Development of ovarian cancer depends, in part, on formation of an adequate blood supply. Tumor angiogenesis is essential for cancer growth, and vascular endothelial growth factor (VEGF) is critical to stimulate growth of vascular endothelial cells. VEGF is produced by ovarian cancers, with secretion markedly increased in ovarian cancers with HER-2 oncogene overexpression. Herceptin antibody to HER-2 receptor has direct antitumor effects, but the antibody also reduces VEGF secretion from ovarian cancers, and, thereby, retards ovarian tumor-associated angiogenesis. More complete blockade of angiogenesis may be elicited by treatments that synergistically suppress blood vessel proliferation, such as squalamine, an angiostatic steroid approved by the FDA as an orphan drug candidate for treatment of ovarian cancer. In studies with ovarian cancer cells in vivo, squalamine elicits antitumor activity by suppressing angiogenic actions of several vascular growth factors including VEGF, an effect due to squalamine binding in caveolae, with downstream blockade of p44/p42 and p38 MAP kinases. Squalamine also shows antitumor efficacy when combined with other therapies, including cisplatin, carboplatin and Herceptin, and is a good candidate for further assessment in clinical trials among patients afflicted with ovarian cancer.

INTRODUCTION

Ovarian cancer is the most deadly gynecologic malignancy. About 26,500 women are diagnosed with this cancer each year and have an overall 5-year survival rate of only 47% (1, 2). For most patients, surgery alone does not cure the cancer due to the spread of tumors beyond the confines of the ovary, and management in the clinic often requires use of toxic chemotherapy regimens. The progressive growth of ovarian cancer depends, in part, on the formation of an adequate blood supply, and tumor angiogenesis has been reported to have prognostic significance in epithelial ovarian cancer (3). Therapy directed toward the vasculature of solid tumors is now being pursued as an important new direction in cancer treatment, because avascular tumors exhibit limited growth (4, 5) and tumor aggressiveness and metastatic potential commonly correlate with tumor vascularity (6).

Vascular endothelial growth factor (VEGF) is produced by most solid tumors and elicits a mitogenic effect on tumor-associated endothelial cells (7, 8). VEGF binding to receptor tyrosine kinases triggers activation of downstream signaling enzymes, including p42/p44 MAP kinase, which, in turn, regulate gene expression and specific endothelial cell responses including proliferation, migration, differentiation and apoptosis (9, 10). VEGF plays an important role in progression of ovarian cancer (3, 11, 12), and the ability of VEGF to increase vascular permeability (7, 8, 13) may also promote formation of malignant ascites (14). Growth factor pathways, such as those dependent on the HER-2 receptor, appear to up-regulate VEGF production in some solid tumors (15). Since HER-2 receptor is overexpressed in a significant number of ovarian cancers (16, 17), it may also play a role in promoting further growth of ovarian malignancy by increasing VEGF-dependent tumor angiogenesis.

Squalamine, a sterol from tissues of dogfish shark (18), has significant anti-angiogenic and antitumor activity in laboratory models of brain, breast and lung cancer (19-22). Squalamine is a 7,24-dihydroxylated 24-sulfated cholestan steroid conjugated to spermidine at C-3 (see chemical structure at left), and it blocks endothelial cell growth and exhibits inhibitory activity in chick embryo chorioallantoic membrane and rabbit corneal micropocket assays (19, 20, 23). This anti-angiogenic agent may have good potential for clinical application because it inhibits endothelial cell proliferation induced by a wide range of growth factors, including VEGF (19). This inhibition may result, in part, from its interaction with endothelial cell surface proton pumps, thereby altering intracellular pH and impeding signaling by growth factors (24, 25). When administered as a single agent in nude mice with lung cancer xenografts, squalamine has limited antitumor activity, but the anti-angiogenic steroid significantly enhances the antitumor efficacy of cisplatin and carboplatin/paclitaxel chemotherapies (20-22). Since platinum-based treatments are often used for human ovarian cancers (1, 2), squalamine in combination with cisplatin or carboplatin was studied to assess its utility as part of a coordinated attack against human ovarian cancers and their blood supply. One additional feature we were particularly interested in was the consequence of HER-2 oncogene overexpression for squalamine modulation of growth in ovarian tumor xenografts. Amplification and/or overexpression of HER-2 oncogene in human cancers, including ovarian cancers, is often associated with poor clinical outcome (16, 17), and human ovarian tumor cells with overexpression of HER-2 membrane receptor also exhibit resistance to cisplatin and carboplatin (26). We therefore examined whether the level of HER-2 expression in paired HER-2-transfected and non-transfected ovarian cancers influenced the degree of tumor growth inhibition seen with squalamine with or without concomitant platinum-based treatment.

BODY: RESEARCH PROGRESS

AIM 1) Evaluation of angiogenic activity due to HER-2 gene overexpression in human ovarian cells.

1.a. Squalamine Does not Affect VEGF Secretion in vitro for Ovarian Cancer Cells with or without HER-2 Gene Overexpression.

HER-2 overexpression is generally thought to lead to tumor development through its effects on promoting uncontrolled cancer cell growth. However, recent findings suggest that HER-2 may also regulate cell survival
functions such as angiogenesis by promoting tumor production of VEGF (15). To explore how HER-2 may contribute to angiogenesis in ovarian cancer, we evaluated HER-2 effects on in vitro VEGF secretion by human ovarian tumor cells. Parent and HER-2-overexpressing ovarian 2008 cells were incubated for 72 h in vitro, and secretion of VEGF into conditioned media was measured by use of established enzyme-linked immunosorbant assay (see Fig. 6 in ref. 27). Parent ovarian cancer cells show significant secretion of VEGF, and, after transfection of ovarian cells with HER-2 gene to high levels, a further increase in VEGF secretion was found. In parallel in vitro studies, treatment of ovarian cancer cells with squalamine had no significant effect on VEGF secretion (27). Thus, HER-2 overexpression may contribute to angiogenesis through up-regulation of VEGF secretion in ovarian cancer, but squalamine is not antiangiogenic at this step in tumor angiogenesis since it does not appear to directly affect VEGF secretion by ovarian tumor cells. This research aim has been completed.

**AIM 2)** Assessment of biologic activities of squalamine, a newly-synthesized anti-angiogenic steroid, using human vascular endothelial cells in vitro.

2.a. **Squalamine Blocks VEGF-Stimulated Proliferation of Endothelial Cells in vitro.**

To assess potential biologic mechanisms for antiangiogenic and antitumor effects of squalamine noted previously, human umbilical vein endothelial cells (HUVEC) were grown in vitro. VEGF elicits significant proliferation of HUVEC cells by 72 h. In the absence of VEGF, squalamine has no effect on proliferation or survival of HUVEC cells. However, in the presence of VEGF, squalamine elicited a significant reduction in VEGF-induced endothelial cell proliferation (see Fig. 5 in ref. 27). This growth-suppressive effect of squalamine appears restricted to endothelial cells since the compound had no direct inhibitory effect on the proliferation of ovarian 2008 cancer cells, either with or without HER-2 gene overexpression (27).

This effect of squalamine appears to be due, in part, to binding of squalamine with caveolae fractions purified from plasma membranes of human vascular endothelial cells. Caveolae are plasma membrane domains that act as signaling platforms to intercept a variety of agonists, both protein and lipid, in endothelial cells. To assess these membrane subfractions as a possible primary site of squalamine interaction with endothelial cells, we prepared caveolae membranes from HUVEC cells using a detergent-free method and measured specific binding of [7β-3H]-squalamine (Perkin Elmer-New England Nuclear) using established methods. An example of purification of a caveolae membrane fraction from human vascular endothelial cells is shown in Fig. 1. The endothelial cells exhibit enrichment of caveolin-1 in caveolae-related domains. In addition, we find localization of specific [3H]-squalamine binding-sites in caveolin-enriched membrane fractions.

![Caveolin - [3H]-SQ (pmol/mg)](image)

**Fig. 1.** Purification of caveolae plasma membrane subfractions from human vascular endothelial cells (HUVEC). HUVEC exhibit significant enrichment of caveolin-1 in caveolae membrane domains (see gradient fractions 4-6) isolated from HUVEC cells by use of established detergent-free methods. In addition, specific binding of [3H]-squalamine localizes to those gradient fractions that contain caveolin (fractions 4-6). Specific binding of [3H]-squalamine was assessed by use of established methods. Results from one representative experiment are shown.

