**ABSTRACT**

Activation of the cellular apoptotic program is a current strategy for the prevention and treatment of human cancer including breast cancer. Because of the ease of synthesis and structural manipulation, small molecules with apoptosis-inducing ability have great potential to be developed into chemotherapeutic drugs. The beta-lactam antibiotics have for the past 60 years played an essential role in treating bacterial infections without causing toxic side effects in the host. We hypothesized that active N-thiolated b-lactams can damage DNA and induce apoptosis in human breast cancer cells in nude mice. In this final report, we have first evaluated potencies of many novel synthetic beta-lactams to inhibit proliferation and induce apoptosis in human cancer cells. We then determined whether several of these b-lactams, L1, HY2, HY14, HY15 and SC4, could damage breast tumor cell DNA and inhibit breast tumor growth in vivo. We have found that these b-lactams inhibited growth of implanted MDA-MB-231 breast tumors in a concentration-dependent manner, associated with their DNA-damaging activities. Our studies have provided strong support for proof-of-concept of the potential use of these N-thiolated beta-lactams in breast cancer prevention and treatment.

INTRODUCTION

Activation of the cellular apoptotic program is a current strategy for the prevention and treatment of human cancer including breast cancer (1). Because of the ease of synthesis and structural manipulation, small molecules with apoptosis-inducing ability have great potential to be developed into chemotherapeutic drugs (2). One particularly important class of small molecule drugs, the beta-lactam antibiotics, have for the past 60 years played an essential role in treating bacterial infections without causing toxic side effects in the host (3, 4). Recently we uncovered new members of this family of drugs, termed N-thiolated beta-lactams, which are highly effective at inhibiting bacterial growth in drug-resistant strains of Staphylococcus aureus (5, 6). Their mode of action appears to differ from that of traditional beta-lactam antibiotics. Most innovatively, we have discovered and characterized for the first time the anti-proliferative and apoptosis-inducing properties of N-thiolated beta-lactam antibiotics against human tumor cells (7). However, whether N-thiolated beta-lactam antibiotics have actual anti-breast cancer effects in vivo remains unknown.

BODY

For details, please see the included APPENDICES. Please also see below KEY RESEARCH ACCOMPLISHMENTS.

Structure-activity relationships of N-methylthiolated beta-lactam antibiotics with C₃ substitutions and their selective induction of apoptosis in human cancer cells (8 and see Appendices). The development of novel anti-cancer drugs that induce apoptosis has long been a focus of drug discovery. Beta-lactam antibiotics have been used for over 60 years to fight bacterial infectious diseases with little or no side effects observed. Recently a new class of N-methylthiolated beta-lactams has been discovered that have potent activity against methicillin resistant Staphylococcus aureas. Most recently, we determined the potential effects of these N-thiolated beta-lactams on tumorigenic cell growth and found that they are apoptosis-inducers in human cancer cell lines. In the current study, we further determined the effects of the substitution of the O-methyl moiety on C₃ and stereochemistry of the beta-lactams on the anti-proliferative and apoptosis-inducing abilities. We have found that Lactam 18, in which C₃ is substituted with an acrylate ester group, is a very effective proliferation inhibitor against human premalignant and malignant breast, leukemic, and simian virus 40-transformed fibroblast cells. Generally speaking, increasing the size of the moiety on C₃ decreases its anti-proliferation potency, possibly indicating steric hindrance with the cellular target or decreased permeability through the cell membrane. We also found that the stereochemistry of the beta-lactams plays an important role in their potency. The 3S,4R isomers are more effective than their enantiomers (3R,4S), suggesting that 3S,4R configuration is more favorable for target interaction.

Beta-lactams and their potential use as novel anticancer chemotherapeutics drugs (9 and see Appendices). The discovery of natural and synthetic antibiotics is one of the most important medical breakthroughs in human history. Many diseases, such as bacterial meningitis, pneumonia, and septicemia, are now curable with the use of antibiotics. Antibiotics are efficacious, generally well tolerated in patients, and have a low toxicity level. It is for these reasons antibiotics remain an attractive target for drug discovery. Traditional beta-
lactam antibiotics (e.g. penicillins, penems, cephalosporins) have a bicyclic ring structure that is conformationally rigid and functions to inhibit bacterial cell wall synthesis. In addition to the bactericidal action of antibiotics, it has been discovered that many antibiotics are capable of inhibiting tumor cell growth. There are currently many antitumor antibiotics approved for cancer therapy, which work to inhibit tumor cell growth by DNA intercalation. The use of beta-lactams as prodrugs has also met with success by aiding delivery of the chemotherapeutic directly to tumor sites. Recently, a novel class of N-thiolated monobactams, so termed because they possess a monocyclic ring instead of the bicyclic ring, has been found to induce apoptosis potently and specifically in many tumor cell lines but not in normal, non-transformed cell lines. Other beta-lactams, such as the polyaromatics, have been found to slow or inhibit tumor cell growth, and the 4-alkylidene beta-lactams are capable of inhibiting matrix metalloproteinases and leukocyte elastase activity. These data indicate that synthesis and evaluation of beta-lactams are a promising area for further development in anticancer research.

Cell death-inducing activities of novel beta-lactams. In order to discover more potent beta-lactams for in vivo studies as proposed in this Concept Award, we have first examined the growth-inhibiting and cell death-inducing activities of numerous beta-lactams that were synthesized by our chemistry collaborators. There are 10 compounds in HY group (HY2 to HY21), 24 compounds in JG group (JG1 to JG 24) and several SC compounds (such as SC4). Chemical structures of some of the compounds are shown in Fig. 1. Our results indicate that in JG group, JG19 and JG5 were most potent cell death inducers when tested in human leukemia HL60 and Raji cell lines (Fig. 2A, B) and that in HY group, the order of potency to induce HL60 cell death was: HY20 > HY18 > HY16 = HY15 > HY14 > HY19 > HY17 (Fig. 2C). Beta-lactam L-1 was used as a comparison (Fig. 2). The results from Western blot analysis also showed that JG19 and JG20 could induce PARP cleavage, a cellular apoptotic marker (Fig. 3).

Beta-lactams effectively inhibit proliferation and induce apoptosis in human breast cancer cells. Previously we reported that L-1 has the great potency to induce apoptosis in cancer cells showed by MTT assay and PARP cleavage (7). In the current experiment we screened more beta-lactams (Fig. 4) in order to discover more potent analogs for in vivo studies. Human breast cancer MCF-7 cells were treated with each of the indicated beta-lactams at 1, 25 or 50 μM or DMSO (as solvent control) for 24 h, followed by performance of an MTT assay, which measures the status of cell viability and, thus, cell proliferation. After treatment with 50 μM of L-47, cellular viability of MCF-7 was decreased by 73%. Compared with 63% inhibition by 50 μM of L-1, L-47 was the most potent one in the tested beta-lactams (Fig. 5A).

We then treated another human breast cancer cell line MDA-MB-231 with 50 μM of L-1, L-30, L-47 or L-53 for different time points, followed by preparation of cell lysates and measurement of PARP cleavage, a cellular apoptotic marker, by Western blotting. The results showed that among the tested lactams, L-47 had the greatest potency to induce PARP cleavage within 8 h of treatment (Fig. 5B).
Beta-lactam HY14, an analog of L-47, significantly inhibits the growth of breast cancer xenografts, associated with its DNA damaging activity in vivo. The data described above clearly demonstrate that β-lactams are apoptosis inducers in cultured leukemia and breast cancer cells. Our experimental results also showed that HY14 was more potent than L-1 in inducing cell death in cancer cells (Fig. 2C). Since we have a large quantity of HY14, we then examined anti-tumor activity of HY14 in vivo. We implanted MDA-MB-231 cells s.c. in nude mice. When the tumors became ~200 mm³, the mice were i.p. treated with either vehicle control or HY14 at 0.3 or 3.0 mg/kg/day. The inhibition (up to 53%) of tumor growth by 3.0 mg/kg/day treatment of HY14 was observed after 30 days injection but only 13% inhibition of tumor growth was showed by 0.3 mg/kg/day treatment (Fig. 6A), indicating that HY has anti-tumor activity which is dose-dependent. The immunohistochemistry results showed that the apoptosis-specific TUNEL positivity was found mainly in MDA-MB-231 tumors treated with HY14 at 3.0 mg/kg/day, less in those treated with 0.3 mg/kg/day of HY14, but none in vehicle-treated tumor (Fig. 6B).

The anti-breast tumor activities of Beta-lactams L1, HY-2, HY15 and SC4. We then examined the antitumor activities of several other beta-lactams of which we have a large quantity. Again, MDA-MB-231 cells were s.c. implanted in nude mice. When the tumors became ~100 mm³, the mice were i.p. treated with either vehicle control or each selected beta-lactam at 10 or 20 mg/kg/day. We found that HY-2, HY15 and SC4 at 10 mg/kg/day inhibited tumor growth by 17%, 46% and 64%, respectively (Fig. 7). L1 at 10 and 20 mg/kg/day caused 30% and 48% inhibition, respectively (Fig. 7), indicating a dose-dependence. The tumor tissue samples are currently analyzed by immunohistochemistry assays.

Beta-lactam 1 is able to damage tumor DNA in vivo and inhibits the growth of breast cancer MDA-MB-231 xenografts. Since we have a large quantity of L1, we then examined its anti-tumor activity at higher concentrations. We implanted MDA-MB-231 cells s.c. in nude mice. When the tumors became ~100 mm³, the mice were i.p. treated with either vehicle control or L1 at 20 or 30 mg/kg/day. Up to 72% inhibition of tumor growth by 30 mg/kg/day treatment of L1 was observed after 30 days injection (Fig. 8), but only ~40% inhibition was found by 20 mg/kg/day treatment with L1, again indicating that L1’s anti-tumor activity is dose-dependent (Fig. 8). The immunohistochemistry results showed that the apoptosis-specific condensed nuclei and TUNEL positivity were found mainly in MDA-MB-231 tumors treated with L1 at 30 mg/kg/day, less in those treated with 20 mg L1/kg/day, but none in vehicle-treated tumor (Fig. 9). Therefore, these beta-lactam antibiotics are able to selectively damage tumor cell DNA in vivo, resulting in cell death and growth inhibition.

We are repeating some of the animal experiments and are processing all the collected tissue samples. These results will be summerized in one or more manuscripts for publication in the near future. These studies should provide strong support for proof-of-concept of the potential use of these N-thiolated beta-lactams in breast cancer prevention and treatment.

Figure 2. Beta-lactams could induce cell death in human leukemia cells.

Trypan blue assays: human leukemia HL60 (A, B) and Jurkat cell line (C) were treated with 50 or 100 μM of each beta-lactam for 24 hrs, and then non-viable cells were determined by Trypan Blue. L1 was used as a positive control.
Figure 3. JG19 and JG20 could induce apoptosis-associated PARP cleavage.
Raji cells were treated with 50 μM JG19 or JG20 for 4, 8, or 20 hours before being harvested. 
The results show that both JG19 and JG20 induce PARP cleavage, indicative of apoptosis.

Figure 5. β-lactams could effectively inhibit proliferation and induce apoptosis in human breast cancer cells.

A. MCF-7 cells were treated with either 1, 25 or 50 μM of indicated lactams or DMSO as solvent control (Ctrl) for 24 h, followed by performance of an MTT assay.

B. MDA-MB-231 cells were treated with 50 μM of indicated b-lactams for different time points, followed by preparation of cell lysates and measurement of PARP cleavage by Western blot.
Figure 6. β-lactam HY-14 could inhibit the tumor growth in nude mice implanted by human breast cancer MDA-MB-231 cells.

Female athymic nude mice (NCRNU-M) were xenografted by injection of $6 \times 10^6$ MDA-MB-231 cells. 15 days after the injection, the mice were divided into three groups: solvent control, low dose (0.3 mg/kg) and high dose (3 mg/kg) treatment with β-lactam HY-14 by subcutaneous injection daily. Tumor size was measured every 5 days and tumor volume ($V$) was determined by the equation: $V = (L \times W^2) \times 0.5$, where $L$ is the length and $W$ is the width of a tumor. Tumor volume was calculated and expressed as cubic millimeters (A). TUNEL (Terminal deoxynucleotidyl Transferase Biotin-dUTP Nick End Labeling) analysis of tumor tissues from three different groups was performed. Nuclei stained in dark brown indicate TUNEL positive (B).
Fig. 7. Effects of other four β-lactams L-1, HY-2, HY-15 and SC4 on tumor growth in nude mice implanted by human breast cancer MDA-MB-231 cells.

Female athymic nude mice (NCRNU-M) were xenografted by injection of 6 \times 10^6 MDA-MB-231 cells. When the tumor size reached ~100 mm³, the mice were divided into six groups: solvent control, 10 mg/kg or 20 mg/kg of L-1, HY-2, HY-15 or SC4 (all at 10 mg/kg). Treatment was performed by daily subcutaneous injection. Tumor size was measured every other day.

Apoptotic-Inducing Activity of Novel Polycyclic Aromatic Compounds in Human Leukemic Cells (10). Persistent, but relatively limited research has been devoted to the use of compounds related to polycyclic aromatic hydrocarbons (PAH) as anticancer agents. In previous reports we have described the cytotoxicity of a number of new and novel PAH against human cancer cell lines. However, the involved molecular mechanisms of inducing cell death were not elucidated. In the current study, we describe the apoptotic pathway as apparently playing a crucial role in cell death induced in human leukemia Jurkat T cells by several diamide and diamine PAH that contain chrysene as their core aromatic ring system. Structure-activity relationships were analyzed. Importantly, no effect was demonstrated in a normal, non-transformed line of human natural killer cells. These results provide additional evidence for the potential chemotherapeutic use of PAH.

