Total:5
0. cycle\output [1772]
1. Submodel6\Accumulator\Function\output [2769]
3. Driver\ms_mph\output [1800]
4. Submodel6\Engine\omega_rpm\output [2172]

xx_state_names
Total:5
2. VehiclePitch\tire_rear2\X\output [18]

To find the "Driver\ms_mph\output" variable in the generated C code for the model you would look for "xx_variables[1800]" or "xx_V[1800]".

4.0 SUMMARY/CONCLUSION

A dynamic link library (DLL) is developed to perform interpolation/table lookup functions from within 20-SIM. The use of these functions allows 20-SIM models to be ported to other platforms through the use of its C code generation capability. A set of DLL functions (C subroutines) were developed to handle external and internal arrays with a maximum dimension of two.

#include <windows.h>
//--------------------------------------------------------------------------- //   Important note about DLL memory management when your DLL uses the static version of the RunTime Library:
   //   If your DLL exports any functions that pass String objects (or structs/ classes containing nested Strings) as parameter or function results, you will need to add the library MEMMGR.LIB to both the DLL project and any other projects that use the DLL. You will also need to use MEMMGR.LIB if any other projects which use the DLL will be performing new or delete operations on any non-TObject-derived classes which are exported from the DLL. Adding MEMMGR.LIB to your project will change the DLL and its calling EXE's to use the BORLNDMM.DLL as their memory manager. In these cases, the file BORLNDMM.DLL should be deployed along with your DLL. //   To avoid using BORLNDMM.DLL, pass string information using "char *" or ShortString parameters.
   //   If your DLL uses the dynamic version of the RTL, you do not need to explicitly add MEMMGR.LIB as this will be done implicitly for you