The nature of squalamine binding was investigated further in a set of equilibrium binding studies. Data obtained from these experiments indicate that in vitro binding of [3H]-squalamine at concentrations ranging from 10-400 nM to caveolae membranes is saturable (see Fig. 2). The squalamine-binding properties of the membranes were analyzed further to obtain an estimate of both the concentration of specific binding sites for squalamine and the equilibrium constant. Preliminary analysis of the data by the method of Scatchard indicated that the dissociation constant (Kd) for the binding process was 7.5 x 10^{-8} M.
Fig. 2. [3H]-squalamine shows specific and relatively high-affinity binding in caveolae membranes from endothelial cells. HUVEC were cultured 48 h prior to the experiment in standard media, but phenol-red free and containing 1% dextran-coated, charcoal-treated (DCC) FBS. Caveolae plasma membranes were prepared in the presence of proteinase inhibitors using established detergent-free methods. Caveolae membranes show enrichment of caveolin, a marker protein for caveolae. In specific binding studies, a 100-fold molar excess of unlabelled squalamine was present with [3H]-squalamine in paired samples to determine displacable binding to membranes. Specific binding from a representative experiment is shown. Inset shows ligand specificity of squalamine binding. Binding data analyzed by the method of Scatchard.

Total binding sites for squalamine at saturation correspond to a maximal binding capacity (Bmax) of 10 pmol/mg protein. The ligand specificity of [3H]-squalamine binding to caveolae membranes was analyzed by competitive binding of a 100-fold molar excess of unlabelled squalamine or other common steroidal compounds (see inset, Fig. 2). The extent of [3H]-squalamine binding by caveolae membranes was largely unaffected by such excess of estradiol-17β (E2), progesterone (PRG), or cortisol (GC). In contrast, unlabelled squalamine elicited nearly complete reduction of specific [3H]-squalamine binding to caveolae membranes. The data suggest that caveolae at the surface membrane of endothelial cells may offer a primary interaction site for squalamine, and these membrane domains may represent a good source for future isolation and characterization of squalamine-binding molecules.

2.b. Squalamine Blocks VEGF-Induced Activation of MAP Kinases in vitro.

VEGF exerts its biologic effects by binding with receptor tyrosine kinases, notably Flt-1 and Flk-1/KDR, present at the surface of endothelial cells (9). Post-receptor signal transduction regulates effects of VEGF, and proliferative effects of VEGF in endothelial cells have been associated with VEGF-induced tyrosine phosphorylation and stimulation of mitogen-activated protein kinases (MAP kinase), extracellular signal-regulated kinase ERK-1 (p44 MAPK) and ERK-2 (p42 MAPK) (9, 10). On the assumption that blockade of endothelial cell proliferation by squalamine may occur, in part, by suppression of MAP kinase signaling cascades induced by growth factors, VEGF-induced tyrosine phosphorylation of MAP kinases was assessed. As expected, VEGF promotes tyrosine phosphorylation of p42/p44 MAP kinase isoforms, with maximal effects evident by 10 min (see Fig. 7 in ref. 27). However, after administration of squalamine, the VEGF-stimulated phosphorylation of MAP kinase isoforms is significantly suppressed, especially after 30 min exposure to VEGF (27).

The SAPK2/p38 MAP kinase pathway is a stress-activated kinase cascade that is also stimulated by VEGF in endothelial cells. To assess potential inhibitory effects of squalamine on this downstream signaling pathway, we conducted experiments to investigate VEGF-induced effects on p38 MAPK (see Fig. 3).

Fig. 3. Squalamine disrupts SAPK2/p38 MAPK phosphorylation induced by VEGF. To detect phosphorylated forms of p38 MAP Kinase, HUVEC cells were plated on glass slides in complete EBM media. When cells reached about 80%
confluency, they were serum-starved for 16-18 h and washed twice with PBS before treatment. We treated cells with control (A), 160 nM of squalamine control for 1 h (B), 50 ng/mL of VEGF for 10 min (C), or a combination of a pre-treatment with squalamine for 1 h followed by the addition of 50 ng/mL of VEGF the last 10 min (D). After treatment, cells were immediately rinsed with cold PBS and prepared for viewing by confocal microscopy, using antibodies against phospho-p38 MAP kinase (Thr180/Tyr182)(Cell Signaling). Representative fields are shown from initial studies (97,98).

As expected, treatment of vascular endothelial cells with VEGF in vitro elicited significant phosphorylation of p38 MAP kinase by 10 min. However, after addition of squalamine, the VEGF-stimulated phosphorylation of p38 MAP kinase appears significantly reduced and less predominant (Fig. 3). Squalamine-mediated changes in VEGF-induced activation of SAPK2/p38 MAP kinase may have mechanistic significance, since activated p38 MAP kinase is associated with F-actin formation and focal adhesion assembly, important functions in the migration and proliferation of vascular endothelial cells (9,10,25).

2.c. Squalamine suppresses VEGF-stimulated endothelial cell tube-like formation in vitro

To assess the role of squalamine inhibition of VEGF signaling early in the process of angiogenesis, HUVEC were plated on growth factor-depleted Matrigel (Fig. 4). At doses as low as 160 nM, squalamine blocks VEGF-induced capillary tube formation. However, VEGF-stimulated capillary tube formation was not significantly disrupted by 1.6 nM squalamine. The inhibitory effect of squalamine on capillary tube formation by endothelial cells appears to occur in a dose-dependent manner. Cells in plates in which networked capillary tubes were inhibited by squalamine displayed a profound alteration in shape and size (i.e., round and small) as compared with more characteristic spindle-shaped, elongate cells that form tubes in the absence of squalamine.

![Image](https://example.com/image.png)

**Fig. 4.** Squalamine suppresses VEGF-induced capillary tube-like formation by vascular endothelial cells in vitro. HUVEC were cultured in serum-free medium on the surface of Matrigel for 72 h with the indicated treatments: a, VEGF, 50 ng/ml; b, VEGF + squalamine 3.2 μM; c, VEGF + squalamine 1.6 μM; d, VEGF + squalamine 0.16 μM; e, VEGF + squalamine 0.016 μM; f, VEGF + squalamine 0.0016 μM. Lyophilized recombinant human VEGF was from PeproTech. Squalamine was donated by Gen Era. HUVEC were grown in Endothelial Cell Basal Medium (EBM², BioWhittaker) supplemented with 2% FBS, 10 ng/ml hEGF, 1.0 μg/ml hydrocortisone, 50 μg/ml gentamicin, 50 ng/ml amphotericin B, and 12 mg/ml bovine brain extract (BBE). HUVEC were serum starved overnight (>12 h) prior to experimental use. In vitro formation of cord-like structures was studied on growth factor-depleted Matrigel-coated 6-well plates. HUVEC (3 x 10⁴ cells/well) were seeded in Matrigel layers in the presence of VEGF (50 ng/ml) and different concentrations of squalamine as noted. Cells were observed with an Olympus CK2 inverted microscope.

Thus, with completion of the experiments reported above, the endpoints proposed for research aim 2 have been successfully attained.
AIM 3 ) Investigation of the efficacy of squalamine alone and combined with other antitumor agents in blocking the in vivo growth and progression of human ovarian cancer xenografts in nude mice.

3.a. Squalamine and Platinum-Based Chemotherapiess Block Growth of Ovarian Tumor Xenografts in vivo.

Potential antitumor effects of the angiostatic steroid squalamine were assessed in murine tumor xenografts in the absence and presence of cisplatin or carboplatin chemotherapy. Human ovarian 2008 cancer cells without or with HER-2 overexpression were grown as subcutaneous tumors in nude mice. Tumors were grown to 150-200 mm³ in size. Then, animals with established tumors were treated with control solution, cisplatin alone at two different dose levels (4 mg/kg on day 1 or 5 mg/kg on days 1,8), squalamine alone (2 mg/kg) on days 1-10, or cisplatin in combination with squalamine (days 1-10) (see Fig. 1 in ref. 27). In one set of experiments, animals were treated with a high dose of cisplatin near the maximum tolerated dose (5 mg/kg on days 1,8) (27). In the second set of experiments, lower doses of cisplatin that resulted in only partial growth inhibition (26,29) were chosen in order to ensure use of the chemotherapeutic agent at a level that would not totally suppress tumor growth, thus allowing detection of any potential additive effects of a squalamine-cisplatin interaction. By 28 days, both 2008 parental and HER-2-overexpressing tumors showed little overall response to therapy with the lower dose of cisplatin alone. However, 2008 parental and HER-2-overexpressing tumors exhibited some minor response to cisplatin alone administered at the higher dose level (27). Squalamine elicited a partial reduction in tumor size as compared to controls in both 2008 parental and HER-2-overexpressing tumors. More profound tumor growth inhibition was elicited by combined treatment with squalamine and cisplatin in both 2008 parental and HER-2-overexpressing cancers (27). This effect of combination therapy was found when squalamine was administered with either low or high doses of cisplatin (27).

