# Report Documentation Page

Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

1. Summary
This paper describes the working mechanism of IMMUNE DRIVER. This system uses the functions that are regularly not used function by IA32 process which maintains the highest market share at present to interrupt program when buffer overflow generated by virus program.

2. Mandatory Environment
CPU: Intel Pentium Pro or higher processor
*IA-32 Processor with processor instruction trace
OS: Microsoft Windows 2000 SP0

Development environment for IMMUNE system:
Microsoft Visual Studio 6.0 SP4
Compuware DriverStudio 2.7 or later

3. Structure
The following is the sketch of this system

![Diagram of IMMUNE Driver and IA32 Processor](image)

Fig.3-1 Sketch of the system
4. Mechanism

4.1. Brief Flowing Chart

This system consists of five parts: [Initialization], [Process detection], [Event registration], [Instruction trace], and [Process termination].

![Flowchart]

Fig. 4-1 Brief flowing chart of IMMUNE DRIVER

(1) Initialization

The process works on the starting of IMMUNE driver.
(2) Process detection
   The preparatory works of detection the buffer overflow before the target process generated.

(3) Registration of branch instruction trace event
   Right after the target process generated, the virus execute buffer overflow code by branch instruction. That is why the events of branch instruction should be monitored, of which only the buffer overflow caused by the instruction of CALL/RET/RETxx are to be detected.

(4) Instruction trace
   When the registered event occurs, the following methods are to be executed depending on the branch instruction.

① CALL instruction processing: Storing the return address of CALL instruction in our stack recorder.
② RET instruction processing: Compare the return addresses in stack recorder with the current return addresses when CALL instruction executed. If they are not match, it is considered that the return address was changed illegally. This is regarded as buffer overflow, which will forcefully terminate the process.

(5) Process termination
   The process that caused buffer overflow is terminated forcibly.
4.2. Initial processing

Flow chart of initialization

![Flow chart image]

(1) Set process name (by initial parameter)
 Specify the process name of monitored buffer overflow from registry.

(2) Register a process generation callback function
 To register a process generation callback function, call the PsSetLoadImageNotifyRoutine function provided by Windows.

Prototype of callback function is defined as following

```c
void LoadImageNotifyRoutine(
    PUNICODE_STRING FullImageName,
    HANDLE ProcessId,
    PIMAGE_INFO ImageInfo
);
```
(3) Initialize Stack recorder
It gives a room and is initialized in the stack recorder. The stack recorder is a buffer used to trace the branch instruction while target process executes. Also, it dynamically gives a room in stack recorder whenever sub thread of the specified process is generated. The stack recorder structure is defined as

```c
typedef struct _ASO_STACK_LIST{
    LIST_ENTRY m_ListEntry;
    ULONG ThreadId;
    ULONG *StackPointer;
    LONG CurrentStackLocation;
} ASO_STACK_LIST, *PASO_STACK_LIST;
```

(4) Register thread creation event hooking (suitable for multiple threads)
It is to hook kernel API called NtCreateThread when the sub thread is being generated. For hooking NtCreateThread, entry point of Int2E interrupt handler is replaced with IMMUNE system.

```c
IDTR idtr;
PENTRY Oldt;
PENTRY Nldt;

__asm  SIDT idtr;

Oldt = (PENTRY)MAKELONG(idtr.LowIDTbase, idtr.HiIDTbase);
gOldINT2EH_Handler = MAKELONG(Oldt[IGATE2E].OffsetLow, Oldt[IGATE2E].OffsetHigh);
Nldt = &(Oldt[IGATE2E]);

__asm {
    CLI
    LEA EAX, ASO_Hook_INT2EH
    MOV EBX, Nldt;
    MOV [EBX], AX
    SHR EAX, 16
    MOV [EBX+6], AX;
    LIDT idtr
    STI
}
4.3. Detection of process generation events

Monitoring starts at the beginning of process execution right after being generated. The target process events are got through the following chart:

![Flowchart for detection of process generation events]

Fig. 4.3 Detection of process generation event

① Detection of process generation

The LoadImageNotifyRoutine is called when any process generates. The function of LoadImageNotifyRoutine is as following:

② To determine a target process

The FullName (one of the arguments of LoadImageNotifyRoutine) is used to distinguish the target process's module name. If it is believed to be the target process, the process will go as shown in ③.
③ To obtain the process starting address
It gets the program starting address by EXE header the program file. It takes the following
codes to get the program starting address.