Clioquinol and pyrrolidine dithiocarbamate complex with copper to form proteasome inhibitors and apoptosis inducers in human breast cancer cells (11 and see Appendices). Introduction A physiological feature of many tumor tissues and cells is the tendency to accumulate high concentrations of copper. While the precise role of copper in tumors is cryptic, copper, but not other trace metals, is required for angiogenesis. We have recently reported that organic copper-containing compounds, including 8-hydroxyquinoline-copper(II) and 5,7-dichloro-8-hydroxyquinoline-copper(II), are a novel class of proteasome inhibitors and tumor cell apoptosis inducers. In the current study, we investigate whether clioquinol (CQ), an analog of 8-hydroxyquinoline and an Alzheimer's Disease drug, and pyrrolidine dithiocarbamate (PDTC), a known copper-binding compound and antioxidant, can interact with copper to form cancer-specific proteasome inhibitors and apoptosis inducers in human breast cancer cells. Tetrathiomolybdate (TM), a strong copper chelator currently being tested in clinical trials, is used as a comparison. Methods Breast cell lines, normal, immortalized MCF-10A, premalignant MCF10AT1K.cl2, and malignant MCF10DCIS.com and MDA-MB-231, were treated with CQ or PDTC with or without prior complexation with copper, followed by measurement of proteasome inhibition and cell death. Inhibition of the proteasome was determined by levels of the proteasomal chymotrypsin-like activity and ubiquitinated proteins in protein extracts of the treated cells. Apoptotic cell death was measured by morphological changes, Hoechst staining, and Poly(ADP-Ribose) Polymerase cleavage. Results When complexed with copper, both CQ and PDTC, but not TM, can inhibit the proteasome chymotrypsin-like activity, block proliferation, and induce apoptotic cell death preferentially in breast cancer cells, less in premalignant breast cells, but are nontoxic to normal/non-transformed breast cells at the concentrations tested. In contrast, CQ, PDTC, TM or copper alone had no effects on any of the cells. Breast premalignant or cancer cells, that contain copper at concentrations similar to those found in patients, when treated with just CQ or PDTC alone, but not TM, undergo proteasome inhibition and apoptosis. Conclusions The feature of breast cancer cells and tissues to accumulate copper can be used as a targeting method for anticancer therapy through treatment with novel compounds such as CQ and PDTC that become active proteasome inhibitors and breast cancer cell killers in the presence of copper.
Appendices. Recent research suggests that copper could be used as a novel selective target for cancer therapies. Copper is a co-factor essential for tumor angiogenesis processes and high levels of copper have been found in many types of human cancers, including prostate, breast and brain. We have reported that organic copper-containing compounds, such as 8-hydroxyquinoline-copper(II), are a novel class of proteasome inhibitors and tumor cell apoptosis inducers (Daniel et al., Biochem Pharmacol. 2004;67:1139-51). Most recently, we have found that when complexed with copper, the known antioxidant pyrrolidine dithiocarbamate (PDTC) forms a potent proteasome inhibitor in human breast cancer, but not normal cells (11). In the current study, we investigate whether the PDTC-copper complex can play similar roles in inhibiting the proteasomal activity and consequently inducing apoptosis in human prostate cancer cells. We used tetrathiomolybdate (TM), a strong copper chelator currently being tested in clinical trials, as a control. We report here that after binding to copper, PDTC, but not TM, can inhibit the proteasomal chymotrypsin-like activity, suppress proliferation, induce apoptotic cell death, and inhibit uptake of radiopharmaceutical 2-[18F]Fluoro-2-deoxy-D-glucose in cultured human prostate cancer cells. In contrast, PDTC, TM or copper alone or a TM-copper mixture had no such effects. Our study suggests that high copper levels in human prostate cancer in vivo can be targeted by a ligand such as PDTC, resulting in formation of an active proteasome inhibitor and apoptosis inducer specifically in prostate tumor, but not normal cells.

Disulfiram, A Clinically Used Anti-Alcoholism Drug and Copper-Binding Agent, Induces Apoptotic Cell Death in Breast Cancer Cultures and Xenografts via Inhibition of the Proteasome Activity (13 and see Appendices). Disulfiram (DSF), a member of the dithiocarbamate family capable of binding copper and an inhibitor of aldehyde dehydrogenase, is currently being used clinically for the treatment of alcoholism. Recent studies have suggested that DSF may have antitumor and chemosensitizing activities although the detailed molecular mechanisms remain unclear. Copper has been shown essential for tumor angiogenesis processes. Consistently, high serum and tissue levels of copper have been found in many types of human cancers, including breast, prostate and brain, supporting the idea that copper could be used as a potential tumor-specific target. Here we report that the DSF-copper complex potently inhibits the proteasomal activity in cultured breast cancer MDA-MB-231 and MCF10DCIS.com, but not normal, immortalized MCF-10A, cells, prior to induction of apoptotic cancer cell death. Furthermore, MDA-MB-231 cells that contain copper at concentrations similar to those found in patients, when treated with just DSF, undergo proteasome inhibition and apoptosis. In addition, when administered to mice bearing MDA-MB-231 tumor xenografts, DSF significantly inhibited the tumor growth (by 74%), associated with in vivo proteasome inhibition (as measured by decreased levels of tumor tissue proteasome activity and accumulation of ubiquitinated proteins and natural proteasome substrates p27 and Bax) and apoptosis induction (as shown by caspase activation and apoptotic nuclei formation). Our study demonstrates that inhibition of the proteasomal activity can be achieved by targeting tumor cellular copper with the non-toxic compound DSF, resulting in selective apoptosis induction within tumor cells.

A Novel Anticancer Gold(III) Dithiocarbamate Compound Inhibits the Activity of a Purified 20S Proteasome and 26S Proteasome in Human Breast Cancer Cell Cultures and Xenografts (14). Although cisplatin has been used for decades to treat human cancer, some toxic side effects and resistance are observed. It has been suggested that gold(III) complexes, containing metal centers isoelectronic and isostructural to cisplatin, are promising anticancer drugs. Gold(III) dithiocarbamate complexes were shown to exhibit in vitro
cytotoxicity, comparable to and even greater than cisplatin, however, the involved mechanism of action remained unknown. Because we previously reported that copper(II) dithiocarbamates are potent proteasome inhibitors, we hypothesized that gold(III) dithiocarbamate complexes could suppress tumor growth via direct inhibition of the proteasome activity. Here, for the first time, we report that a synthetic gold(III) dithiocarbamate, Compound 2, potently inhibits the activity of a purified rabbit 20S proteasome and 26S proteasome in intact, highly metastatic, MDA-MB-231 breast cancer cells, resulting in the accumulation of ubiquitinated proteins and the proteasome target protein p27 and induction of apoptosis. The Compound 2-mediated proteasome inhibition and apoptosis induction were completely blocked by addition of a reducing agent, 1,4-Dithio-DL-threitol or N-Acetyl-L-Cysteine, demonstrating that process of oxidation is required for proteasome inhibition by Compound 2. Treatment of MDA-MB-231 breast tumor–bearing nude mice with Compound 2 resulted in significant inhibition of tumor growth, associated with proteasome inhibition and massive apoptosis induction in vivo. Our findings reveal the proteasome as a primary target for gold(III) dithiocarbamates, and support the idea for their potential use as anticancer therapeutics.

KEY RESEARCH ACCOMPLISHMENTS

- Published 18 articles and 7 abstract
- At least two more manuscript in preparation
- Gave 16 scientific presentations
- Trained and graduated two Ph.D. students
- Partially supported several personnel (Deborah Kuhn, Ph.D., Kenyon Daniel, Ph.D., Di Chen, Ph.D., Lihua Li, M.D., Guoqing Shi, Ph.D., Shirley Orlu, B.S., Cindy Cui, B.S.)

CONCLUSIONS

We have determined whether several novel beta-lactams, L1, SC4, HY2, HY14 and HY15, can inhibit tumor growth in vivo. We have found that these beta-lactams inhibited growth of implanted MDA-MB-231 breast tumors in a concentration-dependent manner, associated with their DNA-damaging and apoptosis-inducing activities. Our studies have provided strong support for proof-of-concept of the potential use of these N-thiolated beta-lactams in breast cancer prevention and treatment.

Abstract

Historically, it has been shown that the β-lactam antibiotics play an essential role in treating bacterial infections while demonstrating selectivity for prokaryotic cells. We recently reported that certain N-methylthio-substituted β-lactam antibiotics had DNA-damaging and apoptosis-inducing activities in various tumor cells. However, whether these compounds affect human normal or nontransformed cells was unknown. In the current study, we first show that a lead compound (lactam 1) selectively induces apoptosis in human leukemic Jurkat T, but not in the nontransformed, immortalized human natural killer (NK) cells. Additionally, we screened a library of other N-methylthiolated β-lactams to determine their structure-activity relationships (SARs), and found lactam 12 to have the highest apoptosis-inducing activity against human leukemic Jurkat T cells, associated with increased DNA-damaging potency. Furthermore, we demonstrate that lactam 12, as well as lactam 1, potently inhibits colony formation of human prostate cancer cells. We also show that lactam 12 induces apoptosis in human breast, prostate, and head-and-neck cancer cells. Finally, lactam 12 induces apoptosis selectively in Jurkat T and simian virus 40-transformed, but not in nontransformed NK and parental normal fibroblast, cells. Our results suggest that there is potential for developing this class of β-lactams into novel anticancer agents.

1. Introduction

Apoptosis, or programmed cell death, is a highly regulated process important in embryonic and immune system development and tissue homeostasis [1,2]. Perturbation of this pathway can lead to autoimmunity, acquired immune deficiency syndrome, neurodegenerative disorders, and cancer [3,4]. Initiation, commitment, and execution are selective for prokaryotic cells. We recently reported that certain N-methylthio-substituted β-lactam antibiotics had DNA-damaging and apoptosis-inducing activities in various tumor cells. However, whether these compounds affect human normal or nontransformed cells was unknown. In the current study, we first show that a lead compound (lactam 1) selectively induces apoptosis in human leukemic Jurkat T, but not in the nontransformed, immortalized human natural killer (NK) cells. Additionally, we screened a library of other N-methylthiolated β-lactams to determine their structure-activity relationships (SARs), and found lactam 12 to have the highest apoptosis-inducing activity against human leukemic Jurkat T cells, associated with increased DNA-damaging potency. Furthermore, we demonstrate that lactam 12, as well as lactam 1, potently inhibits colony formation of human prostate cancer cells. We also show that lactam 12 induces apoptosis in human breast, prostate, and head-and-neck cancer cells. carbapenems, nocardicins, and monobactams [13]. The bacterial targets of these antibiotics are membrane-bound transpeptidases referred to as the penicillin-binding proteins, which are responsible for creating crosslinks within the bacterial cell wall [13]. By disrupting these crosslinking proteins, the β-lactams induce structural deformities within the cell wall, which cause the bacteria to lyse. Recently, a novel class of N-thiolated β-lactams has been shown to inhibit Staphylococcus aureus and methicillin-resistant S. aureus growth [14–16].

Previously we showed that N-thiolated β-lactams, such as β-lactam 1, induced DNA damage, inhibited DNA replication, and induced tumor cell apoptosis in a time- and concentration-dependent manner [17]. Our current study shows, for the first time, that the N-thiolated β-lactam 1 can preferentially induce apoptosis in leukemic Jurkat T cells, but not nontransformed, immortalized human NK cells. Additionally, we also show that lactam 12, an analog of lactam 1, has enhanced apoptosis-inducing activity in Jurkat T cells compared to lactam 1. Furthermore, this study reveals that lactam 12 can induce apoptosis in other human solid tumor cell lines such as breast, prostate, and head and neck. Lactam 12 also induces apoptosis selectively in Jurkat T, but not human NK, cells, and in simian virus 40 (SV40)-transformed human fibroblasts (VA-13), but not in their parental counterpart (WI-38). Both lactams 1 and 12 are able to activate caspase-3 in human prostate cancer cells and inhibit colony formation of these cells in soft agar. These data indicate that further study of N-thiolated β-lactams in the treatment of cancer is warranted.

2. Materials and methods

2.1. Materials

Fetal bovine serum (Tissue Culture Biologicals), 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), dimethyl sulfoxide (DMSO), and trypan blue were purchased from Sigma-Aldrich. RPMI 1640, Dulbecco’s modified Eagle’s medium (DMEM), MEM nonessential amino acids solution, MEM sodium pyruvate solution, penicillin, and streptomycin were purchased from Invitrogen. Fluorogenic peptide substrate Ac-DEVD-AMC (the specific caspase-3/-7 substrate) was obtained from Calbiochem. Polyclonal antibody to human PARP was obtained from Roche Molecular Biochemicals. The APO-DIRECT kit for terminal deoxynucleotidyl transferase-mediated UTP nick-end labeling (TUNEL) staining was purchased from BD Pharmingen.

2.2. Synthesis of β-lactams

The β-lactam analogs (Fig. 1A) were prepared as racemates (with cis stereochemistry) using a procedure described previously [14,15].

2.3. Cell culture, protein extraction, and Western blot assay

Human Jurkat T cells and human prostate cancer LNCaP cells were cultured in RPMI 1640 medium, supplemented with 10% fetal bovine serum, 100 U/mL penicillin, and 100 μg/mL streptomycin. Human YT cells were cultured in RPMI 1640 medium supplemented with 1 mM MEM sodium pyruvate solution, 0.1 mM MEM nonessential amino acids solution, 10% fetal bovine serum, 100 U/mL penicillin, and 100 μg/mL streptomycin. Human breast cancer MCF-7 cells, head-and-neck cancer PCI-13 cells, prostate cancer DU-145 cells, normal (WI-38) and SV-40 transformed (VA-13) human fibroblasts cells were grown in DMEM containing 10% fetal calf serum, 100 U/mL penicillin, and 100 μg/mL streptomycin. All cell lines were maintained at 37°C in a humidified incubator with an atmosphere of 5% CO2.

A whole-cell extract was prepared as described previously [18]. Briefly, cells were harvested, washed with PBS and homogenized in a lysis buffer (50 mM Tris–HCl, pH 8.0, 5 mM EDTA, 150 mM NaCl, 0.5% NP-40, 0.5 mM phenylmethylsulfonyl fluoride, and 0.5 mM dithiothreitol) for 30 min at 4°C. Afterwards, the lysates were centrifuged
at 12,000 g for 15 min at 4°C and the supernatants collected as whole-cell extracts. Equal amounts of protein extract (60 μg) were resolved by SDS-polyacrylamide gel electrophoresis and transferred to a nitrocellulose membrane (Schleicher & Schuell) using a Semi-Dry Transfer System (Bio-Rad). The enhanced chemiluminescence Western blot analysis was then performed using specific antibodies to the proteins of interest.

2.4. Trypan blue assay

The trypan blue dye exclusion assay was performed by mixing 20 μL of cell suspension with 20 μL of 0.4% trypan blue dye before injecting into a hemocytometer and counting. The number of cells that absorbed the dye and those that exclude the dye were counted, from which the percentage of nonviable cell number to total cell number was calculated.

2.5. Morphological assessment of apoptosis

To assess morphological changes of cells, 50 μL of treated or untreated cell suspension were transferred to a glass slide at the indicated time points. The slides were observed under a phase-contrast microscope (Leica) and photographs were taken (100x). Apoptotic cells were identified by their distinct morphological changes.

2.6. TUNEL assay

Terminal deoxynucleotidyl transferase-mediated nick-end labeling (TUNEL) was used to determine the extent of DNA strand breaks [19]. The assay was performed following manufacturer’s instruction using the APO-Direct kit. In brief, the harvested cells were fixed in 1% paraformaldehyde for 15 min on ice, washed with PBS, and then fixed again in 70% ethanol at −20°C overnight. The cells were then incubated in DNA labeling solution (containing terminal deoxynucleotidyl transferase (TdT) enzyme, fluorescein-conjugated dUTP and reaction buffer) for 90 min at 37°C. After removing the DNA labeling solution by rinsing with Rinsing Buffer, the cells were incubated with the propidium iodide/RNase A solution, incubated for 30 min at room temperature in the dark, and then analyzed by flow cytometry within 3 hr of staining.