The antitumor effects of squalamine with and without platinum-based chemotherapy were also assessed using a different human ovarian tumor xenograft, CAOV3, that has been transfected to exhibit HER-2 overexpression (see Fig. 2A in ref. 27). After tumor growth to 50-60 mm³, animals were treated with control solution, carboplatin alone (60 mg/kg) on day 1, squalamine alone (2 mg/kg) on days 1-10, or carboplatin (day 1) in combination with squalamine (days 1-10). By 28 days, CAOV3 HER-2-overexpressing tumors showed minimal response to therapy with carboplatin alone (27). As with the 2008 tumors, squalamine as a single agent elicited a partial reduction in CAOV3 tumor size as compared to controls (27). More marked inhibition of tumor growth was elicited by combined treatment with squalamine and carboplatin (27).

The tumor growth inhibition seen with combined squalamine and platinum-based chemotherapeutics for both human ovarian tumor lines persisted for up to 18 days following cessation of squalamine treatment. We therefore investigated how long bioactivity persisted with combined cisplatin and squalamine treatment of HER-2-overexpressing CAOV3 tumors by maintaining the dual therapy animal cohort until the mean tumor size for these animals reached 500 mm³ (see Fig. 2B in ref. 27). After tumor growth to 50-60 mm³, animals with established tumors were treated with control solution, cisplatin alone (4 mg/kg) on day 1, squalamine alone (2 mg/kg) on days 1-10, or cisplatin (day 1) combined with squalamine (days 1-10). As compared with control tumor xenografts, the calculated tumor growth delay in established tumors was 7 days for cisplatin therapy alone, 28 days for squalamine treatment alone, and 91 days for squalamine with cisplatin (27). Combined squalamine-cisplatin therapy was nontoxic as assayed by no animal death or significant weight loss during the study period (27). This aim has been completed.

3.b. Squalamine and Cisplatin Promote Ovarian Tumor Cell Apoptosis in vivo.

To assess molecular effects of squalamine and cisplatin, ovarian 2008 parent and HER-2-overexpressing tumor xenografts remaining after treatments with squalamine, cisplatin or a combination of the reagents were harvested and assessed for ovarian tumor cell apoptosis in vivo. For evaluation of apoptosis, the modified TUNEL assay (34, 35) was performed on tissue sections. The assays showed evidence of increased apoptosis in ovarian 2008 parental tumor cells treated with squalamine alone, cisplatin or combined cisplatin-squalamine as compared to appropriate controls (all at P<0.05) (see Fig. 3A in ref. 27). The 2008 HER-2-overexpressing ovarian tumors displayed less apoptotic activity than 2008 parental cancers with all treatments (27). Although apoptosis tended to be higher after administration of either squalamine or cisplatin alone, only treatment with
squalamine in combination with cisplatin elicited a significant increase in the extent of apoptosis of HER-2-overexpressing ovarian cancers (P<0.001) (27). The results suggest that squalamine enhances cytotoxic effects of cisplatin chemotherapy for human ovarian cancer cells by increasing levels of tumor cell apoptosis produced by cisplatin exposure, either with or without HER-2 oncogene overexpression. In independent experiments, similar results have been obtained after treatments with squalamine in combination with carboplatin (data not shown). This aim has been completed.

3.c. Squalamine Down-Regulates Ovarian Tumor-Associated Angiogenesis but not VEGF Production in vivo.

Tissue sections of parent and HER-2-overexpressing 2008 tumor xenografts remaining after treatments with squalamine, cisplatin or a combination of the reagents were prepared for immunohistochemical staining with human von Willebrand Factor (vWF) to detect blood vessels (27,34). On scoring of tumor microvessel density, 2008 HER-2-overexpressing tumors exhibited more angiogenic activity than 2008 parental cancers (P<0.001) (see Fig. 3B in ref. 27). Treatment with squalamine alone elicited a reduction of tumor-associated blood vessel density for either ovarian tumor (27), and the immunohistochemical analyses also revealed a reduction of tumor-associated angiogenesis in mice treated with cisplatin plus squalamine (P<0.01) (27). No significant differences in microvessel density were found between groups treated with cisplatin alone and controls. The results suggest that squalamine is antiangiogenic for ovarian cancer cells with or without HER-2 overexpression. Squalamine-induced suppression of tumor microvessels is also a sustainable event since it was noted up to 18 days following the last squalamine dose. Similar studies based on treatments with squalamine combined with carboplatin are confirmatory. This aim has been completed.

KEY RESEARCH ACCOMPLISHMENTS

- Profound growth inhibition was elicited by squalamine alone and by combined treatment with squalamine and cisplatin or squalamine and carboplatin for both parental and HER-2-overexpressing ovarian tumor xenografts.

- Immunohistochemical evaluation of tumors revealed decreased microvessel density and increased apoptosis. Although HER-2-overexpressing tumors had more angiogenic and less apoptotic activity than parental cancers, growth of both tumor types appear to be similarly suppressed by treatment with squalamine combined with cisplatin or squalamine combined with carboplatin.

- In in vitro studies, we found that squalamine does not directly affect proliferation of ovarian cells. However, squalamine significantly blocked VEGF-induced activation of p42/p44 MAP kinase and p38 MAP kinase and cell proliferation in human vascular endothelial cells.

- Squalamine binds with high avidity to a caveolin-enriched plasma membrane domain purified from human vascular endothelial cells. This membrane fraction corresponds with caveolae, a region that functions as a ‘signaling platform’ for the regulation of vascular endothelial cell growth.

- The results suggest that squalamine is anti-angiogenic for ovarian cancer xenografts and appears to enhance cytotoxic effects of cisplatin and carboplatin chemotherapy independent of HER-2 tumor status.

- It is important to note that this preclinical work has helped to promote the initiation of independent clinical trials of squalamine for treatment of patients with resistant or recurrent ovarian cancer (38).

REPORTABLE OUTCOMES

Presentations

2. Pietras, R.J. “New approaches to antitumor therapy”. Presented at Marion Medical Center Cancer Forum, Santa Maria, California (September, 2002).

Publications

Additional Research Opportunities

Results from the preclinical research activity outlined above has led to the promotion of new clinical trials of squalamine in the treatment of patients with resistant or recurrent ovarian cancer. The PI of the present grant, Dr. Pietras, was a co-investigator in this ongoing series of clinical trials:

Dr. Pietras, the Principal Investigator, was the Chairman of a FASEB Summer Research Conference on “Steroid Hormone Receptors” that was held July 31-August 5, 2004 in Tucson, Arizona, and work derived from the funded research was presented at the Conference.

No patents, development of cell lines, informatics or additional funding opportunities to be reported at this time.

CONCLUSIONS

The potential role of squalamine, a natural anti-angiogenic steroidal compound, in treatment of ovarian cancers with or without standard cisplatin or carboplatin chemotherapy was assessed. Since HER-2 gene overexpression is associated with cisplatin and carboplatin resistance in vitro and promotion of tumor
angiogenesis *in vivo*, the response of ovarian cancer cells with or without HER-2 gene overexpression to squalamine and cisplatin or squalamine and carboplatin was also evaluated in tumor xenograft models and in tissue culture. Profound growth inhibition was elicited by squalamine alone and by combined treatment with squalamine and cisplatin or squalamine and carboplatin for both parental and HER-2-overexpressing ovarian tumor xenografts. Immunohistochemical evaluation of tumors showed decreased microvessel density and increased apoptosis. Although HER-2-overexpressing tumors had more angiogenic and less apoptotic activity than parental cancers, growth of both tumor types was similarly suppressed by treatment with squalamine combined with cisplatin. In *in vitro* studies, we found that squalamine does not directly affect proliferation of ovarian cells. However, squalamine binds with high avidity to vascular endothelial cell caveolae, plasma membrane subdomains that function as ‘signaling platforms’ for the regulation of vascular endothelial cell growth. As a consequence of primary interactions at the plasma membrane, squalamine significantly blocks VEGF-induced activation of p24/p44 MAP kinase, p38 MAP kinase and cell proliferation in human vascular endothelial cells. The results suggest that squalamine is anti-angiogenic for ovarian cancer xenografts and appears to enhance cytotoxic effects of cisplatin and carboplatin chemotherapy independent of HER-2 tumor status. In addition, it is important to note that this preclinical work has helped to promote the initiation of clinical-translational Phase II trials of squalamine for the treatment of patients with resistant or recurrent ovarian cancer.

