### 14. ABSTRACT

Recently we generated a prostate specific chimeric promoter, called PSES, by combining the active prostate specific enhancers from PSA and PSMA genes which are prominently expressed in androgen independent prostate cancers. The goal of this research is to develop a novel therapeutic agent, Ad-IU-1, using PSES to control the replication of adenovirus and the expression of a therapeutic gene, herpes simplex thymidine kinase (TK). AD-IU-1 replicate as efficient as a wild type adenovirus in PSA/PSMA positive cells, but not in PSA/PSMA negative cells. Prodrug GCV augmented Ad-IU-1’s killing activity against PSA/PSMA positive cells, but not PSA/PSMA negative cells in vitro. Ad-IU-1 was more effective in inhibit the growth of androgen-independent CWR22rv tumors. Due to recent improvement in our adenoviral vector construction which allows us to insert a bigger transgene into the viral genome, we further investigated a fusing suicide gene, FCYttk, by combining two suicide genes, a yeast cytosine deaminase, FCY, and improved TK, ttk. FCYttk had a better killing activity than TK against prostate cancer cells. We are on the process of constructing FCYttk-armed prostate restricted replicative adenovirus for future clinical investigation.

INTRODUCTION

Metastatic human prostate cancer (PC) is commonly treated by hormone, radiation, and/or chemotherapy. Inevitably, these patients will eventually relapse and develop androgen-independent disease with osseous metastasis. Since no effective therapy is presently available for the treatment of PC metastasis, we are developing a novel gene therapy modality for hormonal refractory prostate cancer based on a prostate-specific chimeric promoter, PSES, generated in my laboratory. In this study, we proposed to generate a herpes simplex virus thymidine kinase armed prostate restricted replicative adenovirus to treat androgen-independent prostate cancers. Specific Aim 1 intends to simplify and combine the most important enhancer elements from PSA and PSMA enhancers/promoters to generate a strong and simple prostate-specific chimeric enhancer, sPSES. Specific Aim 2 will test whether sPSES retains prostate specific activity in an adenoviral vector. Specific Aim 3 will test whether sPSES can control adenoviral replication by controlling adenovirus E1a and E1b expression, and investigate how replication competent adenovirus eradicates prostate cancers by micro positron emission tomography (microPET) imaging.

BODY

Task 1. To generate a strong and simple prostate-specific enhancer. (Months 1-6):

a. Generate deletion construct (Months 1-4). We have successfully deleted L2 and L5 in AREc3 (Figure 1), and replaced the 90 bp proximal region GATATTATCTTCATGATCTTGGATTGAA

AACAGACCTACTCTGGAGGAACATATTGTTATTCGATTG

TCTTGACAGTAAACAAATCTTGTGTAAGAGACAT

TATCTTTATTATCTAGGACAGTAAGCAAGCCTGGA

CTGAGAGAGATATCATCTTGCAAGGATGCCTGCT

TTACAAACATCTCTTGAA

Figure 1. Sequences of the enhancer core of the PSA gene, AREc3, located the 4.3 kb upstream of PSA promoter. Sequence analysis on AREc3 revealed 6 putative GATA transcriptional factor binding sites besides reported 3 androgen response elements.

Figure 2. Sequences of PSME located in the third intron in the PSMA gene (FOLHI). PSME is characterized by the repeat sequence (marked by underline and bold) and an Alu sequence (marked by lower case). Several potential transcription factor binding sites, such as AP-1, AP-3, and SRY/SOX, are indicated.
(marked by italic in Figure 2) of PSME with simple AP-3 binding site. These manipulations reduced the size of PSES from 513 bp to 407 bp. The simplified version of PSES is called m6.

b. Test the tissue-specificity of new deletion constructs (Months 3-6). The tissue specific activity of m6 has been tested in several cell lines. Figure 3 demonstrated that m6 retained a strong prostate specificity, active only in PSA/PSMA positive prostate cancer LNCaP and C4-2 cells.

Figure 3. pGL3/m6/TATA (0.5 µg) was transfected into various cell lines (2 x 10⁵ cells for each). After 2 days, cells were harvested, lysed with passive lysis buffer (Promega) and analyzed for luciferase activities. This experiment was conducted in the absence of androgen. The luciferase activity was determined by being divided by the basal activity represented by transfection of pGL3/TATA. pGL3/m6/TATA is active only in PSA/PSMA positive LNCaP and C4-2 cells.

Task 2. To test tissue-specificity of the modified PSES chimeric enhancer, m6, in an adenoviral vector (Months 7-24):

a. Construct Ad-m6-Luc (Months 7-12). Ad-m6-Luc has been generated.

b. Test the tissue-specificity of Ad-m6-Luc in tissue culture cells (Months 13-18). Ad-m6-Luc exhibited the same prostate specificity in all cell lines tested. However, this study was not continued due to a technical difficulty in making Ad-IU-1 initially (see discussion below).

c. Test the tissue-specificity of Ad-m6-Luc in vivo (Months 19-22). This study was not continued due to a technical difficulty in making Ad-IU-1 initially (see discussion below).
Task 3. Investigate the capability of m6 to drive adenovirus replication in a prostate cancer-specific manner (Months 13-36):

a. Construct Ad-IU-1 (Months 7-16). The first attempt to make Ad-IU-1 according to the original plan has failed due to a size limitation of adenoviral vector. We have changed our construction strategy and made Ad-IU-1 as illustrated below.

b. In vitro test tissue-specific expression of TK, E1a and E1b proteins in Ad-IU-1 infected cells (Months 17-20). This study was skipped due to the unexpected difficulty in making AD-IU-1 originally.

c. In vitro test the tissue specific replication of Ad-IU-1 (Months 19-22). Ad-IU-1 replicated as efficient as AdE4PSESE1a, a PSES controlled replicative adenovirus, in PSA/PSMA positive cells, and its replication efficiency was dramatically attenuated in PSA/PSMA negative cells (see Table 1 in the attached manuscript).

d. In vitro test the therapeutic efficacy of Ad-IU-1 (Months 20-23). Ad-IU-1 had less toxicity than AdE4PSESE1a in treating PSA/PSMA positive cell in the absence of prodrug GCV; on the other hand, Ad-IU-1 was 10 to 100 fold more potent than AdE4PSESE1a in killing PSA/PSMA positive cell in the absence of the prodrug ganciclovir, GCV. Ad-IU-1 had minimal toxicity toward PSA/PSMA negative cells DU145 in the presence or absence of GCV (see Figure 2 in the attached manuscript).

e. In vivo test the therapeutic efficacy of Ad-IU-1 (Months 22-36). CWR22rv subcutaneous tumors in the castrated nude mice were used to test the therapeutic efficacy of Ad-IU-1. The therapeutic efficacy of Ad-IU-1 was significantly enhanced by GCV. Without GCV, Ad-IU-1 has a
similar therapeutic effect as AdE4PSESE1a on CWR22rv tumors (see Figure 4 and 5 in the attached manuscript).

f. MicroPET image C4-2 tumors (Months 9-20). It has been finished and published (see Reportable Outcomes section). In general, microPET imaging of tumor is less sensitive than PSA assay. The reviewers of this proposal also pointed out this problem.

g. MicroPET image the therapeutic effect of Ad-IU-1 (Months 21-36). We have made 8-[18F]-fluoropenciclovir for TK microPET imaging study (see Reportable Outcomes section). However, due to the unexpected delay of this project, this study is still ongoing.

Additional results: It has been reported that cytosine deaminase (CD)- thymidine kinase (TK) fusion fusion gene (CD/TK) exert a much better therapeutic effect than CD and TK themselves. CD/TK-based gene therapy has been studied extensively in clinic to treat prostate cancer by Svend O. Freytag (1-6). We constructed a fusion gene, FCYttk, between a yeast cytosine deaminase (FCY) and a modified thymidine kinase (ttk), an N-terminal deleted form of sr39TK. FCYttk demonstrated better killing activity than bacterial CD when supplemented with the prodrug 5-FC, and demonstrated similar killing activity to sr39TK when supplemented with the prodrug, GCV (unpublished data). We transfected pcDNA3.1-FCYttk expression vector into CWR22rv cells and treated the cells with PBS, GCV, 5-FC or GCV+5-FC. FCYttk/GCV/5-FC treatment exerted much stronger killing activity than FCYttk/GCV or FCYttk/5-FC treatment alone (Figure 4).

*Figure 4.* FCYttk in vitro cell killing assay. CWR22rv cells were seeded in a 24-well (1x10^5 cells/well) plate and transfected with pAd1020PSESFcyttk. The cells were treated with GCV (5 ug/mL), 5-FC (25 uM) 24 hours after transfection. Medium was changed every 2 days. At 5day, cell number was analyzed using crystal violet staining. GCV at 5 µg/ml and 5-FC at 25 uM concentration are no-toxic to CRW22rv (unpublished data).
We are on the process of constructing a FCYttk-armed prostate-restricted replicative adenovirus.
h. **KEY RESEARCH ACCOMPLISHMENTS**

1. Successfully shorten PSES as planned and demonstrate the prostate specific activity of the shortened form of PSES, m6.

2. Successfully construct Ad-m6-Luc and Ad-IU-1.

3. Have tested $[^{11}C]$-choline and $[^{18}F]$-FDG microPET imaging in prostate cancer nude mice model.

4. Successfully synthesize 9-(4-[18F]fluoro-3-hydroxymethylbutyl)guanine ([18F]FHBG) for microPET imaging Ad-IU-1 activity.

5. Ad-IU-1 demonstrated a prostate specific replication and killing activity.

6. The tumor killing activity of Ad-IU-1 is significantly enhanced by GCV as hypothesized originally.

**REPORTABLE OUTCOMES**

Some of the results of this study have been published.

**CONCLUSIONS**

We have successfully shortened PSES as planned and demonstrated the prostate specific activity of the shortened form of PSES, m6. We made a prostate restricted replicative adenovirus-armed with TK, Ad-IU-1, as proposed. Ad-IU-1 replicated efficiently in PSA/PSMA positive prostate cancer cells. Its replication efficiency was significantly attenuated in PSA/PSMA negative cells. Both in vitro and in vivo tumor-killing activities of Ad-IU-1 are significantly enhanced by the prodrug GCV as our original hypothesis. We are on the process of conducting a toxicology
studies to prepare Ad-IU-1 for clinical investigation. At the same time, we are improving Ad-IU-1 by replacing it TK gene with a more powerful suicide gene, FCYttk.

Abstract—Acyclic nucleoside 2-amino-6-(4-methoxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (ABE, 1) is a new hepatitis B virus (HBV) specific antiviral reagent and shows high anti-HBV activity. Carbon-11 labeled ABE may serve as a novel reporter probe for positron emission tomography (PET) to image HBV and herpes simplex virus thymidine kinase (HSV-tk) in cancers. The radiolabeling precursors 2-amino-6-(4-hydroxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (10) and 2-N-Boc protected analogue 2-N-bis(Boc)amino-6-(4-hydroxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (12), and the reference standard ABE were synthesized from bis(trifluoroethyl) (2-idoethoxy)methylphosphonate (5), guanine (6), and 2-amino-6-chloropurine (8). The target radiotracer 2-amino-6-(4-[11]C)methoxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester ([11]C]ABE, [11]C]J) was prepared by O-[11]C)methylation of the unprotected HO-precur sor 10, or 2-N-Boc protected HO-precur sor 12 with [11]C)methyl triflate followed by a quick deprotection reaction, and isolated by solid-phase extraction (SPE) purification in 40–55% radiochemical yields. © 2004 Elsevier Ltd. 1. Introduction

Hepatitis B virus (HBV) infection is responsible for both acute and chronic hepatitis. Chronic HBV infection dramatically increases risks for development of liver cancer and cirrhosis. 1–3 The World Health Organization (WHO) estimates about 400 million chronic carriers worldwide, with roughly 4 million deaths annually from the resulting cirrhosis and hepatocellular carcinoma. Treatment of HBV infection constitutes one of the therapeutic challenges in virology, and only a few drugs are currently available for the clinical treatment of HBV such as interferon α and lamivudine. 4 Several nucleoside analogues like 9-[2-(phosphonomethoxy) ethyl]adenine (PMEA) and its analogues, 5–8 ganciclovir (GCV), penciclovir (PCV), and 5-substituted analogue of thymidine 1-(2′-deoxy-2′-fluoro-β-D-arabinofuranosyl)-5-iodouracil (FIAU) have also been investigated as potent chemotherapeutic agents against viruses, for example, HBV and human immunodeficiency virus (HIV), and certain forms of cancer. 1–7 Radiolabeled fluorinated (fluorine-18) or iodinated (iodine-124, 125, and 131) produgs such as fluorinated GCV and PCV analogues 8-[18]F-fluoroganciclovir ([18]F]FGCV), 9-[3-[18]F]fluoro-1-hydroxy-2-propoxy)methyl]guanine ([18]F]FHPG), 8-[18]F-fluoropenciclovir ([18]F]FPCV), 9-[4-[18]F]fluoro-3-hydroxymethylbutyl]guanine ([18]F]FHBG); and fluorinated and iodinated FIAU analogues [18]F]FIAU, [124]I]FIAU, and [125]I]FIAU have been synthesized as gene reporter probes for biomedical imaging techniques positron emission tomography (PET) or single photon emission computed tomography (SPECT) to image herpes simplex virus thymidine kinase (HSV-tk) gene expression, 9–22 and we have also developed new carbon-11 labeled GCV and PCV analogues 8-[11]C)methoxyganciclovir ([11]C]MeO-GCV and
8-[11C]methoxypenciclovir ([11C]MeOPCV) as novel HSV-tk gene reporter probes (Fig. 1).23,24 2-Amino-6-(4-methoxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]-purine bis(2,2,2-trifluoroethyl) ester (ABE, 1) is a novel HBV-specific antiviral reagent and shows high anti-HBV activity in vitro, and its active metabolite was highly detected in the liver.4 Compound ABE might be suitable for hepatitis B chemotherapy. Carbon-11 labeled antiviral nucleoside analogue 2-amino-6-(4-[11C]methoxyphenylthio)-9-[2-(phosphonomethoxy)-ethyl]purine bis(2,2,2-trifluoroethyl) ester ([11C]ABE, [11C]I) may serve as a novel reporter probe for PET to image HBV and HSV-tk in cancers. In this study, we report the synthesis of [11C]ABE, for the first time.

2. Results and discussion

2.1. Chemistry

The synthesis of the unprotected HO-precursor 2-amino-6-(4-hydroxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (10) and reference standard ABE, I as indicated in Scheme 1 was performed with the modifications according to procedures reported in the literature.4 2-Chloroethyl chloromethyl ether (2) was treated with tris(2,2,2-trifluoroethyl)phosphate (3) to quantitatively give bis(trifluoroethyl)-2-chloroethoxy)methylphosphonate (4). Compound 4 was converted to bis(trifluoroethyl)2-iodoethoxy)methylphosphonate (5) with sodium iodide through halogen exchange reaction in 80% yield. Following the procedures reported in the literature,25 guanine (6) was treated first with trifluoroacetic anhydride and then with 4-methoxybenzenethiol and eventually with ethanolic methylamine to afford 2-amino-6-[4-methoxyphenyl]sulfanyl]purine (7) in 66% yield. Compound 7 was treated first with 1,8-diazabicyclo[5,4,0]undec-7-ene (DBU) and then with compound 5 to yield the reference standard 1 in 42% yield. 2-Amino-6-chloropurine (8) was treated first with DBU and then with compound 5 to provide desired 9-isomer N'-substituted product 2-amino-6-chloro-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (9) as the major product in 33% yield, and undesired 7-isomer N'-substituted product as the minor byproduct.18-20 Compound 9 was then reacted with 4-hydroxythiophenol to give the unprotected precursor 10 in 55% yield.

The synthesis of compound 1 has been reported in the reference,4 in which it was synthesized from compound 9 with 4-methoxybenzenethiol. In this paper, an improved synthetic approach25 through the reaction of compound 7 with compound 5 was used for the synthesis of compound 1. The purpose of this modification is to increase the yield of compound 1 through the avoidance of the formation and separation of undesired N'-substituted product, the 7-isomer of compound 9. However, the improved method25 did not work well for the synthesis of compound 10, since the hydroxyl group in 4-hydroxythiophenol will be also reacted with compound 9, therefore, the reported method4 through compound 9 appears to be the only approach to prepare compound 10.

The 2-amino group in purine ring may affect the O-[11C]methylation of the unprotected HO-precursor 10, therefore, we also designed and synthesized a 2-N-Boc protected HO-precursor 2-N-bis(Boc)amino-6-(4-hydroxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (12),26,27 The synthesis of the 2-N-Boc protected precursor 12 as outlined in Scheme 2 was performed with the modifications according to procedures indicated in the Scheme 1. Compound 9 was reacted with tert-butoxycarbonyl anhydride (Boc2O) to afford 2-N-bis(Boc)amino-6-chloro-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (11) in 77% yield. Compound 11

![Chemical structures](image)

was then reacted with 4-hydroxythiophenol to give the 2-N-Boc protected precursor 12 in 31% yield. The direct methylation of compound 12 with methyl triflate (CH₃OTf) gave the O-methylated product 2-N-bis(Boc)-amino-6-(4-methoxyphenylthio)-9-{2-(phosphonomethoxy)ethyl}purine bis(2,2,2-trifluoroethyl) ester (13) in very low yield, in which compound 13 will serve as a reference intermediate for the radiolabeling of 2-N-Boc protected precursor 12. Thus, the small-scale synthesis of compound 13 was carried out, in which the reference standard 1 was directly reacted with Boc₂O to provide compound 13 in 45% yield. The deprotection of compound 13 with 1N HCl in acetonitrile gave the reference standard 1. The methylation of 2-N-Boc protected precursor 12 with CH₃OTf under basic conditions using tetrabutylammonium hydroxide (TBAH) followed by a quick deprotection with 1N HCl to remove the 2-N-Boc groups also gave the reference standard 1.