2.7. Caspase-3/-7 activity assay

To measure cell-free caspase-3/-7 activity, whole-cell extracts (20-30 μg) from untreated or treated LNCaP, MCF-7, PCI-13, DU-145, VA-13, and WI-38 cells were incubated with 20 μM of the fluorogenic substrate caspase-3/-7 (Ac-DEVD-AMC) for 30 min at 37°C in 100 μL of assay buffer (50 mM Tris, pH 8.0). Measurement of the hydrolyzed AMC groups was performed on a VersaFluor™ Fluorometer (Bio-Rad) as described previously [20].

2.8. Soft agar assay

The soft agar assay was performed as described previously [21] with a few modifications. In brief, in a 6-well plate, a bottom feeder layer (0.6% agar) was prepared with DMEM media containing 10% fetal bovine serum, 100 U/mL penicillin, and 100 μg/mL streptomycin. A top layer (0.3% agar) was prepared with DMEM and the same media as described above but containing 2 × 10⁵ prostate cancer LNCaP cells and 50 μM of lactam 1 or 12, or equal volume of solvent (DMSO) as a control. Plates were incubated at 37°C in 5% CO₂ in a humidified incubator for 3 weeks. MTT (1 mg/mL) was added to each well and incubated overnight to allow complete formation of purple formazan crystals. The plates were then scanned and photographed, and the number of colonies was quantified by Quantity one v. 4.0.3 software (Bio-Rad).

2.9. Nuclear staining

To assay nuclear morphology, the detached or remaining attached cells were washed with PBS, fixed with 70% ethanol for 1 hr, and stained with Hoechst 33342 (1 mM) for 30 min. The nuclear morphology was visualized by fluorescence microscopy (40×; Leitz) [18].

3. Results

3.1. Screening for more apoptotically active analogs of lactam 1

Lactam 1 contains a chloro (−Cl) group in the ortho position on the benzene ring (Fig. 1A). To examine whether deletion or substitution of the Cl group could affect its cell death-inducing ability, other halogen and nonhalogen analogs of lactam 1 were synthesized (Fig. 1A). These compounds were then tested in the trypan blue dye exclusion assay, using lactam 1 as a comparison (Fig. 1B). Jurkat T cells were treated with each of these compounds at 50 μM for 24 hr, followed by measurement of loss of cell membrane permeability, indicative of a late apoptotic stage (Fig. 1B) [22,23]. As a control, lactam 1 induced ~52% cell death (Fig. 1B). Interestingly, removal of the Cl group from the benzene ring significantly decreased the cell death-inducing activity to ~25% (lactam 8; Fig. 1B). Furthermore, replacement of the Cl group with a smaller halogen atom (−F; lactam 9) also decreased the death-inducing activity (to ~35%), while analogs with a larger halogen group (−Br and −I; lactams 10 and 11, respectively; Fig. 1A) increased the cell death rates to 55 and 60% (Fig. 1B). These data suggest that the size of the group in the ortho position on the benzene ring is important for the compound’s cell death-inducing activity. Indeed, the analog with −NO₂ substitution, lactam 12 (Fig. 1A), exhibited the strongest effect with a total of

~94% cell death (Fig. 1B). Therefore, the order of potency of the tested compounds was: X = H < F < Cl < Br < I < NO₂.

3.2. Lactam 1 induces apoptosis preferentially in leukemic Jurkat T over nontransformed, immortalized NK cells

Previously, we reported that β-lactam analogs, such as lactam 1 (Fig. 1A) [17], were able to induce tumor cell apoptosis. However, whether lactam 1 affects normal or nontransformed cells was unknown. To determine whether lactam 1 was able to induce apoptosis preferentially in tumor/transformed vs. normal/nontransformed cells, we treated human leukemic Jurkat T cells and immortalized, nontransformed NK cells (YT line) [24] with lactam 1 in both concentration- and time-dependent experiments. Treatment of Jurkat T cells with 10 μM of lactam 1 for 24 hr induced apoptosis-specific PARP cleavage fragment p85 (Fig. 2A), whose levels were further increased when 25 μM of lactam 1 was used (Fig. 2A). After treatment with 50 μM of lactam 1, PARP degradation was further increased, as evidenced by a significant decrease in expression of intact PARP protein (Fig. 2A). In contrast, no PARP cleavage was detectable in the YT cells after treatment with lactam 1 at even 50 μM (Fig. 2A).

In the kinetic experiment, both Jurkat T and YT cells were treated with 30 μM of lactam 1 for 3, 6, or 24 hr. PARP cleavage was detected in Jurkat T cells first at 3 hr, which was then increased at 6 hr (although the levels of PARP/p85 fragments at 24 hr were decreased in this Western blotting; Fig. 2B). Importantly, no PARP cleavage was observed in YT cells in the same kinetics experiment (Fig. 2B). To confirm the tumor cell-selective killing activity of lactam 1, a trypan blue dye exclusion assay was performed in the same kinetic experiment. After 24 hr, there was 42% cell death in the Jurkat T cells compared to 9% in YT cells (Fig. 2C). Furthermore, by using phase-contrast microscopy, more cell death was observed in Jurkat T cells than YT cells (Fig. 2D). These data support the conclusion that lactam 1 could induce apoptotic cell death selectively in tumor over nontransformed cells.

3.3. Lactam 12 has enhanced apoptosis-inducing activity specific to Jurkat T, but not normal YT cells

To determine if lactam 12 is capable of inducing apoptosis at lower concentrations than lactam 1, a dose-response experiment was performed with both compounds. Jurkat T cells were treated with lactam 12 at 2, 10, 25, and 50 μM for 24 hr, using 50 μM of lactam 1 as a comparison. Again, treatment with lactam 1 caused ~50% cell death, measured by trypan blue exclusion assay (Fig. 3A). Under the same experimental conditions, lactam 12 induced cell death in a concentration-dependent manner: 25% at 10 μM, 45% at 25 μM, and 80–90% at 50 μM (Fig. 3A). Therefore, lactam 12 is ~2-fold more potent than lactam 1. This conclusion was further supported by PARP cleavage.

Fig. 2. Selective induction of apoptosis by lactam 1 in leukemic Jurkat T over immortalized/nontransformed NK cells. Jurkat T and NK (YT) cells were treated with 10, 25, and 50 μM of lactam 1 for 24 hr (A) or with 30 μM of lactam 1 for indicated hours (B–D). (A and B) Measurement of PARP cleavage in Western blot assay. The intact PARP (116 kDa) and a PARP cleavage fragment (p85) are shown. (C) Trypan blue dye exclusion assay. The numbers given are percentages of nonviable cells to total cells. Standard deviations are shown with error bars from a mean of at least three different experiments. (D) Morphological changes of Jurkat T and YT cells after treatment. Photographs under a phase-contrast microscope (100×).
assay using lysates prepared after 12-hr treatment (Fig. 3B). Cleavage of PARP occurred in lactam 12-treated cells in a dose-dependent manner with the highest level of PARP cleavage observed at 50 μM (Fig. 3B). The levels of PARP cleavage induced by 50 μM of lactam 1 were equivalent to ~50% of that by 50 μM of lactam 12 (Fig. 3B).

In the same experiment, when immortalized, nontransformed NK cells were treated with lactam 12 (using lactam 1 as a control), neither cell death (Fig. 3C) nor PARP cleavage (Fig. 3D) were observed. Therefore, like lactam 1, lactam 12 also induces apoptotic cell death preferentially in tumor over nontransformed cells.

To further compare the potency of lactams 1 and 12, Jurkat T cells were treated with 25 μM of lactam 12 vs. 50 μM of lactam 1 for 3, 6, 12, and 24 hr, followed by determination of trypan blue incorporation and PARP cleavage. After 3 hr, lactam 12 at 25 μM caused 15% vs. 11% cell death with lactam 1 at 50 μM (Fig. 4A). Similarly, at 6 hr, 24% of trypan blue-positive cells were found after 25 μM lactam 12 treatment, while only 20% observed in 50 μM lactam 1-treated cells (Fig. 4A). Only at later time points (12 and 24 hr), lactam 1 at 50 μM was slightly more potent than lactam 12 at 25 μM (Fig. 4A). Similar levels of cleaved PARP were observed in Jurkat T cells treated with either 25 μM of lactam 12 or 50 μM of lactam 1 at each time point (Fig. 4B). Therefore, lactam 12 is able to induce similar amounts of apoptosis in Jurkat T cells at a concentration half of that of lactam 1.

Furthermore, we examined levels of sub-G1 populations, as a measurement of cells with DNA fragmentation [18], in Jurkat T cells treated with lactam 12 or 1. Treatment with 50 μM of lactam 12 increased the sub-G1 populations by 34 and 57%, respectively, at 12 and 24 hr (Fig. 5A). In comparison, 50 μM of lactam 1 treatment for 12 and 24 hr induced sub-G1 populations by 10 and 16%, respectively [17], confirming the greater potency of lactam 12.

3.4. Lactam 12 is able to induce DNA damage in Jurkat T cells

We have previously shown that lactam 1 induces damage to DNA, leading to the inhibition of DNA replication and

![Fig. 3. Dose-response comparison between Jurkat T and YT cells treated with lactams 12 and 1 to induce cell apoptosis. Jurkat T (A and B) and YT cells (C and D) were treated with 2, 10, 25, and 50 μM of lactam 12 vs. 50 μM of lactam 1 for either 12 (B and D) or 24 hr (A and C), followed by trypan blue exclusion (A and C) or Western blot assay using anti-PARP antibody (B and D). Results are representative of three different experiments. Standard deviations are shown with error bars from a mean of at least three independent experiments (A and C).](image)

![Fig. 4. A kinetic comparison between lactams 12 and 1 to induce apoptosis in Jurkat T cells. Jurkat T cells were treated with 25 μM of lactam 12 vs. 50 μM of lactam 1 for 3, 6, 12, and 24 hr, followed by trypan blue dye exclusion assay (A), and PARP cleavage in Western blot assay (B). Results are representative of three different experiments. Standard deviations are shown with error bars from a mean of at least three independent experiments.](image)
Fig. 5. Lactam 12 induces sub-G1 cell population and TUNEL-positivity. Jurkat T cells (0 hr) were treated with 50 μM of lactam 12 for the indicated hours. (A) Measurement of sub-G1 DNA content by flow cytometry analysis. The percentage of sub-G1 cell population represents the cell populations with DNA fragmentation. (B) Measurement of DNA strand breaks by TUNEL assay. The numbers indicate the percentage of TUNEL-positive population. Results of representative of three independent experiments are shown.

subsequent induction of apoptosis [17]. To determine whether lactam 12 is also capable of damaging tumor cell DNA, Jurkat T cells were treated with 50 μM of lactam 12, followed by performance of TUNEL assay, which detects DNA strand breaks [17]. A significant population (~70%) of the cells exhibited DNA strand breaks after 3 hr of incubation with lactam 12 (Fig. 5B). A total of 82-90% of the cells were TUNEL-positive after 12-24-hr treatment with lactam 12 (Fig. 5B). In this experiment, 66% of TUNEL-positive cells were observed after treatment with 50 μM of lactam 1 for 24 hr (data not shown). Thus, the increased DNA-damaging capability of lactam 12 is most likely responsible for its enhanced cell death-inducing activity (Figs. 1-4).

3.5. Lactams 1 and 12 induce apoptosis and inhibit colony formation in human prostate cancer cells

So far, we demonstrated that lactam 12, like lactam 1, is able to induce DNA damage and subsequently induce apoptosis in human leukemia cells (Figs. 1-5) [17]. To determine if this lactam could also activate death program in solid tumor cells, human prostate cancer LNCaP cells were treated for 48 hr with lactam 12 at 2-25 μM or lactam 1 at 50 μM (as a control), followed by measurement of cell-free caspase-3/-7 activity. A dose-dependent increase in caspase-3/-7 induction was observed in LNCaP cells treated with lactam 12: by 2-, 2.5-, and 4.2-fold, respectively, at 2, 10, and 25 μM (Fig. 6A). Treatment with 50 μM of lactam 1 also increased levels of caspase-3/-7 activity by 2.5-fold over the control (Fig. 6A). These data are consistent with the conclusion that lactam 12 has greater apoptosis-inducing potency than lactam 1.

We then investigated the in vivo effects of these two lactams in a soft agar assay that measures the transforming activity of human tumor cells. LNCaP cells were plated in soft agar along with 50 μM of lactam 1, 50 μM of lactam 12, or solvent (DMSO), followed by a 21-day incubation to allow for colony formation. The solvent (DMSO)-treated plates allowed for the development of ~500 colonies (Fig. 6B and C). Lactam 1 inhibited 91%, and lactam 12 completely blocked (~100%), colony formation of LNCaP cells (Fig. 6B and C). Therefore, both lactams are able to inhibit the transformation capability of prostate cancer cells.

3.6. Lactam 12 induces apoptosis in several solid tumor cell lines and SV-40-transformed, but not normal, human fibroblasts

In a previous study, we showed that lactam 1 induced apoptosis in several solid tumor cell lines [17]. In this study we also investigated the effects of lactam 12 on several solid tumor cell lines including human breast (MCF-7), head-and-neck (PCI-13), and prostate (DU-145) cancer cells. Furthermore, we wanted to investigate whether lactam 12-induced cell death was selective in transformed (VA-13) over the normal (WI-38) human fibroblasts. We treated these cell lines with 50 μM lactam 12 or an equal percentage of DMSO, followed by separation of the attached and detached cell populations. Both attached and detached cell populations were then used for detection of apoptotic nuclear change. We found that after a 48-hr treatment with lactam 12, ~60% of MCF-7 and PCI-13 cells and ~50% of DU-145 and VA-13 cells became detached. However, no detachment was observed in WI-38 cells after treatment with lactam 12. Little or no detachment was observed in all the cell lines treated with DMSO. All the detached tumor or transformed cells exhibited typical apoptotic nuclear condensation.
6.00- 

DMSO-treated cells (Fig. 7B). In addition, accompanying the lack of the detachment in normal WI-38 cells treated with lactam 12 (Fig. 7A), there was little or no induction of caspase-3/-7 activity observed in these cells (Fig. 7B). Taken together, these data further support the conclusion that lactam 12 is able to induce apoptotic cell death preferentially in tumor and transformed over the normal cells.