Angiogenesis is important for growth and progression of ovarian cancers. Squalamine is a natural antiangiogenic sterol, and its potential role in treatment of ovarian cancers with or without standard cisplatin chemotherapy was assessed. Since HER-2 gene overexpression is associated with cisplatin resistance in vitro and promotion of tumor angiogenesis in vivo, the response of ovarian cancer cells with or without HER-2 gene overexpression to squalamine and cisplatin was evaluated both in tumor xenograft models and in tissue culture. Ovarian cancer cells with or without HER-2 overexpression were grown as subcutaneous xenografts in nude mice. Animals were treated by intraperitoneal injection with control vehicle, cisplatin, squalamine or cisplatin combined with squalamine. At the end of the experiment, tumors were assessed for tumor growth inhibition and for changes in microvessel density and apoptosis. Additional in vitro studies evaluated effects of squalamine on tumor and endothelial cell growth and on signaling pathways in human endothelial cells. Profound growth inhibition was elicited by squalamine alone and by combined treatment with squalamine and cisplatin for both parental and HER-2-overexpressing ovarian tumor xenografts. Immunohistochemical evaluation of tumors revealed decreased microvessel density and increased apoptosis. Although HER-2-overexpressing tumors had more angiogenic and less apoptotic activity than parental cancers, growth of both tumor types was similarly suppressed by treatment with squalamine combined with cisplatin. In in vitro studies, we found that squalamine does not directly affect proliferation of ovarian cells. However, squalamine significantly blocked VEGF-induced activation of MAP kinase and cell proliferation in human vascular endothelial cells. The results suggest that squalamine is anti-angiogenic for ovarian cancer xenografts and appears to enhance cytotoxic effects of cisplatin chemotherapy independent of HER-2 tumor status.

Introduction

Ovarian cancer is the most deadly gynecologic malignancy. About 26,500 women are diagnosed with this cancer each year and have an overall 5-year survival rate of only 47% (Ozols, 1999). For most patients, surgery alone does not cure the cancer due to the spread of tumors beyond the confines of the ovary, and management in the clinic often requires use of toxic chemotherapy regimens. The progressive growth and spread of ovarian cancer depends, in part, on the formation of an adequate blood supply, and tumor angiogenesis has been reported to have prognostic significance in epithelial ovarian cancer (Alvarez et al., 1999). Therapy directed toward the vasculature of solid tumors is now being pursued as an important new direction in cancer treatment because avascular tumors exhibit only limited growth and tumor aggressiveness, and metastatic potential commonly correlates with tumor vascularity (Folkman, 1971; Gimbrone et al., 1972).

Vascular endothelial growth factor (VEGF) is produced by most solid tumors and elicits a mitogenic effect on tumor-associated endothelial cells (Keck et al., 1989; Leung et al., 1989). VEGF binding to receptor tyrosine kinases triggers activation of downstream signaling enzymes, including MAP kinase, which, in turn, regulate gene expression and specific endothelial cell responses including proliferation, migration, differentiation and apoptosis (Soker et al., 1996; Rousseau et al., 1997). Several studies suggest that VEGF plays an important role in progression of ovarian cancer (Paley et al., 1997; Yamamoto et al., 1997; Alvarez et al., 1999), and the ability of VEGF to increase vascular permeability (Ferrara et al., 1993; Keck et al., 1989; Leung et al., 1989) may also promote formation of malignant ascites (Zebrowski et al., 1999). Growth factor pathways, such as those dependent on the HER-2 receptor, appear to up-regulate VEGF production in some solid tumors (Petit et al., 1997).

Since HER-2 receptor is overexpressed in a significant number of ovarian cancers (Slamon et al., 1989; Wong...
et al., 1995; Hellstrom et al., 2001), it may also play a role in promoting further growth of ovarian malignancy by increasing VEGF-dependent tumor angiogenesis.

Squalamine, a natural sterol from tissues of the dogfish shark (Moore et al., 1993), has significant antiangiogenic and antitumor activity in laboratory models of brain, breast and lung cancer (Sills et al., 1998; Teicher et al., 1998; Schiller and Bittner, 1999). Squalamine is a 7,24-dihydroxylated 24-sulfated cholestane steroid conjugated to spermidine at C-3. Squalamine blocks endothelial cell growth and has inhibitory activity in chick embryo chorioallantoic membrane and rabbit corneal micropocket assays (Sills et al., 1998; Williams, 1999). This anti-angiogenic agent may have good potential for clinical application because it inhibits endothelial cell proliferation induced by a wide range of growth factors, including VEGF (Sills et al., 1998). This inhibition may result, in part, from its interaction with endothelial cell surface proton pumps, thereby altering intracellular pH and impeding signaling by growth factors (Akhter et al., 1999; Eckhardt, 1999). However, a receptor with high affinity for binding squalamine has not yet been identified. When administered as a single agent in nude mice with lung cancer xenografts, squalamine has limited antitumor activity, but the antiangiogenic steroid significantly enhances the antitumor efficacy of cisplatin and carboplatin/paclitaxel chemotherapies (Teicher et al., 1998; Schiller and Bittner, 1999; Williams, 1999). Since platinum-based treatments are often used for human ovarian cancers (Ozols, 1999), squalamine in combination with cisplatin was studied to assess its utility as part of a coordinated attack against human ovarian cancers and their blood supply. One additional feature we were particularly interested in was the consequence of HER-2 oncogene overexpression for squalamine modulation of growth in ovarian tumor xenografts. Amplification and/or overexpression of HER-2 proto-oncogene in human cancers, including ovarian cancers, is often associated with poor clinical outcome (Slamon et al., 1989; Wong et al., 1995), and human ovarian tumor cells with overexpression of HER-2 membrane receptor also exhibit resistance to cisplatin (Pegram et al., 1997). We therefore examined whether the level of HER-2 expression in paired HER-2-transfected and non-transfected ovarian cancers influenced the degree of tumor growth inhibition seen with squalamine with or without concomitant platinum-based treatment.

Results

Squalamine and platinum-based chemotherapeutics block growth of ovarian tumor xenografts in vivo

Potential antitumor effects of the angiostatic steroid squalamine were assessed in murine tumor xenografts in the absence and presence of cisplatin chemotherapy. Human ovarian 2008 cancer cells without (Figure 1a) or with HER-2 overexpression (Figure 1b) were grown as subcutaneous tumors in nude mice. Tumors were grown to 150–200 mm³ in size. Then, animals with established tumors were treated with control solution, cisplatin alone, squalamine alone (2 mg/kg) on days 1–10, or cisplatin in combination with squalamine (days 1–10).

![Figure 1](image_url)

**Figure 1** Squalamine inhibits growth of ovarian 2008 parental and HER-2-overexpressing tumor xenografts in nude mice and enhances the cytotoxic effects of cisplatin. (a) Ovarian 2008 parental tumor cells were inoculated subcutaneously in nude mice. (b) Ovarian 2008 HER-2-overexpressing cancer cells were inoculated subcutaneously in nude mice. After 7 days, animals with tumors of comparable size were randomized to treatment with control vehicle (CON), squalamine (SQ; 2 mg/kg on days 1–10), cisplatin at two different doses (Pt 1 = 4 mg/kg on day 1; Pt 2 = 5 mg/kg on days 1, 8), or cisplatin administered in combination with squalamine (SQ/Pt 1; or SQ/Pt 2). At the end of the experiment, HER-2 receptor expression levels were assessed and, as possible, confirmed to be low in parental tumors and high in HER-2-overexpressing xenografts. Results are expressed as mean ± s.e.m. for tumor volumes (mm³) measured over a 28-day experimental period.
Cisplatin was administered at two different dose levels (see Pietras et al., 1994; Pegram et al., 1997). In one set of experiments, animals were treated with a high dose of cisplatin near the maximum tolerated dose (5 mg/kg on day 1 and day 8; Pt 2). In the second set of experiments, lower doses of cisplatin that resulted in only partial growth inhibition (4 mg/kg on day 1; Pt 1) were chosen in order to ensure use of the chemotherapeutic agent at a level that would not totally suppress tumor growth, thus allowing detection of any potential additive effects of a squalamine-cisplatin interaction. By 28 days, both 2008 parental (Figure 1a) and HER-2-overexpressing (Figure 1b) tumors showed little overall response to therapy with the lower dose of cisplatin alone (both at $P > 0.05$). However, 2008 parental ($P < 0.01$) and HER-2-overexpressing ($P < 0.05$) tumors exhibited some minor responses to cisplatin administered at high doses (see Figure 1). Squalamine elicited a partial reduction in tumor size as compared to controls ($P < 0.01$) in both 2008 parental (Figure 1a) and HER-2-overexpressing (Figure 1b) tumors. More profound tumor growth inhibition (94–95% of controls) was elicited by combined treatment with squalamine and cisplatin ($P < 0.001$) in both 2008 parental (Figure 1a) and HER-2-overexpressing (Figure 1b) cancers. This effect of combination therapy was found when squalamine was administered with either low or high doses of cisplatin.