2-Amino-6-(3-methoxyphenylthio)-9-{2-(phosphonomethoxy)ethyl}purine bis(2,2,2-trifluoroethyl) ester (meta-ABE, IC₅₀ 0.04 µM) and 2-amino-6-(2-methoxyphenylthio)-9-{2-(phosphonomethoxy)ethyl}purine bis(2,2,2-trifluoroethyl) ester (ortho-ABE, IC₅₀ 0.08 µM) have similar in vitro anti-HBV activity to the target compound 1 (para-ABE, IC₅₀ 0.03 µM). The potentiation effect order of 6-aryltio analogues is para > meta > ortho, which is consistent with the potentiation effect order of O₆-alkylguanine (O₆-BG) analogues most likely because the steric effect at the ortho-position plays a more important role than the electronic effect. Therefore, para-ABE was designed as the target compound for radiolabeling.

2.2. Radiochemistry

The synthesis of the target tracer [¹¹C]ABE, [¹¹C]I using both unprotected precursor 10 and protected precursor 12 are outlined in Schemes 1 and 2. The unprotected HO-precursor 10 was labeled by [¹¹C]methyl triflate (¹¹C)CH₃OTf through O₂[¹¹C]methylation of hydroxyphenyl position under basic conditions using TBAH. The tracer was isolated by solid-phase extraction (SPE) purification to produce pure target compound radiolabeled [¹¹C]I with 50–55% radiochemical yields, based on [¹¹C]O₂, decay corrected to end of bombardment (EOB). The large polarity difference between the HO-precursor and the labeled methylated product permitted the use of SPE technique for purification of labeled product from radiolabeling.
reaction mixture. The reaction mixture was diluted with NaHCO₃ and loaded onto C-18 cartridge by gas pressure. The cartridge column was washed with water to remove unreacted [¹¹C]OTf and precursor and reaction solvent, and then final labeled product was eluted with ethanol. Similarly, 2-N-Boc protected HO-precursor 12 was labeled with [¹¹C]CH₃OTf followed by a quick deprotection reaction with 1N HCl and isolated by SPE purification technique to produce [¹¹C]I in 40–55% radiochemical yields. Comparing the radiochemistry of unprotected precursor 10 and protected precursor 12, no distinct difference was found. It is likely the concern that 2-amino group in purine ring may affect the N-[¹¹C]methylation reaction of HO-precursor is unnecessary. The N' [¹¹C]methylation at 2-amino group in the purine ring is a potential competing reaction in comparison with the O-[¹¹C]methylation at 4-hydroxy group in the 6-(4-hydroxyphenylthio) ring. However, we do not have any evidence for labeling of the 2-amino group in the purine ring, it is consistent with our previous works on the synthesis of the radiolabeled O⁶-BG analogues. It is also consistent with the theoretical explanation that the deprotonation at the 4-hydroxyl group is easier than at the 2-amino group since the acidity of HO⁻ is greater than the acidity of H₂N⁻, and the [¹¹C]methylation with [¹¹C]methyl triflate will prefer to occur at the oxygen position rather than at the nitrogen position. The identity of the labeled product was determined by analytical high pressure liquid chromatography (HPLC) method, and the evidence provided by the exact same HPLC retention time data of the labeled product [¹¹C]I and reference standard 1 shows [¹¹C]methyl triflate does not label the 2-amino group and confirms the theoretical explanation. Chemical purity, radiochemical purity and specific radioactivity were determined by analytical HPLC method. The chemical purity of precursors 10, 12, and reference standard 1 was >97%. The radiochemical purity of target tracer [¹¹C]I was >95%, and the chemical purity of target tracer [¹¹C]I was >93%. The average (n = 3–5) specific radioactivity of target tracer [¹¹C]I was 0.6–0.8 Ci/μmol at the end-of-synthesis (EOS).

3. Conclusion
An efficient and convenient chemical and radiochemical synthesis of the unprotected precursor and 2-N-Boc protected precursor, reference intermediate and standard, and target tracer of ABE has been developed. Radiosynthesis produced [¹¹C]ABE in amounts and purity suitable for the preclinical application of [¹¹C]ABE in animal studies by PET imaging techniques. Labeled product suitable for injection, with the specific radioactivities in a range of 0.6–0.8 Ci/μmol at EOS, can be obtained in 20–25min from EOB, including SPE purification and formulation. These chemistry results provide the foundation for further biological evaluation of [¹¹C]ABE as a novel potential PET cancer imaging agent for hepatitis B virus and herpes simplex virus thymidine kinase in vivo.
4. Experimental

4.1. General

All commercial reagents and solvents were used without further purification unless otherwise specified. Melting points were determined on a MEL-TEMP II capillary tube apparatus and were uncorrected. \(^1\)H NMR spectra were recorded on a Bruker QE 400 NMR spectrometer using tetramethylsilane (TMS) as an internal standard. Chemical shift data for the proton resonances were reported in parts per million (\(\delta\)) relative to internal standard TMS (\(\delta\) 0.0). The low resolution mass spectra (LRMS) were obtained using a Bruker Biflex III MALDI-ToF mass spectrometer, and the high resolution mass spectra (HRMS) measurements were obtained using a Kratos MS80 mass spectrometer, in the Department of Chemistry at Indiana University. Chromatographic solvent proportions are expressed on a volume: volume basis. Thin layer chromatography was run using Analtech silica gel GF uniplates (5 × 10 cm²). Plates were visualized by UV light. Normal phase flash chromatography was carried out on EM Science silica gel 60 (230–400 mesh) with a forced flow of the indicated solvent system in the proportions described below. All moisture-sensitive reactions were performed under a positive pressure of nitrogen maintained by a direct line from a nitrogen source.

Analytical HPLC was performed using a Prodigy (Phenomenex) 5 µm C-18 column, 4.6 × 250 mm; 3:1:3 CH₃CN–MeOH–20mM, pH6.7 KH₂PO₄ mobile phase, 1.5mL/min flow rate, UV (240nm) and \(\gamma\)-ray (NaI) flow detectors. Semi-prep C-18 guard cartridge column 1 × 1 cm was obtained from E. S. Industries, Berlin, NJ, and part number 300121-C18-BD 10 µm. Sterile vented Millex-LG 0.22 µm vented filter unit was obtained from Millipore Corporation, Bedford, MA.

4.2. Bis(trifluoroethyl) (2-chloroethoxy)methylphosphonate (4)

Compound 4 was prepared by the reaction\(^4\) of 2-chloroethyl chloromethyl ether (2) with tris(2,2,2-trifluoroethyl)phosphine (3) as a colorless liquid in a quantitative yield, \(R_t = 0.58\) (1:1 hexane/EtOAc).

4.3. Bis(trifluoroethyl) (2-iodoethoxy)methylphosphonate (5)

Compound 5 was prepared by the reaction\(^4\) of compound 4 with sodium iodide as a light brown liquid in 80% yield, \(R_t = 0.31\) (CH₂Cl₂). \(^1\)H NMR (CDCl₃, ppm): \(\delta\) 4.40–4.55 (m, 4H, CH₂CF₃), 4.01 (d, 2H, \(J = 8.09\) Hz, OCH₂P), 3.86 (t, 2H, \(J = 6.61\) Hz, CH₂O), 3.27 (t, 2H, \(J = 6.62\) Hz, CH₂CH₂O). LRMS (FAB, \(m/z\)): 453 [M+Na]+, 100%. HRMS (FAB, \(m/z\)): calculated for C₁₃H₁₄F₃I₃NaO₃P 452.9163. Found: 452.9163.

4.4. 2-Amino-6-[(4-methoxyphenyl)sulfonyl]purine (7)

To a 250mL two-necked flask containing guanine (6, 5.00 g, 31.1 mmol) and dry pyridine (50mL) was added trifluoroacetic anhydride (17.0mL, 120 mmol) dropwise over a period of 10 min at 0°C. After 30 min, a solution of 4-methoxybenzenethiol (10mL, 81.3 mmol) in dry acetonitrile (10mL) was added dropwise over a period of 15 min. The reaction was allowed to warm up to rt and was stirred at rt overnight. Then ethanolic methylamine (16mL) was added and the solution was stirred at rt for 2h. After concentration under reduced pressure, the residue obtained was triturated with petroleum ether (bp 40–60°C) and was then collected by filtration. The solid was suspended in water (100mL), stirred, and filtered. Crystallization of the resultant solid from ethanol gave a colorless crystalline solid 7 (5.58 g, 66%), mp 259–260°C. \(^1\)H NMR (DMSO-d₆, ppm): \(\delta\) 12.54 (s, 1H, 9- NH), 7.93 (s, 1H, 8-CH), 7.49 (d, 2H, \(J = 8.82\) Hz, Ph), 7.00 (d, 2H, \(J = 8.82\) Hz, Ph), 6.13 (s, 2H, 2-NH₃), 3.79 (s, 3H, OCH₃). LRMS (FAB, \(m/z\)): 154 (100%), 296 [M+Na]+, 9.6%. HRMS (FAB, \(m/z\)): calculated for C₁₃H₁₁N₄NaO₃S 296.0582. Found 296.0582.

4.5. 2-Amino-6-(4-methoxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (ABE, 1)

To a 100mL two-necked flask were charged with compound 7 (1.00 g, 3.66 mmol), dry DMF (20mL) and DBU (0.6 mL, 4.01 mmol). The solution was heated at 80°C for 1h. Then compound 5 (1.74 g, 4.04 mmol) was added to the reaction mixture and the mixture was heated at 100°C overnight. Solvent was removed by rotatory evaporation, and the residue was dissolved in CH₂Cl₂ and transferred to the top of a silica gel column. The column was eluted with 50:1 CH₂Cl₂/MeOH to afford a white solid 1 (0.88 g, 42%), mp 84–85°C, \(R_t = 0.36\) (20:1 CH₂Cl₂/MeOH). The chemical purity (CP) of compound 1 was determined by analytical HPLC method, \(t_R = 6.95\) min, CPI = 99.4%. The analysis of the chemical purity of compound 1 was also confirmed by the \(^1\)H NMR method. \(^1\)H NMR (CDCl₃, ppm): \(\delta\) 7.70 (s, 1H, 8-CH), 7.52 (d, 2H, \(J = 8.09\) Hz, Ph), 6.93 (d, 2H, \(J = 8.83\) Hz, Ph), 4.90 (s, 2H, NH₂, D₂O exchangeable), 4.30–4.50 (m, 4H, OCH₂CF₃), 4.10–4.30 (m, 2H, NCH₂CH₂O), 3.85–4.01 (m, 4H, OCH₂P and NCH₂CH₂O), 3.82 (s, 3H, OCH₃).

4.6. 2-Amino-6-chloro-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (9)

Compound 9 was prepared by the reaction\(^4\) of 2-amino-6-chloropurine (8) with compound 5 in dry DMF and DBU as a white solid in 33% yield, mp 103–104°C, \(R_t = 0.26\) (25:1 CH₂Cl₂/MeOH). \(^1\)H NMR (CDCl₃, ppm): \(\delta\) 7.83 (s, 1H, 8-CH), 5.08 (s, 2H, 2-NH₂), 4.25–4.45 (m, 6H, NCH₂CH₂O and CH₂CF₃), 3.88–3.98 (m, 4H, OCH₂P and NCH₂CH₂O). LRMS (EI, \(m/z\)): 212 (100%), 471 (M⁺, 42%). HRMS (EI, \(m/z\)): calculated for C₁₃H₁₃Cl₂F₆N₂O₃P 471.0298. Found 471.0289.

4.7. 2-Amino-6-(4-hydroxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis(2,2,2-trifluoroethyl) ester (10)

Compound 10 was prepared by the reaction\(^4\) of compound 9 with 4-hydroxythiophenol in dry pyridine...
and dry DMF as a white solid in 55% yield, mp 55°C (dec.), Rf = 0.20 (25:1 CH₂Cl₂/MeOH). The chemical purity (CP) of compound 10 was determined by analytical HPLC method. tR 10 = 4.10 min, CP 10 = 98.7%. The analysis of the chemical purity of compound 10 was also confirmed by the 1H NMR method. 1H NMR (DMSO-d₆; ppm): δ 9.85 (s, 1H, OH, D₂O exchangable), 7.88 (s, 1H, 8-CH), 7.36 (d, 2H, J = 8.09 Hz, Ph), 6.83 (d, 2H, J = 8.83 Hz, Ph), 6.26 (s, 2H, 2-NH₂, D₂O exchangable), 4.55-4.73 (m, 4H, CH₂CF₃), 4.20 (q, 2H, J = 5.14 Hz, NCH₂CH₂O), 4.13 (d, 2H, J = 8.09 Hz, OCH₂P), 3.86 (t, 2H, J = 5.15 Hz, NCH₂CH₂O), LRMS (EI, m/z): 561 (M⁺, 100%). HRMS (EI, m/z): calcd for C₁₈H₁₃F₂N₄O₃S 561.0670. Found 561.0665.

4.8. 2-N-Bis(Boc)amino-6-chloro-9-[2-(phosphonomethoxy)ethyl]purine bis{2,2,2-trifluoroethy} ester (11)

To a 25 mL two-necked flask equipped with a stir-bar were charged with compound 9 (0.50 g, 0.066 mmol), 4-dimethylaminopyridine (DMAP, 0.010 g, 0.082 mmol), dry THF (10 mL), and Boc₂O (0.7 mL, 3.05 mmol). The reaction mixture was stirred at rt overnight. After removal of solvent, the residue was dissolved in CH₂Cl₂ and transferred to a silica gel column. The column was eluted with 50:1 CH₂Cl₂/MeOH to give a viscous solid 11 (0.55 g, 77%). Rf = 0.18 (50:1 CH₂Cl₂/MeOH). 1H NMR (CDCl₃, ppm): δ 8.22 (s, 1H, 8-CH), 4.32-4.52 (m, 6H, NCH₂CH₂O and CH₂CF₃), 3.98 (s, 1H, 5.15 Hz, NCH₂CH₂O), 3.94 (d, 2H, J = 7.35 Hz, OCH₂P), 1.47 (s, 18H, Boc). LRMS (EI, m/z): 471 (100%), 671 (M⁺, 2.1%). HRMS (EI, m/z): calcd for C₂₅H₂₅F₂N₅O₄P 671.1346. Found 671.1338.

4.9. 2-N-Bis(Boc)amino-6-[4-(4-hydroxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis{2,2,2-trifluoroethy} ester (12)

To a 25 mL two-necked flask fitted with a condenser were charged with compound 11 (0.52 g, 0.77 mmol), 4-hydroxythiophenol (0.12 g, 0.95 mmol), pyridine (0.2 mL), and DMF (5 mL). The mixture was heated at 60°C for 5h. After removal of solvent at 45–50°C, the residue was dissolved in CH₂Cl₂ and transferred to the top of a silica gel column. The column was eluted with 50:1 CH₂Cl₂/MeOH to give a white foam solid 12 (0.18 g, 31%). Rf = 0.15 (40:1 CH₂Cl₂/MeOH). The chemical purity (CP) of compound 12 was determined by analytical HPLC method. tR 12 = 2.68 min, CP 12 = 98.3%. The analysis of the chemical purity of compound 12 was also confirmed by the 1H NMR method. 1H NMR (CDCl₃, ppm): δ 8.07 (s, 1H, 8-CH), 7.46 (d, 2H, J = 8.83 Hz, Ph), 6.83 (d, 2H, J = 8.83 Hz, Ph), 5.73 (s, 1H, OH), 4.31-4.48 (m, 6H, NCH₂CH₂O and CH₂CF₃), 3.86-4.00 (m, 4H, NCH₂CH₂O and OCH₂P), 1.36 (s, 18H, Boc). LRMS (EI, m/z): 561 (100%), 761 (M⁺, 4%). HRMS (EI, m/z): calcd for C₂₃H₂₄F₂N₅O₄P 761.1719. Found 761.1721.

4.10. 2-N-Bis(Boc)amino-6-[4-(methoxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis{2,2,2-trifluoroethy} ester (13)

To a 100 mL two-necked flask containing compound 1 (0.10 g, 0.17 mmol), DMAP (0.001 g), and dry THF (30 mL) was added Boc₂O (0.16 mL, 0.70 mmol). The solution was stirred at rt overnight. Solvent was removed at reduced pressure. The residue was dissolved in CH₂Cl₂ and transferred to the top of a silica gel column. The column was eluted first with CH₂Cl₂, then 50:1 CH₂Cl₂/MeOH to afford a viscous solid 13 (0.060 g, 45%). Rf = 0.18 (50:1 CH₂Cl₂/MeOH). The chemical purity (CP) of compound 13 was determined by analytical HPLC method. tR 13 = 4.34 min, CP 13 = 97.8%. The analysis of the chemical purity of compound 13 was also confirmed by the 1H NMR method. 1H NMR (CDCl₃, ppm): δ 8.06 (s, 1H, 8-CH), 7.52 (d, 2H, J = 8.82 Hz, Ph), 6.92 (d, 2H, J = 8.82 Hz, Ph), 4.30-4.50 (m, 6H, NCH₂CH₂O and CH₂CF₃), 3.87-4.00 (m, 4H, NCH₂CH₂OCH₂P), 3.84 (s, 3H, OCH₃), 1.35 (s, 18H, Boc). LRMS (EI, m/z): 121 (100%), 775 (M⁺, 12.5%). HRMS (EI, m/z): calcd for C₂₅H₂₅F₂N₅O₄P 775.1876. Found 775.1879.

4.11. 2-Amino-6-[4-(11C)methoxyphenylthio)-9-[2-(phosphonomethoxy)ethyl]purine bis{2,2,2-trifluoroethy} ester ([11C]ABE, [11C]C1)

4.11.1. Starting from unprotected precursor 10. [11C]CO₂ was produced by the [14N(p,γ)]¹¹C nuclear reaction in small volume (12.3 cm³) aluminum gas target (CTI) from 11MeV proton cyclotron on research purity nitrogen (+3% O₂) in a Siemens radionuclide delivery system (RDS-112). The precursor 10 (0.6–1.0 mg) was dissolved in CH₃CN (300 µL). To this solution was added TBAH (2–3 µL, 1M solution in methanol). The mixture was transferred to a small volume, three-neck reaction tube. [11C]OTf that was produced by the gas-phase production method [22] from [11C]CO₂ through [11C]CH₄ and [11C]Br was passed into the air-cooled reaction tube at −15 to −20°C, which was generated by a Venturi cooling device powered with 100 psi compressed air, until radioactivity reached a maximum (~3 min), then the reaction tube was heated at 70–80°C for 3 min. The contents of the reaction tube were diluted with NaHCO₃ (1 mL, 0.1M). This solution was passed onto a C-18 cartridge by gas pressure. The cartridge was washed with H₂O (2 × 3 mL), and the aqueous washing was discarded. The product was eluted from the column with EtOH (2 × 3 mL), and then passed onto a rotatory evaporator. The solvent was removed by evaporation under high vacuum. The labeled product [¹¹C]CJ was formulated with NaH₂PO₄ (50mM), whose volume was dependent upon the use of the labeled product I in tissue biodistribution studies (~6 mL, 3 × 2 mL) or in micro-PET imaging studies (1–3 mL) of tumor-bearing athymic mice [25], sterile-filtered through a sterile vented Millex-GS 0.22 µm cellulose acetate membrane and collected into a sterile vial. Total radioactivity was assayed and total volume was noted. The overall synthesis, purification and formulation time was ~30 min from EOB. The decay corrected yield, from [¹¹C]CO₂ was 50–55%. Retention times in the analytical HPLC system were: tR 10 = 4.10 min, tR [¹¹C]CJ = 6.95 min.