4. Discussion

Developing novel anticancer drugs that induce apoptosis in tumor cells has long been a goal of cancer drug discovery research. Many of the drugs in current use focus on targeting dysregulated cell cycle and apoptosis programs in cancer cells [25]. We previously have shown that N-thiolated β-lactams cause DNA damage in tumor cells that leads to induction of apoptosis through p38 activation, cytochrome c release, and caspase activation [17]. Here we show that lactam 1 selectively induces apoptosis in human leukemic Jurkat T cells, but not nontransformed, immortalized human NK cells (Fig. 2). Furthermore, lactam 1 is capable of inducing Jurkat cell apoptosis at concentrations as low as 10 μM after 24-hr treatment (Fig. 2A).

Often, addition/substitution of groups on a molecule leads to development of more potent drugs. In order to determine whether structural changes to lactam 1 could produce a more potent tumor cell death inducer, analogs of lactam 1 were synthesized (Fig. 1A). Substitutions of the -Cl group with other halogens of higher atomic mass (-Br, -I) did increase the efficacy of the compound. In contrast, substitution with a lower atomic mass halogen (-F) or a hydrogen (H) atom had a concomitant decrease in cell death induction (Fig. 1). Lactam 12, containing an -NO₂ substituent, proved to be a highly active compound and induced 93–100% of cell death at 50 μM vs. 52% of cell death by lactam 1 at the same concentration (Fig. 1B). Furthermore, lactam 12 was superior to lactam 1 at inducing apoptosis in human Jurkat T cells because lactam 12 can induce the same amount of PARP cleavage as at a lower concentration than lactam 1 (Figs. 3 and 4). Additionally, lactam 12 at 25 μM was able to exert its cell death-inducing effect at as early as 3 hr (Fig. 4A and B). We also found that lactam 12 had greater potency than lactam 1 when used in human prostate cancer cells to activating caspase-3/-7 and inhibiting colony formation (Fig. 6). Due to lack of caspase-3 in MCF-7 cells, it was believed that lactam 12-mediated MCF-7 cell death was associated with caspase-7 activity (Fig. 7). Additionally, like lactam 1, lactam 12 was also able to selectively induce apoptosis in human leukemic Jurkat T cells over nontransformed.
Fig. 7. Lactam 12 induces apoptosis and caspase activation in different solid tumor cell lines and SV40-transformed but not normal cells. (A) Nuclear staining assay. MCF-7, PCI-13, DU-145, VA-13, and WI-38 cells were treated with 50 μM lactam 12 or DMSO for 48 hr, followed by collection of both detached and attached cell populations. After lactam 12 treatment, ~60% of MCF-7 and PCI-13 cells and ~50% of DU-145 and VA-13 cells became detached, whereas <5% were detached from each of these cell lines after DMSO treatment. No detachment was found in WI-38 cells after each treatment. Both detached and attached cell populations were stained with the nuclear staining dye Hoechst 33342. Each sample was then analyzed by fluorescence microscopy for nuclear morphology. (B) Cell-free caspase-3/-7 activity assay. Aliquots of the above detached and attached cells of each line were combined for whole-cell extraction. Cell-free caspase-3/-7 activity was then determined by incubating each whole-cell extract with caspase-3/-7 substrate and measuring free AMCs. Error bars denote standard deviations. Similar results were obtained in three independent experiments.
immortalized human NK cells (Fig. 3). Also, lactam 12 was able to selectively induce apoptotic cell death in simian virus 40-transformed, but not the parental normal, human fibroblasts (Fig. 7). The molecular mechanism for the enhanced activity in lactam 12 remains unknown. One interpretation is that the presence of --NO₂ group in this drug increases its binding to the cellular target(s). Alternatively, this drug might have increased uptake rates by the cells.

The mechanism of action of many chemotherapeutic drugs is through DNA damage and then subsequent apoptosis induction in tumor cells [26]. As mentioned above, we have recently shown that lactam 1 is capable of inducing apoptosis after DNA damage [17]. In the present study, we show, by TUNEL assay, that lactam 12 also causes DNA damage in ~70% of cells just after 3-hr treatment (Fig. 5B). At this time, there was only 2% cell death (Fig. 5A), suggesting that the DNA damage occurs much earlier than apoptotic cell death. However, apoptotic cells increased at later time points with increased TUNEL-positive cells (Fig. 5A and B). This result is consistent with our previous study [17] and several other studies that have shown that several traditional chemotherapeutic drugs or DNA-damaging agents cause DNA strand breaks that trigger apoptotic cell death [27,28].

Malignant transformation of a cell can lead to tumor formation and metastasis. The desired effect of any anticancer drug is to inhibit tumor growth and formation in situ. Soft agar colony forming assay is an assay that has been developed to mimic tumor cellular growth in tissue. We hypothesized that the N-thiolated β-lactams that induce cell death should be able to inhibit colony formation in soft agar assay. Indeed, when LNCaP prostate cancer cells were cultured in the presence of lactam 1 or 12, 91 and 100% inhibition of colony formation was observed, respectively, as compared to the solvent control (Fig. 6).

Based on our previous [17] and current studies, we propose that these N-thiolated β-lactams act by inducing DNA damage that leads to apoptosis preferentially in cancer and transformed over normal/nontransformed cells. Although it appears that the N-methylthio moiety is necessary for the cell death-inducing activity [17], addition of a larger group in the ortho position on the phenyl ring can also increase the effectiveness of the compound (Fig. 1). Our results strongly suggest the potential for developing this class of β-lactams into novel anticancer agents. Immediate future studies focusing on determining the molecular targets and chemical action of the N-thiolated β-lactams would help rational development of these compounds.

Acknowledgments

We thank Professor Monika Konaklieva (Department of Chemistry, American University) for providing samples of lactams 9 and 10, Dr. Ronald H. Goldfarb for the YT cell line, Dr. Theresa L. Whiteside for PCI-13 cell line, Dr. Said Sebti for the use of the phase-contrast microscope, and Kenyon G. Daniel for critical reading of the manuscript. We also appreciate the assistance of the Flow Cytometry Core at H. Lee Moffitt Cancer Center & Research Institute. We thank the United States Army Medical Research and Material Command (DAMD17-03-1-0175), the National Cancer Institute—National Institutes of Health, and H. Lee Moffitt Cancer Center & Research Institute for research grants to Professor Q. Ping Dou, National Institutes of Health for a research grant (NIH ROI A151351) to Professor Edward Turos, and a Moffitt Summer Internship grant to Randy Hill to support this work.

1. ABSTRACT

The development of novel anti-cancer drugs that induce apoptosis has long been a focus of drug discovery. Beta-lactam antibiotics have been used for over 60 years to fight bacterial infectious diseases with little or no side effects observed. Recently a new class of N-methylthiolated beta-lactams has been discovered that have potent activity against methicillin resistant Staphylococcus aureus. Most recently, we determined the potential effects of these N-thiolated beta-lactams on tumorigenic cell growth and found that they are apoptosis-inducers in human cancer cell lines. In the current study, we further determined the effects of the substitution of the O-methyl moiety on C3 and stereochemistry of the beta-lactams on the anti-proliferative and apoptosis-inducing abilities. We have found that lactam 18, in which C3 is substituted with an acrylate ester group, is a very effective proliferation inhibitor against human premalignant and malignant breast, leukemic, and simian virus 40-transformed fibroblast cells. Generally speaking, increasing the size of the moiety on C3 decreases its anti-proliferation potency, possibly indicating steric hindrance with the cellular target or decreased permeability through the cell membrane. We also found that the stereochemistry of the beta-lactams plays an important role in their potency. The 3S,4R isomers are more effective than their enantiomers (3R,4S), suggesting that 3S,4R configuration is more favorable for target interaction.

2. INTRODUCTION

Selectively targeting tumorigenic cells versus normal cells is a primary goal in anti-cancer drug discovery. Small molecules with apoptosis-inducing ability have great potential to be developed into novel chemotherapeutic drugs because of the ease of synthesis and structural manipulation (1-3). Initiation, commitment, and execution are the three fundamental steps of apoptosis (4). Several apoptotic stimuli, such as irreparable DNA damage, signal to activate the initiator caspases (e.g. caspases-8/10), which in turn activate downstream effector caspases (e.g. caspases-3/7). The effector caspases can also be activated through the release of mitochondrial proteins, such as cytochrome c (5). It is generally believed that proteolytic cleavage of a variety of intracellular substrates by effector caspases leads to apoptosis (6-9).

One particularly important class of small molecule drugs, the beta-lactam antibiotics, have played an essential role in treating bacterial infections without causing toxic side effects in the host for the past 60 years. Sir Alexander Fleming first coined...
the name "penicillin" in 1928 after his discovery that molds from the Penicillium genus secrete powerful antimicrobial compounds, called beta-lactams (10). X-ray crystallography revealed that penicillin is a thiazolidine ring fused to a four-membered beta-lactam ring (11). The beta-lactams are powerful and potent inhibitors of bacterial growth and many different moieties of bicyclic beta-lactams have been isolated or synthesized since the discovery of penicillin (12). There are several classes of bicyclic beta-lactams that possess antibacterial properties, including the penams, penems, carbapenems, cephalosporins, and clavulanic acids (10).

A novel class of beta-lactams was discovered by the Squibbs and Takeda laboratories in 1981, which have an N-sulfonic acid group attached directly to the nitrogen in the lactam ring (13, 14). The term "monobactam" was coined for these lactams, which have a flexible monocyclic ring and lack the carboxylic acid moiety, yet still retain a high bactericidal potency. Recently, a structurally related family of N-thiolated compounds, termed N-methylthio beta-lactams, were found to inhibit growth of Staphylococcal and meticillin-resistant S. aureus (MRSA) (15-17). Additionally, we have shown that these N-methylthio beta-lactams possess potent anti-proliferative properties, and are capable of inducing DNA strand breakage, inhibiting DNA replication, and inducing apoptosis in a time- and concentration-dependent manner when tested in several human cancer, but not normal cell lines (18, 19).

In this study, we screened several additional N-thiolated beta-lactams with substitutions made to the O-methyl moiety of carbon 3 (C3) for their structure-activity relationships and found that increasing the size of the C3 substitution results in decreased anti-proliferative activity in human breast cancer cells. Additionally, increasing the size of the C3 substituent may interfere with cellular uptake. We identified one particularly active lactam (lactam 18), which possesses an acrylate ester moiety off of C3, for further study. Lactam 18 induces caspase-3 activation and apoptosis, associated with increased Hsp70 protein expression and p38 phosphorylation. We have also found that the stereochemistry plays an important role in the activities of N-thiolated beta-lactam antibiotics, including anti-proliferation, S/G/M cell cycle arrest, and apoptosis induction. The 3R,4R-configured [(+)] isomers of lactam 18 and another-lactam 19 are both more potent than their 3R,4S-configured isomers or the racemic mixtures. Furthermore, these (+)-lactams are more efficacious than racemic lactam 1, which was identified from our previous studies (18). These effects of beta-lactams were found mainly in cultured human cancer and transformed cells, but not in normal/non-transformed cells. These data indicate that further study of N-thiolated beta-lactams in the treatment of cancers is warranted.

MATERIALS AND METHODS

3.1. Reagents

Fetal Bovine Serum was purchased from Tissue Culture Biologicals (Tulare, CA). Mixture of penicillin-streptomycin-L-glutamine, RPMI, Dulbecco’s modified Eagle’s medium (DME/M), DME/M/F12 (1:1) medium, horse serum, MEM non-essential amino acids solution, MEM sodium pyruvate solution, penicillin, and streptomycin were purchased from Invitrogen (Carlsbad, CA). (4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), dimethylsulfoxide (DMSO), epidermal growth factor (EGF), sodium bicarbonate, hydrocortisone, cholera enterotoxin, bovine insulin, propidium iodide and trypan blue were purchased from Sigma-Aldrich (St. Louis, MO). Polyclonal antibodies to actin, monoclonal antibodies to HSP70 and p-p38, and anti-goat and anti-mouse IgG-horseradish peroxidase were obtained from Santa Cruz Biotechnologies (Santa Cruz, CA). CaspACE FITC-VAD-FMK marker was purchased from Promega (Madison, WI). Fluorogenic peptide substrate Ac-DEVD-AMC (for caspase-3/7 activities) was obtained from Calbiochem (San Diego, CA).

3.2. Synthesis of beta-lactams

The beta-lactam analogs (Figure 1) were prepared as racemates and enantiomers (with cis stereochemistry) using a procedure described previously (15, 16).

3.3. Cell culture, protein extraction, and Western blot assay

Human leukemic Jurkat T cells and natural killer YT cells were cultured in RPMI 1640 medium, supplemented with 10% fetal bovine serum, 100 units/ml penicillin, and 100 µg/ml streptomycin. Further supplementation with 1 mM MEM sodium pyruvate solution, 0.1 mM MEM non-essential amino acids solution was added to YT cells. Human breast cancer MCF-7 cells, normal (WI-38) and SV-40 transformed (VA-13) human fibroblasts cells were grown in Dulbecco’s modified Eagle’s medium containing 10% fetal calf serum, penicillin, and streptomycin. Premalignant MCF-10ATIKcl.2 transformed human breast cells containing 10% fetal bovine serum, 100 units/ml penicillin, and 100 µg/ml streptomycin. All cell lines were maintained at 37°C in a humidified incubator with an atmosphere of 5% CO2.

3.4. Cellular proliferation assay

The MTT assay was used to determine the effects of beta-lactams on overall proliferation of tumor cells. Cells were plated in a 96-well plate and grown to 70-80% confluency, followed by addition of each compound at an indicated concentration for 24 h. MTT (1 mg/ml) in PBS was then added to wells and incubated at 37°C for 4 hours to allow for complete cleavage of the tetrazolium salt by metabolically active cells. Next, MTT was removed and 100 µl of DMSO was added, followed by
SAR of N-methylthiolated beta-lactams

colorimetric analysis using a multilabel plate reader at 560 nm (Victor®; Perkin Elmer). Absorbance values plotted are the mean from triplicate experiments.

3.5. Trypan blue assay
The trypan blue dye exclusion assay was performed by mixing 20 µl of cell suspension with 20 µl of 0.4% trypan blue dye before injecting into a hemocytometer and counting. The number of cells that absorbed the dye and those that exclude the dye were counted, from which the percentage of nonviable cell number to total cell number was calculated.

3.6. Cell cycle assay
Cell cycle analysis based on DNA content was performed as follows. Cells were harvested, counted, and washed twice with PBS. Cells (5 x 10⁶) were then suspended in 0.5 ml of PBS, pipetted, and fixed in 5 ml of 70% ethanol for at least 2 h at -20°C. Cells were centrifuged, resuspended in 1 ml of propidium iodide staining solution (30 µg propidium iodide, 1 mg RNase A, and 1 mg of glucose per ml of PBS) and incubated at room temperature for 30 min before flow cytometry analysis. The cell cycle distribution is shown as the percentage of cells containing G₁, S, G₂, and M DNA judged by propidium iodide staining.