```c
PVOID ImageBase = (PVOID)ImageInfo->ImageBase;
MZ_HEADER *mz_Header = (MZ_HEADER *)ImageBase;
MZ_NE *mz_ne = (MZ_NE *)((char *)ImageBase + sizeof(MZ_HEADER));
IMAGE_NT_HEADERS *ImageNtHeaders =
    (IMAGE_NT_HEADERS *)((char *)ImageBase + mz_ne->ne_header);
char *EntryPoint =
    ((char *)((ULONG)ImageInfo->ImageBase + ImageNtHeaders->OptionalHeader.AddressOfEntryPoint));
```
Setting the detection of process execution starting

Setting a hardware break point in the process starting address got in above mentioned (3). Call the trace callback function (ASO_Hook_INT01H) when the process starts. The following codes are used for the registration

```
MOV EAX, KickStartAddress // Process start address
MOV DR0, EAX

MOV EAX, DR7
OR EAX, 0x00000000:    // Set LEN0 = 00 (1Byte Length)
OR EAX, 0x000000000:   // Set R/W0 = 00 (On Execution Only)
OR EAX, 0x00000200:    // Set GE
OR EAX, 0x00000002:    // Enable G0
MOV DR7, EAX:          // Set DR7
```
5) Setting the execution break point

To set hardware break point in execution entry point to be able to begin the trace as soon as the program starts. Call the INT01 handler when break point is hit during the execution of entry point.

The following codes are used for the registration

```
MOV EAX, KickStartAddress  // Entry Point (main0 address)
MOV DR0, EAX

MOV EAX, DR7
OR   EAX, 0x00000000:     // Set LEN0 = 00 (1Byte Length)
OR   EAX, 0x00000000:     // Set R/W0 = 00 (On Execution Only)
OR   EAX, 0x00000200:     // Set GE
OR   EAX, 0x00000002:     // Enable G0
MOV DR7, EAX:               // Set DR7
```
⑥ Registration of branch instruction handler
To register the trace callback function (ASO_Hook_INT01H). Replace the IDT (Interrupt Descriptor Table) of 01H.

The following codes are used for the registration

```c
IDTR idtr;
PITENTRY Oldt;
PITENTRY Nidt;

__asm{
    SIDT idtr;
}

Oldt = (PITENTRY)MAKELONG(idtr.LowIDTbase, idtr.HighIDTbase);
gOldINT01H_Handler= MAKELONG(Oldt[IGATE01].OffsetLow, Oldt[IGATE01].OffsetHigh);
Nidt = &(Oldt[IGATE01]);
__asm{
    LEA EAX, ASO_Hook_INT01H// INT01 Hook function
    MOV EBX, Nidt;
    MOV [EBX], AX
    SHR EAX, 16
    MOV [EBX+6], AX;
    LIDT idtr
}
```

⑦ Saving of process ID
When starting, the process gets an ID from Windows. The ID is saved to distinguish the target process when the event occurred by IA-32 branch instruction.
4.4. Starting of tracing

When entry point of program is run, the INT01 handler is called by pre-set break point. From this moment, trace function turns active.
The following codes are used for enabling trace function.