4.11.2. Starting from protected precursor 12. The solution of the precursor 12 (0.6–1.0 mg) in CH₃CN (300 µL) and TBAH (2–3 µL, 1M solution in methanol) was reacted with [¹¹C]OTf. The radiolabeling mixture
containing [11C]13 in reaction tube was added with 1 N HCl (0.5 mL) and heated at 70-80°C for another 3 min. The contents of the reaction tube were diluted with NaHCO3 (0.5 mL, 0.1 M). The target tracer [11C]1 was isolated from the radiolabeling mixture by a C-18 cartridge through SPE purification in ~25 min with 40-55% radiochemical yield. Retention times in the analytical HPLC system were \( t_R 12 = 2.68 \) min, \( t_R [11C]13 = 4.34 \) min, \( t_R [11C]1 = 6.95 \) min.

Abstract—[11C]Choline has been evaluated as a positron emission tomography (PET) biomarker for assessment of established human prostate cancer tumor models. [11C]Choline was prepared by the reaction of [11C]methyl triflate with 2-dimethylaminoethanol (DMAE) and isolated and purified by solid-phase extraction (SPE) method in 60–85% yield based on [11C]CO2, 15–20 min overall synthesis time from end of bombardment (EOB), 95–99% radiochemical purity and specific activity >0.8 Ci/μmol at end of synthesis (EoS). The biodistribution of [11C]choline was determined at 30 min post iv injection in prostate cancer tumor models C4-2, PC-3, CWR22Rv, and LNCaP tumor-bearing athymic mice. The results showed the accumulation of [11C]choline in these tumors was 1.0% dose/g in C4-2 mouse, 0.4% dose/g in PC-3 mice, 3.2% dose/g in CWR22Rv mice, and 1.4% dose/g in LNCaP mice; the ratios of tumor/muscle (T/M) and tumor/blood (T/B) were 2.3 (T/M, C4-2), 1.4 (T/M, PC-3), 2.5 (T/M, CWR22Rv), 1.2 (T/M, LNCaP) and 2.6 (T/B, C4-2), 2.6 (T/B, PC-3), 7.8 (T/B, CWR22Rv), 3.2 (T/B, LNCaP), respectively. The micro-PET imaging of [11C]choline in prostate cancer tumor models was acquired from a C4-2, PC-3, CWR22Rv, or LNCaP implanted mouse at 30 min post iv injection of 1 mCi of the tracer using a dedicated high resolution (<3 mm full-width at half-maximum) small FOV (field-of-view) PET imaging system, IndyPET-II scanner, developed in our laboratory, which showed the accumulation of [11C]choline in C4-2, PC-3, CWR22Rv, or LNCaP tumor implanted in a nude athymic mouse. The initial dynamic micro-PET imaging data indicated the average T/M ratios were approximately 3.0 (C4-2), 2.1 (PC-3), 3.5 (CWR22Rv), and 3.3 (LNCaP), respectively, which showed the tumor accumulation of [11C]choline in all four tumor models is high. These results suggest that there are significant differences in [11C]choline accumulation between these different tumor types, and these differences might offer some useful measure of tumor biological process.

1. Introduction

Prostate cancer is the most commonly diagnosed cancer and is the second leading cause of cancer death in men over the age 40 in the United States. According to estimates, about 220,900 American men would be diagnosed with prostate cancer in the year of 2003 and 28,900 men would die from this disease. Detection of prostate cancer by various imaging methods is vital to overall management and treatment of prostate cancer patients. Biomedical imaging technique positron emission tomography (PET) coupled with appropriate radiopharmaceuticals has become a clinically valuable and accepted diagnostic tool to image prostate cancer. PET has been widely used in the diagnosis and staging of primary tumors, detection of subclinical disease, assessment of therapy response, and detection of recurrence.

The most widely used radiopharmaceutical for studies in oncology is [18F]-2-fluoro-2-deoxyglucose (FDG). FDG is the only PET cancer imaging agent used clinically. FDG has been reported to be an effective imaging agent for the detection of primary and metastatic prostate cancer. FDG-PET has been used successfully in an
increasing number of oncological applications and is considered a valuable adjunct to anatomic imaging methods, providing unique functional information for better characterization of disease. FDG has shown promise in predicting outcomes and detecting prostate tumors based on metabolic activity of the tumor(s); however, the low cellular uptake rate of FDG in prostate cancer limits its usefulness, and several other radiopharmaceuticals have been developed that evaluate prostate tumors based on other physiologic properties. For example, [11C]choline has been used as a PET tracer for human cancer detection and succeeded in visualizing prostate cancer and many other types of cancers in patients. [18F]Fluorocholine and F-18 labeled choline analogues also have been developed as new and promising oncologic PET tracers for prostate cancer and breast cancer in humans. However, the mechanism of the choline accumulation in tumors is not clear. The concept of [11C]choline as an oncologic PET tracer has been reported as follows. An elevated level of phosphatidylycholine has been revealed in tumors, which is the most abundant phospholipid in the cell membranes of all eukaryotic cells and provides a potential target for tumor imaging. This elevation is thought as the result of increased uptake of choline, a precursor of the biosynthesis of phosphatidylcholine. Thus, [11C]choline, [18F]Fluorocholine, and F-18 labeled choline analogues can be used as PET biomarkers for imaging choline kinase in cell membranes in cancers, and [11C]choline and [18F]Fluorocholine have been found clinically useful in humans for the study of prostate cancer.

PET has been used clinically to measure enzyme reactions, ligand–receptor interactions, cellular metabolism, and cell proliferation. Until recently, however, PET has not been suitable for small animal models because of resolution limitations. In an effort to develop novel prostate cancer biomarkers for molecular imaging, a series of PET cancer imaging agents that target either receptors or enzymes have been synthesized in this laboratory. In an effort to develop micro-PET instrumentation for small and intermediate sized animals imaging applications, high-resolution, high-sensitivity dedicated research scanners, IndyPET and IndyPET-II, have been designed and characterized by the same laboratory. Development of micro-PET instrumentation for small animal imaging and the availability of positron-emitting tracers have made this technology accessible for the noninvasive, quantitative, and repetitive imaging of biological function in living animals. Because small animal PET is immediately extrapolated to the clinic, laboratory advances should rapidly be translated to clinical practice. To the best of our knowledge, the [11C]choline study of the prostate cancer animal models is still not reported in the literature. We have used [11C]choline-PET for imaging of breast cancer animal models, and we extrapolated whether [11C]choline might be able to assess prostate cancer tumor models using micro-PET in vivo. In this paper, we evaluate the behavior of [11C]choline in four established human prostate cancer tumor models C4-2, PC-3, CWR22rv, and LNCaP tumor-bearing athymic mice.

2. Results and discussion

[11C]Choline was prepared by the reaction of [11C]methyl triflate with 2-dimethylaminoethanol (DMAE) and isolated and purified by solid-phase extraction (SPE) method in 60–85% yield based on [11C]CO2, 15–20 min overall synthesis time from end of bombardment (EOB), 95–99% radiochemical purity, and specific activity >0.8 Ci/μmol at end of synthesis (EOS). [11C]Choline was synthesized before by others using very similar chemistry. The difference in the present paper is that [11C]methyl triflate is used instead of [11C]methyl iodide, in which [11C]methyl triflate is a proven methylation reagent with greater reactivity than [11C]methyl iodide. A simple home-built technique for convenient labeling and isolation of [11C]-methylquaternary amines by N-11C-methylation method was employed in the radiosynthesis of [11C]choline. The quality control (QC) process to determine the radiochemical purity of [11C]choline and the quantity of DMAE in the final product was performed using HPLC methods. The UV-detector we used did have the detection threshold for DMAE, and we did establish the retention time of DMAE, however, the chromatogram obtained from the HPLC system that we utilized did not show the peak of DMAE in the final [11C]choline solution. It was therefore impossible to determine accurately the quantity of DMAE in the final product. The published QC data for the concentration of DMAE in the final solution were 9–13 ppm using two separate reverse phase HPLC methods and 6.9 ppm using cation-exchange chromatography, which employed the same SPE technique for the [11C]choline synthesis. The final solution of [11C]choline with low concentration of starting material we prepared is suitable for injection in animals.

2.2. Prostate cancer tumor models

The prostate cancer tumor models we used were the human prostate cancer/athymic mouse xenograft models implanted with several popular human prostate cancer cell lines C4-2, PC-3, CWR22rv, and LNCaP. LNCaP, an androgen-responsive, androgen receptor (AR) positive, prostate-specific antigen (PSA) secreting human prostate cancer cell line, was derived from a cervical lymph node metastasis by Horoszewicz et al. It serves as a parental cell line. C4-2 is a hormone-refractory derivative of the LNCaP epithelial prostate cancer cell line that was derived by passing through castrated mice and remains AR- and PSA-positive. PC-3 is an androgen-independent (AI), AR-, and PSA-negative human prostate cancer cell line established by Kaighn et al. from the bone marrow aspirates of a patient with confirmed metastatic disease. CWR22rv is one of the more recently developed transplantable human prostate tumor models. This tumor exhibits androgen-dependent growth and PSA secretion in male nude athymic mice and regresses in response to androgen withdrawal. The CWR22rv cell line is a valuable model for the study of androgen-independent prostate cancer.
tool for studying prostate cancer progression to a hormone-refractory state, because it possesses features of clinical advanced disease: AR expression, AI proliferation, and androgen-responsiveness. It serves as a model possessing an intermediate, or transition, phenotype between that of hormone-sensitive, AR-positive cell lines (e.g., LNCaP) and AI-, AR-negative cell lines (e.g., PC-3). These models have proven to be useful and become popular for investigations of human prostate cancer.

2.3. In vivo biodistribution of $^{11}$C]choline in tumor models

In vivo biodistribution data of $^{11}$C]choline in C4-2, PC-3, CWR22rv, and LNCaP tumor cell lines implanted athymic mice are indicated in Table 1. Since it was difficult to generate C4-2 tumor model, we only had one C4-2 tumor-bearing mouse for the biodistribution study. The data presented here for PC-3 and CWR22rv tumor-bearing mice represented the average value in three mice, and the data presented here for LNCaP tumor-bearing mice represented the average value in five mice. The average values were taken not only over several mice, but also over the several tumors in each mouse. In C4-2, PC-3, CWR22rv, and LNCaP tumor-bearing athymic mice, the liver and kidneys were found to show very high accumulation of $^{11}$C]choline, consistent with findings using $^{18}$F]fluorocholine in CWR22rv and PC-3 xenografts. In comparison with heart, liver, lungs, spleen, kidneys, and small intestine, biodistribution studies of $^{11}$C]choline in four prostate cancer tumor models did not show higher accumulation in tumors than in other tissues; and in comparison with blood, brain, bone, and muscle, biodistribution studies of $^{11}$C]choline in four prostate cancer tumor models did show higher accumulation in tumors than in other tissues. The ratios of tumor/muscle (T/M) and tumor/blood (T/B) may serve as the important parameters to guide in vivo evaluation of $^{11}$C]choline as a PET biomarker in prostate cancer tumor models. In general, the higher T/M and T/B ratios will show the higher tumor accumulation of tracer in biodistribution studies, and tumors will be more visible with the tracer in micro-PET imaging studies. In order to be able to claim that the tumor accumulation of the tracer is high, the lower threshold for T/M and T/B ratios should be set at least more than 1. The biodistribution study results of T/M and T/B ratios presented here are very similar or superior to the reported findings using $^{18}$F]FDG (T/M: 1.4; T/B: 4.4) and $[^1]	ext{C}]$acetate (T/M: 1.5; T/B: 2.2) in CWR22rv xenografts. The biodistribution data are similar in LNCaP and C4-2 mice, and different in PC-3 and CWR22rv mice, since the biological properties between LNCaP tumor and C4-2 tumor are similar, and the biological properties between LNCaP, C4-2 tumors and PC-3 tumor and CWR22rv tumor are different. These results suggest the differences in radioactivity retention in tumors might be in relation to biological differences between these various cell lines.

2.4. IndyPET-II scanner

The animal PET scanners, IndyPET and IndyPET-II, were designed and developed by Hutchins and co-workers. These are high resolution (<3 mm full-width at half-maximum), high sensitivity, research PET scanner developed for small field-of-view (FOV) imaging applications including rodent imaging (mice and rats), intermediate size animals (dogs, pigs, and primates), and dedicated human imaging applications (brain, breast). The micro-PET scanner we used is IndyPET-II scanner.

2.5. In vivo micro-PET imaging of $^{11}$C]choline in tumor models

Tumor-specific micro-PET imaging was performed using the IndyPET-II scanner for 15 min static scans after an initial 30 min accumulation period of $^{11}$C]choline. In vivo micro-PET images of $^{11}$C]choline in C4-2, PC-3, CWR22rv, and LNCaP tumors implanted in a nude athymic mouse are shown in Figure 1. The PET images show a lot of accumulation of the tracer in the liver. The regions of the tumor are difficult to decipher from the images, because the activity spilling over from the liver might result in overestimation of tumor accumulation. The tracer retention in C4-2 tumor mouse and

LNCaP tumor mouse is clear, and the C4-2 tumor and LNCaP tumor in micro-PET images are visible. The tracer retention in PC-3 tumor mouse and CWR22rv tumor mouse in micro-PET images is unclear, which is not consistent with their biodistribution data.

In order to quantify PET data, the initial dynamic micro-PET imaging studies were performed in C4-2, PC-3, CWR22rv, and LNCaP tumor-bearing mice. The time activity curves for T/M ratios versus time are shown in Figure 2 (a. C4-2 tumor; b. PC-3 tumors; c. CWR22rv tumor; d. LNCaP tumors) with the average T/M ratio at an approximate value 3.0 (C4-2), 2.1 (PC-3), 3.5 (CWR22rv), and 3.3 (LNCaP), respectively. The T/M ratio found from dynamic PET data is systematically much higher than that from biodistribution data. A region of interest (ROI) was placed on the organ or tumor of interest in the transaxial micro-PET images that include the entire organ or tumor volume. The average radioactivity concentration within a tumor or an organ was obtained from the average pixel values within the multiple ROI volume. The T/M ratio data showed the tumor retention of [11C]choline in all four prostate cancer tumor models is high. T/M is more or less constant over the whole time period. This is also the case for T and M or both were increasing or decreasing at a same rate. Figure 2 demonstrated both the differences in reproducibility between tumor types and the obvious differences in kinetics between tumors. These differences are correlated with both the biodistribution data and the cell biology of the various tumor lines. In particular, the tumors with the highest overall accumulation of radioactivity (CWR22rv tumor, 3.16% dose/g) also had the more protracted uptake phase. This is also the similar case in LNCaP tumor (1.36% dose/g). It is likely the highest overall retention of radioactivity in tumors would accumulate more slowly. The dynamic IndyPET-II data are similar in LNCaP and C4-2 mice, and different in PC-3 and CWR22rv mice, because the cell biology between LNCaP tumor and C4-2 tumor are similar, and the cell biology between LNCaP, C4-2 tumors and PC-3 tumor and CWR22rv tumor are differ-
ent. These results suggest the kinetic differences in radioactivity accumulation in tumors might be in relation to cell biology differences between these various cell lines.

It is interesting to note that the tumor/muscle ratios of biodistribution studies are lower than the micro-PET derived ratios in all the four models. This is unusual and the opposite finding (i.e., lower ratios by micro-PET may have been expected). This might suggest that the ROI's in PET images need to be carefully examined. With the IndyPET-II scanner, a mouse study had a quantitative accuracy of less than 10% in error, and most within the 3% range, regardless of whether the ROI is superficial or deep within the mouse body. The partial volume effect in estimating the ROI values from micro-PET images were small in these IndyPET-II scans because the resolution of the IndyPET-II scanner is around 2.5 mm and the implanted prostate tumors were in the range of 1 cm or more than 1 cm in diameter, which was well above the resolution limit of this animal PET system. Moreover, the dynamic IndyPET-II imaging studies were co-registered with the EVS RS-9 micro-CT imaging studies, which helped to select and draw ROI. Therefore, we conclude the dynamic IndyPET-II data are more reliable and less partial volume effects were involved. However, the discrepancy between biodistribution and micro-PET data need to be further studied.

3. Conclusion

In summary, we have developed a simple technique for the radiosynthesis and routine production of $[^{11}]$Ccholine. In vivo biodistribution studies and in vivo micro-PET images of $[^{11}]$Ccholine in prostate cancer athymic mice showed that $[^{11}]$Ccholine had different accumulation with C4-2, PC-3, CWR22rv, and LNCaP tumors. These results suggest that there are significant differences in $[^{11}]$Ccholine accumulation between these different tumor types, and these differences might offer some useful measure of tumor biological process.
4. Materials and methods

4.1. General

All commercial reagents and solvents were used without further purification. The \(^{13}C\)methyl triflate was made according to the literature procedures \(^{26,31}\) by the metathetical reaction of \(^{13}C\)methyl bromide over a hot column of silver triflate supported on porous graphite. One silver triflate column was used for 20–40 \(^{13}C\)methyl triflate runs before replacement.

Analytical HPLC was performed using a Prodigy (Phenomenex) 5 \(\mu\)m C-18 column, 4.6×250 mm; 3:1:1 CH\(_3\)CN/MeOH/20 mM, pH 6.7 KH\(_2\)PO\(_4\) mobile phase, flow rate 1.5 mL/min, and UV (240 nm) and \(\gamma\)-ray (NaI) flow detectors. Semi-prep C-18 SiO\(_2\) Sep-Pak type cartridges were obtained from Waters Corporation, Milford, MA. Sterile vented Millex-GS 0.22 \(\mu\)m vented filter units were obtained from Millipore Corporation, Bedford, MA.