3.7. Caspase-3 activity assay
To measure cell-free caspase-3 activity, whole cell extracts (30 µg) from untreated or treated cells were incubated with 20 µM of the fluorogenic substrate caspase-3/-7 (Ac-DEVD-AMC) for 30 min at 37°C in 100 µl of assay buffer (50 mM Tris, pH 8.0). Measurement of the hydrolyzed AMC groups was performed on a Victor® Multilabel plate reader® (Perkin Elmer) as described previously [18].

3.8. Immunostaining of apoptotic cells
Immunostaining of apoptotic cells was performed by addition of the FITC-VAD-FMK marker and visualized on an Axiovert 25 microscope (Zeiss; Thornwood, NY). Briefly, cells were grown to ~80% confluence in 60 mm dishes, and then treated under conditions described in the figure legends. Detection of caspase activity was determined according to the manufacturer’s protocol with a few modifications. Briefly, total cell population was collected and incubated with a 10 µM FITC-VAD-FMK for 20 min in the dark. Cells were then centrifuged at 300 xg for 3 minutes, washed 3X in PBS, and then resuspended in 50 µl PBS. Cell suspension was then transferred to glass slides in the presence of Vector Shield mounting medium with DAPI. Images were captured using AxioVision 4.1 and adjusted using Adobe Photoshop 6.0 software.

3.9. Nuclear staining
After each drug treatment, both detached and attached populations of VA-13 and WI-38 lines were stained with Hoechst 33342 to assess apoptosis. Briefly, cells were washed 2X in PBS, fixed for 1 h with 70% ethanol at 4°C, washed 3X in PBS, and stained with 50 µM Hoechst for 30 min in the dark at room temperature. Detached cells were plated on a slide and attached cells were visualized on the culture plate with a fluorescent microscope at 10X or 40X resolution (Zeiss, Thornwood, NY). Images were obtained using an AxioVision 4.1 and adjusted using Adobe Photoshop 6.0.

4. RESULTS

4.1. Structure-activity relationship analysis of N-thiolated beta-lactams
We have previously shown that lactam 1, which contains an O-methyl moiety at carbon-3 (C₃) of the beta-lactam ring, induces apoptosis in a relatively selective manner in tumor and transformed cells, but not normal or non-transformed cell lines (18). More than 35 N-thiolated beta-lactam analogs were then screened using an MTT assay in breast cancer MCF-7 cells to assess their anti-proliferative potency compared to lactam 1. Several of these analogs with substitutions to the O-methyl group at C₃ (Figure 1) were then selected for further structure-activity relationship (SAR) studies (Figure 2). MCF-7 cells were treated with 50 µM of selected lactams for 24 h, followed by MTT assay. Lactam 18, which possesses an ester moiety at C₃, is twice as potent as lactam 1 (Figure 2). Additionally, it was found that as the C₃ group increased in size, the effectiveness to inhibit proliferation decreased. For instance, increasing the size of the halogen, from -Cl to -I (lactam 13 versus lactam 14), lead to a 2-fold decrease in potency (Figure 2). A similar observation was made in comparing the bioactivities of C₃-sulfonated lactams 16 and 17. Mesyl lactam 16 inhibited 57% of MCF-7 cell growth, while dansyl lactam 17 has much less effect on inhibiting proliferation (Figure 2). A possible explanation may be that lactam 17 with the large dansyl group is incapable of crossing the cell membrane. Although lactam 15 with an N₄ group at C₃ is less potent than lactam 14 with I at C₃, as predicted, it is yet unclear why lactam 15 is less potent than mesyl lactam 16 (Figure 2). The order of potency is determined as follows: Lactam 18 > 1 > 16 > 13 > 14 > 17 > 15.

4.2. Lactam 18 is more potent than lactam 1 at inducing apoptosis associated with Hsp70 expression and p38 phosphorylation
We decided to focus on lactam 18 due to its increased anti-proliferative potency over lactam 1 (Figure 2). To determine whether lactam 18 is capable of inducing apoptosis, we treated leukemia Jurkat T cells with 20 µM lactam 18 for 24 h, using lactam 1 as a control. A fluorescent marker specific for activated caspases was then added to the cells and then visualized by fluorescence microscopy (Figure 3A). Lactam 18 displayed greater apoptosis-inducing activity than lactam 1 (Figure 3A).
SAR of N-methylthiolated beta-lactams

Microarray analysis showed up-regulation of many genes by lactam 1 treatment, including HSP70 (manuscript in preparation). To confirm this finding, Jurkat T cells were treated with lactam 1 and lactam 18 for 16 h at either 25 or 50 μM. It was found that Jurkat T cells had increased Hsp70 protein expression after treatment of both lactams; lactam 18 induced a greater amount of Hsp70 expression at 25 μM than lactam 1 at the same concentration (Figure 3B). This is consistent with the idea that the beta-lactams induce a stress response in the cell, most likely due to their disruption of DNA synthesis (18).

We have previously reported that p38 MAP kinase activation is associated with β-lactam-induced apoptosis (18). Activation of p38 MAP kinase can trigger apoptosis following multiple stimuli, such as DNA damage (21, 22). Western blot for phosphorylated (activated) pp38 reveals that treatment with 25 μM lactam 18 leads to an increase in pp38 levels (9.0-fold), compared to that of 25 μM lactam 1 (2.6-fold) (Figure 3B). Actin was used as a loading control.

4.3. (+)-Lactam 19 inhibits cellular proliferation more effectively than (-)-lactam 19

To determine if the stereochemistry has any bearing on the potency of beta-lactams, lactams 18 and 19 were synthesized in enantiomerically pure forms (Figure 1). Premalignant MCF-10AT1Kcl2 breast cancer cells were treated with (+)-lactam 19 (3S,4R-configuration), (-)-lactam 19 (3R,4S-configuration), or racemic lactam 1 (as a control) for 24 h at indicated doses (Figure 4A). All of these lactams inhibited proliferation in a dose-dependent manner, with (+)-lactam 19 at 50 μM inhibiting 85% cell growth, (-)-lactam 19 inhibiting 56% and lactam 1 inhibiting 49% at the same concentration (Figure 4A). These results are similar to that from another experiment using malignant MCF-7 breast cancer cells (data not shown). Trypan blue incorporation also shows increased tumor cell killing with (+)-lactam 19 to that of (-)-lactam 19, 42% versus 26%, respectively, at 25 μM (Figure 4B).

4.4. beta-Lactams 18 and 19 induce tumor cell-selective apoptosis

We have previously shown that lactam 1 preferentially induces apoptosis in human cancer cells over normal, non-transformed cells lines (19). To determine if lactam 18 possessed a similar tumor cell-specific activity, human leukemic Jurkat T cells and immortalized, non-transformed natural killer cells (YT) were treated with lactam 1 and lactam 18, and the effects were determined. After 16 h treatment, it was found that lactam 18-treated Jurkat cells had a 19-fold increase in caspase-3 activity at 25 μM, compared to 9-fold induced by lactam 1 at the same concentration (Figure 5A). Both lactam 18 and lactam 1 had little or no apoptosis-inducing effects on the immortalized, non-transformed YT cells (Figure 5A).

To assess whether the isomers of lactam 19 (Figure 1) also have explicit activity against cancer cells, we treated Jurkat T cells and YT cells with (+)-lactam 19, (-)-lactam 19 and racemic lactam 1 (as a control), and determined the effects on apoptotic cell death. We found that only the Jurkat, but not YT, cells exhibited high levels of caspase-3 activity when treated with these beta-lactams (Figure 5B). Additionally, (+)-lactam 19 at 25 μM induced a 7.4-fold increase in caspase-3 activity compared to 5.5-fold increase by (-)-lactam 19 and 3.1-fold increase by lactam 1 at 25 μM (Figure 5B). Therefore, the 3S,4R-configured isomer, (+)-lactam 19, is more potent than (-)-Lactam 19 and racemic lactam 1.

To further confirm the effect of stereoselectivity on the apoptosis-inducing effects of beta-lactams, we synthesized an isomeric pair of lactam 18, 3S,4R-isomer [(+)-lactam 18] and 3R,4S-isomer [(-)-lactam 18] (Figure 1). Jurkat and YT cells were then treated with 50 μM (+)-lactam 18, (-)-lactam 18, racemic lactam 18 or lactam 1 for 24 h, followed by trypan blue dye exclusion assay (Figure 6A). (+)-lactam 18 induced much higher amount of cell death than its isomer (-)-lactam 18, 98% vs. 58%, respectively (Figure 6A). Interestingly, the racemic lactam 18 was almost equally potent to that of (+)-lactam 18 (Figure 6A). All lactam 18 compounds initiated more cell death than lactam 1 (Figure 6A). Again, it was found that normal, non-transformed YT cells did not undergo cell death after treatment with any of these beta-lactams (Figure 6A).

Another experiment using SV-40 transformed (VA-13) and normal (WI-38) human fibroblasts demonstrates again that (+)-lactam 18 is the more active isomer. A nuclear stain of VA-13 and WI-38 cell lines treated with 50 μM of each beta-lactam for 24 h reveals that there is a high degree of detachment and DNA condensation, characteristics indicative of apoptosis, in cells treated with (+)-lactam 18, racemic lactam 18 and lactam 1 (Figure 6B). (-)-lactam 18, on the other hand, showed decreased activity when compared with (+)-lactam 18 and racemic lactam 18. There was a very minor amount of cellular detachment observed in the normal WI-38 fibroblasts treated with (+)-lactam 18 (data not shown), supporting that these beta-lactams selectively kill transformed VA-13 cells (Figure 6B).

4.5. (+)-Lactam 18 induces S/G2/M cell cycle arrest

We have previously shown that beta-lactams decrease G1 population, associated with DNA damage (18). To further investigate the cause of apoptosis after N-methylthio beta-lactam treatment, analysis of cell cycle changes were performed on an exponentially growing cell population (Table 1). As a control, lactam 1 was found to decrease G1 phase DNA content by 6% after 6 h incubation (Table 1). Racemic lactam 18 had a very similar effect on cell cycle as racemic lactam 1 (Table 1). However, when cells were treated with (+)-lactam 18, there was a 15% decrease in G1, demonstration that the 3S,4R configuration has increased growth-inhibitory activity (Table 1).
SAR of N-methylthiolated beta-lactams

5. DISCUSSION

Currently, many anticancer therapies, from radiation treatment to chemotherapeutic agents, are very toxic. Therefore, drug discovery for anticancer therapy is as concerned with selectivity of normal versus cancer tissues, as it is the potency of the therapy itself. Antibiotic therapies have typically used the unique molecular targets of microbes in order to avoid toxicity to the patient during treatment. Recently we have shown that some of these compounds possess anti-proliferation activity in human tumor cells (18). Thus, these compounds that are already known to be essentially non-toxic to humans may be anticancer agents as well. Of particular interest are the N-thiolated beta-lactams, which we have previously found to be potent against MRSA (17). Additionally, we found these compounds act as potential anticancer agents through S-phase arrest, DNA damage, and apoptosis induction (18). These compounds are also able to selectively induce apoptosis in cancerous over normal cells (19).

This novel class of N-thiolated beta-lactams possesses potent anti-cancer activity, which is directly related to the nature of the substituents on each of the four ring sites. We have previously reported on the effects of additions/substitutions to the N-thio group and aryl ring (18, 19). The work reported here is a further characterization of the SAR between the various substitution groups on beta-lactam ring. At the core of the beta-lactam molecule is a four-membered ring that is substituted at each position (Figure 1). Each of the positions, we have previously published, plays a role in the potency of the compound. Position 1 is the N-methythio position and changes at this position that either eliminate the methylthio moiety or lengthen the chain result in decreased potency (18). Position 2 is substituted with a benzene ring and changes here also effect potency (19). Physical position on the ring with regards to ortho-, para-, or meta substitution as well as the nature of the substituent affected the potency dramatically [for details see (19)]. Position 4, which is substituted with a double-bonded oxygen, is the “backbone” of the beta-lactam and therefore cannot be changed without losing the general beta-lactam framework (10, 23). The work presented here examines the SAR at position 3 and completes the survey of each position of the four-membered ring.

We determined that the size and polarity of the group at C3 is important for their lactam’s activity. As these C3 substituents increase in size or in polarity, the efficacy of the compound seems to drop. For example, replacing the chloro (Cl) moiety of lactam 13 for azido (N3), lactam 15, decreases the anti-proliferative activity from 75 to 5% respectively (Figure 2). However, a simple single atom change in the same period (Cl to I; lactam 13 vs. lactam 14) seems to result in only a partial increase in potency. Similarly, the potencies of C3-sulfonated compounds 16 and 17 can be directly attributed to their C3 substitutions: lactam 17 with its large, polar dansyl moiety has significantly diminished activity compared to its smaller, less polar mesyl analog, lactam 16 (Figure 2). Likewise, lactam 16 seems to be similar in or slightly less potent than lactam 14, indicating that the size of the substituent may be slightly more significant than the overall charge (Figure 2). Lactam 18 displays very potent activity with its acrylate ester off C3. This may indicate that these substitutions may affect the capability of these compounds to cross the cell membrane.

Of primary importance in anticancer drug research is that the compound being investigated demonstrate selectivity between normal cells and tumor cells. Cytotoxic agents are less desirable than those compounds that can differentially activate apoptosis in cancer cells vs. tumor cells. Previously we have reported that lactam 1-induced apoptosis is caspase-dependent and associated with cytochrome c release (18). Here we show that lactam 18-induced apoptosis is also caspase-dependent (Figure 5A). However, the efficacy to induce apoptosis by lactam 18 is much improved over lactam 1 (Figure 3) and that the apoptosis induced by lactam 18 is tumor cell-specific (Figure 5A). beta-Lactams cause DNA strand breakage and subsequent cell cycle arrest (18). Our microarray studies show a 3.5-fold increase in HSP70 expression in Jurkat T cells treated with lactam 1 (data not shown). Increased expression of Hsp70 protein (Figure 3B) indicates that treatment with lactam 18 induces a stress response in leukemia Jurkat T cells. Another important molecular event in lactam-induced apoptosis is the increase in p38 phosphorylation. Abrogation of p38 activity with a specific inhibitor (PD169316) leads to tumor cell survival (18). Not only is lactam 18 capable of inducing p-38 activation, it is capable of inducing a greater amount of pp38 levels at 25 μM compared to 50 μM of lactam 1 (Figure 3B).

Stereochemistry can play an important role in the efficacy of a particular compound. Often only one of the isomers displays a significant selectivity for the molecular target while the other can cause adverse side effects (24-26). Here we find that two 3S,4R-configured beta-lactam compounds, (+)-lactam 18 and (-)-lactam 19, do have a higher potency than their 3R,4S enantiomers or a racemic mixture. Specifically, (+)-lactam 19 has greater anti-proliferation and cell death-inducing activities than both (-)-lactam 19 and the racemic lactam 1 (Figure 4). (+)-Lactam 19 triggers an equivalent amount of capase-3 activation at half the concentration of lactam 1 and this activity again is tumor cell-selective (Figure 5). Additionally, another isomer, (+)-lactam 18, displays a similar potency to (+)-lactam 19 while still retaining the tumor cell-selectivity (Figures 5B and 6).