```
MOV EAX, DR6:       // Get DR6 Register Value

// Check MemoryBreak0 Flag
TEST EAX, 0x00000001  // Check MemoryBreak0 bit
JNZ MEMORY_BREAK_BP0

MEMORY_BREAK_BP0:
MOV EAX, DR0
MOV gBreakAddress, EAX

XOR EAX, EAX
MOV DR0, EAX

MOV EAX, DR7
AND EAX, 0xFFFFFFFFD:     // Disable G0
MOV DR7, EAX

MOV EAX, DR6
AND EAX, 0xFFFFFFFFE     // Disable B0
MOV DR6, EAX

JMP MEMORY_BREAK_COMMON
```

4.5. Branch instruction process

When the branch instruction is hit, it is to be processed as below:

Event Start

MemoryBreak0?

Yes

MemoryBreak1?

Yes

MemoryBreak2?

Yes

MemoryBreak3?

Yes

BreakSingleStep?

Yes

Register branch instruction monitoring handler. (the sub thread of the specified process is generated)

No

To trace process

Return

Fig. 4-4
Trace start

Clear a trace flag of DR6

Get LastBranchFromIp (MSR=0x01DB)

Get executed instruction from LastBranchFromIp

Relative near CALL? (0xE8)
- Yes
  - To CALL process
- No

Direct near/far CALL? (0xFF)
- Yes
  - To CALL or JMP process
- No

Direct far CALL? (0x9A)

  - To CALL process
- No

near RET? (0xC3)
- Yes
  - To RET process
- No

far RET? (0xCB)
- Yes
  - To RET process
- No
near RET with POP?
(0xC2)

Yes

No

far RET with POP?
(0xCA)

Yes

To RETN process

No

To RETN process

CALL or JMP process start

CALL/2?
(0x10)

Yes

To CALL process

No

CALL/3?
(0x18)

Yes

To CALL process

No

JMP ESP?
(0x18)

Yes

To JMP ESP process

No

To CALL process

No

To JMP ESP process
During the branch instruction are executing in process. ASO_Hook_INT01H is called. Only the instruction of CALL and RET that are necessary for IMMUNE system in handler distinguish according the following codes.

// DR6 <- 0x00000000
MOV EAX, DR6
AND EAX, 0xFFFFFBFFF
MOV DR6, EAX

// EDX:EAX <- LastBranchFromIp
MOV ECX, 0x0000001B: // MSR = 0x01DB(LastBranchFromIp)
RDMSR:

PUSH ES
MOV BX, 0x001B
MOV ES, BX
MOV EDX, EAX
MOV EAX, ES:[EAX]
POP ES

//
// Branch on Instruction type
//

CMP AL, 0xE8       // Relative near call
JZ CALL_FOUND

CMP AL, 0xFF       // Direct near/far call

JZ RETN_FOUND

JMP CALL_NOTFOUND

CALL OR JMP FOUND:
TEST AH, 0x10       // CALL/2
JNZ CALL_FOUND
TEST AH, 0x18       // CALL/3
JNZ CALL_FOUND
CMP AH, 0xE4        // JMP ESP
JZ JMPESP_FOUND

JMP CALL_NOTFOUND
4.6. In the case of CALL instruction executes

When execution of CALL instruction is detected in target process, the return addresses are saved in stack recorder according to the following flow chart:

- CALL process start
- Get return address from stack recorder
- Store return address to stack recorder
- Reset the instruction trace
- IRET end
(1) When CALL instruction is executed, the original return address stored in stack area is got according the following codes.

CALL_FOUND:
PUSH ES
  // Get Stack segment (CS)
MOV ECX, EBP
ADD ECX, + 4 + 4 + 4 + 4 + 4
MOV EAX, [ECX]
MOV ES, AX
  // Get Stack pointer
MOV ECX, EBP
ADD ECX, + 4 + 4 + 4 + 4
LES EDX, [ECX]          // Now EDX point to Stack Address
  // Get RetIP
MOV ECX, EDX
MOV AX, 0x001B           // User mode only
MOV ES, AX
  //
MOV EDX, ES:[ECX]        // Retrieve RetIP on Stack
  //
  // Now EDX point to RetIP on Stack
  //
POP ES
(2) The return address got from (1) is stored in stack recorder inside the IMMUNE system.
   It is to be processed as following:

```c
KeRaiseErrlql(HIGH_LEVEL, &OldIrql);
PASO_STACK_LIST StackList = (PASO_STACK_LIST)gStackList[ThreadId];
if (StackList == 0){
    // Error
    }
else if (StackList->CurrentStackLocation > STACK_LIMIT){
    StackList = NULL;
}
else if (StackList->CurrentStackLocation >= 0){
    StackList->StackPointer[StackList->CurrentStackLocation] = ExpectedRetIp;
    StackList->CurrentStackLocation++;
}
KeLowerIrql(OldIrql);
```

(3) Reset the instruction trace. Because the instruction trace setting is effective until the branch instruction is detected.
4.7. In the case of RET instruction executes

When execution of RET instruction is detected in target process, it is to follow the chart below to check the overflow.

```
<table>
<thead>
<tr>
<th>RET process start</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get real return address</td>
</tr>
<tr>
<td>--------------------</td>
</tr>
<tr>
<td>Compare return address of stack</td>
</tr>
<tr>
<td>recorder same or different</td>
</tr>
<tr>
<td>Same</td>
</tr>
<tr>
<td>Reset the instruction trace</td>
</tr>
<tr>
<td>----------------</td>
</tr>
<tr>
<td>Different</td>
</tr>
<tr>
<td>(Detected the buffer overflow)</td>
</tr>
<tr>
<td>To process interruption</td>
</tr>
</tbody>
</table>

IRETD  End
```
1. When RET instruction is executed, the real return address stored in stack area is got according to the following codes.

```
RET_FOUND:
PUSH ES
// Get Stack segment (SS)
MOV ECX, EBP
ADD ECX, +4 +4 +4 +4 +4
MOV EAX, [ECX]
MOV ES, AX

// Get Stack pointer
MOV ECX, EBP
ADD ECX, +4 +4 +4 +4
MOV EAX, [ECX]
LES EDX, [ECX]  // Now EDX point to Stack Address

SUB EDX, +4  // Back 4 Bytes from Current Stack Address
MOV ECX, EDX

MOV AX, 0x001B
MOV ES, AX
MOV EDX, ES:[ECX]
```
KeRaiseIrql(HIGH_LEVEL, &OldIrql);
PASO_STACK_LIST StackList = (PASO_STACK_LIST)gStackList[ThreadId];
if (StackList == 0){
    // Stack not found
}else if (StackList->CurrentStackLocation > 0){
    StackList->CurrentStackLocation --;
    ULONG ExpectedRetlp
    = StackList->StackPointer[StackList->CurrentStackLocation];
    StackList->StackPointer[StackList->CurrentStackLocation] = 0;
    if (ExpectedRetlp != Tolp){
        LONG i;
        BOOLEAN StackFound = FALSE;
        for (i = StackList->CurrentStackLocation; i >= 0; i --){
            if (StackList->StackPointer[i] == Tolp){
                LONG j;
                for (j = i; j <= StackList->CurrentStackLocation; j++){
                    StackList->StackPointer[j] = 0;
                }
                StackList->CurrentStackLocation = i;
                StackFound = TRUE;
                break;
            }
        }
        if (!StackFound){
            // Not found
            Terminate_VirusCode(Fromlp, Tolp, ExpectedRetlp);
        }
    }
}else{
    DbgPrint(" Illegal Stack Location\n");
}
KeLowerIrql(OldIrql);
③ When the return addresses are identical, it is believed to be the normal process and this process is finished. When the addresses are not identical, it is believed that overflow occurs. That is when the process of termination described in 4.7(Terminate VirusCode) will be executed.

④ Reset the instruction trace.
4.8. Force process termination

① The process will be forcefully terminated by the hidden illegal codes in executed instruction address (real return address) according to RET instruction.