4.2. Synthesis of \(^{13}C\)choline

The precursor 2-dimethylaminomethanol (10 \(\mu\)L) was dissolved in acetonitrile (250 \(\mu\)L). The mixture was transferred to a small volume, three-neck reaction tube. \(^{13}C\)Methyl triflate was passed into the air-cooled reaction tube at \(-15\) to \(-20^\circ\)C, which was generated by a Venturi cooling device powered with 100 psi compressed air, until activity reaches a maximum (2–3 min), then the reaction tube was isolated and heated at 70–80 \(^\circ\)C for 2–3 min. The reaction tube was connected to the SiO\(_2\) Sep-Pak type cartridge. The product solution was passed onto the Sep-Pak cartridge for solid-phase extraction (SPE) by gas pressure. The reaction tube and Sep-Pak were washed with ethanol (2×5 mL), and the washing solution was discarded to a waste bottle. The product was eluted from the Sep-Pak with 90:8:2 H\(_2\)O/EtOH/HOAc (4.6 mL) and sterile-filtered through a 0.22 \(\mu\)m cellulose acetate membrane and collected into a sterile vial. The pH was adjusted to 5.5–7.0 with 2 M NaOH and 150 mM Na\(_2\)HPO\(_4\) mixed solution (1:20, ~0.4 mL). Total radioactivity was assayed and the total volume was noted. The overall synthesis time was 15–20 min. The decay-corrected yield, from \(^{13}C\)O\(_2\), was 60–85%, and the radiochemical purity was 95–99% by analytical HPLC method. Retention times in the analytical HPLC system we utilized were 2.0 min for \(^{13}C\)choline and 2.4 min for DMAE.

4.3. Prostate cancer athymic mice

All animal experiments were performed under a protocol approved by the Indiana University institutional animal care and use committee. Six weeks old male, athymic nude mice (Harlan) were used for the generation of subcutaneous prostate tumor xenografts. For the generation of C4-2 and LNCaP models, 10 million cells (per injection site per animal) in the log phase were gently mixed with 100 \(\mu\)L of ice cold Matrigel (Becton-Dickinson Biosciences) and injected in the lower flank region of the mouse using a 27 gauge 1/2 cc syringe. For generating PC-3 tumors 2 million cells/injection site per animal were used without any Matrigel. CWR22rv tumors were generated by injecting 5 million cells in the presence of Matrigel per injection site per animal. Palpable tumors became evident within 4–8 weeks post-implantation. The size of the palpable tumors was in the range of 1 cm or more than 1 cm in diameter. The tumors were firm without necrotic tissue around the tumors. The tumor sizes varied between the different models.

4.4. Biodistribution studies of \(^{13}C\)choline in prostate cancer athymic mice

Athymic mice 8 weeks post-xenograft implantation were injected intravenously with sub-pharmacologic doses (1–3 mCi) of \(^{13}C\)choline via the tail vein while under conscious restraint. At 30 min post injection, mice were sacrificed by decapitation under halothane anesthesia, their tissues quickly excised, weighed, and the decay-corrected radioactive content measured using an auto Packard Cobra Quantum gamma counter. The tissue localization at 30 min time point, expressed as % of injected dose per gram of tissue (% dose/g), weight normalized % dose/g and % of injected dose per organ were calculated from the tissue count and weight data using an Excel spreadsheet program.

4.5. Micro-PET imaging of \(^{13}C\)choline in prostate cancer athymic mice

The IndyPET-II scanner was used for these studies. The mouse was anesthetized with acepromazine (0.2 mg/kg, i.m.) and xylene (0.2 mg/kg, i.m.). One millicurie of \(^{13}C\)choline was administered intravenously to the mouse in tail vein. The micro-PET imaging of \(^{13}C\)choline in prostate cancer athymic mice was acquired by the ordered subsets expectation maximization (OSEM) using six subsets/four iterations for 5 min from a C4-2, PC-3, CWR22rv, or LNCaP tumor-bearing mouse at 30 min post iv injection of 1 mCi of the tracer. Dynamic imaging was performed for 60 min starting at the injection of 1 mCi of \(^{13}C\)choline to each mouse. The frame durations were defined as 300 s for entire 3600 s scan. All images were acquired in list-mode and sorted into 15×20 frames, 10×60 frames, and 9×300 frames. Images were reconstructed using filtered back projection with a 70% Hanning filter (4.242 cm\(^{-1}\) cutoff frequency).

ABSTRACT

An improved total synthesis of [18F]FHBG starting from triethyl-1,1,2-ethanetricarboxylate and 2-amino-6-chloropurine is reported. [18F]FHBG was prepared by nucleophilic substitution of the appropriate precursor with [18F]KF/Kryptofix 2.2.2 followed by a quick deprotection reaction and purification with a simplified Silica Sep-Pak solid-phase extraction (SPE) method in 20–25% radiochemical yield.

INTRODUCTION

In an effort to develop novel cancer biomarkers for molecular imaging, a series of positron emission tomography (PET) cancer imaging agents that target either receptors or enzymes have been synthesized in this laboratory. In the past, we have synthesized several carbon-11, fluorine-18 and iodine-123/125 labeled quinazoline derivatives for epidermal growth factor receptor (EGFr) imaging, numerous carbon-11 labeled matrix metalloproteinase inhibitors that target enzymes matrix metalloproteinases, which are overexpressed in human malignant tumor tissues of various organs including the breast, prostate, stomach, colon, and lung, as well as a number of carbon-11 labeled O6-benzylguanine derivatives that target human DNA repair protein alkylguanine-DNA alkyltransferase overexpressed in many cancer types. We also prepared [11C]choline as PET cancer imaging agent to study phosphatidylcholine in cancers. The objective of this study was to synthesize PET gene reporter probes such as fluorine-18 labeled ganciclovir (GCV, 9-[(1,3-dihydroxy-2-propoxy)methyl]guanine) and penciclovir (PCV, 9-[4-hydroxy-3(3-hydroxyalkoxy)methyl]guanine) analogs 8-[18F]fluorganciclovir ([18F]FGCV), 9-[3-(3-[18F]fluoro-1-hydroxy-2-propoxy)methyl]guanine ([18F]FHPG); 8-[18F]fluoropenciclovir ([18F]FPCV), 9-(4-[18F]fluoro-3-hydroxymethylbutyl)guanine ([18F]FHBG) for in vivo imaging of herpes simplex virus thymidine kinase (HSV-tk) expression. In our previous work, we have reported an improved total synthesis of [18F]FHPG. Here, we report an improved total synthesis of [18F]FHBG, which includes full experiment procedures, yields, analytical details and new findings in synthetic methodology for target tracer [18F]FHBG, as well as key intermediate PCV and tosylated precursor.

RESULTS AND DISCUSSION

1. Synthesis of Penciclovir

The synthesis of penciclovir (PCV) as indicated in Sch. 1 was performed with the modifications according to procedures reported in the literature. The commercially available starting material triethyl-1,1,2-ethanetricarboxylate (2) was converted into 2-(hydroxymethyl)butane-1,4-diol (3) through key intermediate Penciclovir (PCV) and tosylated precursor.
reduction reaction with excessive sodium borohydride (NaBH₄) in tert-butyl alcohol in a yield of 66%. The crude product contained a polar contaminant that was suspected to be boric acid resulted from hydrolysis of NaBH₄. Although the contaminant did not affect the further use of 3, it was convenient to remove it by column chromatography (10:1 EtOAc/MeOH). Using lithium aluminum hydride (LAH) instead of NaBH₄ resulted in a mixture of two unidentified components. The ¹H NMR spectrum of pure 3 (in D₂O) showed four multiplets corresponding to the CH and CH₂-functions in the molecule. The selective 1,3-protection of the triol 3 was achieved through the reaction with 2,2-dimethoxypropane catalyzed by p-toluenesulfonic acid. The reaction took 19 hours to produce 1,3-dioxane (4) in 57%. A small amount of 7-membered ring by-product was also formed. The separation of the desired 6-membered ring product from the undesired 7-membered ring by-product proved to be successful by column chromatography (2:1 EtOAc/hexane). Bromination of compound 4 with carbon tetrabromide and triphenylphosphine afforded the 2-bromoethyl-1,3-dioxane (5). As compound 5 decomposed
readily at room temperature, the reaction and work-up should be performed at 0°C, including removal of solvent. Purification of 5 was impracticable and unnecessary. Coupling of crude bromide 5 with 2-amino-6-chloropurine under a basic media gave a mixture of undesired 7-isomer purine (6b) and the desired product 9-isomer purine (6a) in 4% and 54%, respectively. The TLC (EtOAc) R\textsubscript{f} values of the isomers were 0.32 and 0.31 for 6b and 6a, respectively, and careful column chromatography with ethyl acetate as eluant made the separation possible. 7-isomer 6b is new and was fully characterized for the first time. \textsuperscript{1}H NMR, LRMS, HRMS and elemental analysis data of 6b confirmed its structure. Hydrolysis of 9-isomer 6a with aqueous hydrochloric acid at reflux, followed by neutralization and filtration, afforded PCV 7 in 80% yield.

The overall chemical yield of PCV from 2 was 16%.

2. Synthesis of FHBG (1) and Radiosynthesis of \textsuperscript{[18F]}FHBG (1)

The synthesis of a standard sample FHBG (1) and target tracer \textsuperscript{[18F]}FHBG (1) as indicated in Sch. 2 was performed with the modifications reported in the literature.\textsuperscript{15,25,33,34} The protection of the 2-amino group and one of the hydroxyl groups of PCV, 7 was achieved by reacting with monomethoxytrityl chloride in the presence of 4-dimethylaminopyridine (DMAP) and triethylamine.\textsuperscript{30} Using 2.5 equivalent of monomethoxytrityl chloride at 50–60°C, the desired product \textsuperscript{N\textsuperscript{2}}-(p-anisyldiphenylmethyl)-9-[(4-hydroxy)-3-p-anisyldiphenylmethoxymethylbutyl]guanine (8a) was obtained in 53% yield, and formation of the undesired fully protected by-product \textsuperscript{N\textsuperscript{2}}-(p-anisyldiphenylmethyl)-9-[(4-p-anisyldiphenylmethoxy)-3-p-anisyldiphenylmethoxymethylbutyl]guanine (8b) could be limited to 16%. The compounds were separated by chromatography. Compound 8a reacted with p-tosyl chloride at room temperature overnight afforded the desired precursor tosylate (9a) in 29%, together with undesired by-product (9b) in 22%. The compounds were separated by chromatography and their structures confirmed with extensive \textsuperscript{1}H NMR data.\textsuperscript{15,25,30,33,34} Fluorination of tosylate 9a with anhydrous potassium fluoride in dry acetonitrile catalyzed by Kryptofix 2.2.2 gave intermediate 4-fluoroguanine 10 in 69%. Intermediate 10 was easily hydrolyzed by treatment with 1 N HCl aqueous solution to give the unlabeled standard sample FHBG, 1 in 97%.

The overall chemical yield of the tosylate precursor 9a from PCV was 15%, and the overall chemical yield of the standard sample FHBG, 1 from PCV was 10%.
[18F]FHBG (1) was synthesized by a modification of the procedures reported in the literature.[15,33,34] The tosylated precursor 9a was labeled by conventional nucleophilic substitution with K[18F]/Kryptofix 2.2.2 in CH3CN at 120°C for 20 min to provide the radiolabeled intermediate 10. The radiolabeling reaction was monitored by analytical radio-HPLC method by using a Prodigy (Phenomenex) 5 µm C-18 column, 4.6 x 250 mm; 3:1 CH3CN:MeOH; 20 mM, pH 6.7KH2PO4 mobile phase, 1.5 mL/min flow rate, and UV (240 nm) and γ-ray (NaI) flow detectors. Retention times in the analytical HPLC system were: RT10 = 17.50 min, RTK[18F] = 1.88 min. The radiolabeling mixture containing the intermediate 10 was passed through a Silica Sep-Pak column to remove Kryptofix 2.2.2 and non-reacted potassium [18F]fluoride. The large polarity difference between 10 and Kryptofix 2.2.2 and non-reacted potassium [18F]fluoride permitted the use of a simple
solid-phase extraction (SPE) technique\textsuperscript{[14,39,40]} for fast isolation of 10 from the radiolabeling reaction mixture. The key part in this technique is a SiO\textsubscript{2} Sep-Pak type cartridge, which contains \(0.5–2\) g of adsorbent. The Sep-Pak was eluted with 15\% MeOH/CH\textsubscript{2}Cl\textsubscript{2} and the solvent was evaporated under high vacuum (0.1–1.0 mmHg) to give the residue 10. As remaining catalyst Kryptofix 2.2.2 and non-reacted potassium \([^{18}\text{F}]\)fluoride would affect the deprotection reaction of 10, they had to be removed prior to deprotection of 10. Compound 10 was treated with 1 N HCl at 80\(^\circ\)C for 10 min and the reaction mixture neutralized with 6 N NaOH to provide 1. To simplify the synthetic procedure, the final reaction mixture was purified with the SPE method instead of HPLC which makes it amenable to automation.\textsuperscript{[33]} The crude product was passed through a Silica Sep-Pak column to remove radioactive by-product with ethanol. The large polarity difference between 1 and the radioactive by-product permitted the use of SPE technique for fast purification of radiotracer 1. The radiochemically pure compound 1 was isolated from the Sep-Pak using a 90 : 8 : 2 H\textsubscript{2}O/EtOH/HOAc eluant and the combined product containing fraction was treated with 2 M NaOH and 150 mM Na\textsubscript{3}PO\textsubscript{4} mixed solution to adjust to pH 5.5–7.0. The radiochemical yield of 1 was 20–25\%, and the synthesis time was \(\sim 70\) min from end of bombardment (EOB). Chemical purity, radiochemical purity, and specific radioactivity were determined by analytical HPLC. Retention times in the analytical HPLC system were: \(\text{RT}_{9a} = 19.80\) min, \(\text{RT}_1 = 1.80\) min. The chemical purity of precursor 9a and standard sample 1 was \(>95\%\). The radiochemical purity of target radiotracer 1 was \(>99\%\), and the chemical purity \(\sim 93\%\). The average (\(n = 3–5\)) specific radioactivity of radiotracer 1 was 0.8–1.2 Ci/\(\mu\)mol at end of synthesis (EOS).

In comparison with the results reported in the literature,\textsuperscript{[15,25,33,34]} several improvements in the synthetic methodology for FHBG and \([^{18}\text{F}]\)FHBG have been made. They include increased radiochemical yield and specific activity, enhanced radiochemical purity, shortened synthesis time, new dual Sep-Pak techniques for fast and efficient preparative separation of \([^{18}\text{F}]\)FHBG from precursors, and new HPLC systems for the quality control (QC) method of target tracer \([^{18}\text{F}]\)FHBG.

Compounds 6b, 8b, and 9b are new compounds.

In conclusion, an improved total synthesis of \([^{18}\text{F}]\)FHBG has been developed. Several improvements and new findings in the synthetic methodology, radiolabeling, preparative separation and analytical details for PCV, FHBG, precursor and \([^{18}\text{F}]\)FHBG have been made and addressed. This improved method is efficient and convenient. It is anticipated that the approaches and improvements described here can be applied with advantage to the synthesis of other radiolabeled GCV and PCV analogs for PET imaging of HSV-tk gene expression.
EXPERIMENTAL

All commercial reagents and solvents were used without further purifica-
tion unless otherwise specified. Tetrahydrofuran (THF) solvent was distilled
from LiAlH₄ immediately prior to use. Melting points were determined on a
MEL-TEMP II capillary tube apparatus and were uncorrected.¹H NMR spectra
were recorded on a Bruker QE 300 NMR spectrometer using tetramethylsilane
(TMS) as an internal standard. Chemical shift data for the proton resonances
were reported in parts per million (δ) relative to internal standard TMS (δ 0.0).
The low resolution mass spectra were obtained using a Bruker Biflex III
MALDI-Tof mass spectrometer, and the high resolution mass measurements
were obtained using a Kratos MS80 mass spectrometer, in the Department of
Chemistry at Indiana University. Elemental analysis was performed by
Midwest Microlab (Indianapolis, IN). Chromatographic solvent proportions
are expressed on a volume: volume basis. Thin layer chromatography was run
using Analtech silica gel GF uniplates (5 × 10 cm²). Plates were visualized by
UV light. Normal phase flash chromatography was carried out on EM Science
silica gel 60 (230–400 mesh) with a forced flow of the indicated solvent
system in the proportions described below. All moisture-sensitive reactions
were performed under a positive pressure of nitrogen maintained by a direct
line from a nitrogen source.

Analytical HPLC was performed using a Prodigy (Phenomenex) 5 µm
C-18 column, 4.6 × 250 mm; 3 : 1 : 1 CH₃CN : MeOH : 20 mM, pH 6.7
KH₂PO₄ mobile phase, 1.5 mL/min flow rate, and UV (240 nm) and γ-ray
(NaI) flow detectors. Semi-preparative C-18 SiO₂ Sep-Pak type cartridge was
obtained from Waters Corporate Headquarters, Milford, MA. Sterile vented
Milllex-GS 0.22 µm vented filter unit was obtained from Millipore Corporation,
Bedford, MA.