The antitumor effects of squalamine with and without platinum-based chemotherapy were also assessed using a different ovarian tumor xenograft, CAOV3, that has been transplanted to exhibit HER-2 overexpression (Figure 2a). After tumor growth to 50–60 mm³, animals were treated with control solution, carboplatin alone (60 mg/kg) on day 1, squalamine alone (2 mg/kg) on days 1–10, or carboplatin (day 1) in combination with squalamine (days 1–10). By 28 days, CAOV3 HER-2-overexpressing tumors showed minimal response to therapy with carboplatin at a dose below the maximum tolerated dose (Figure 2a). As with the 2008 tumors, squalamine as a single agent elicited a partial reduction in CAOV3 tumor size as compared to controls ($P < 0.05$) (Figure 2a). More marked inhibition of tumor growth was elicited by combined treatment with squalamine and carboplatin ($P < 0.001$; Figure 2a).

The tumor growth inhibition seen with combined squalamine and platinum-based chemotherapeutics for both human ovarian tumor lines persisted for up to 18 days following cessation of squalamine treatment. We therefore investigated how long bioactivity persisted with combined cisplatin and squalamine treatment of HER-2-overexpressing CAOV3 tumors by maintaining the dual therapy animal cohort until the mean tumor size for these animals reached 500 mm³ (Figure 2b). After tumor growth to 50–60 mm³, animals with established tumors were treated with control solution, cisplatin alone (4 mg/kg) on day 1, squalamine alone (2 mg/kg) on days 1–10, or cisplatin (day 1) in combination with squalamine (days 1–10). As compared with control tumor xenografts, the calculated tumor growth delay in established tumors was 7 days for cisplatin therapy alone, 28 days for squalamine treatment alone, and 91 days for squalamine combined with cisplatin administration (Figure 2b). Combined squalamine-cisplatin therapy was nontoxic as assayed by no animal death or significant weight loss during the study period.

**Squalamine and cisplatin promote ovarian tumor cell apoptosis in vivo**

To assess molecular effects of squalamine and cisplatin, ovarian 2008 parent and HER-2-overexpressing tumor
xenografts remaining after treatments with squalamine, cisplatin (4 mg/kg dose; Pt 1) or a combination of the reagents were harvested at day 28 and assessed for ovarian tumor cell apoptosis in vivo. For evaluation of apoptosis, the modified TUNEL assay (Ellis et al., 1991; Steller, 1995) was performed on tissue sections. The assays showed evidence of increased apoptosis in ovarian 2008 parental tumor cells treated with squalamine alone, cisplatin or combined cisplatin-squalamine as compared to appropriate controls (all at \( P < 0.05 \)) (Figure 3a). The 2008 HER-2-overexpressing ovarian tumors displayed less apoptotic activity than 2008 parental cancers with all treatments \(( P < 0.05 \)). Although apoptosis tended to be higher after administration of either squalamine or cisplatin alone, only treatment with squalamine in combination with cisplatin elicited a significant increase in the extent of apoptosis of HER-2-overexpressing ovarian cancers \(( P < 0.001 \) ) (Figure 3a).

The results suggest that squalamine enhances cytotoxic effects of cisplatin chemotherapy for human ovarian cancer cells by increasing levels of tumor cell apoptosis produced by cisplatin exposure, either with or without HER-2 oncogene overexpression.

**Squalamine down-regulates ovarian tumor-associated angiogenesis but not VEGF production in vivo**

Tissue sections of parent and HER-2-overexpressing 2008 tumor xenografts remaining after treatments with squalamine, cisplatin (4 mg/kg dose; Pt 1) or a combination of the reagents at day 28 (Figure 1) were also prepared for immunohistochemical staining with human von Willebrand Factor (vWF) to detect blood vessels. On review and scoring of tumor microvessel density, 2008 HER-2-overexpressing tumors exhibited more angiogenic activity than 2008 parental cancers \(( P < 0.001 \) ) (Figure 3b). Treatment with squalamine alone elicited a significant reduction of tumor-associated blood microvessel density for either ovarian tumor \(( P < 0.001 \) ) (Figure 3b), and the immunohistochemical analyses also revealed a reduction of tumor-associated angiogenesis in mice treated with cisplatin plus squalamine \(( P < 0.01 \) ) (Figure 3b). No significant differences in microvessel density were found between groups treated with cisplatin alone and controls. The results suggest that squalamine is antiangiogenic for ovarian cancer cells with or without HER-2 overexpression. Squalamine-induced suppression of tumor microvessels is also a sustainable event since it was noted up to 18 days following the last squalamine dose.

In further studies on expression of VEGF in tumor xenografts in vivo, ovarian 2008 parent and HER-2-overexpressing tumors were freshly excised at the end of the experiment (day 28) and dissected free of contaminating mouse tissue. The tumor xenografts were then dissociated and homogenized for further analysis of VEGF expression by Western blot (Figure 4). Under nonreducing conditions, protein bands of the appropriate molecular size occur in both 2008 parent and HER-2-overexpressing tumors (Ferrara et al., 1993). Moreover, 2008 HER-2-overexpressing tumors appear to have significantly higher levels of VEGF than the 2008 parent tumors (Figure 4). Among parental and HER-2-overexpressing tumors treated in vivo with squalamine, levels of VEGF were comparable to those of appropriate paired controls (Figure 4), suggesting that squalamine treatment does not influence tumor-induced VEGF production.

**Squalamine blocks VEGF-stimulated proliferation of endothelial cells in vitro**

To assess the biologic mechanism for the antiangiogenic and antitumor effects of squalamine noted with the ovarian 2008 parent and 2008 HER-2-overexpressing tumor xenografts, human
umbilical vein endothelial cells (HUVEC) were grown in vitro. VEGF alone elicits significant proliferation of HUVEC cells by 72 h. In the absence of VEGF, squalamine had no effect on survival or proliferation of the endothelial cells. However, in the presence of VEGF, squalamine elicited a significant reduction in VEGF-induced endothelial cell proliferation (P<0.001) (Figure 5). This growth-suppressive effect of squalamine appears restricted to endothelial cells since the compound had no direct inhibitory effect on the proliferation of ovarian 2008 cancer cells, either with or without HER-2 gene overexpression (Figure 5).

Figure 4 Higher levels of VEGF protein in ovarian HER-2-overexpressing tumors as compared with that of parental tumors grown in vivo. Ovarian 2008 parental (PAR) and HER-2-overexpressing (HER2) tumors xenografts treated in vivo without squalamine (CN) or with squalamine (SQ) were freshly harvested, dissociated, homogenized and processed for electrophoresis and Western blotting with anti-VEGF antibody. Equal amounts of protein were loaded in each lane. VEGF45 is known to be the most abundant molecular species in the majority of cells, and purified VEGF45 is about 45 kDa in size under non-denaturing conditions, but the molecule also occurs in monomeric forms ranging from 18–23 kDa depending, in part, on glycosylation (Ferrara et al., 1993)

Figure 5 Squalamine inhibits VEGF-induced proliferation of endothelial cells in vitro, but does not directly affect the growth of ovarian epithelial tumor cells in vitro. Human umbilical vein endothelial cells (HUVEC), ovarian 2008 parental cells (2008PR) and ovarian 2008 HER-2-overexpressing cells (2008H2) were grown in vitro in the presence of vascular endothelial cell growth factor (VEGF; 20 ng/ml) or control vehicle (CON), squalamine (SQ; 16 μM) or combinations of VEGF with squalamine (VEGF/SQ) for three days. In additional control studies, squalamine at 8 and 16 μM also elicited no direct effect on proliferation in vitro of CAOV3 ovarian cancer cells with HER-2 overexpression (data not shown). All data are from triplicate determinations of cell numbers, with results presented as mean ± s.e.m.

Figure 6 VEGF secretion by ovarian cancer cells with or without HER-2 gene overexpression. Ovarian 2008 parental cells (PAR) and ovarian 2008 HER-2-overexpressing cells (HER2) were grown in vitro, either with control medium (Cn) or medium containing squalamine (SQ; 16 μM). After 72 h, media were collected and processed for ELISA assay of VEGF secretion. Using a lower dose of squalamine at 8 μM for treatment of ovarian 2008 cells with HER-2 overexpression, similar effects on VEGF secretion were found (n=2; data not shown). Data represent mean ± s.e.m. units of VEGF secretion.