```c
void __stdcall Terminate_VirusCode(ULONG Fromlp, ULONG Tolp)
{
    IsDetected = TRUE;
    // Rewrite Fromlp(Next instruction of JMP ESP) to INT3
    __asm{
        PUSH EAX
        PUSH EDX

        MOV AL, 0xCC    // INT 3
        MOV EDX, Fromlp
        MOV SS:[EDX], AL

        POP EDX
        POP EAX
    }
}
```
4.9. To set a hook of thread generating events

The sub thread is under monitoring as soon as it is created by target process. So, the system is able to catch the event generated by sub thread.

```
Event Start

Is it the target process?

No

Yes

Get a start address of CreateThread0

Set a break point at the start address

Return
```

The API CreateThread0 is hooked when target thread is generated. Whenever sub thread is generated, it starts to monitor the branch instruction same as main thread.
The following codes are used to set the hook of thread generating events (CreateThread).

```assembly
KIRQL OldIrql;
KeRaiseIrql(HIGH_LEVEL, &OldIrql);

__asm{
PUSHAD

// for CreateThread()
MOV EAX, EBP       // Current EBP
MOV EAX, [EAX]     // Previous EBP (ASO_Hook_INT2BH)
MOV EAX, [EAX]     // Previous EBP (CreateThread)
ADD EAX, 0x10      // Stack + 10H (lpStartAddress)
MOV EBX, [EAX]     // EBX <- Thread address
CMP EBX, 0x7800BE4A // if EBX == _beginthread's start_address (2K+SP0) then

JNZ SET_MEMORYBREAK

// for _beginthread()
MOV EAX, EBP       // 現在の EBP
MOV EAX, [EAX]     // Previous EBP (ASO_Hook_INT2BH)
MOV EAX, [EAX]     // Previous EBP (CreateThread)
MOV EAX, [EAX]     // Previous EBP (_beginthread)
ADD EAX, 0x0C      // Stack + 0CH (start_address)
MOV EBX, [EAX]     // EBX <- Thread address

SET_MEMORYBREAK:

PUSH EBX           // Param1
CALL InstallNewInt01Handler
POPAD
}
```
4.10. About JMP ESP instruction

JMP ESP is necessary instruction to execute codes in stack area, as in the case of virus invaded through network. The program codes in stack area can be invaded through buffer overflow. JMP ESP instruction returns control of program codes. No matter the return address matches or not with the call origin, it will be on the list of prohibition. Because DOS and Windows of early versions use the way to run a program with limited memory, the program codes are created in stack area. In recent years, OS doesn't use this way so it can also be prohibited.
5. BOF test
5.1. BOF sample codes test
We have a simple BOF test that SQL slammer attacking to non-patched Microsoft SQL Server 2000 using an emulated program implemented slammer virus code. This emulated program, sqlslammer.exe, force to execute notepad up to infinity when the program attack to non-patched SQL Server. If you set enable for the immune system, the immune system can detect this attack and immediately kill the process of SQL Server.

5.2. BOF test of metamorphic coding type
Metamorphic coding will carry out the BOF detection. This detection by old way of signal pattern matching was quite hard. The metamorphic coding has generally three types

(1) Register replacement type
    POP EDX
    MOV EDI, 0008H
    MOV ESI,EBP
    MOV EAX 000DH
    ADD EDX, 005FH
    MOV EDX, [EDX]
    MOV [EDI+EAX*000000CC9,EBX]

    POP EAX
    MOV EDX,0008H
    MOV EDX,EBP
    MOV EDI,000DH
    ADD EAX,005FH
    MOV ESI,[EAX]
    MOV [EDX+EDI*000000CC9],ESI

(2) Magic number exchanging type
    MOV DWORD PTR [ESI],11000000H
    MOVDWORD PTR
    [ESI+0004],110000FFH
    MOV EDI,11000000H
    MOV [ESI],EDI
    POP EDI
PUSH EDX
MOV DH, 40
MOV EDX, 110000FFH
PUSH EBX
MOV EDX, EBX
MOV [ESI+0004], EDX
MOV EDX, 11000000H
MOV [ESI], EBX
POP EDX
PUSH ECX
MOV ECX, 11000000H
ADD ECX, 000000FFH
MOV [ESI+0004], ECX

(3) Control order changing type
INSTRUCTION_A
INSTRUCTION_B
INSTRUCTION_C:
LABEL_2:
INSTRUCTION_B
JMP
FAKE INSTRUCTIONS
LABEL_3:
INSTRUCTION_C
START::
LABEL_1:
INSTRUCTION_A

FAKE INSTRUCTIONS
In the three cases showed above, there is signature change after linkage. IMMUNE system successfully detected BOF and terminated the process since the buffer overflow generated in all the three cases.
6. Extension of IMMUNE system
6.1. For Windows XP machine

This system is suitable for Microsoft Windows 2000. The following points should be taken care when dealing with Windows XP.

① Operation after process detection

In Windows XP, the notice can't be captured even though the breakpoints were set at the very beginning of process. The following changes must be made.