2-(Hydroxymethyl)butane-1,4-diol (3). Triethyl-1,1,2-ethanetricarbox-
ylate, 2 (23 mL, 101.5 mmol) and NaBH₄ (10.0 g) were dissolved in tert-
butyl alcohol (200 mL). The mixture was heated to reflux, and then MeOH (13 mL)
was added in portions over 0.5 h. After addition the mixture was refluxed for
an additional 1 h, then cooled to room temperature (r.t.). HCl (6 M, about
25 mL) was added carefully until the solution was neutral. A large amount of
white solid formed. The mixture was filtered, and the residue was washed with
EtOH (100 mL). After removal of solvent the residue was subject to column
chromatography on silica gel eluted with 10 : 1 EtOAc/MeOH to afford a
viscous colorless oil 3 (8.10 g, 66%), Rf = 0.30 (10 : 1 EtOAc/MeOH).¹H
NMR (300 MHz, D₂O): δ 3.67 (t, 2H, CH₂CH₂OH, J = 6.61 Hz), 3.60 (d, 4H,
HOCH₂CH₂, J = 5.15 Hz), 1.78 (h, 1H, CH, J = 5.88 Hz), 1.56 (q, 2H,
CH₂CH₂OH, J = 6.62 Hz).
5-(2-Hydroxyethyl)-2,2-dimethyl-1,3-dioxane (4). Compound 3 (8.10 g, 67.42 mmol) and 2,2-dimethoxypropane (13 mL, 105.72 mmol) were dissolved in dry THF (20 mL). The mixture was stirred and p-toluenesulfonic acid monohydrate (0.64 g, 3.36 mmol) was added, and the clear solution was stirred at r.t. for 19 h. Triethylamine (10 mL) was added to quench the reaction, and the solution was stirred for 30 min. Then solvents were removed to leave a colorless liquid. The residue was subject to column chromatography on silica gel eluted with 2 : 1 EtOAc/hexane to give a colorless liquid 4 (6.13 g, 57%), R_f = 0.44 (2 : 1 EtOAc/hexane). ¹H NMR (300 MHz, CDCl₃): δ 3.95 (dd, 2H, Heq., J₁ = 11.77 Hz, J₂ = 4.42 Hz), 3.71 (t, 2H, CH₂OH, J = 6.62 Hz), 3.64 (dd, 2H, Hax., J₁ = 11.77 Hz, J₂ = 8.09 Hz), 1.88–2.02 (m, 2H, CH and OH), 1.52–1.59 (q, 2H, CH₂, J = 6.60 Hz), 1.43 (s, 3H, CH₃), 1.42 (s, 3H, CH₃).

5-(2-Bromoethyl)-2,2-dimethyl-1,3-dioxane (5). Compound 4 (1.11 g, 6.93 mmol) and carbon tetrabromide (3.44 g, 10.37 mmol) were dissolved in dry DMF (30 mL). The mixture was cooled under ice bath and triphenylphosphine (2.72 g, 10.37 mmol) was added, and the solution was stirred at 0°C for 2 h. To the light brown solution was added cold aqueous NaHCO₃ solution (30 mL), followed by cold water (30 mL). The mixture was extracted with cold hexane (50 mL × 3). The combined organic layer was washed with cold NaHCO₃ solution (30 mL) and cold water (30 mL), dried over Na₂SO₄. Solvent was removed under 0°C to afford a colorless liquid residue that was kept in vacuum and at 0°C for 1 h. Cold hexane (40 mL) was added to extract the bromide. After removal of solvent at 0°C the colorless liquid was kept in vacuum for 1 h to give colorless oil 5 (1.55 g, ~100%). ¹H NMR (300 MHz, CDCl₃): δ 3.96 (dd, 2H, Heq., J₁ = 11.77 Hz, J₂ = 3.68 Hz), 3.61 (t, 2H, CH₂Br, J = 6.62 Hz), 1.88–2.02 (m, 3H, CHCH₂CH₂), 1.43 (s, 3H, CH₃), 1.41 (s, 3H, CH₃).

2-Amino-6-chloro-9-[2-(2,2-dimethyl-1,3-dioxan-5-yl)ethyl]purine (6a) and 2-amino-6-chloro-7-[2-(2,2-dimethyl-1,3-dioxan-5-yl)ethyl]purine (6b). Compound 5 (2.72 g, 12.17 mmol), 2-amino-6-chloropurine (2.26 g, 13.33 mmol) and anhydrous K₂CO₃ (3.5 g, 25.32 mmol) were dissolved in dry DMF (40 mL). The mixture was sealed by a septum and stirred at r.t. for 5 h. Then the mixture was diluted with ethyl acetate and transferred to a separation funnel, and washed with water. The water layer was extracted with another portion of ethyl acetate. The combined organic layer was washed with brine twice, dried over Na₂SO₄. Removal of solvent afforded a solid residue that was subject to column chromatography on silica gel eluted with ethyl acetate. First the by-product 7-isomer 6b (0.13 g, 4%) eluted, mp 130°C (dec.), R_f = 0.32 (EtOAc). ¹H NMR (300 MHz, DMSO-d₆): δ 8.08 (s, 1H, 8-H), 6.91 (s, 2H, 2-NH₂), 3.30–4.10 (m, 6H, 1₀- and 4₀-H), 2.12–2.30 (m, 2H, 2₀'-H), 1.35–1.52 (m, 1H, 3₀'-H), 1.24 (s, 3H, CH₃), 1.19 (s, 3H, CH₃). The analysis...
calculated for C\(_{13}\)H\(_{18}\)ClN\(_5\)O\(_2\) was C, 50.08; H, 5.82. The values found were C, 50.13; H, 5.83. LRMS (EI, m/z): 154 (100%), 312 [M + H]\(^+\), 13.9%. HRMS (FAB, m/z): calcd for C\(_{13}\)H\(_{19}\)ClN\(_5\)O\(_2\) 312.1227, found 312.1234. The desired product 9-isomer 6a eluted at R\(_f\) = 0.31 (EtOAc) and, after removal of the solvents, was obtained as a white solid (2.03 g, 54%).

\[
\text{1H NMR (300 MHz, DMSO-}d_6\text{): } \delta 8.16 (s, 1H, 8-H), 6.91 (s, 2H, 2-NH\(_2\)), 4.05 (t, 2H, 1\(\text{H, } J = 7.35 \text{ Hz}\)), 3.77 (dd, 2H, 4\(\text{H}_{eq.}, \ J_1 = 11.77 \text{ Hz}, \ J_2 = 4.41 \text{ Hz}\)), 3.53 (dd, 2H, 4\(\text{H}_{ax.}, \ J_1 = 11.77 \text{ Hz}, \ J_2 = 8.83 \text{ Hz}\)), 1.72 (q, 2H, 2\(\text{H, } J = 7.35 \text{ Hz}\)), 1.50–1.60 (m, 1H, 3\(\text{H}\)), 1.31 (s, 3H, CH\(_3\)), 1.25 (s, 3H, CH\(_3\)).
\]

9-[4-Hydroxy-3-(hydroxymethyl)butyl]guanine (penciclovir, PCV, 7). Compound 6a (1.92 g, 6.16 mmol) was dissolved in aqueous hydrochloric acid (2 M, 6 mL). The mixture was refluxed for 2 h. When it was still hot 10% aqueous NaOH solution was added to neutralize the solution. Then the solution was allowed to cool to r.t. A large amount of off-white solid formed. The solid was filtered, washed with water and then acetone, dried under vacuum to give an off-white solid 7 (1.24 g, 80%).

\[
\text{1H NMR (300 MHz, DMSO-}d_6\text{): } \delta 10.52 (s, 1H, 1-NH), 7.67 (s, 1H, 8-CH), 6.41 (s, 2H, 2-NH\(_2\)), 4.42 (t, 2H, OH, } J = 5.15 \text{ Hz}, \), 3.98 (t, 2H, 1\(\text{H, } J = 7.35 \text{ Hz}\)), 3.25–3.48 (m, 4H, 4\(\text{H}\)), 1.69 (q, 2H, 2\(\text{H, } J = 7.36 \text{ Hz}\)), 1.43 (h, 1H, 3\(\text{H, } J = 5.88 \text{ Hz}\)).
\]

N\(^2\)-(p-Anisyldiphenylmethyl)-9-[4-hydroxy-3-p-anisyldiphenylmethoxybutyl]guanine (8a) and N\(^2\)-(p-anisyldiphenylmethyl)-9-[4-(p-anisyldiphenylmethoxy)-3-p-anisyldiphenylmethoxymethylbutyl]guanine (8b). PCV 7 (1.00 g, 3.95 mmol), monomethoxytrityl chloride (3.00 g, 9.72 mmol), dimethylaminopyridine (0.050 g, 0.41 mmol) and triethylamine (3.5 mL) were dissolved in dry DMF (50 mL). The mixture was heated at 50–60\(^\circ\)C for 6 h. After cooling to r.t. ethyl acetate was added, and the mixture was washed with water. The water layer was extracted with another portion of EtOAc. The combined organic layer was washed with water, dried over MgSO\(_4\), evaporated to dryness. The residue was subject to column chromatography on silica gel eluted with 2.5% and 4.5% MeOH/CH\(_2\)Cl\(_2\). Undesired by-product 8b was obtained at R\(_f\) = 0.26 (4% MeOH/CH\(_2\)Cl\(_2\)) and gave a white solid (0.68 g, 16%), m.p. 145\(^\circ\)C (dec.).

\[
\text{1H NMR (300 MHz, DMSO-}d_6\text{): } \delta 10.48 (s, 1H, 1-NH), 7.55 (s, 1H, 2-NH), 6.66–7.32 (m, 43H, Ph and 8-CH), 3.72 (s, 6H, 9-CH\(_3\)), 3.59 (s, 3H, 2-CH\(_3\)), 2.34 (t, 2H, 1\(\text{H, } J = 6.62 \text{ Hz}\)), 2.78–2.92 (m, 4H, 4\(\text{H}\)), 1.52–1.65 (m, 1H, 3\(\text{H}\)), 1.08–1.20 (m, 2H, 2\(\text{H}\)). The analysis calculated for C\(_{70}\)H\(_{63}\)N\(_5\)O\(_6\) was C, 78.55; H, 5.93. The values found were C, 77.56; H, 5.92. LRMS (EI, m/z): 273 (100%), 1092 [M + Na]\(^+\), 3.9%. HRMS (FAB, m/z): calcd for C\(_{70}\)H\(_{63}\)Na\(_2\)O\(_6\) 1092.4676, found 1092.4684. The second compound obtained from fractions at R\(_f\) = 0.13 (4% MeOH/CH\(_2\)Cl\(_2\)) gave product 8a as a white solid (1.66 g, 53%).

\[
\text{1H NMR (300 MHz, DMSO-}d_6\text{): } \delta 10.49 (s, 1H, 1-NH), 7.57 (s, 1H, 2-NH), 7.44 (s, 1H, 8-CH), 7.05–7.37 (m, 24H, Ph), 6.89 (d, 2H, 7.44 (s, 1H, 8-CH)).

Ph, \( J = 8.82 \) Hz), 6.75 (d, 2H, Ph, \( J = 8.82 \) Hz), 4.38 (t, 1H, OH, \( J = 5.14 \) Hz), 3.73 (s, 3H, 9-OCH\(_3\)), 3.65 (s, 3H, 2-OCH\(_3\)), 3.08–3.45 (m, 4H, 1'-and 4'-H), 2.67–2.85 (m, 2H, 5'-H), 1.35–1.45 (m, 1H, 3'-H), 1.15–1.25 (m, 2H, 2'-H).

\( N^2-(p\text{-Anislydiphenylmethyl})-9\{[4\text{-tosyl})-3-p\text{-anislydiphenylmethoxy-}
\]methylbutyl\}guanine (9a) and 1-tosyl-\( N^2-(p\text{-anislydiphenylmethyl})-9\{[4\text{-}
\])tosyl)-3-p-anislydiphenylmethoxy-}
\]methylbutyl\}guanine (9b).

Compound 8a (1.12 g, 1.40 mmol) and \( p\)-tosyl chloride (1.56 g, 8.18 mmol) were dissolved in dry pyridine (20 mL). The mixture was stirred at r.t. for 21 h. To this solution was added water (10 mL) to quench the reaction, and then stirred for 15 min. The mixture was evaporated to dryness. The residue was dissolved in ethyl acetate, washed with water. The aqueous phase was extracted with another portion of ethyl acetate. The combined organic phase was washed with brine twice, dried with MgSO\(_4\) and evaporated to dryness. The residue was purified by column chromatography on silica gel eluted with 2.5% MeOH/CH\(_2\)Cl\(_2\) to give two components. By-product 9b was obtained as a brown solid (0.34 g, 22%), m.p. 95–98°C, \( R_f = 0.35 \) (4% MeOH/CH\(_2\)Cl\(_2\)).

1H NMR (300 MHz, CDCl\(_3\)): \( \delta \) 7.96 (d, 2H, Ph, \( J = 7.35 \) Hz), 7.74 (d, 2H, Ph, \( J = 8.09 \) Hz), 6.95–7.45 (m, 29H, Ph and 2-NH), 6.80 (d, 2H, Ph, \( J = 8.09 \) Hz), 6.70 (d, 2H, Ph, \( J = 8.09 \) Hz), 6.37 (s, 1H, 8-CH), 3.78–4.03 (m, 2H, 4'-CH\(_2\)-OTs), 3.77 (s, 3H, 9-OCH\(_3\)), 3.72 (s, 3H, 2-OCH\(_3\)), 3.28–3.47 (m, 2H, 1'-CH\(_2\)), 2.80–3.04 (m, 2H, 5'-CH\(_2\)-OTrM), 2.42 (s, 6H, CH\(_3\)), 1.45 (brs, 1H, 3'-CH), 1.20–1.38 (m, 2H, 2'-CH\(_2\)). The analysis calculated for C\(_{64}\)H\(_{59}\)N\(_5\)O\(_9\)S\(_2\): C, 69.48; H, 5.38. The values found were C, 68.88; H, 5.40.

LRMS (EI, \( m/z \)): 273 (100%), 1106 [M + H]+, 2.6%. HRMS (FAB, \( m/z \)): calcd for C\(_{64}\)H\(_{60}\)N\(_5\)O\(_9\)S\(_2\) 1106.3833, found 1106.3861. Product 9a eluted at \( R_f = 0.29 \) (4% MeOH/CH\(_2\)Cl\(_2\)).

\( N^2-(p\text{-Anislydiphenylmethyl})-9\{[4\text{-fluoro})-3-p\text{-anislydiphenylmethoxy-}
\]methylbutyl\}guanine (10).

Tosylate 9a (0.050 g, 0.053 mmol), Kryptofix 2.2.2 (0.12 g, 0.32 mmol) and anhydrous potassium fluoride (0.070 g, 1.21 mmol) were dissolved in anhydrous acetonitrile (5 mL) in a 10 mL V-vial. The vial was sealed and heated at 115–120°C for 40 min while stirring. The vial was sealed and heated at 115–120°C for 40 min while stirring. The vial was sealed and heated at 115–120°C for 40 min while stirring. The vial was sealed and heated at 115–120°C for 40 min while stirring. Solvent was removed by evaporation, and the residue was transferred to the top of a column (silica gel) with the aid of CH\(_2\)Cl\(_2\). The column was eluted with 2.0–2.5% MeOH/CH\(_2\)Cl\(_2\). A yellowish solid 10 (0.029 g, 69%) was obtained, \( R_f = 0.29 \) (4% MeOH/CH\(_2\)Cl\(_2\)).
Improved Total Synthesis of [18F]FHBG

9-(4-Fluoro-3-hydroxymethylbutyl)guanine (FHBG, 1). The solution of compound 10 (0.029 g, 0.036 mmol) in methanol (2.5 mL) was acidified with 1 N HCl (0.5 mL), and then heated at 115°C for 10 min. The solution was neutralized with 1 N aqueous NaOH. A small amount of silica gel was added to absorb the solution, and the mixture was transferred to the top of a silica gel column. The column was eluted with 4:1 MeCN/H2O to afford 1 as a white solid (9.0 mg, 97%), Rf = 0.19 (4:1 MeCN/H2O). 1H NMR (300 MHz, DMSO-d6): 6.62–7.42 (m, 28H, Ph), 4.57 (s, 2H, 4-Ch2), 4.21 (t, 2H, 10-Ch2, J = 4.41 Hz), 3.75 (s, 3H, 9-OCH3), 3.70 (s, 3H, 2-OCH3), 3.31 (d, 2H, 5-Ch2, J = 70.59 Hz), 1.51–1.98 (m, 2H, 2-Ch2), 0.78–0.93 (m, 1H, 3'-CH). LRMS (EI, m/z): 154 (100%), 780 [(M-F)+, 1.0%]. HRMS (FAB, m/z): calcld for C50H46N5O4 780.3550, found 780.3547.

9-(4-[18F]fluoro-3-hydroxymethylbutyl)guanine ([18F]FHBG, 1). No-carrier-added (NCA) aqueous H18F (0.5 mL) prepared by 18O(p,n)18F nuclear reaction in a RDS-112 cyclotron on an enriched H218O water (95 +%) target was added to a Pyrex vessel which contains K2CO3 (4 mg, in 0.2 mL H2O) and Kryptofix 2.2.2 (10 mg, in 0.5 mL CH3CN). Azeotropic distillation at 115°C with HPLC grade CH3CN (3 : C21 mL) under a nitrogen steam efficiently removed water. The tosylated precursor 9a (2–3 mg, dissolved in 0.5 mL CH3CN) was introduced to the anhydrous potassium [18F]fluoride-Kryptofix 2.2.2 complex. The reaction mixture was sealed and heated at 120°C for 20 min and was subsequently allowed to cool down, at which time the crude product was passed through a Silica Sep-Pak cartridge to remove Kryptofix 2.2.2 and un-reacted potassium [18F]fluoride. The Sep-Pak column was eluted with 15% MeOH/CH2Cl2 (3.5 mL), and the fractions were passed onto a rotatory evaporator. The solvent was removed by evaporation under high vacuum (0.1–1.0 mmHg). The residue was acidified with 1 N HCl (0.6 mL) and heated for 10 min at 80°C. The contents were neutralized with 6 N NaOH (0.1 mL), diluted with ethanol (3 mL), and evaporated under vacuum. The crude product was passed through a Silica Sep-Pak cartridge with the aid of ethanol. The Sep-Pak was eluted with EtOH to remove the radioactive by-product. The radiochemically pure product [18F]FHBG, 1 was eluted from the Sep-Pak with 90 : 8.2 H2O/EnO/HOAc and adjusted pH to 5.5–7.0 by addition of a 2 M NaOH and 150 mM NaH2PO4 mixed solution, whose volume was dependent upon the use of the labeled product in tissue biodistribution studies (~3 mL, 3 × 1 mL) or in micro-PET imaging studies (1.5 mL, 3 × 0.5 mL) of HSV-tk prostate cancer tumors in athymic mice. The mixture
was sterile-filtered through a 0.22 μm cellulose acetate membrane and collected into a sterile vial. The radiochemical yield of $^{18}$FHBG was 20–25%, and the synthesis time was ~70 min from EOB. Retention times in the analytical HPLC system were: RT9a = 19.80 min, RT1 = 1.80 min. The chemical purities of precursor 9a and standard sample 1 were >95%, the radiochemical purity of target radiotracer 1 was >99%, and the chemical purity of radiotracer 1 was ~93%. The average ($n = 3–5$) specific radioactivity of radiotracer 1 was 0.8–1.2 Ci/μmol at EOS.