Squalamine does not affect VEGF secretion in vitro for ovarian cancer cells with or without HER-2 gene overexpression

HER-2 overexpression is generally thought to lead to tumor development through its effects on promoting uncontrolled cancer cell growth. However, recent findings suggest that HER-2 may also regulate cell survival functions such as angiogenesis by promoting tumor production of VEGF (Petit et al., 1997). To explore how HER-2 may contribute to angiogenesis in ovarian cancers, we evaluated HER-2 effects on in vitro VEGF secretion by human ovarian tumor cells. Parent and HER-2-overexpressing ovarian 2008 cancer cells were incubated for 72 h in vitro, and secretion of VEGF into conditioned media was determined by use of established enzyme-linked immunosorbent assay (ELISA) (Ferrara et al., 1993; Petit et al., 1997) (Figure 5). Parent ovarian cancer cells show significant secretion of VEGF, and, after transfection of ovarian cells with HER-2 gene to high levels, a further increase in the level of VEGF secretion was found, a result consistent with the in vivo findings described above (see Figure 4). In parallel in vitro studies, treatment of ovarian cancer cells with squalamine elicited no significant effect on secretion of VEGF (Figure 6), again reminiscent of our in vivo findings. Thus, HER-2 overexpression may contribute to angiogenesis through up-regulation of VEGF secretion in ovarian cancer, but squalamine is not anti-angiogenic at this step in tumor-associated angiogenesis since it does not appear to directly affect secretion of VEGF by ovarian epithelial tumor cells.
Squalamine blocks VEGF-induced activation of MAP kinase in vitro

VEGF exerts its biologic effects by binding with receptor tyrosine kinases, notably Flt-1 and Fik-1/KDR, present at the surface of endothelial cells (Mustonen and Alitalo, 1995; Soker et al., 1996). Post-receptor signal transduction regulates the effects of VEGF, and the proliferative action of VEGF in endothelial cells has been associated with VEGF-induced tyrosine phosphorylation and stimulation of mitogen-activated protein kinases (MAP kinase), extracellular signal-regulated kinase ERK-1 (p44 MAPK) and ERK-2 (p42 MAPK) (Soker et al., 1996; Rousseau et al., 1997). On the assumption that blockade of endothelial cell proliferation by squalamine may occur, in part, by suppression of MAP kinase signaling cascades induced by growth factors, VEGF-induced tyrosine phosphorylation of MAP kinases was assessed. As expected, VEGF promotes tyrosine phosphorylation of MAP kinase isomers, with maximal effects evident by 10 min (Figure 7). However, after administration of squalamine, the VEGF-stimulated phosphorylation of MAP kinase isomers is significantly suppressed, especially after 30 min exposure to VEGF (Figure 7).

Discussion

It is well-known that solid tumors are angiogenesis-dependent for growth, and angiogenesis is stimulated by tumor-secreted angiogenic factors, such as VEGF, that bind to tyrosine kinase receptors and promote endothelial cell proliferation and new capillary formation (Folkman, 1971; Gimbrone et al., 1972; Folkman and Haudenschild, 1980). Similarly, the present studies suggest that angiogenesis is essential for growth of ovarian tumors in vivo. Squalamine, a natural anti-angiogenic steroid, blocks VEGF-induced growth of human umbilical vein endothelial cells, suggesting it presumptively could have a positive role in regulating the growth of ovarian cancers. The experiments described in this paper show further that squalamine suppresses in vivo growth of ovarian cancer xenografts to a similar extent with or without HER-2 oncogene overexpression in the tumor and enhances the cytotoxic effects of platinum-based chemotherapy. Resistance to cisplatin treatment in ovarian tumors with or without HER-2 overexpression may therefore be overcome when the cisplatin is combined with squalamine, a feature of squalamine that could have direct application to the design of appropriate clinical trials.

Several studies suggest that VEGF plays an important role in the progression of ovarian cancer (Paley et al., 1997; Yamamoto et al., 1997; Alvarez et al., 1999), and evidence for interactions between VEGF-induced angiogenesis and growth factor receptor pathways in tumors is beginning to emerge. Since the HER-2 growth factor receptor is overexpressed in a significant number of ovarian cancers, it may play an important role in promoting growth of ovarian cancers (Slamon et al., 1989; Wong et al., 1995; Juhl et al., 1997; Hellstrom et al., 2001). In the laboratory, HER-2 amplification is rate-limiting for expression of the malignant phenotype of ovarian cancer in a dose-dependent manner (Juhl et al., 1997), and HER-2 antireceptor antibodies elicit cytotastic growth inhibition of ovarian cancer cells overexpressing HER-2 (Pietras et al., 1994). We have demonstrated in this paper that VEGF is produced by transfected and non-transfected human ovarian 2008 cancers, and stimulation of the HER-2 pathway appears to further up-regulate tumor secretion of VEGF. In our studies on VEGF expression in ovarian 2008 tumors overexpressing HER-2 were associated with significantly higher levels of VEGF than ovarian 2008 parent control tumors, consistent with data from the in vitro experiments with the same cancer cells. These findings correspond well with prior observations on the stimulatory influence of HER-2 signaling on VEGF production in human breast cancers (Petit et al., 1997). The data also are consistent with clinical data demonstrating HER-2 oncogene overexpression is associated with a poor prognosis for ovarian cancer patients with this abnormality (Slamon et al., 1989; Berchuck et al., 1990; Wong et al., 1995). In these individuals, VEGF overproduction may stimulate angiogenesis to a greater extent than would otherwise be seen, leading to rapid tumor growth and shorter patient survival times.

Squalamine specifically inhibits endothelial cell proliferation induced by a wide range of growth factors, including VEGF. This inhibition may result from its interaction with endothelial cell surface proton pumps, thus altering intracellular pH and impeding downstream signaling by growth factors (Akhter et al., 1999; Eckhardt, 1999). Alternatively, calcium-dependent cell signaling following exposure to growth factors

---

**Figure 7** Squalamine blocks VEGF-stimulated tyrosine phosphorylation of MAP kinase in HUVEC cells in vitro. Quiescent HUVEC cells were treated with control vehicle (Cn), VEGF (50 ng/ml), squalamine (SQ; 1.6 μM) or VEGF in combination with squalamine (VEGF+SQ) for 10 or 30 min in vitro. Lysates were prepared and processed as described in Materials and methods. (a) Western blotting was performed with anti-phospho-p44/42 MAP kinase monoclonal antibody as indicated in Materials and methods. (b) Paired samples were used for Western blotting with anti-phospho-p44/42 MAP kinase monoclonal antibody to confirm similar total protein load in each lane. Treatment of HUVEC cells in vitro with squalamine at 0.8 μM elicited a similar block of VEGF-stimulated tyrosine phosphorylation of MAP kinase (data not shown).
such as VEGF may be dysregulated when squalamine forces intracellular redistribution of calmodulin (Chen et al., 1999). Irrespective of which mechanism may be operating, we find that squalamine blocks proliferation of human umbilical vein endothelial cells in vitro, while it does not directly interfere with growth of ovarian tumor cells or production of VEGF by these tumor cells in vitro. VEGF has been shown to initiate biologic responses by binding with receptor tyrosine kinases, including Flt-1, Flik-1/KDR and neuropilin, present at the surface of endothelial cells (Mustonen and Alitalo, 1995; Soker et al., 1998; Abedi and Zachary, 1997). The proliferative action of VEGF in endothelial cells is associated with the subsequent VEGF-induced tyrosine phosphorylation and stimulation in concert of focal adhesion kinase (FAK) and MAP kinases, including p38 MAP kinase, ERK-1 (p44 MAPK) and ERK-2 (p42 MAPK) (Soker et al., 1996; Rousseau et al., 1997; Kroll and Waldenberger, 1997). On testing the assumption that blockade of endothelial cell proliferation by squalamine may occur, in part, by suppression of MAP kinase signaling cascades induced by VEGF in endothelial cells, we found that squalamine significantly curbs VEGF-stimulated phosphorylation of MAP kinase isoforms p42 and p44 in HUVEC. Thus, squalamine may prevent endothelial cell growth and associated angiogenesis by interrupting signal transduction necessary for endothelial cell activation. In addition, administration of squalamine alone to nude mice with human ovarian cancer xenografts elicits a partial reduction in tumor size as compared to controls in both parental and HER-2-overexpressing tumors. This in vivo effect of squalamine is further enhanced by coadministration of cisplatin and is associated with a reduction of tumor-associated angiogenesis and with enhanced apoptosis of ovarian cancer cells with both 2008 tumor lines, notably when squalamine and cisplatin are used together. The chemotherapeutic effect on apoptosis presumably is due to interruption of the tumor-associated blood supply. Given the relatively small response of both ovarian tumor lines to cisplatin treatment, it is noteworthy that cisplatin plus squalamine is a far better treatment than squalamine alone, and the combination has similar anticancer efficacy with both tumor lines.