```asm
 asm{
   PUSHAD
   MOV EAX, CR0;
   PUSH EAX
   AND EAX, ~0x10000
   MOV CR0, EAX       // Remove specialized memory flag of reading
}
char *TaleOfImage = (char *)((ULONG)ImageInfo->ImageBase + ImageInfo->ImageSize - 32);
```

if ((TaleOfImage[5] == (char)0xCD) && (TaleOfImage[6] == (char)0x20) && (TaleOfImage[7] == (char)0xE9)) {
    // Already patched
} else {
    // Replace the process
    memcpy(TaleOfImage, EntryPoint, 5);
    TaleOfImage[5] = (char)0xCD;       // INTxx
    TaleOfImage[6] = (char)0x20;       // 0x20
    TaleOfImage[7] = (char)0xE9;       // far JMP
    *(ULONG *)&TaleOfImage[8] = (ULONG)EntryPoint - (ULONG)TaleOfImage - 7;
    EntryPoint[0] = (char)0xE9;        // far JMP
    *(ULONG *)&EntryPoint[1] = (ULONG)TaleOfImage - (ULONG)EntryPoint - 5;
}
2) Detect the thread generating
The native API call mode of processor supporting SYSENTER/SYSEXIT instruction is changed in Windows XP. So, the old way of INT 2EH hook can’t be used any more. Only the native API service table replacement should be used.

KIRQL OldIrql:
KeRaiseIrql(HIGH_LEVEL, &OldIrql);

PServiceDescriptorTableEntry Table = &KeServiceDescriptorTable;
OldNtCreateThread = (NTCREATETHREAD)Table->ServiceTableBase[0x35];
Table->ServiceTableBase[0x35] = (unsigned int)NewNtCreateThread;

KeLowerIrql(OldIrql);
7. References

Appendix 1  Setup  
The component of the module

<table>
<thead>
<tr>
<th>Name</th>
<th>Remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>AntiStackOverflow.sys</td>
<td>IMMUNE Driver</td>
</tr>
<tr>
<td>ASOFace.exe</td>
<td>IMMUNE GUI</td>
</tr>
<tr>
<td>IMMUNE.reg</td>
<td>Registry file for starting IMMUNE Driver</td>
</tr>
</tbody>
</table>

Installation

1. Copy IMMUNE driver file
   Copy AntiStackOverflow.sys to the directory of %SystemRoot%\System32\drivers

2. Create registry
   Double click IMMUNE.reg to create a registry for starting the IMMUNE driver

3. Enable IMMUNE system
   Restart Windows

4. Customize detecting target process
   It's able to change the name of detecting target process by changing the value of the following registry.

   Key:
   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Antistackoverflow\Parameters
   Value: AppName
   The default value is sqlservr.exe