ABSTRACT

An improved total synthesis of [18F]FHPG starting from 1,3-dibenzyloxy-2-propanol and guanine has been developed. [18F]FHPG was prepared by nucleophilic substitution of the appropriate precursor with [18F]KF/Kryptofix 2.2.2 followed by a quick deprotection reaction and purification with a simplified Silica Sep-Pak solid-phase extraction (SPE) method in 10–15% radiochemical yield, and 70 min synthesis time from end of bombardment (EOB).

INTRODUCTION

Radiolabeled ganciclovir (GCV, 9-[(1,3-dihydroxy-2-propoxy)methyl]guanine) and penciclovir (PCV, 9-[4-hydroxy-3(hydroxymethyl)butyl]guanine) analogs such as 8-[18F]fluoroganciclovir ([18F]FGCV), 9-[(3-[18F]fluoro-1-hydroxy-2-propoxy)methyl]guanine ([18F]FHPG); 8-[18F]fluoropenciclovir ([18F]FPCV), 9-(4-[18F]fluoro-3-hydroxymethylbutyl)guanine ([18F]FHBG) (Fig. 1) have shown great potential as positron emission tomography (PET) imaging agents to detect herpes simplex virus thymidine kinase (HSV-tk) gene expression. Considerable efforts have been devoted to the synthesis of these gene reporter probes and numerous improved synthesis were reported in the literature, in which [18F]FGCV and [18F]FPCV were labeled with fluorine-18 at 8-position of guanine ring of GCV and PCV; [18F]FHPG and [18F]FHBG were labeled with fluorine-18 at the side chain of GCV and PCV. The potential importance of these compounds as gene therapy imaging tools is great, and broader research investigation to fully explore and validate their utility is important. However, the limited commercial availability, complicated synthetic procedure and high costs of starting materials GCV and PCV can present an obstacle to more widespread evaluation of these intriguing agents.

Figure 1. Chemical structures of GCV, PCV, [18F]FGCV, [18F]FPCV, [18F]FHPG, [18F]FHBG.
Wishing to study these compounds in this laboratory, we decided to make our own material by following the literature methods. Although several papers dealing with the synthesis of $^{18}$F]FHPG from GCV have appeared, there are gaps in synthetic detail among them, and certain key steps gave poor yields or were difficult to repeat in our hands. Consequently, we investigated alternate approaches and modifications that eventually resulted in an improved total synthesis of $^{18}$F]FHPG starting from very beginning materials 1,3-dibenzyloxy-2-propanol and guanine that was superior to previous works or addressed more synthetic details to reveal and explain technical tricks. In this paper we provide full experiment procedures, yields, analytical details and new findings for this improved $^{18}$F]FHPG total synthesis, as well as key intermediate GCV and tosylated precursor.

**RESULTS AND DISCUSSION**

**Synthesis of Ganciclovir**

The synthesis of ganciclovir (GCV) as indicated in Sch. 1 was performed with the modifications according to procedures reported in the literature.[20,21]

The commercially available starting material 1,3-dibenzyloxy-2-propanol (2) was converted into its chloromethyl ether 1,3-dibenzyloxy-2-chloro-...
methoxypropane (4) through a chloromethylation reaction. Compound 4 was easy to decompose on silica gel column. Therefore, the purification of crude product 4 is impossible and unnecessary. The staring material guanine (3) was reacted with 1,1,1,3,3,3-hexamethyldisilazane (HMDS) to provide guanine derivative 2,6,9-tris(trimethylsilyl)guanine (5). The reaction went very slow, which took 4 days. The indication of reaction completion was that the initial suspension turned to be a clear solution. Compound 5 was sensitive to moisture, and it should be used for next step reaction immediately after removal of volatiles. The coupling reaction between 4 and 5 gave desired product 9-isomer 9-[(1,3-dibenzyloxy-2-propoxy)methyl]guanine (6a) and undesired by-product 7-isomer 7-[(1,3-dibenzyloxy-2-propoxy)methyl]guanine (6b). The reaction needed to be catalyzed by either tetrabutylammonium fluoride (TBAF)[20] or tetrabutylammonium iodide (TBAI).[21] However, there was not much difference observed in the reaction, and the ratio of products $6a/6b$ was around 2 : 1 for both catalysts. The claimed high yield of 9-isomer with TBAF[20] was not achievable in our hands. The separation of the two isomers was challenging, since they gave the same $R_f$ value on TLC. Thus, the preparative TLC and the flash column chromatography did not work for the purification of 9-isomer from its mixture with 7-isomer. Fortunately, repeated recrystallization of the mixture of the two isomers in ethanol could provide pure 9-isomer 6a and 7-isomer 6b. 6b came out from their solution first, and then 6a. The purities of 6a and 6b could be monitored by $^1$H NMR spectrum, which was used to guide the recrystallization. The transfer hydrogenolysis reaction of compound 6a to remove the protecting benzyl groups gave the key intermediate GCV, 7. The reaction was catalyzed by either palladium chloride (PdCl$_2$)[20] or palladium black.[21] However, we found with PdCl$_2$[20] the chain of the reaction product GCV was cleaved; with 1 : 1 palladium black/6a[21] the deprotection reaction would not complete no matter how long the reaction was heated. The ratio of palladium black/6a we used was 3 : 1, which gave deprotective GCV, 7 in a yield of 87.7%.

The overall chemical yield of GCV from 2 and 3 was 15.6%.

**Synthesis of FHPG (1) and Radiosynthesis of $[^{18}$F]FHPG (1)**

The syntheses of standard sample 9-[(3-fluoro-1-hydroxy-2-propoxy)-methyl]guanine (FHPG, 1) and target tracer $[^{18}$F]FHPG (1) as indicated in Sch. 2 were performed with the modifications according to procedures reported in the literature.[13,18,19,22]

The protection of the 2-amino group and one of the two hydroxyl groups of GCV, 7 was furnished by reacting with monomethoxytrityl chloride in the presence of 4-dimethylaminopyridine (DMAP) and triethylamine.[22] The
bulky methoxytrityl group favored the desired product $N^2-(\text{P-}{\text{anisyldiphenylmethyl}})-9\cdot[\text{1-}\cdot\text{(P-}{\text{anisyldiphenylmethoxy}})-3\cdot\text{hydroxy}\cdot\text{2-propoxy}[\text{methyl}]\text{guanine}}$ (8a) in 36.2% chemical yield, if the ratio of starting materials and reaction temperature are appropriate, although the formation of the undesired fully protected by-product $N^2-(\text{p-}{\text{anisyldiphenylmethyl}})-9\cdot[1,3\cdot\text{bis(}\text{p-}{\text{anisyldiphenylmethoxy}})-2\cdot\text{propoxy}[\text{methyl}]\text{guanine}}$ (8b) is not avoidable, in 20.7% chemical yield. Compound 8a reacted with $p$-tosyl chloride at room temperature afforded the desired precursor tosylate $N^1-(\text{p-}{\text{anisyldiphenylmethyl}})-9\cdot[(\text{1-}\cdot\text{anisyldiphenylmethoxy})-3\cdot\text{tosyl}\cdot\text{2-propoxy}]\text{methyl}]\text{guanine}}$ (9a) in a

---

**Scheme 2.** Synthesis of FHPG and $[^{18}\text{F}]$FHPG. a. MTrCl, DMAP, Et$_3$N, DMF; b. TsCl, pyridine; c. K$[^{18}/19]\text{F}$, Kryptofix 2.2.2, CH$_3$CN; d. 1 N HCl, MeOH.
yield of 50.8%, together with the undesired by-product 1-tosyl-N^2-(p-anisylidiphenylmethyl)-9-[(1-anisyldiphenylmethoxy)-3-tosyl-2-propoxy)methyl]guanine (9b) in a yield of 17.5%. The tosylate 9a was purified by recrystallization from ethanol in the literature.\cite{22} We found it was convenient to perform flash column chromatography to produce pure and reliable precursor 9a. The fluorination of the tosylate 9a with anhydrous potassium fluoride in dry acetonitrile catalyzed by Kryptofix 2.2.2 gave the intermediate \( N^2-(p\text{-anisyldiphenylmethyl})-9-[(1\text{-p-anisyldiphenylmethyl})-3\text{-fluoro-2-propoxy}]\text{methyl} \text{guanine} (10) \) in a yield of 29.7%. This intermediate 10 was easily hydrolyzed by 1 N HCl aqueous solution to give the unlabeled standard sample FHPG, 1 in a yield of 87.3%.

The overall chemical yield of the tosylate precursor 9a from GCV was 18.4%, and the overall chemical yield of the standard sample FHPG, 1 from GCV was 4.8%.

\([^{18}\text{F}]\text{FHPG (1)}\) was synthesized by a modification of the procedures as reported in the literature.\cite{15,18,19} The tosylated precursor 9a was labeled by a conventional nucleophilic substitution with K\([^{18}\text{F}] \)/Kryptofix 2.2.2 in CH\(_3\)CN at 120°C for 20 min to provide a radiolabeling intermediate 10. The radio-labeling reaction was monitored by analytical radio-HPLC method, in which we employed a new HPLC system\cite{23,24} by using a Prodigy (Phenomenex) 5 \( \mu \text{m} \text{C-18 column, 4.6} \times 250 \text{mm; 3:1:1 CH}_3\text{CH}: \text{MeOH}: 20 \text{mM}, \text{pH 6.7 KHPO}_4 \) mobile phase, 1.5 mL/min flow rate, and UV (240 nm) and \( \gamma \)-ray (NaI) flow detectors. Retention times in the analytical HPLC system were: \( \text{RT} 10 = 15.00 \text{ min, RTK}^{[18}\text{F]} = 1.88 \text{ min.} \) The radiolabeling mixture containing the intermediate 10 was passed through a Silica Sep-Pak to remove Kryptofix 2.2.2 and non-reacted K\([^{18}\text{F}] \). The large polarity difference between 10 and Kryptofix 2.2.2 and non-reacted K\([^{18}\text{F}] \) permitted the use of a simple solid-phase extraction (SPE) technique\cite{23-25} for fast isolation of 10 from the radiolabeling reaction mixture. The key part in this technique is a SiO\(_2\) Sep-Pak type cartridge, which contains \( \sim 0.5-2 \) g of adsorbent. The Sep-Pak was eluted with 15% MeOH/CH\(_3\)Cl\(_2\) and the solvent was evaporated under high vacuum to give the residue 10. The existence of the catalyst Kryptofix 2.2.2 and non-reacted K\([^{18}\text{F}] \) would affect the deprotection reaction of 10; therefore, they needed to be removed before 10 was deprotected to give the target labeled product 1. The residue 10 was followed a quick deprotection with 1 N HCl for 10 min and neutralized with 6 N NaOH to provide 1. To simplify the synthetic procedure, the final reaction mixture was purified with SPE method instead of HPLC method so that it will be amenable for automation.\cite{19} The crude product was once again passed through the second Silica Sep-Pak to remove radioactive by-product by simple SPE with ethanol. The large polarity difference between 1 and radioactive by-product permitted the use of SPE technique for fast purification of radiotracer 1 from radiolabeling mixture.
Improved Total Synthesis of Gene Expression Imaging Agent

The radiochemically pure compound 1 was isolated with 90:8:2 H2O/EtOH/HOAc from the Sep-Pak and adjusted pH to 5.5–7.0 with 2 M NaOH and 150 mM NaH2PO4 mixed solution. The radiochemical yield of 1 was 10–15%, and the synthesis time was ~70 min from EOB. Chemical purity, radiochemical purity, and specific radioactivity were determined by analytical HPLC method. Retention times in the analytical HPLC system were: RT9a = 14.03 min, RT1 = 2.02 min. The chemical purities of precursor 9a and standard sample 1 were >95%, the radiochemical purity of target radiotracer 1 was >99%, and the chemical purity of radiotracer 1 was ~93%. The average (n = 3–5) specific radioactivity of radiotracer 1 was 0.8–1.2 Ci/μmol at EOS.

In comparison with the results reported in the literature,[13,18,19,22] several improvements in the synthetic methodology for FHPG and [18F]FHPG have been made. They include increased radiochemical yield and specific activity, enhanced radiochemical purity, shortened synthesis time, new Sep-Pak techniques for fast and efficient preparative separation of [18F]FHPG from precursors, and new HPLC systems for the quality control (QC) method of target tracer [18F]FHPG.

Compounds 6b, 8b, and 9b are new compounds.

In conclusion, an improved total synthesis of [18F]FHPG has been developed. Several improvements and new findings in the synthetic methodology, radiolabeling, preparative separation and analytical details for GCV, FHPG, precursor and [18F]FHPG have been made and addressed. This improved method is efficient and convenient. It is anticipated that the approaches and improvements described here can be applied with advantage to the synthesis of other radiolabeled GCV and PCV analogs for PET imaging of HSV-tk gene expression.

EXPERIMENTAL SECTION

All commercial reagents and solvents were used without further purification unless otherwise specified. Tetrahydrofuran (THF) solvent was distilled from LiAlH4 immediately prior to use. Melting points were determined on a MEL-TEMP II capillary tube apparatus and were uncorrected. 1H NMR spectra were recorded on a Bruker QE 300 NMR spectrometer using tetramethylsilane (TMS) as an internal standard. Chemical shift data for the proton resonances were reported in parts per million (δ) relative to internal standard TMS (δ 0.0). The low resolution mass spectra were obtained using a Bruker Biflex III MALDI-Tof mass spectrometer, and the high resolution mass measurements were obtained using a Kratos MS80 mass spectrometer, in the Department of Chemistry at Indiana University. Chromatographic solvent
proportions are expressed on a volume:volume basis. Thin layer chromatography was run using Analtech silica gel GF uniplates (5 x 10 cm²). Plates were visualized by UV light. Normal phase flash chromatography was carried out on EM Science silica gel 60 (230–400 mesh) with a forced flow of the indicated solvent system in the proportions described below. All moisture-sensitive reactions were performed under a positive pressure of nitrogen maintained by a direct line from a nitrogen source. Analytical HPLC was performed using a Prodigy (Phenomenex) 5 µM C-18 column, 4.6 x 250 mm; 3 : 1 : 1 CH₃CN: MeOH: 20 mM KH₂PO₄ mobile phase, 1.5 mL/min flow rate, and UV (240 nm) and γ-ray (NaI) flow detectors. Semi-preparative C-18 SiO₂ Sep-Pak type cartridge was obtained from Waters Corporate Headquarters, Milford, MA. Sterile vented Millex-GS 0.22 µm vented filter unit was obtained from Millipore Corporation, Bedford, MA.

1,3-Dibenzyloxy-2-chloromethoxypropane (4)

The mixture of 1,3-dibenzyloxy-2-propanol 2 (9.1 mL, 36.7 mmol) and paraformaldehyde (2.39 g, 79.6 mmol) in anhydrous 1,2-dichloroethane (100 mL) was cooled to 0°C. Dry HCl gas was bubbled through the suspension at 0°C for 6 h. Anhydrous Na₂SO₄ was added to the mixture. After stirring the solvent was removed under vacuum to give a viscous liquid residue 4 (~100%). The crude product was used for the next step reaction without further purification.

2,6,9-Tris(trimethylsilyl)guanine (5)

The mixture of guanine 3 (5.50 g, 36.4 mmol), ammonium sulfate (0.70 g, 132.1 mmol) and 1,1,1,3,3,3-hexamethyldisilazane (250 mL) was refluxed under nitrogen for 4 days until it became clear. Volatiles were removed under reduced pressure to give viscous syrup 5 (~100%). The crude product was used for the next step reaction without further purification.

9-[(1,3-Dibenzyloxy-2-propoxy)methyl]guanine (6a) and
7-[(1,3-Dibenzyloxy-2-propoxy)methyl]guanine (6b)

Compounds 2 and 4 as obtained above were combined through the aid of dry THF (200 mL). The mixture was stirred at room temperature (r.t.). Tetrabutylammonium fluoride (TBAF, 0.40 g) dried by azeotroping
distillation in anhydrous benzene (40 mL) was added to the mixture. The resulting solution was then refluxed for 22 h. After removal of solvent, the yellowish residue was transferred to a separation funnel with the aid of ethyl acetate, and then more ethyl acetate and water were added. Large amount of yellowish precipitate formed when shaking. The solid was filtered, washed with water and ethyl acetate, and dried under vacuum. The organic layer of the filtrate was washed twice with water. After removal of solvent the yellow viscous residue was subject to column chromatography on silica gel eluted with 9:1 EtOAc/MeOH to give a yellow solid. Both of solids were a mixture (9.33 g, 58.9%) of undesired by-product 7-isomer \(6b\) and desired 9-isomer \(6a\), which could not be separated by TLC and gave the same \(R_f\) value (\(R_f = 0.29\), 9:1 EtOAc/MeOH) on TLC. The NMR spectrum showed the ratio of \(6a/6b\) was about 2:1. They were separated and purified by recrystallization in ethanol. Crude product (~7.0 g) was stirred with ethyl acetate (200 mL) at r.t., and then filtered. The solid was transferred to a 1000 mL flask containing ethanol (500 mL). The suspension was heated to reflux, and filtered through a frit (fine). The clear yellowish solution was left at 4°C overnight to give the first precipitate that was mostly 7-isomer \(6b\). ¹H NMR (300 MHz, DMSO-\(d_6\)): \(\delta\) 10.92 (s, 1H, 1-NH), 8.11 (s, 1H, 8-CH), 7.10–7.40 (m, 10H, Ph), 6.24 (s, 2H, 2-NH₂), 5.68 (s, 2H, 1'-CH₂), 4.40 (s, 4H, PhCH₂), 4.10 (q, 1H, 3'-CH, \(J = 4.78\) Hz), 3.30–3.60 (m, 4H, 4'-CH₂). LRMS (EI, \(m/z\)): 91 (100%), 436 [(M + H)⁺, 0.4%]. HRMS (FAB, \(m/z\)) calculated for \(C_{23}H_{26}N_5O_4\) 436.4838, found 436.1993. The filtrate was then left at −16°C overnight to give the second precipitate that was pure 9-isomer \(6a\). The solution was concentrated, and left at −16°C to give third, forth and more portions of pure 9-isomer \(6a\). The purity was monitored by NMR spectrum. The pure product \(6a\) (2.81 g, 17.8%) was obtained. \(6a\), ¹H NMR (300 MHz, DMSO-\(d_6\)): \(\delta\) 10.63 (s, 1H, 1-NH), 7.81 (s, 1H, 8-CH), 7.15–7.35 (m, 10H, Ph), 6.49 (s, 2H, 2-NH₂), 5.45 (s, 2H, 1'-CH₂), 4.40 (s, 4H, PhCH₂), 4.02 (q, 1H, 3'-CH, \(J = 4.78\) Hz), 3.30–3.50 (m, 4H, 4'-CH₂).