A vast amount of anti-cancer research is ongoing to develop apoptosis-inducing drugs. While the molecular targets and chemical actions of N-thiolated beta-lactams are not fully characterized, we believe that the compounds possess great potential for chemotherapeutic drug development. These antibiotics compounds are predicted to have little to no effect on normal cells, supported by our results. Thus, the anti-tumor potential and expected lack of toxicity of these beta-lactams makes them excellent candidates for anticancer drug development. Our ongoing studies focus on identifying the molecular interactions of beta-lactams in human cancer cells and their anti-tumor activities in vivo.
SAR of N-methylthiolated beta-lactams

6. ACKNOWLEDGMENTS

We thank Timothy Long, Randy Hill, David M. Smith and Aslam Kazi for their contribution to the previous research of beta-lactams. We thank the United States Army Medical Research and Materiel Command (DAMD17-03-1-0175 and W81XWH-04-0688), the National Cancer Institute-National Institutes of Health, and Barbara Ann Karmanos Cancer Institute for research grants to Professor Q. Ping Dou, and the National Institutes of Health for a research grant (NIH ROI A151351) to Professor Edward Turos. Thanks to the Flow Cytometry Core at Karmanos Cancer Institute for assistance with cell cycle analysis.

Figure 2. Structure-activity relationship (SAR) analysis of N-thiolated beta-lactams. MCF-7 cells were plated in a 96-well plate and grown to 70-80% confluency followed by addition of 50 μM beta-lactam for 24 h. Cells were then incubated with 1 mg/ml MTT for 3 h and proliferation rates were determined using a multi-label plate reader (Victor3, Perkin Elmer; ±SD).

Figure 3. Lactam 18 induces caspase activity associated with Hsp70 expression and p38 phosphorylation. A. Jurkat T cells were treated with 20 μM lactam 1 or lactam 18 for 24 h. Following the treatment, the cells were then incubated with a FITC-conjugated marker that binds to activated caspases. Cell suspension was then transferred to glass slides in the presence of Vector Shield mounting medium with DAPI. Images were captured using Axiolab 4.1 and adjusted using Adobe Photoshop 6.0 software. B. Jurkat cells treated with 25 or 50 μM of lactam 1 or lactam 18 for 16 h, followed by Western blot analysis using specific antibodies to HSP70, p-p38, and Actin. Data shown are representative from three independent experiments.

Figure 4. (+)-Lactam 19 effects proliferation and cell death in a dose-dependent manner. A. MCF10AT1Kcl.2 cells were plated in a 96-well plate and grown to 70-80% confluency followed by addition of 50 μM of indicated beta-lactams for 24 h. Cells were then incubated with 1 mg/ml MTT for 4 h and proliferation rates were determined using a multi-label plate reader (Victor3, Perkin Elmer; ±SD). B. Jurkats T cells treated with lactam 1, (+)-lactam 19, (-)-lactam 19 at indicated doses and assayed for cell death by trypan blue incorporation (±SD).

Figure 5. beta-Lactams induce apoptosis in a tumor cell-specific manner. A. Jurkat T and YT cells were treated with lactam 1 and lactam 18 at indicated concentration for 16 h, followed by measurement of cell-free caspase-3 activity by incubating whole cell extracts with caspase-3 substrate and measuring free AMCs. B. (+)-lactam 19 is 2-fold more potent that lactam 1 at inducing apoptosis in a tumor cell specific manner. Jurkat T and YT cells were treated for 24 h with 25 and 50 μM of lactam 1 versus 25

1. ABSTRACT

The discovery of natural and synthetic antibiotics is one of the most important medical breakthroughs in human history. Many diseases, such as bacterial meningitis, pneumonia, and septicemia, are now curable with the use of antibiotics. Antibiotics are efficacious, generally well tolerated in patients, and have a low toxicity level. It is for these reasons antibiotics remain an attractive target for drug discovery. Traditional beta-lactam antibiotics (e.g. penicillins, penems, cephalosporins) have a bicyclic ring structure that is conformationally rigid and functions to inhibit bacterial cell wall synthesis. In addition to the bactericidal action of antibiotics, it has been discovered that many antibiotics are capable of inhibiting tumor cell growth. There are currently many antitumor antibiotics approved for cancer therapy, which work to inhibit tumor cell growth by DNA intercalation. The use of beta-lactams as prodrugs has also met with success by aiding delivery of the chemotherapeutic directly to tumor sites. Recently, a novel class of N-thiolated monobactams, so termed because they possess a monocyclic ring instead of the bicyclic ring structure, has been found to induce apoptosis potently and specifically in many tumor cell lines but not in normal, non-transformed cell lines. Other beta-lactams, such as the polyaromatics, have been found to slow or inhibit tumor cell growth, and the 4-alkylidene beta-lactams are capable of inhibiting matrix metalloproteinases and leukocyte elastase activity. These data indicate that synthesis and evaluation of beta-lactams are a promising area for further development in anticancer research.

2. INTRODUCTION

Cancer is a heterogeneous disease and can be characterized as the growth of a malignant cell population that eventually leads to the interference of normal physiological functions. Anticancer drug research focuses on inhibition of tumor cell growth and induction of apoptosis in the malignant cell population. Apoptosis, or programmed cellular death, first described by Kerr et al. in 1972, is characterized by the ability of a cell to undergo a step-by-step self suicide program without affecting neighboring or adjoining cells (1). Activation of the apoptotic program in tumorigenic cells is essential for cancer prevention and treatment. A significant focus in anticancer drug discovery is to selectively induce tumor cell apoptosis with limited toxicity to normal cells. Tumor cells often have multiple alterations in their apoptotic machinery and/or signaling pathways that lead to increased levels of...
These results strongly suggest that further examination of lavendamycin analogs as chemotherapeutic agents is necessary.

Lavendamycin, which possesses a quinoline-5,8-dione core, is an antibiotic derived from Streptomyces lavendulae and isolated in 1981 (24). While the native compound did not pass clinical trials due to poor solubility and general toxicity, newly designed analogs show promise as potential chemotherapeutic drugs (25). The analogs of this compound possess a modified ring structure of the native compound to increase solubility and selectivity for p53-deficient cells (25). When lung carcinoma A549 cells were treated with the analog MB-97, the cells accumulated and activated p53 (25). These results suggest that this compound acts as a strong DNA damaging agent, a property it shares with other antibiotic/antitumor compounds like streptonigrin and the anthracyclines (25). Parental compounds of the MB-97 lavendamycin analog showed in vivo toxicity in the range of 0.4 mg/kg, whereas the new analog did not display toxicity until a treatment of 400 mg/kg was reached. Administration of another lavendamycin analog, MB-51, at doses of 300 mg/kg to mice bearing tumors resulted in an 80% reduction of tumor mass (25). These results strongly suggest that further examination of lavendamycin analogs as chemotherapeutic agents is necessary.

Currently, the beta-lactams are the most exploited family of antibiotics used for the treatment of bacterial infections (figure 1A). Beta-lactams are secreted by molds from the Penicillium genus and Sir Alexander Fleming first coined the name "penicillin" in 1928. Fleming observed bacteriolysis in a broth contaminated with Penicillium at St. Mary's Hospital in London, England (4). It would be many years until the import of this discovery was fully appreciated. Later studies at Oxford by Abraham, Florey and Chain resulted in the isolation of penicillin and subsequent drug trials (4). X-ray crystallography performed by Dorothy Hodgkin revealed that penicillin is a thiazolidine ring fused to a four membered beta-lactam ring (5; figure 1A). Later research focused on identifying several other antibiotics isolated from natural sources. Bacteria from the genus Cephalosporium also excrete beta-lactam containing compounds. Today the cephalosporin antibiotics, and their derivatives, comprise a large portion of the antibiotic therapies used (6,7). Several other classes of bicyclic beta-lactams were found to also possess antibacterial properties, such as penams, carbapenems and clavulanic acids (figure 1A).

The beta-lactams are powerful and potent inhibitors of bacterial growth and many different moieties of bicyclic beta-lactams have been isolated or synthesized since the discovery of penicillin (8). In 1981, two independent groups from the Squibbs and Takeda laboratories isolated the first N-thiolated beta-lactams from natural sources (9,10). These beta-lactams were the first to have a N-sulfonic acid group attached directly to the nitrogen in the lactam ring. The term "monobactam" was coined for these lactams, which have a flexible monocyclic ring, lack the carboxylic acid moiety, yet still retain a high bactericidal property (figure 1B).

Of late, a new class of N-thiolated beta-lactams was found to inhibit Staphylococcal and methicillin-resistant S. Aureus (MRSA) growth (11-13). The novel lactams most active against MRSA have an N-methylthio-substitution. These compounds are unaffected by penicillinases, such as beta-lactamase, an enzyme produced by some bacteria that degrades beta-lactams (14).

3. CURRENT ANTIBIOTIC MODALITIES IN CANCER TREATMENT

The tetracyclines are antibiotics that have been used for the treatment of infection for decades (15). This family of compounds includes: tetracycline, doxycycline, and minocycline. Although these compounds are known for their effects on mitochondria, their ability to inhibit matrix metalloproteinases, the enzymes required for angiogenesis, may prove more beneficial (15). Col-3, a modified tetracycline, is now in clinical trials. Doxycycline has been shown to reduce tumor burden in mouse models and osteolytic bone metastasis as a result from breast cancer (15). These results have enabled doxycycline to enter clinical trials.

Rapamycin (RAPA) is a microbial macrolide from Streptomyces hygroscopicus and is used as an immnosuppressive to prevent organ rejection (16). It can also induce anti-proliferative effects by inhibiting cyclin-dependent kinases and inhibit retinoblastoma protein phosphorylation leading to cell cycle arrest (17-19). RAPA has been shown to have growth-suppressive effects in a broad range of cancers (20). For instance, Nepomuceno et al. have shown that RAPA is capable of preventing the growth of Epstein Barr virus positive (EBV+) B-cell lymphomas. Severe Combined Immune Deficient (SCID) mice treated with 1.5 mg/kg/day RAPA remained tumor free for up to six weeks after injection with peripheral blood from liver transplant patients, while mice without RAPA treatment developed tumors within three weeks (21). Their results suggest that rapamycin may be able to control other EBV-related cancers and those associated with organ transplant.

The novel histone deacetylase inhibitor, FK228, has been recently isolated from Chromobacterium violaceum (22). This antibiotic is a bicyclic peptide with a non-cysteine disulfide bridge that has been found to reverse H-ras transformed NIH-3T3 cells (22). The activity of FK228 against tumor cells is in the ng/mL range while effects against normal cells are not seen below concentrations of 1 µg/mL (23). The action of FK228 indicates that it is more effective against large tumors with an established blood supply over small tumors that do not yet require a capillary network (23). Specifically, FK228 down-regulates mRNA levels of vasoendothelial growth factor, a principle component of the angiogenesis pathway. This evidence strongly supports FK228 as a potential candidate for cancer chemotherapy.

Lavendamycin, which possesses a quinoline-5,8-dione core, is an antibiotic derived from Streptomyces lavendulae and isolated in 1981 (24). While the native compound did not pass clinical trials due to poor solubility and general toxicity, newly designed analogs show promise as potential chemotherapeutic drugs (25). The analogs of this compound possess a modified ring structure of the native compound to increase solubility and selectivity for p53-deficient cells (25). When lung carcinoma A549 cells were treated with the analog MB-97, the cells accumulated and activated p53 (25). These results suggest that this compound acts as a strong DNA damaging agent, a property it shares with other antibiotic/antitumor compounds like streptonigrin and the anthracyclines (25). Parental compounds of the MB-97 lavendamycin analog showed in vivo toxicity in the range of 0.4 mg/kg, whereas the new analog did not display toxicity until a treatment of 400 mg/kg was reached. Administration of another lavendamycin analog, MB-51, at doses of 300 mg/kg to mice bearing tumors resulted in an 80% reduction of tumor mass (25). These results strongly suggest that further examination of lavendamycin analogs as chemotherapeutic agents is necessary.
N-thiolated beta-lactams as anticancer drugs

Discovered in 1966, bleomycin (derived from *Streptomyces verticillus*) is a well-studied antibiotic/antitumor agent (26). This compound is a principle treatment for testicular cancer and demonstrates reduced myelotoxicity (27). The most well known mode of action for this compound is its oxygen-dependent degradation of DNA (27). Unfortunately, bleomycin possesses potential fatal pulmonary toxicity (27). A recent 2003 clinical trial examined the effects of bleomycin treatment with mitomycin C as a follow up treatment to postoperative irradiation for patients with advanced head and neck cancer (28). This combined therapy improved survivability and the toxic effects (primarily mucositis) were considered within acceptable limits (28).

The anthracycline class of antibiotics include doxorubicin, daunorubicin, idarubicin, and epirubicin. Doxorubicin (DOX) and daunorubicin (DNR) have been used for over 30 years to treat a variety of solid and hematological tumors. DOX and DNR work by intercalation into DNA and inhibition of Topoisomerase II via binding to the Topo II/DNA ternary complex to promote its stabilization (29,30). Unfortunately, DOX and DNR also have high toxicity due to their mechanism of action, production of reactive oxygen species (ROS), which leads to toxicity of the cardiomyocytes and subsequent chronic and acute cardiomyopathies (31-33). Improvements in DOX and DNR structures lead to the development of idarubicin and epirubicin. Although these two analogs do have decreased toxicity and improved activity, there still is a significant risk to patients using these chemotherapeutic drugs (34,35).

Antibiotics are an intriguing class of compounds, not only for their ability to control bacterial infection but also for their capability to function as chemotherapeutic agents in cancer. There are an unlimited number of compounds bacteria can create. Based on the properties of existing antibiotics, studies into active analogs or novel synthetic compounds continue. Typically, antibiotics have reduced or no toxicity though there are exceptions, e.g. high doses can result in toxicity. Furthermore, these compounds can serve the dual roles of treating cancer or fighting potential infection during chemotherapy as an adjunct treatment. One of the more recent antibiotics to enter into the class of antibiotic/antitumor compounds is the class of beta-lactams.