As in the experiments described above with ovarian cancers, squalamine alone was previously reported to be a potent inhibitor of the growth of blood vessel cells in preclinical studies of lung (Teicher et al., 1998; Schiller and Bittner, 1999) and brain (Sills et al., 1998) cancers. To evaluate the possible clinical efficacy of squalamine combined with standard cytotoxic anti-tumor therapy in suppressing growth of ovarian cancers, the anti-angiogenic steril was administered to the 2008 parent and 2008 HER-2-overexpressing tumors in combination with cisplatin and to CAOV3 HER-2-overexpressing tumors in combination with cisplatin or carboplatin chemotherapy. Use of postoperative chemotherapy is standard treatment for all advanced-stage and for many early-stage patients with ovarian cancer, and adjuvant therapy with platinum-based regimens significantly prolongs survival (Ozols, 1999). The experimental results provide evidence of significant antitumor efficacy of the several ovarian cancers following combined treatment with squalamine and cisplatin (or carboplatin) as compared with appropriate controls. These results are consistent with earlier studies demonstrating enhancement by squalamine of the antitumor efficacy of cisplatin, carboplatin or carboplatin/paclitaxel therapies in nude mice with lung cancer xenografts (Teicher et al., 1998; Schiller and Bittner, 1999). Data in this paper show a strong correlation between the ability of squalamine-based chemotherapy to inhibit tumor angiogenesis and tumor growth and increase tumor apoptosis. Since platinum-based chemotherapies are often used for treatment of ovarian cancers (Ozols, 1999), extrapolation of our experimental results to the clinical setting leads us to infer that squalamine in combination with platinum compounds may prove useful as part of a coordinated attack against both ovarian tumor blood supply and ovarian cancers.

Squalamine has been tested in two phase I clinical trials employing patients with a variety of solid malignancies and who have failed conventional therapies, and the chemical has been shown to be well-tolerated by human subjects (Patnaik et al., 1999). Phase II combination chemotherapy studies incorporating squalamine are ongoing in patients with advanced ovarian cancer. The outcome of these clinical trials will provide the first answers as to whether or not squalamine offers a degree of outcome improvement over cytotoxic therapy alone to patients afflicted with disseminated ovarian cancer comparable to that seen with the xenograft models described in this report.

Materials and methods

Cell lines

Human ovarian 2008 parental cells (provided by Dr S Howell) were derived from a patient with serous cystadenocarcinoma of the ovary (Disia et al., 1972), and human CAOV3 ovarian carcinoma cells were obtained from American Type Culture Collection (Rockville, MD, USA). Using methods described elsewhere (Chazin et al., 1992; Piethra et al., 1994; Peggarn et al., 1997), ovarian cancer cells with low expression of HER-2 gene were stably transfected with a vector containing the full-length cDNA of human HER-2 gene, with molecular characterization of HER-2 overexpression as before (Piertras et al., 1994; Peggarn et al., 1997). Both parental and HER-2-overexpressing ovarian cancer cells were routinely cultured in RPM1 1640 media supplemented with 10% heat-inactivated fetal bovine serum, 2 mM freshly added glutamine and 1% penicillin G-streptomycin-fungizone solution (Irvine Scientific, Santa Ana, CA, USA). Human umbilical vein endothelial cells were obtained from Clonetics (San Diego, CA, USA), with immunospecific staining to confirm that cells are endothelial (Morales et al., 1995). The latter cells were grown in endothelial cell growth medium (EGM) which contains endothelial cell basal medium supplemented with 2% fetal bovine serum, 10 ng/ml hEGF, 1.0 µg/ml hydrocortisone,
50 µg/ml gentamicin, 50 ng/ml amphotericin-B, and 12 µg/ml bovine brain extract (BBE) (Folkman and Haudenschild, 1980; Morales et al., 1995).

**Measurement of VEGF protein levels**

Secretion of VEGF protein was quantitated in extracellular media by enzyme-linked immunosorbent assay (ELISA) after centrifugation and concentration by Amicon® filtration (Ferrara et al., 1993; Goldman et al., 1993).

**Quantitation of cell proliferation in vitro**

Human ovarian tumor or endothelial cells (10,000 cells/well) were plated on 12-well plates and allowed to attach overnight in the appropriate complete media. The medium was then removed and replaced with either fresh complete medium, medium supplemented with squalamine, VEGF (PeproTech, Rocky Hill, NJ, USA), or squalamine plus VEGF. The choice of squalamine doses for use in the in vitro studies was based on results from preliminary experiments and pharmacokinetic studies (Williams et al., 2001). Cell proliferation was determined by both direct counts and Coulter-counter analyses. All assays were performed in triplicate.

**Detection of p44/42 MAP kinase activity by Western blot**

Tyrosine phosphorylation of MAP kinase was determined as before (Sebolt-Leopold et al., 1999). HUVEC cells were grown in 100 mm culture dishes to 80–90% confluence and in complete EGM media. Then, cells were starved in endothelial cell basal medium containing 1% fatty acid-free, steroid-depleted bovine serum albumin for 8 h. Prior to addition of VEGF (50 ng/ml) for various times at 37°C, cells were incubated in the presence or absence of 1.6 µM squalamine for 1 h. After treatment, cells were immediately rinsed with cold PBS three times and chilled at 0–4°C prior to lysis in 100 µl cold lysis buffer containing 20 mM Tris (pH 8.0), 137 mM NaCl, 10% glycerol, 1% Triton X-100, 20 mM EDTA, 0.5 µg/ml leupeptin, 0.5 µg/ml aprotinin, 50 µg/ml tryspin inhibitor, 0.1 mg/ml 4-(2-aminoethyl)-benzenesulfonyl fluoride and 1.0 mM sodium orthovanadate (Sigma, St. Louis, MO, USA). Total protein concentration was determined by BCA assay (Pierce Biochemical, Rockford, IL, USA). Protein samples (50 µg/lane) were separated on a 4–12% precast Tris-Glycine gel (Novex, San Diego, CA, USA). Proteins were then transferred to a nitrocellulose membrane and subjected to immunodetection with anti-phospho-p44/42 MAP kinase E10 monoclonal antibody (New England Biolabs, Beverly, MA, USA), using the ECL Western blotting system (Amersham Pharmacia, Arlington Heights, IL, USA) as before (Chazin et al., 1992; Pegram et al., 1997). In paired control experiments, a p44/42 MAP kinase antibody (New England Biolabs) was used for detection of total enzyme protein.

**Tumor cell inoculation and drug treatment in nude mice**

All animal studies were conducted according to protocols approved by the UCLA animal research committee. Five to six-week-old female athymic nude mice (25–30 gm) were obtained from Harlan Sprague-Dawley (Indianapolis, IN, USA) and primed for 7 days with 17β-estradiol applied subcutaneously in a biodegradable carrier-binder (1.7 mg of estradiol per pellet, 60-day release form, Innovative Research of America, Sarasota, FL, USA). Thereafter, 2 × 10^7 tumor cells were injected subcutaneously in the mid-back region of the mice and grown as xenografts (Pietras et al., 1994; Pegram et al., 1997). After growth of tumors to 150–200 mm^3, animals were randomized by body weight and tumor nodule size to different treatment groups of 5–7 mice. Animals were treated by intraperitoneal injection with control solution, cisplatin (Platinol), carboxplatin (Paraplatin; Bristol Myers Squibb, Princeton, NJ, USA), squalamine (2 mg/kg on days 1–10; Genacra Corporation, Plymouth Meeting, PA, USA) or cisplatin (or carboxplatin) in combination with squalamine. Based on previous work (Pietras et al., 1994; Pegram et al., 1997; Schiller and Bittner, 1999; Plumb et al., 2000), cisplatin (4 mg/kg) and carboxplatin (60 mg/kg) were generally administered at doses less than the maximum tolerated dose in an attempt to allow any additional effects of combination treatment with platinum-based agents and squalamine to be more easily detected (Schiller and Bittner, 1999). However, in selected experiments, cisplatin (5 mg/kg on day 1, 8) was also administered alone and in combination with squalamine at maximum tolerated doses as determined previously for these cell lines in nude mouse models (Pietras et al., 1994; Pegram et al., 1997; Kollfschoten et al., 2000). The 2 mg/kg squalamine dose was selected as being the minimal daily dose previously shown to be significantly active in a tumor xenograft model in combination with a platinum agent (Williams et al., 2001). Tumor volume was monitored by dimension measurements as before (Pietras et al., 1994). In most studies, experiments were terminated after 28 days to allow harvesting of tumor xenografts for assessment of selected molecular endpoints, including HER-2 expression by immunohistochemical methods (see Pietras et al., 1994; Pegram et al., 1997). Mean tumor growth inhibition for each treatment group was determined as before (Pietras et al., 1994; Pegram et al., 1997). In selected experiments, tumor growth delay was calculated by graphing the volume of each treatment group and calculating the number of additional days it took to reach 500 mm^3 compared with control (Teicher et al., 1998). In all studies, toxicities of treatment regimens were estimated by following changes in animal body weight and the incidence of drug-associated deaths.