**9-[(1,3-Dihydroxy-2-propoxy)methyl]guanine**

\(\text{(Ganciclovir, GCV, 7)}\)

Compound \(6a\) (0.50 g, 1.15 mmol) was dissolved in hot ethanol (30 mL), and then palladium black (1.50 g) and cyclohexene (20 mL) were added. The mixture was refluxed under nitrogen for 24 h until TLC showed starting material was gone. The catalyst was filtered through celite while the mixture was hot, washed with ethanol and hot DMF until the filtrate on TLC plate
showed no spot under UV. The ethanol and DMF filtrates were evaporated to dryness separately. The solid residues were combined with 1:1 EtOH/H$_2$O, heated to dissolve, and filtered through celite topped with activate charcoal. After removal of solvents the colorless solid was recrystallized with 4:1 EtOH/H$_2$O to afford a white crystal solid 7 (0.26 g, 87.7%). $^1$H NMR (300 MHz, DMSO-$d_6$): δ 10.63 (s, 1H, 1-NH, D$_2$O exchangeable), 7.79 (s, 1H, 8-CH), 6.48 (s, 2H, 2-NH$_2$, D$_2$O exchangeable), 5.42 (s, 2H, 1'-CH$_2$), 4.60 (t, 2H, OH, $J = 5.15$ Hz, D$_2$O exchangeable), 3.20–3.65 (m, 5H, 3'-CH and 4'-CH$_2$).

$N^2$-(p-Anisylidiphenylmethyl)-9-[[1-(p-anisylidiphenylmethoxy)-3-hydroxy-2-propyloxy)methyl]guanine (8a) and $N^2$-(p-Anisylidiphenylmethyl)-9-[[1,3-bis(p-anisylidiphenylmethoxy)-2-propyloxy)methyl]guanine (8b)

GCV 7 (1.00 g, 3.98 mmol), monomethoxytrityl chloride (2.65 g, 8.58 mmol), 4-dimethylaminopyridine (DMAP, 0.030 g, 0.25 mmol), and triethylamine (2.5 mL) were dissolved in dry DMF (50 mL). The mixture was stirred at 55°C for 6 h. Methanol (10 mL) was added to quench the reaction, and solvents were evaporated. The residue was transferred to a separation funnel through the aid of ethyl acetate, washed with aqueous NaHCO$_3$ solution and water, dried over MgSO$_4$. After evaporation the resulting solid was dissolved in 4% MeOH/CH$_2$Cl$_2$, absorbed by a small amount of silica gel, and dried under vacuum. This silica gel was then transferred to the top of a column, and eluted with 2.5–3.0% MeOH/CH$_2$Cl$_2$. Two components were collected. The first component was undesired by-product 8b as a white solid (0.87 g, 20.7%), mp 115°C (dec.), $R_f = 0.34$ (5% MeOH/CH$_2$Cl$_2$). $^1$H NMR (300 MHz, DMSO-$d_6$): δ 10.68 (s, 1H, 1-NH), 7.84 (s, 1H, 8-CH), 7.67 (s, 1H, 2-NH), 6.53–7.36 (m, 42H, Ph), 4.91 (s, 2H, 1'-CH$_2$), 3.75 (s, 6H, OCH$_3$), 3.57–3.67 (m, 1H, 3'-CH), 3.48 (s, 3H, OCH$_3$), 2.63 (brs, 4H, 4'-CH$_2$). LRMS (EI, $m/z$): 273 (100%), 1094 [(M + Na)$^+$, 1.6%]. HRMS (FAB, $m/z$): calcld for C$_{69}$H$_{61}$NaN$_5$O$_7$ 1094.4469, found 1094.4452. The second component was the desired product 8a as a white solid (1.13 g, 36.2%), $R_f = 0.15$ (5% MeOH/CH$_2$Cl$_2$). $^1$H NMR (300 MHz, DMSO-$d_6$): δ 10.67 (s, 1H, 1-NH, D$_2$O exchangeable), 7.78 (s, 1H, 8-CH), 7.68 (s, 1H, 2-NH, D$_2$O exchangeable), 6.66–7.33 (m, 28H, Ph), 4.97 (dd, 2H, 1'-CH$_2$, $J_1 = 36.03$ Hz, $J_2 = 11.03$ Hz), 4.44 (t, 1H, OH, $J = 5.14$ Hz, D$_2$O exchangeable), 3.74 (s, 3H, OCH$_3$), 3.56 (s, 3H, OCH$_3$), 3.40–3.50 (m, 1H, 3'-CH), 2.80–3.07 (m, 2H, 5'-CH$_2$), 2.51–2.80 (m, 2H, 4'-CH$_2$).
Improved Total Synthesis of Gene Expression Imaging Agent

$N^2$-(p-Anisyldiphenylmethy1)-9-[(1-anisyldiphenylmethoxy)-3-tosyl-2-propoxy)methyl]guanine (9a) and 1-Tosyl-$N^2$-(p-anisyldiphenylmethy1)-9-[(1-anisyldiphenylmethoxy)-3-tosyl-2-propoxy)methyl]guanine (9b)

Compound 8a (0.28 g, 0.35 mmol) and p-tosyl chloride (0.26 g, 1.35 mmol) were dissolved in dry pyridine (5 mL). The mixture was stirred at r.t. for 2 days. To this brown solution was added water (1 mL) to quench the reaction, and then solvents were evaporated. The residue was dissolved in ethyl acetate, washed with water, dried over Na$_2$SO$_4$. After removal of solvent the solid was dissolved in a small volume of CH$_2$Cl$_2$, and transferred to a silica gel column, then eluted with 1% MeOH/CH$_2$Cl$_2$ to afford undesired by-product 9b as a light brown solid (0.067 g, 17.5%), mp. 95°C (dec.), $R_f$ = 0.36 (1% MeOH/CH$_2$Cl$_2$). $^1$H NMR (300 MHz, DMSO-$d_6$): $\delta$ 6.56–8.27 (m, 38H, Ph and 8-CH), 5.11 (dd, 2H, 1'-CH$_2$, $J_1$ = 44.85 Hz, $J_2$ = 11.03 Hz), 3.73 (s, 3H, OCH$_3$), 3.53 (s, 3H, OCH$_3$), 3.38–3.57 (m, 3H, 3'-CH and 4'-CH$_2$), 2.30–2.71 (m, 2H, 5'-CH$_2$), 2.41 (s, 6H, CH$_3$). LRMS (EI, $m/z$): 273 (100%), 1108 [(M + H)$^+$, 1.4%]. HRMS (FAB, $m/z$): calcd for C$_{63}$H$_{58}$N$_5$O$_{10}$S$_2$ 1108.3625, found 1108.3667. Then the column was eluted with 3% MeOH/CH$_2$Cl$_2$ to give the desired product 9a as a light brown solid (0.17 g, 50.8%), $R_f$ = 0.15 (3% MeOH/CH$_2$Cl$_2$). $^1$H NMR (300 MHz, DMSO-$d_6$): $\delta$ 10.67 (s, 1H, 1-NH), 7.77 (s, 1H, 2-NH), 6.62–7.67 (m, 32H, Ph), 4.93 (dd, 2H, 1'-CH$_2$, $J_1$ = 59.56 Hz, $J_2$ = 11.76 Hz), 3.89–4.29 (m, 2H, 5'-CH$_2$), 3.54 (s, 6H, CH$_3$), 3.37–3.64 (m, 3H, 3'-CH and 4'-CH$_2$), 2.37–2.67 (m, 2H, 5'-CH$_2$), 2.43 (s, 3H, CH$_3$).

$N^2$-(p-Anisyldiphenylmethy1)-9-[1-(p-anisyldiphenylmethy1)-3-fluoro-2-propoxy)methyl]guanine (10)

Tosylate 9a (0.10 g, 0.11 mmol), potassium fluoride (0.14 g, 2.41 mmol) and Kryptofix 2.2.2. (0.24 g, 0.64 mmol) were dissolved in dry acetonitrile (8 mL). The mixture was heated to 115–120°C for 40 min. The solvent was removed, and the residue was transferred to the top of a silica gel column with the aid of CH$_2$Cl$_2$. The column was eluted with 3% MeOH/CH$_2$Cl$_2$ to give the desired product 10 as a light brown solid (0.17 g, 50.8%), $R_f$ = 0.15 (3% MeOH/CH$_2$Cl$_2$). $^1$H NMR (300 MHz, CDC$_3$): $\delta$ 11.64 (brs, 1H, 1-NH), 7.80 (brs, 1H, 2-NH), 6.52–7.40 (m, 28H, Ph), 4.97 (s, 2H, 1'-CH$_2$), 3.89–4.29 (m, 2H, 5'-CH$_2$), 3.74 (s, 3H, OCH$_3$), 3.58 (s, 3H, OCH$_3$), 3.42–3.66 (m, 1H, 3'-CH), 2.73–2.93 (m, 2H, 4'-CH$_2$).
9-[(3-Fluoro-1-hydroxy-2-propoxy)methyl]guanine (FHPG, 1)

The solution of compound 10 (0.025 g, 0.031 mmol) in methanol (2.5 mL) and 1 N aqueous HCl (0.5 mL) was refluxed for 15 min while TLC showed no starting material left. The solution was neutralized with 1 N aqueous NaOH to pH ~ 7 – 8. Silica gel was added to absorb the solution, and then the mixture was made to dry under vacuum and transferred to the top of a column. The column was eluted with 20:1 MeCN/H₂O to give the target compound FHPG 1 as a light brown solid (7.0 mg, 87.3%), Rf = 0.34 (12:1 MeCN/H₂O). ¹H NMR (300 MHz, DMSO-d₆): δ 10.89 (s, 1H, 1-NH, D₂O exchangeable), 7.81 (s, 1H, 8-CH), 6.78 (s, 2H, 2-NH₂, D₂O exchangeable), 5.42 (s, 2H, 1'-CH₂), 4.93 (t, 1H, OH, J = 5.88 Hz, D₂O exchangeable), 4.24 – 4.58 (m, 2H, 4'-CH₂F), 3.73 – 3.88 (m, 1H, 3'-CH), 3.28 – 3.43 (m, 2H, 5'-CH₂).

9-[(3-[¹⁸F]Fluoro-1-hydroxy-2-propoxy)methyl]guanine ([¹⁸F]FHPG, 1)

No-carrier-added (NCA) aqueous H[¹⁸F] (0.5 mL) prepared by ¹⁸O(p,n)¹⁸F nuclear reaction in a RDS-112 cyclotron on an enriched H₂¹⁸O water (95 + %) target was added to a Pyrex vessel which contains K₂CO₃ (4 mg, in 0.2 mL H₂O) and Kryptofix 2.2.2 (10 mg, in 0.5 mL CH₃CN). Azeotropic distillation at 115°C with HPLC grade CH₃CN (3×1 mL) under a nitrogen steam efficiently removed the target H₂O. The tosylated precursor 9a (2–3 mg, dissolved in 0.5 mL CH₃CN) was introduced to the anhydrous potassium [¹⁸F]fluoride-Kryptofix 2.2.2 complex. The reaction mixture was sealed and heated at 120°C for 20 min and was subsequently allowed to cool down, at which time the crude product was passed through a Silica Sep-Pak cartridge to remove Kryptofix 2.2.2 and non-reacted K[¹⁸F]. The Sep-Pak was eluted with 15% MeOH/CH₂Cl₂ (3.5 mL), and then passed onto a rotatory evaporator. The solvent was removed by evaporation under high vacuum. The residue was acidified with 1N HCl (0.6 mL) and heated for 10 min at 80°C. The contents were neutralized with 6 N NaOH (0.1 mL), diluted with ethanol (3 mL), and evaporated in vacuo. The crude product was passed through the second Silica Sep-Pak cartridge through the aid of ethanol. The Sep-Pak was eluted with EtOH to remove radioactive by-product. The radiochemically pure product [¹⁸F]FHPG, 1 was eluted from the Sep-Pak with 90:8:2 H₂O/EtOH/ HOAc and adjusted pH to 5.5–7.0 with 2 M NaOH and 150 mM NaH₂PO₄ mixed solution, whose volume was dependent upon the use of the labeled product in tissue biodistribution studies (~3 mL, 3×1 mL) or in micro-PET imaging studies (1.5 mL, 3×0.5 mL) of HSV-tk prostate cancer tumors in athymic mice, and sterile-filtered through a 0.22 µm cellulose acetate membrane filter. The radiochemically pure product [¹⁸F]FHPG, 1 was eluted from the Sep-Pak with 90:8:2 H₂O/EtOH/ HOAc and adjusted pH to 5.5–7.0 with 2 M NaOH and 150 mM NaH₂PO₄ mixed solution, whose volume was dependent upon the use of the labeled product in tissue biodistribution studies (~3 mL, 3×1 mL) or in micro-PET imaging studies (1.5 mL, 3×0.5 mL) of HSV-tk prostate cancer tumors in athymic mice, and sterile-filtered through a 0.22 µm cellulose acetate membrane filter.
membrane and collected into a sterile vial. The radiochemical yield of \([^{18}F]\)FHPG was 10–15%, and the synthesis time was \(~70\) min from end of bombardment (EOB). Retention times in the analytical HPLC system were: \(RT_{9a} = 14.03\) min, \(RT_1 = 2.02\) min. The chemical purities of precursor \(9a\) and standard sample \(1\) were \(>95\)%, the radiochemical purity of target radiotracer \(1\) was \(>99\)%, and the chemical purity of radiotracer \(1\) was \(~93\)%.

The average \((n = 3–5)\) specific radioactivity of radiotracer \(1\) was \(0.8–1.2\) Ci/\(\mu\)mol at end-of-synthesis (EOS).

Key words: Suicide gene therapy, PSA, PSMA, prostate-specific promoter, PSES, HSV-TK, GCV
Abstract

Enzyme prodrug suicide gene therapy has been hindered by gene delivery and transduction efficiency. In order to further explore the potential of this approach, we developed a prostate-restricted replicative adenovirus (PRRA) armed with herpes simplex virus thymidine kinase (HSV-TK). This suicide gene (HSV-TK) and prodrug (ganciclovir (GCV)) combination has been extensively explored in both preclinical and clinical studies. In our previous Ad-OC-TK/ACV phase I clinical trial, we demonstrated both safety and proof of principle using a prostate-specific promoter in men with prostate cancer. In this study, we aimed to inhibit the growth of androgen-independent (AI), PSA/PSMA-positive prostate cancer cells by AdIU1, an HSV-TK-armed prostate-restricted replicative adenovirus (PRRA). In vitro, the growth of an androgen-independent PSA/PSMA-expressing prostate cancer cell line, CWR22rv, was significantly inhibited by treatment with AdIU1 plus GCV (10 µg/ml), as compared to AdIU1 treatment alone. AdIU1 alone or AdE4PSESE1a (a PRRA lacking HSV-TK) with and without GCV (10 µg/ml) treatment demonstrated no in vitro cytotoxicity. In vitro cytotoxicity was observed following treatment with AdIU1 plus GCV only in PSA/PSMA-positive CWR22rv and C4-2 cells, but not the PSA/PSMA-negative cell line, DU-145. In vivo assessment of AdIU1 plus GCV treatment revealed a therapeutic effect against CWR22rv tumors in nude mice, which was not seen following treatment with AdIU1 alone, AdE4PSESE1a or AdE4PSESE1a plus GCV. In summary, we developed a novel therapeutic strategy for the treatment of AI prostate cancer.
Introduction

Prostate cancer remains the leading cancer diagnosis in men. The incidence of prostate cancer is age-dependent and has steadily increased over the last several decades (ref). Localized prostate cancer can be managed effectively with numerous improving modalities, while advanced and metastatic disease eventually progresses to an androgen-independent (AI) state with limited treatment options. The aging population of men with an increasing prostate cancer incidence combined with an absence of successful therapies for advanced disease, require the development of novel therapies.

Tumor-specific suicide gene therapy using a tissue-specific promoter is a rational treatment strategy for prostate cancer (ref: cmv-tk, OC-TK). Herpes simplex virus thymidine kinase (HSV-TK)-based suicide gene therapy has been used to target prostate cancer for over a decade (ref: Baylor, uva). The prodrug ganciclovir (GCV) is phosphorylated by HSV-TK to its monophosphate form, which is rapidly converted to di- and triphosphate forms by cellular kinases, the latter of which is toxic to cells. The GCV-triphosphate is incorporated into DNA during cell division, causing single-strand DNA breaks and inhibition of DNA polymerase (ref). Prior preclinical studies have demonstrated that HSV-TK/prodrug-based suicide gene therapy inhibited the growth of mouse and human prostate cancer cells in vivo (ref). Clinical studies using the HSV-TK/GCV system for the treatment of prostate cancer have also shown the effectiveness of this suicide gene therapy strategy (ref). However, previous HSV-TK/GCV studies suffered from inefficient gene transduction rates in vivo.

Tumor-specific oncolytic adenoviruses have been effective and safe treatment options for patients with metastatic disease. We have demonstrated that Ad-OC-E1a, a PRRA could specifically and effectively inhibit the growth of human prostate cancer in vitro and in vivo (ref). Others have demonstrated similar in vitro and in vivo efficacy as well as safe administration to men with locally advanced and metastatic prostate cancer (ref: CN706,
More recently, Freytag et al. have demonstrated the safety and efficacy of a conditionally replicating, non-tissue-specific adenovirus containing the suicide genes TK and CD when combined with external beam radio therapy (ref).