4. TRADITIONAL ROLES OF BETA-LACTAMS

The family of beta-lactams, so named because they all contain a beta-lactam ring, have been used for many years to treat bacterial infections. Traditional beta-lactam antibiotics, such as the penicillins and cephalosporins, contain, in addition to the beta-lactam ring, a carboxyl group in close proximity to the lactam nitrogen, which is required for antimicrobial activity. These antibiotics act as bactericidal agents by serving as a substrate for peptidoglycan transpeptidase, the enzyme responsible for crosslinking the N-acetylglucuronic acid (NAG) and N-acetylmuramic acid (NAM) moieties in the peptidoglycan layer surrounding the periplasmic space and membrane of bacteria. The transpeptidase enzyme is acylated by the beta-lactam, which results in a weakened cell wall and osmotic lysis of the bacteria. Since the commercial availability of penicillin in 1940, many other beta-lactam antibiotics with medicinal effects have been isolated and synthesized. Many thought that the war on infectious diseases was over after the discovery of penicillin as we have used antibiotics to treat and cure many diseases that were once fatal, namely tuberculosis, bacterial meningitis, and pneumonia. Unfortunately, bacteria developed resistance by producing enzymes to hydrolyze the beta-lactam moiety rendering the antibiotic inactive (36). This resistance has spawned a renewed interest in identifying and synthesizing new active antibiotics to treat resistant strains, derived mainly through resistant genes located in plasmids. Bacterial infections caused by methicillin-resistant *Staphylococcus aureus* (MRSA) are currently susceptible to only one current antibiotic (vancomycin).

Antibiotics are substances created by microorganisms or synthetically designed to kill or inhibit the growth of bacteria. These compounds are the staple of treatment for bacterial infection. In addition, there are numerous anti-tumor antibiotics that are currently used to treat cancer, such as the anthracyclines, bleomycin, mitomycin C, daunomycin, and mithramycin. The major mechanism of action for these antitumor antibiotics is DNA intercalation or inhibition of DNA synthesis. Beta-lactam antibiotics are traditionally used only for bacterial infections, however, several novel classes of beta-lactams have been shown to possess anticancer properties as well. We have found that a class of beta-lactams, the N-thiolated beta-lactams, induce tumor cell apoptosis by introducing DNA damage in a potent, and more importantly, a tumor cell-specific manner with little or no effect on normal cells (37,38). Cainelli *et al.*, describe that 4-alkylidene-beta-lactams inhibit matrix metalloproteinases-2, and -9 (MMP), essential for the tumor induced neovascularization (39). Banik *et al.*, also show that beta-lactams with polyaromatic substituents induce tumor cell death in a variety of cancer cell lines, such as ovarian, prostate, breast, colon, and leukemic *in vitro* and demonstrated inhibition of tumor cell growth in mice (40) (see Section 6 for details).

5. BETA-LACTAMS AS PRODRUGS FOR ANTICANCER CHEMOTHERAPIES

5.1. Background

The most widely applied beta-lactams for prodrug based cancer chemotherapy have been the cephalosporins. The cephalosporins were chosen as prodrug candidates because of their inherent reactivity when hydrolyzed by beta-lactamase enzymes. Hydrolytic cleavage of the beta-lactam ring causes a secondary reaction that triggers the expulsion of the 3'-substituent (figure 2). The cytotoxic component can be attached to this position and then released when the cephalosporin beta-lactam ring is hydrolyzed by the enzyme.
Cephalosporins have also been used in the selective targeting of anticancer compounds to tumor cells using Antibody Directed Enzyme Prodrug Therapy (ADEPT) and this method has received much attention in recent years (41,42). ADEPT is a drug delivery strategy that employs an enzyme covalently attached to a monoclonal antibody that is specific for a tumor cell antigen. This strategy allows for the delivery of the cytotoxic agent masked as a prodrug to specifically target tumor cells. To achieve site-specific generation of the cytotoxic agent, the monoclonal antibody-enzyme immunoconjugate (mAb-enz) is given to the patient first. This allows for prelocalization of the mAb-enz on the targeted tumor cell surface. The prodrug, which is the substrate of the enzyme, is then administered leading to targeted release of the drug.

The benefits of this method are many compared to administering the prodrug or parent drug alone (43-46). The catalytic nature of the enzyme will allow for the conversion of a stoichiometric excess of prodrug substrate. In addition, lower doses of the antibody-enzyme conjugate and higher doses of the prodrug can be administered, which reduces the toxicity. The surrounding tumor cells not bearing the target epitope can also be effectively dosed with the cytotoxic drug. This can lead to lower side effects due to tumor-specific localization of the parent drug. Furthermore, beta-lactamase enzymes are not endogenous to humans, making them highly exploitable for ADEPT and therefore eliminating premature cleavage of the prodrug by other naturally occurring enzymes. In order for the monoclonal antibody-enzyme immunoconjugate system to be successful, there are several criteria required for therapeutic efficacy. First, the mAb-enzyme conjugate should not elicit an immune response and have a high tumor/blood ratio. Secondly, the antibody portion of the immunoconjugate must selectively target and have a high binding affinity for the tumor cell antigen. Lastly, the unbound conjugate must be readily cleared from the bloodstream before the prodrug is administered. The following section will discuss antibody-enzyme-prodrug systems that have undergone evaluation to treat various types of cancers.

5.2. Nitrogen Mustards

The alkylating agents or nitrogen mustards include cyclophosphamides, chloroambucil, and melphalan, and function by replacing an alkyl group for a hydrogen atom, leading to the formation of DNA adducts, or abnormal base pairing and cross linking of DNA. Cyclophosphamide and ifosfamide exist as prodrugs and are activated by hepatic enzymes into active species (47). While the nitrogen mustards are efficacious, they are extremely cytotoxic which results in unwanted side effects. For example, 7-(phenylacetamido) cephalosporin mustard (CM) prodrug was at least 50 times less toxic than phenylendiamine mustard (PDM) toward H2981 human adenocarcinoma cell line in vitro (48). The monoclonal antibody-enzyme conjugate L6-BC3L was shown to activate CM in an immunologically specific manner, which resulted in a level of cytotoxicity comparable to PDM (48). In vivo studies indicated that CM was less toxic to nude mice than PDM, however treatment was hampered due to severe tail necrosis following intravenous injection (49).

A modified analog of CM, 7-(4-carboxybutamido) cephalosporin mustard (CCM), showed higher activity in vitro when administered with L6-ECBL. CCM was found to be less cytotoxic than PDM on H2981 cells, with IC50 values of 25-45 μg and 1.5 μg, respectively. When the monoclonal antibody-enzyme conjugate L6-ECBL was administered 96 h prior to CCM, there was observed significant antitumor activity in vivo (49). The in vivo experiments concluded that administration of CCM in nude mice was less toxic than CM, and both prodrugs (CM and CCM) were significantly less toxic than PDM.

The prodrug C-Mel, a cephalosporin carbamate derivative of melphalan, was also shown to have antitumor activity (50). C-Mel was activated in an immunologically specific manner by the L49-sFv-βL conjugate. In vitro cytotoxicity assays using 3677 human melanoma cells treated with the C-Mel prodrug in conjunction with L49-sFv-βL showed that c-Mel was 40 times less toxic than melphalan alone, IC50 = 53 μg and 1.3 μg, respectively. In vivo studies demonstrated that nude mice with growing tumors treated with L49-sFv-βL and C-Mel at 150 mg/kg/injection underwent complete regressions, and 3 out of 5 mice were eventually cured (50).

5.3. Methotrexate

Methotrexate (MTX) is a folic acid analog, or antimetabolite, which was first developed and used clinically in the 1940's (51). MTX interacts with dihydrofolate reductase (DHFR), an enzyme critical in folate metabolism (52). Unfortunately, drug resistance can often occur due to increased endocytosis of the antifolate by multidrug resistance protein (MDRPs) pumps and folate transporters (53-56). The prodrug of MTX is a potent cytotoxic agent and antimetabolite developed for ADEPT therapy. MTX was found to be a good substrate of beta-lactamase but showed identical cytotoxicity to that of the parent drug alone (45). No further evaluations have been conducted.

5.4. 5-Fluorouracil

Another group of antimetabolites include the pyrimidine analogs, such as 5-fluorouracil and gemcitabine, and the purine analogs, such as 6-mercaptopurine and 6-thioguanine. These analogs substitute for nucleic acid bases in both DNA and RNA synthesis, but drug resistance to these antimetabolites has been implicated due to the nucleoside transporters (NT), which mediate uptake of nucleic acids into dividing cells (57). 5-Fluorouracil is an anticancer drug often used in the treatment of colon cancer. The prodrug of 5-fluorouracil was shown to be cleaved by beta-lactamase, however, the in vitro cytotoxicity was found to be the same as that of the parent drug alone (58).
N-thiolated beta-lactams as anticancer drugs

5.5. Vinca Alkaloids

The vinca alkaloids are potent anticancer drugs derived from natural sources that are used to treat the acute leukemias, lymphomas, and some solid tumors. Two cephalosporin-vinca alkaloid prodrugs were found to have a 5-fold less cytotoxicity to LS174T colon adenocarcinoma cells than the parent drug LY233425 and LY266070 (59,60). LY233425-cephalosporin prodrug was found to be equipotent when administered with the F(ab')-beta-lactamase conjugate with the parent drug (59). In vivo studies with mouse models of human colorectal carcinoma tumors demonstrated long term regressions when LY266070-cephalosporin prodrug was administered with mAb-beta-lactamase (60).

5.6. Doxorubicin

Cephalosporin-doxorubicin prodrugs have been developed that show promising anticancer properties when used in conjunction with mAb-beta-lactamase conjugates. In vitro studies of C-Dox on H2981 lung adenocarcinoma cells revealed that the prodrug was less toxic than doxorubicin alone. The prodrug was also immunospecifically activated by the L6-EC1β-lactamase conjugate to release doxorubicin in vitro (61). Additionally, another study showed that a different mAb-beta-lactamase/cephalosporin-doxorubicin prodrug system effectively delivered doxorubicin to a series of MCF7 breast carcinoma, OVCAR3 ovarian carcinoma, and T380 and LS174T colon tumor xenografts (62). The maximum tolerated dose of the prodrug was equivalent to that of the free drug when compared to the degree of tumor suppression, however tumors did not regress. A polymer prodrug of cephalosporin-doxorubicin has been developed and was shown to increase the survival rate and decrease the tumor growth rate of mice when treated in conjunction with a polymer bound beta-lactamase enzyme (63). The combination of polymer-prodrug and polymer-enzyme was non-toxic with the doses used in the study.

5.7. Mitomycin C

Two cephalosporin prodrugs of mitomycin C were evaluated against H2987 lung adenocarcinoma and clone 62 melanoma cell lines (64). In vitro studies showed that one of the prodrugs (prodrug 1) had comparable cytotoxicity to the parent drug, whereas another prodrug (prodrug 3) was 40- and 10-fold less toxic toward H2987 and clone 62 melanoma cells. Prodrug 3 was also immunospecifically activated by L6-F(ab')-beta-lactamase and 96.5-F(ab')-beta-lactamase conjugates that are selective toward H2987 and clone 62 cells, respectively (64).

5.8. Paclitaxel

Anticancer drugs derived from natural sources comprise a large body of the drugs currently approved for chemotherapies. Treatments with paclitaxel (Taxol), derived from Taxus brevifolia (Pacific yew tree) and a semisynthetic analog, docetaxol, target rapidly dividing cancer cells by increasing microtubule polymerization, thereby inhibiting anaphase during cell cycle (65,66).

A prodrug of paclitaxel has been shown to be immunospecifically activated by the fusion protein L49-sFv-beta-lactamase (67). In vitro cytotoxicity assays performed on 3677 melanoma cells expressing the melanotransferrin (p97) antigen revealed that the prodrug was 12 to 30 times less cytotoxic than the parent drug (67).

5.9. Radioimmunotoxins

Radioimmunotherapy is a method to deliver a radioisotope to a specific target area namely tumor cells. One disadvantage of method is that it can lead to dose-limiting toxicities through radiation exposure to non-targeted organs. A recent study has shown that a radioimmunoconjugate containing a cleavable linker can release the radioisotope upon administering an enzyme thus lowering systemic radiation exposure (68). This approach utilized a 121I-labeled cephalosporin conjugated to Tositumomab, a mAb specific for the CD20 antigen via a synthetic linker. Upon administration of the beta-lactamase enzyme, the radiolabel would be released causing rapid clearance from the blood and normal organs. In vivo studies of mouse models with human Ramos B lymphoma tumor xenografts revealed no decrease of the injected dose after 1 h of beta-lactamase treatment (68). However, after 4 h there was a noticeable decrease in the radioactive content from the tumor as well as blood, liver, lung and marrow demonstrating that there was rapid clearance of the radiolabel after injection of the radioimmunoconjugate and beta-lactamase enzyme (68). In addition, there was an enhanced tumor to blood % injected dose ratio at the beginning time points of the study.

The ADEPT system allows for the use of agents that, when given systemically, are too toxic for use in the clinic. The diversity of cancer drugs that are utilized is well demonstrated. Additionally, many studies have shown that the active drug is generated at the tumor site and at concentrations that could not be used in normal systemic administration of the parent drug. Further advancements to improve the efficacy of mAb-enzyme/prodrug therapies have resulted in modifying the mAb-beta-lactamase conjugate. Recombinant formed monoclonal antibody-beta-lactamase conjugates showed improved anticancer therapeutic activities compared to the synthetically formed conjugates (69).

6. POTENTIAL USE OF BETA-LACTAMS AS ANTICANCER DRUGS

6.1. N-Thiolated beta-Lactams

6.1.1. Structure-Activity Relationships
**N-thiolated beta-lactams as anticancer drugs**

Currently, there are many types of antibiotics (e.g. anthracyclines, bleomycin) that have been used to treat cancer. However, research into the possibility of utilizing beta-lactam antibiotics as potential anticancer medications has been relatively non-existent. Our most recent studies suggest that beta-lactams could play a role as anticancer drugs (37,38). In the following sections, we will discuss the different N-methylthio beta-lactams and their effects on cancer cells as well as some insights into possible mechanisms of action. We have demonstrated that N-thiolated beta-lactams have tumor cell-killing ability through induction of DNA-damage and subsequent apoptosis (37). Synthesis of other beta-lactams have aided in identifying important structure-activity-relationships (SARs). Additionally, we have also shown that N-thiolated beta-lactams have the ability to preferentially induce apoptosis in tumor cells, but not in normal or non-transformed cell (38).

Perhaps one of the most important findings with beta-lactams was that they did not need to possess a bicyclic ring with its rigid conformity to be bactericidal (9,10). This allows for a broader range of synthetic analogs to be made that possess antibacterial or antitumor activity. We have screened a large number of synthetic beta-lactams for their ability to promote tumor cell death (37,38). Of the compounds screened, we chose a lead compound, Lactam 1, to be the basis for additional synthesis of analogs (figure 3). Our findings yielded several important SARs. Lactam 1 was shown to induce apoptosis in a variety of tumor cell lines, namely, breast (MDA-MB-231, MCF-7), prostate (PC-3, DU-145), head-and-neck (PCI-13), SV-40 transformed lung cells (VA-13) and leukemic (Jurkat T) cell lines (37,38).