**Tissue preparation and paraffin-embedded tissue sections**

At the end of the experiments, mice were sacrificed, and tumors were excised, fixed in formalin and embedded in paraffin according to established procedures (Luna, 1968). Paraffin-embedded tumors were prepared in 4–6 µm sections, mounted on positively-charged Superfrost Plus slides (Fisher, Houston, TX, USA) prior to immunohistochemical staining, and sections were then deparaffinized in xylene, followed by 100, 95, 70 and 50% ethanol and rehydration in H₂O.

**Quantification of tumor vessel counts**

Histological sections of tumors from in vivo treatments of ovarian cancers were analysed for degree of angiogenesis by estimates of tumor-associated blood microvessel density. Tumor microvessel density was measured by counting the number of capillary blood vessels per high power field in sections stained with antibodies against von Willebrand Factor (vWF) as before (O’Reilly et al., 1997). In brief, anti-human vWF/HRP antibodies (EPOS; Dako, Carpinteria, CA, USA) were applied on tissue sections to mark endothelial cells and were then detected using a specific substrate system. Vessels were counted by use of a light microscope.
Apoptosis assay

Histological sections of tumors from in vivo treatments of ovarian cancers were analysed for apoptosis using a detection system described previously (Ellis et al., 1991; O’Reilly et al., 1997). Apoptosis was assessed by a specific colorimetric detection system (Promega, Madison, WI, USA) (Ellis et al., 1991; Steller, 1995). In brief, fragmented apoptotic cells were end-labeled using a modified TUNEL (dT-T-mediated dUTP nick-end labeling) assay. Biotinylated nucleotides was incorporated at 3′-OH DNA ends using terminal deoxynucleotidyl transferase. Horseradish peroxidase-labeled streptavidin was then bound to biotinylated nucleotides and was detected using peroxidase substrate, hydrogen peroxide, and the stable chromogen diaminobenzidine. Using this procedure, apoptotic nuclei stained brown. An apoptotic index was estimated by the percentage of cells scored with a light microscope at 200-fold magnification (O’Reilly et al., 1997).

Detection of VEGF in tumors

In selected in vivo experiments, human tumor xenografts were freshly excised and dissected free of mouse tissues. Human tumor tissue was then dissociated and homogenized in vitro by established methods (Pietras and Roberts, 1981). Total protein concentration in homogenates was assessed by BCA assay (Pierce Biochemical), and protein samples were separated on a 4–12% precast Tris-Glycine gel (Novex). Proteins were then transferred to a nitrocellulose membrane and subjected to immunodetection with anti-VEGF monoclonal antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA), using the ECL Western blotting system (Amersham Pharmacia) as before (Chazin et al., 1992; Pietras et al., 1994).

Statistical analysis

Statistical evaluation of data by t-tests and analysis of variance as appropriate was conducted using methods described before (Pietras et al., 1994; Pegram et al., 1997). All computations were made with Stat View and Super ANOVA software (Abacus Concepts, Berkeley, CA, USA).

Acknowledgments

We dedicate this article to the memory of Dr James A Roberts (1947–2001), Professor of Gynecologic Oncology at Stanford University, a friend and a leader in ovarian cancer research who provided many helpful discussions. We also thank Dr Kenneth Holroyd, Dr Dennis J Slamon, Dr Mark Pegram and Dr Rebecca Rausch for advice in the execution of this work. This work was supported by grants from the National Institutes of Health (R29CA60835), the United States Department of Defense Ovarian Cancer Research Program (OC990068), and the Stiles Program in Integrative Oncology.

A phase IIA trial of continuous 5-day infusions of MSI-1256F (squalamine lactate) plus carboplatin for therapy of persistent or recurrent advanced ovarian cancer

Abstract No: 878

Author(s): Susan A Davidson, Linnea Chap, Richard Pietras, Allen Astrow, Walter Gajewski, Kevin Brader, Michael Petrone, Avinash Desai, Stephen Solomon, Kenneth Holroyd, Frank Major, Lisa Adler, Allen Cohn, Univ of Colorado Health Sciences Ctr, Denver, CO; University of California Los Angeles, Los Angeles, CA; Saint Vincents Medical Center, New York, NY; Women and Infants Hospital of Rhode Island, Providence, RI; Vanderbilt University Medical Center, Nashville, TN; Genaera Corporation, Plymouth Meeting, PA; Rocky Mountain Cancer Center, Denver, CO.

Abstract: Squalamine (MSI-1256F) is an anti-angiogenic aminosterol that acts directly on activated endothelial cells after intracellular uptake. MSI-1256F when administered as a five-day continuous infusion in conjunction with carboplatin (AUC=6) every three weeks at 200mg/m2/day. Thirty three patients with stage III or stage IV ovarian cancer, with either progression on primary paclitaxel and carboplatin therapy (refractory disease) or recurrence within 6 months of initial response to paclitaxel and carboplatin therapy (resistant disease) received squalamine lactate. Patients with recurrence, resistant or sensitive, within 12 months of initial response to a secondary or tertiary regimen were also permitted (recurrent disease). PATIENT CHARACTERISTICS: median age 59 years (range 25-73 years), 28 Caucasian, 2 African American, 1 Asian, and 2 Hispanic, ECOG PS 0-1 (18 60, 15-1), 21 stage III and 12 stage IV. Response data is available for 22 evaluable patients at this time. Median time on the study was 81 days. There were 8 objective responses in the first 22 evaluable patients. Survival data is maturing. TOXICITY: Grade 4 thrombocytopenia, anemia, leukopenia, myalgia and asthenia occurred in 3 patients. Other grade 4 adverse events like headache, nausea, pain and allergic reaction to carboplatin occurred in two patients. Also single incidence of anorexia, nausea, vomiting, diarrhea, constipation, atrial fibrillation, tachycardia, sinus bradycardia, hypokalemia, hyponatremia, dyspnea, increased cough, apnea, liver function abnormalities, injection site reaction and dizziness were reported. Additional patients are being enrolled at the 200 mg/m2/day squalamine dose to complete enrollment in the study. Updated data on these additional patients and survival data will be presented. These results with Squalamine suggest it to be an exciting option for advanced refractory ovarian cancer patients, a group of patients for whom new therapeutic alternatives are much needed. Further studies are being planned.

SQUALAMINE BLOCKS TUMOR-ASSOCIATED ANGIGENESIS AND GROWTH OF OVARIAN CANCER. R. J. Pietras, M. Gorrin-Rivas and H. Chen. UCLA School of Medicine, Dept. of Medicine-Hem/Oncology, Los Angeles, CA 90095, USA.

Methods: The mechanism of action of squalamine was assessed in vitro by assay of several steps of angiogenesis, a process involving human vascular endothelial cell (HUVEC) proliferation, migration and differentiation to tube-like structures, with many events stimulated by factors released by tumor cells (Oncogene 21:2805, 2002).

Results: Ovarian cells were found to secrete significant levels of vascular endothelial cell growth factor (VEGF), a direct activator of angiogenesis, but squalamine did not reduce VEGF secretion by tumor cells, and it evoked no direct growth inhibition of ovarian cells in vitro. However, squalamine, at doses as low as 160 nM, did halt HUVEC growth and markedly reduced VEGF-induced capillary tube-like formations by HUVEC growing in Matrigel culture (P<0.001). These physiologic effects correlated well with squalamine-induced blockade of the rapid VEGF-stimulated phosphorylation of p42/p44 MAP kinase in HUVEC, an early cell response to activate proliferation. Squalamine also reduced VEGF-induced phosphorylation of focal adhesion kinase (FAK) and stress-activated
protein kinase-2/p38 (SAPK2/p38), blocking, in turn, assembly of F-actin stress fibers in HUVEC. These effects follow primary interaction of squalamine with caveolar domains at surface membranes of endothelial cells, sites for the concentration of vital signaling complexes to regulate the angiogenic process.

**Conclusions:** The results suggest that potent antitumor efficacy of squalamine is due to coordinated disruption of tumor-associated angiogenesis that supports progression of human ovarian cancers. [Supported by US Army OCRP and Stiles Program in Oncology].