We recently develop a prostate-specific chimeric enhancer, PSES, by combining enhancers from PSA and PSMA genes. PSES showed high activity specifically in PSA/PSMA-positive prostate cancer cells, regardless of androgen status (ref). This PSES promoter has been used to control the replication of a PRRA, which demonstrated prostate-specific replication and therapeutic efficacy both in vitro and in vivo (ref: E4). In this study, we developed a novel HSV-TK-armed replicative adenovirus, AdIU1, using the PSES promoter to drive the expression of adenoviral E1a, E1b and E4 genes in addition to HSV-TK. AdIU1 demonstrated its selective cytotoxicity toward androgen-independent (AI) PSA/PSMA-expressing prostate cancer both in vitro and in vivo.
Materials and Methods

Cells and Cell Culture

HER 911E4 cells are derived from adenoviral E1b (bp 79 to 5,789)-immortalized HER 911 (human embryonic retinoblastoma) cells that stably express adenoviral E4 proteins under control of the tetR promoter. HER911E4 cells were cultured in DMEM, supplemented with 10% FBS, 1% penicillin/streptomycin, 0.1 mg/mL hygromycin B (Calbiochem, San Diego, CA) and 2 µg/mL doxycycline (Sigma, St. Louis, MO). AI, androgen receptor (AR)- and PSA/PSMA-positive prostate cancer cell lines C4-2 and CWR22rv, and AI, AR- and PSA-negative cell lines DU-145 and PC3 were cultured in RPMI 1645 supplemented with 10% FBS and 1% penicillin/streptomycin. The cells were maintained at 37°C in a 5% CO₂ incubator.

Construction of the prostate-restricted replicative adenovirus (PRRA), AdIU1.

The construction of the backbone for AdIU1, AdE4PSESE4, was described previously (ref). To construct AdIU1, the CMV-EGFP expression cassette in AdE4PSESE1a was replaced by a PSES-HSV-TK expression cassette. HSV-TK and E1b in the left arm and E4 and E1a in the right arm were placed under the transcriptional control of PSES. Figure 1 illustrates the structure of the each virus used in this study. The adenoviral genome was released from the cloning vector by digestion with Pac I restriction enzyme and transfected into HER911E4 cells using Lipofectamine 2000 transfection reagent (Invitrogen, CA, USA). The plate was incubated at 37°C under 5% CO₂ for 7 to 10 days after transfection, until a cytopathic effect was observed. AdIU1 was further amplified in HER911E4 cells. The recombinant adenovirus was purified by CsCl gradient centrifugation. All gradient-purified viral stocks were dialyzed in dialysis buffer (1mM MgCl₂, 10mM Triz HCl (pH 7.5) and 10% glycerol) for 24 hours at 4°C, changing the buffer three times. Aliquots of purified virus were stored at -70°C.
**Viral replication assay**

CWR22rv, C4-2, PC-3 and DU-145 cells were seeded in 6-well plates (1 x 10^6 cells per well) 1 day prior to viral infection and subsequently infected with AdIU1 or AdE4PSESE1a (1000 virus particles (v.p.)/cell). The media were changed 24 hours after infection, and the viral supernatants were harvested 3 days after infection. The cells were examined under light microscopy daily for up to 5 days. Then, the titers of the harvested viral supernatants were determined by titer assay. HER911E4 cells were seeded in 96-well plates (5 x 10^3 cells per well) 1 day prior to infection. The cells were infected with serial volume dilutions of the harvested supernatants, ranging from 1 to 10^-11 µL per well, with each row of 8-wells receiving the same dose of virus. The media were changed on day 4, and the cells were examined under the microscope on day 7. The dose of the produced viruses was represented as an LD_{50} value, the dilution factor that caused a cytopathic effect in at least 4 wells of cells in a single row on a 96-well plate by day 7.

**Dose-dependent *in vitro* cell killing assay**

CWR22rv and DU145 cells were seeded on to 24-well plates at a density of 1.5 x 10^5 cells/well. After 24 hours, the cells were infected with 0.1-1000 v.p. per cell of AdIU1 or AdE4PSESE1a. 24 hours after infection, the media were removed and replaced by fresh media with or without GCV (10µg/ml). Media with or without GCV were changed every 2 days. Viable cells were analyzed by crystal violet assay 7 days post-infection.

**Time-dependent *in vitro* killing assay**

CWR22rv and DU-145 cells were plated in 24-well plates at densities of 1x10^5 cells/well. Cells were divided into 4 treatment groups, no treatment, AdIU1 (100 v.p./cell), GCV, and AdIU1 (100 v.p./cell) plus GCV. The media were changed 24 hours after infection, and
GCV (10µg/ml) was added 24 hours after the media change. Cell viability was analyzed at day 1, 3, 5 and 7 by crystal violet assay.

**In vivo evaluation of AdIU1 therapy**

All animal methods and procedures were approved by the Indiana University School of Medicine Institutional Animal Care and Use Committee (IACUC). CWR22rv xenografts were established by injecting 2 x 10^6 cells s.c. in the flanks of 6 week-old male, athymic nude mice. The injected mice were castrated 3 days after cells injection. Mice with similar tumor sizes (3 – 5 mm) were divided into four groups receiving, AdE4PSESE1a (negative control PRRA), AdE4PSESE1a plus GCV, AdIU1, or AdIU1 plus GCV treatment. 2 x 10^9 v.p. of either AdE4PSESE1a or AdIU1 in 100µL 1xPBS were injected intratumorally. 5 days after virus injection, GCV (40 mg/kg) was administered i.p. twice-daily for 10 days. Tumor sizes were measured every 5 days, and the following formula was applied to calculate tumor volume, length x width^2 x 0.5236. Mice were sacrificed and tumors harvested for histological examination 30 days after injection.

**Histology and Immunohistochemistry**

Tumors were harvested, immediately fixed in formalin and embedded in paraffin. The tissue sections were stained with hematoxylin and eosin (H&E), according to the standard protocol. For immunohistochemistry, tumor sections were deparaffinized, rehydrated and heated in a microwave oven for 20 min in activity antigen-retrieval solution (10mM citric buffer, pH 6.0). Endogenous peroxidase was blocked with 3% hydrogen peroxide solution. The slides were rinsed with distilled water, washed twice with PBS for 3 min and blocked with Superblock (Scytek Laboratories, Burlingame, CA, USA) in a humidified chamber for 60 min at room temperature. After rinsing with PBS, the slides were incubated with avidin (Vector Laboratories, Inc., Burlingame, CA, USA) for 15 min, washed with PBS and blocked
with biotin in a humidified chamber for 15 min at room temperature. A monoclonal mouse antibody to adenovirus type 5 (Abcam, Cambridge, MA, USA) and a mouse monoclonal antibody Ki67 antigen (Novostra Laboratories Ltd., UK) were applied. These slides were incubated with primary antibodies overnight in humidified chambers at 4°C. After 1 PBS rinse, a biotinylated secondary antibody was applied to the slides and incubated for 1h. After washing with PBS, slides were incubated with avidin-peroxidase complex (ABC) reagent (Vector Laboratories, Inc., Burlingame, CA, USA) for 30min, washed once with PBS, stained with freshly prepared diaminobenzidin (DAB) solution for 15 min and counterstained with hematoxylin.

**In situ Terminal Deoxynucleotide Transferase-Mediated Nick End Labeling Assay.**

The *in situ* apoptosis detection kit was purchased from Roche Diagnostics (Indianapolis, IN). Tumor tissue sections were deparafinized using a sequential xylene protocol and rehydrated through gradients of ethanol and distilled water. Slides were treated with 10nmol/L Tris solution containing 1 µg/ml proteinase K for 15 min. All slides were rinsed with PBS and incubated with 100µL terminal deoxynucleotidyl transfererase-mediated nick end labeling (TUNEL) reaction mixture (or 100µL control labeling solution for negative control) in a humid chamber at 37°C for 30 min. The slides were washed 3X with PBS and incubated with 100µL TUNEL POD solution in a humid chamber at 37°C for 30min. After washing with PBS, the slides were stained with freshly prepared DAB solution for 10min, rinsed with PBS, and counterstained with hematoxylin.
Results

Construction of a TK-armed PRRA.

AdIU1 was constructed by replacing the CMV-GFP expression cassette in AdE4PSESE1a with a PSES-HSV-TK expression cassette to extend the therapeutic potential of the PSES-based PRRA (Fig. 1). HER911E4 cells were transfected with recombinant adenoviral HSV-TK plasmid linearized by Pac I restriction enzyme digestion, and AdIU1 was purified from the harvest viral supernatant. To assess the prostate-specificity and viral replication efficiency of AdIU1, we performed an in vitro viral replication assay. PSA/PSMA-positive and –negative cells were infected with AdIU1. Viral plaques were observed only in the PSA/PSMA-positive cells (Table 1), demonstrating the fact that AdIU1 replication is tightly controlled by PSES and restricted to PSA/PSMA-positive cells.

Selective cell killing activity of AdIU1 plus GCV against AI, PSA/PSMA-positive human prostate cancer cells in vitro.

We performed a prodrug sensitivity assay in vitro. Each cell line, AI, PSA/PSMA-positive CWR22rv and C4-2, as well as AI, PSA/PSMA-negative DU-145 were seeded in triplicate in 24-well plates at a density of 2 × 10^4 cells/well and were incubated with increasing concentrations of GCV (0 to 100 µg/ml). Cell viability was determined after 5 days using crystal violet assay, and a corresponding IC50 dose was determined for each cell line (data not shown). We determined the optimal GCV treatment dose to be 10µg/ml.

To evaluate the selective cytotoxicity of AdIU1 and AdE4PSESE1a viruses, we infected each cell line with wide dose ranges (0.1-1000 v.p./cell) of virus, and then treated infected cells with or without GCV (10 µg/ml) (Fig. 2). The AI, PSA/PSMA-positive human prostate cancer cell, CWR22rv was significantly inhibited by 0.1 v.p. of AdIU1 in the presence of GCV. AdIU1 without GCV had similar killing activity as AdE4PSESE1a (negative control) either in the presence or absence of GCV. The AI, AR- and PSA/PSMA-
negative cell line, DU 145 was unaffected by either virus.

AdIU1/GCV showed cytotoxicity in AI, PSA/PSMA-positive cancer cells

CWR22rv (PSA/PSMA-positive) and DU-145 (PSA/PSMA-negative) cells were seeded in-24 well plates. The 24 wells were divided into 4 groups, no treatment, AdIU1, GCV alone, and AdIU1 plus GCV treatment. The GCV alone group demonstrated limited cytotoxicity. This confirmed that 10ug/mL GCV treatment was not toxic to either prostate cancer cell lines. The CWR22rv cell line demonstrated cell growth inhibition at day 7 after AdIU1 exposure, which was significantly enhanced when GCV was administered following AdIU1 infection. The DU-145 cell line demonstrated limited cytotoxicity in all four groups investigated (Fig. 3).

In vivo growth inhibition of CWR22rv xenograft by AdIU1/GCV

Human prostate CWR22rv xenograft tumors were induced by subcutaneous injection of CWR22rv cells into athymic nude mice. The mice were castrated 3 days after CWR22rv inoculation to test whether AdIU1 or AdE4PSESE1a was able to eliminate AI tumors in a castrated host. After tumor formation, the mice were randomized into 4 groups (AdIU1, AdE4PSESE1a, AdIU1 plus GCV and AdE4PSESE1a plus GCV). The mice were injected intratumorally with AdIU1 or AdE4PSESE1a as a control. Day 0 was the time of virus injection. On day 5, groups receiving GCV treatments were injected with GCV (40 mg/kg) 2 times a day for 10 days. Tumor volumes were measured at the times indicated in Figure 4. AdIU1/GCV effectively caused growth delay of CWR22rv xenografts. Light microscopic observation of H&E-stained tumors in mice injected with AdIU1/GCV showed substantial treatment effect. (Fig. 5). We also observed a large number of fibroblasts following combined treatment. To compare proliferation between the GCV treatment group and non-treated group, we performed immunohistochemistry using the proliferation antigen, Ki67.
We observed no significant difference in proliferation antigen expression between both groups. Also, we observed that all necrotic tumors stained positive for apoptosis by TUNEL assay. Anti-adenovirus type 5 E1a immunohistochemical staining revealed that extensive viral infection existed throughout the AdIU1, AdE4PSESE1a, and AdE4PSESE1a plus GCV treatment group tumors; however, adenovirus staining was absent in the AdIU1 plus GCV treatment group.
Discussion

Replication-defective recombinant adenoviruses have been widely studied *in vitro* and *in vivo* as a vector to deliver cancer therapeutic genes. Adenoviral based cancer gene therapy still maintains unrealized potential. The ability to infect and transduce a variety of mammalian cells, including prostate cells ([ref: PhaseI OC-TK]) in a cell cycle replication-independent manner without genotoxicity. However, there are several limitations in the use of these vectors for cancer gene therapy. Prior adenoviral investigations have demonstrated decreased Coxsackie-Adenoviral receptors on some cancer types. Additionally, the absence of integration into the genome allows for only a transient duration of exogenous gene expression expression.

The current investigations build on the ability of the adenovirus to infect prostate cancer cells and provide both expanded infection and longer exogenous gene expression with a prostate restricted replication-competent oncolytic virus, AdIU1. AdIU1 can replicate and kill infected cells by viral lysis, leading to *in vivo* amplification of input viral dose, spreading to adjacent cancer cells after lysis of initially infected cells. Additionally, AdIU1-infected cells produce HSV-TK to enhance killing with prodrug administration and allow for imaging of the viral process ([ref: PET-TK]). Several studies have demonstrated the importance of tissue-specific vectors, revealing systemic toxicity with the administration of high dose of nonspecific vectors. Through the use of prostate-specific promoters and enhancers, the expression of a therapeutic gene or adenoviral replication can be limited to cells that contain the appropriate activators and transcription factors. Currently, *kallikrein 2, PSA, rat probasin,* and *osteocalcin (OC)* are each under extensive investigation as regulators of prostate restricted replication adenovirus ([ref]). In our previous investigations, prostate-specific enhance sequence (PSES), was developed by locating the minimal sequence, AREc3 and PSME(del2) in AREc and PSME, respectively and placing AREc3 upstream from PSME (del2) ([ref]). PSES showed high activity specifically in PSA/PSMA-positive and AI prostate
cancer cells (ref AdE4).

Gene therapy with HSV-TK as a suicide gene has been performed in a variety of tumor models in vitro as well as in vivo. We already showed that both PSA and OC promoters can transcriptionally regulate HSV-TK gene-based therapy to inhibit the growth of AI PSA-producing cells. In this study, we investigated the gene-directed enzyme/prodrug therapeutic effect of AdIU1 (a novel PRRA expressing PSES promoter-driven HSV-TK suicide gene).

The in vitro tissue-specific cytotoxicity of AdIU1/GCV (10 ug/ml) in CWR22rv, C4-2 and DU-145 cells were assessed. Whereas the growth of CWR22rv and C4-2 cell lines were significantly inhibited by a small number of AdIU1 virus particles and GCV, the growth of the DU 145 could only be inhibited by a much greater exposure to AdIU1/GCV, this was expected, as DU-145 cells are PSA/PSMA-negative prostate cancer cells.

Collectively these results demonstrate that AdIU1/GCV has selective cytotoxicity in AI, PSA/PSMA-expressing cells with a good therapeutic window. As expected, intratumoral injection of AdIU1 and treatment with GCV effectively induced growth delay of CWR22rv tumors in nude mice. H&E staining revealed a large fibroblast infiltrate within the virus plus prodrug treatment groups. Furthermore, AdIU1/GCV-treated tumors were significantly inhibited in growth. To compare proliferation between GCV-treated tumors and non-treated tumors, we performed immunohistochemistry using the proliferation antigen, Ki67. We observed no different expression proliferation each groups. We observed heavy necrosis and apoptosis induction in combined treated groups.

In conclusion, we have established a prostate-restricted replication-competent adenovirus using PSES promoter to drive both oncolysis and HSV-TK expression only in AI PSA/PSMA-positive prostate cancer cells.

**Figure Legend**

**Figure 1.** Schematic illustration of AdIU1. AdIU1 was constructed by placing adenoviral E1a and E4 genes under the control of PSES to direct adenovirus replication, and HSV-TK gene, a pro-drug enzyme gene, under the control of another copy of PSES enhancer to restrict specific expression to maximize cell-killing activity through a bystander effect under the catalysis of ganciclovir (GCV).

**Figure 2.** In Vitro Killing assay. $1.5 \times 10^5$ CWR22rv and DU145 cells were seeded in 24-well plates and infected by serial dilutions of AdIU1 from 0.1 v.p/cell to 1000 v.p/cell, with replicative-deficient adenovirus AdE1aPSESE4 as controls. Crystal violet staining was performed to detect attached cells. Then 1% SDS was added to lyses the cells and for OD$_{590}$ reading. Cell survival rate curves were drawn to evaluate the killing activity of AdIU-1.

**Figure 3.** In vitro cytotoxicity assay. Growth of cells, infected with 100 virus particle/cell of AdIU1 virus, was significantly inhibited by addition of Ganciclovir (GCV) (10ug/mL), especially in CWR22rv(a). The other hand DU 145 (b) cells had no effect.

**Figure 4.** Effect of antitumor of AdIU1 in vivo. CWR22rv prostate tumor xenografts was established S.C. in athymic nude mice. Tumors were treated with AdE4PSESE1a (n=7), AdE4PSESE1a+GCV (n=8), AdIU1 (n=8) or AdIU1+GCV (n=8) by intratumoral injection at day 0 and after 5 days, injected GCV (100 mg/kg of body weight/day) 2times a day for 10days. And tumor volumes were measured every 5 days.

**Figure 5.** Tumors were removed for histological examination after the mice were killed at 30 days. (a) AdIU1 plus GCV, (b) AdIU1, (C) AdE4PSESE1a plus GCV and (d) AdE4PSESE1a treatment group (H&E, X 2). These slide showed a lot of fibroblast GCV treatment groups, also AdIU1 with GCV group showed small number of necrosis spot and tumor volume is very small. All necrosis spot show the apoptotic signal by the TUNEL Assay. AdIU1 with GCV group, E1a expression is rare.
Proliferation antigen, Ki67 immunohistochemistry, we observed no different expression proliferation each groups.