Other important SARs were observed also when cells were treated with the beta-lactams in cellular toxicity assays. Foremost, is the necessity of the N-methyl-thio group that when absent abolishes the apoptosis-inducing activity. Also observed was the inverse relationship between the number of carbon atoms off the N-thio group. Increasing the number of carbons from one to two decreased the amount of apoptosis observed by ~50% (Lactam 1 vs. Lactam 3). A four carbon chain off the N-thio group further decreased apoptosis-inducing activity by ~65%, and substitution of the N-methylthio group with a N-benzylthio group lead to ~70% decrease in apoptosis. Observations about the position of the chloro group off the phenyl ring also provided key SAR information. Isomers with the –Cl group in the meta or para position revealed that Lactams-5 and –6, while still capable of inducing apoptosis, were less potent than Lactam 1 (37). To determine if deletion or substitution of the ortho –Cl on the phenyl ring would increase or decrease activity, several analogs of Lactam 1 were synthesized with substituted halogen or non-halogen groups for the –Cl (figure 3). It was found that increasing the size of the group in the ortho position correlated with increased cell death (38). In fact, elimination of the ortho substituted group resulted in the least amount of activity, while substitution with a nitro group lead to the greatest amount of activity. The –NO2 substituted analog, Lactam 12, exhibited the strongest effect and consistently induced apoptosis comparable with Lactam 1, but at half the concentration (38).

According to these results, several key features should be retained for future design and synthesis of beta-lactams with antitumor properties: 1) the N-methyl-thio group must remain intact without additional carbon chains, 2) although meta and para substitutions on the phenyl ring still preserve their apoptotic producing abilities, substitutions in the ortho position are most potent, and lastly 3) the larger groups in the ortho position correlates with enhanced apoptotic-inducing activity (37,38).

### 6.1.2. Apoptosis Induction

A number of synthetic N-methylthio-beta-lactam compounds have been found to induce apoptosis in a number of tumor cell lines, such as the human leukemias Jurkat T cells, breast cancer (MCF-7, MDA-MB-231), prostate (PC-3, DU-145), and head-and-neck (PCI-13) cells (37,38). Several of these compounds (figure 3) caused induction of caspase-3/-7 activity, effector caspases whose activation is indicative of the apoptosis (70). The potency of these beta-lactams is as follows, Lactam 12 > 10 > 11 > 1 > 6 > 5 > 3 > 4 > 9 > 8 > 7 > 2 (37,38). A nuclear stain to determine the morphological changes of apoptotic nuclei showed that Lactam 12 induced cellular detachment of 50-60 % of total cell population (38). Additionally, beta-lactam treatment instigated cleavage of poly(ADP-ribose) polymerase (PARP) from its 116 kDa full length form to the 85 kDa fragment (37) which occurred in conjunction with caspase-3 activity, the caspase shown to directly cleave PARP (71). Caspase-8, an initiator caspase capable of mitochondria-dependent and –independent apoptosis initiation (72), was also found to become active after beta-lactam treatment (37). Cytochrome c is a mitochondrial protein that is released during apoptosis when the membrane potential of the mitochondria is compromised and combines with several other proteins (dATP, Apaf-1, caspase-9) to form the apoptosome, which is capable of activating caspase-3 (73). The N-methylthio beta-lactams are also able to cause cytochrome c release from the mitochondria, prior to activation of caspase-3, in time- and concentration-dependent manners (37). These data confirm that beta-lactams can indeed cause apoptosis in tumor cells.

There are other lactam compounds that can also induce apoptosis. Watabe et al. found that gamma-lactams, which contain a five-membered ring, are capable of inducing apoptosis in HL-60 cells (74). MT-21, a synthetic gamma-lactam, activates caspase-9 followed by the subsequent activation of caspase-3. Unlike our findings with beta-lactams, caspase-8 was not found to participate in the apoptosis signaling cascade after gamma-lactam treatment (74). Lactacystin, a gamma-lactam possessing a thio ester moiety and originally isolated from actinomycetes (75), has been found to be a potent inhibitor of chymotryptic- and tryptic-like catalytic activities of the proteasome through covalent bonding to the N-terminal threonine of the beta-subunits (76). Proteosome inhibition leads to an accumulation of p27 (77), IkB-α (78), and Bax (79), which can cause G1 cell cycle arrest and apoptosis (80, 81). It is for these reasons many believe that proteosome inhibitors are good candidates for anticancer chemotherapeutic drugs (82-84).
N-thiolated beta-lactams as anticancer drugs

6.1.3. DNA-Damage and Signal Transduction Pathways

To further investigate the cause of apoptosis after N-methylthio beta-lactam treatment, analysis of cell cycle changes were performed. Lactam 1 was found to increase S-phase DNA content and initiate a concomitant decrease in G1 phase DNA. This S-phase cell cycle arrest was found to be due to an inability for treated cells to undergo DNA replication as was found from a [3H] thymidine incorporation assay. DNA replication was inhibited in a time- and concentration-dependent manner with a halfmaximal inhibition (IC50) of [3H] thymidine in Jurkat cells at 32 μM with Lactam 1 treatment (37). A terminal deoxynucleotidyl transferase-mediated nick-end labeling (TUNEL) assay, which detects DNA strand breaks, then provided additional data to support the hypothesis that the DNA replication inhibition was due to damage of the genomic DNA. After just 1 h of treatment with, over half of the cell population contained DNA strand breaks and after 4 h 98 % of the cells showed DNA strand breakage (37). In a similar experiment it was found that Lactam 12 induced greater DNA damage that Lactam 1 (by 27%) after a 24 h period (37).

It was also determined that p38 MAP kinase activation is required for beta-lactam induced apoptosis (37). Activation of p38 MAP kinase can trigger apoptosis following multiple stimuli, such as DNA damage (85, 86). Protein levels of phosphorylated p38 increased significantly with Lactam treatment and cotreatment with the p38 inhibitor (PD169316) inhibited PARP cleavage and activation of caspase-3, -8, and -9 (37). Additional experiments revealed that p38 activation occurs upstream of caspase activation and that p38 activity was necessary for caspase-mediated cell death in beta-lactam treatment. Conversely, DNA strand breaks were still observed after cotreatment with PD169316 and Lactam 1, indicating that N-thiolated beta-lactams induced DNA damage leading to p38 activation, followed by caspase activation and subsequent apoptotic cell death.

6.1.4. Preferential Tumor Cell Killing

Many currently used chemotherapeutic drugs for cancer intercalate with cellular DNA, thus making it impossible for the cell to function which leads to subsequent apoptotic death. Unfortunately, these drugs are not “tumor-specific” and they will intercalate with any rapidly dividing cell, such as the epithelial cells lining the gastrointestinal tract, which can lead to nausea and vomiting. Tumor cell specific therapies are those that solely target tumor cell characteristics exclusively. For instance, Gleevec (STI571) is an ATP inhibitor that targets growth and proliferative signaling pathways stimulated by the Bcr-Abl oncoprotein in chronic myelogenous leukemia (87).

To determine if Lactam 1 possessed a tumor cell-specific activity human leukemia Jurkat T cells and immortalized, non-transformed natural killer cells (YT cells) were treated with Lactam 1 and the effects were determined. It was found that only the Jurkat, but not YT, cells showed apoptosis-specific PARP cleavage and decreased cell viability in both time- and concentration-dependent manner (38). Additionally, treatment with Lactam 12, which substitutes the –Cl moiety for a –NO2 on the benzene ring, was found to potently and specifically induce apoptosis in only the Jurkat T cells while not affecting the non-transformed YT cells. Both Lactam 1 and Lactam 12 inhibited colony formation, indicative of cellular transformation, of prostate cancer LNCaP cells as observed in a soft agar assay. These lactams were also able to induce TUNEL-positive cells as well as caspase-3/-7 activity and apoptotic nuclear morphology of transformed tumor cell line types, but not in non-transformed cell lines (38). For example, Lactam 12 induced apoptotic morphological changes and caspase-3 activity exclusively in SV-40 transformed human fibroblasts (VA-13) but not in normal non-transformed fibroblasts (W138) (38). This is consistent with the idea that beta-lactams could be developed into tumor-specific drugs.

6.2. 4-Alkylidene-beta-Lactams

The matrix metalloproteinases (MMPs) are a class of mammalian proteases that can, among other functions, degrade the extracellular matrix (88). Angiogenesis, the formation of new blood vessels, requires the activity of the MMPs to digest the basement membrane. The MMPs play a pivotal role in cancer progression by allowing neovascularization, which is essential for tumor growth, invasion, and metastasis (89). MMPs can be constitutively activated in cancer cells, but not in normal cells (90). Thus, targeting MMP expression and activity is a unique approach in the field of cancer research.

A class of beta-lactams, the 4-alkylidene-oxazetidin-2-ones, has been identified that exhibit inhibitory activity to both MMP-2 and MMP-9 as well as leukocyte elastase (LE) (39). LE can activate MMP-2 and MMP-9, and inactivate their tissue inhibitor (91). Compounds with protected hydroxy groups (Compounds 1 and 8) were found to inhibit LE. Compound 8 in particular showed an IC50 of 9 μM to LE activity. The green tea polyphenol (-)-epigallocatechin-3-gallate (EGCG), a known LE inhibitor, was used as a comparison and was found to be ~22-fold more active (IC50=0.4 μM) than Compound 8 (39). When the hydroxyl group was unprotected, or removed all together, the beta-lactam lost its potent activity against LE, but gained considerable activity against MMP-2 and MMP-9. Two compounds in particular (Compounds 2 and 18) showed the greatest inhibitory activity on MMP-2 with IC50's of 85 μM and 60 μM, respectively (39). This is a promising area of drug research because inhibition of angiogenesis not only inhibits tumor growth, but also prevents invasion and metastasis via the circulatory system.

6.3. Polyaromatic Beta-Lactams

In 2001, Banik et al. described polyaromatic imine beta-lactams with biological activity against cancer cells (40). Several synthesized compounds were tested in vitro for their cytotoxicity on nine cancer cell lines (40). Compounds with phenanthrene and chrysene substituents had the most activity in vitro, as measured by MTT assay. The maximal activity
N-thiolated beta-lactams as anticancer drugs

concentrations ranged from 2.5 to 40.6 μM, some well within the therapeutic range. Conversely, beta-lactams with naphthalene, anthracene, and pyrene substituents showed virtually no cytotoxicity (40).

A series of in vivo assays using athymic nude (nu/nu) mice was performed with the active beta-lactams mentioned above. Mice were injected with K-562 leukemia, HT-29 colon, or SKOV-3 ovarian cancer cells. A variety of treatment times and regimens were tested (40). Mice given polyaromatic beta-lactam treatments (Compound 17a) at 60 mg/kg showed negligible toxicity compared to the control mice that were given cisplatin and adriamycin. The polyaromatic induced only a slight weight loss (3.52 g), which was quickly recovered after discontinuation of treatment (40). It was also found that treatment with the beta-lactam compound delayed the onset of tumor formation by 7 ± 2 days in mice injected with HT-29 cells. Additionally, many of the mice injected with SKOV-3 cells did not form any tumors at all (40).

7. CONCLUSIONS AND PERSPECTIVES

Cancer is lethal to 42% of those diagnosed. With millions of new patients each year, the initiative to develop suitable chemotherapeutic agents is a driving focus of medical research. However, the currently available chemotherapeutic agents are incapable of selectively targeting cancer cells from normal cells leading to treatments that are almost as hazardous as the disease itself. Beta-lactams are compounds that have been used for many years to combat microbial infections. Therefore, it is already known that these compounds possess minimal effects on non-bacterial cells; this trait is desirable of chemotherapeutic agents. Recently, the potential of beta-lactams as anticancer agents has come to light. Beta-lactams can be used as pro-drugs that are capable of specifically targeting tumor cells. Likewise, the N-methylthiolated beta-lactams are capable of inducing apoptosis in a wide array of tumor cells types, with little effect on normal cells. Thus making these compounds, and other beta-lactams (eg. 4-alkylidene and polyaromatics), attractive targets for structure-activity relationship studies and analog synthesis. While further study on this class of compounds in animal models should be performed to completely assess their toxicity, selectivity, and efficacy in vivo, the profiles reported here show an optimistic future for expanding the role of these compounds from simple antibiotics to anticancer therapeutics.

8. ACKNOWLEDGMENTS

We thank Timothy Long, Randy Hill, and David M. Smith for their contribution to the research of beta-lactams. We thank the United States Army Medical Research and Material Command (DAMD17-03-1-0175), the National Cancer Institute-National Institutes of Health, and Barbara Ann Karmanos Cancer Institute for research grants to Professor Q. Ping Dou, and the National Institutes of Health for a research grant (NIH ROI ALS1351) to Professor Edward Turos.

1. ABSTRACT

Recent research suggests that copper could be used as a novel selective target for cancer therapies. Copper is a cofactor essential for tumor angiogenesis processes and high levels of copper have been found in many types of human cancers, including prostate, breast and brain. We have reported that organic copper-containing compounds, such as 8-hydroxyquinolino-copper([II]), are a novel class of proteasome inhibitors and tumor cell apoptosis inducers (Daniel et al., Biochem Pharmacol. 2004;67:1139-51). Most recently, we have found that when complexed with copper, the known antioxidant pyrrolidine dithiocarbamate (PDTC) forms a potent proteasome inhibitor in human breast cancer, but not normal cells (Daniel, Chen, et al., submitted). In the current study, we investigate whether the PDTC-copper complex can play similar roles in inhibiting the proteasomal activity and consequently inducing apoptosis in human prostate cancer cells. We used tetrahydroxybutadine (TM), a strong copper chelator currently being tested in clinical trials, as a control. We report here that after binding to copper, PDTC, but not TM, can inhibit the proteasomal chymotrypsin-like activity, suppress proliferation, induce apoptotic cell death, and inhibit uptake of radiopharmaceutical [18F]Fluoro-2-deoxy-D-glucose in cultured human prostate cancer cells. In contrast, PDTC, TM or copper alone or a TM-copper mixture had no such effects. Our study suggests that high copper levels in human prostate cancer in vivo can be targeted by a ligand such as PDTC, resulting in formation of an active proteasome inhibitor and apoptosis inducer specifically in prostate tumor, but not normal cells.

2. INTRODUCTION

Copper is an essential trace metal for animals. The amount of copper in an organism is tightly regulated (1, 2). High levels of copper have been found in many types of human cancers including prostate, breast, colon, lung, and brain (3-11). Consistently, angiogenesis, the formation and differentiation of blood vessels, is essential for tumor growth, invasion, and metastasis (12-15). Indeed, molecular processes of angiogenesis require of copper, but not other trace metals, as an essential cofactor (12-21).

The ubiquitin/proteasome system plays an important role in the degradation of cellular proteins. This proteolytic system involves two distinct steps: ubiquitination and degradation (22, 23). The eukaryotic proteasome contains at least three known
activities, which are associated with its β subunits. These are the chymotrypsin-like (cleavage after hydrophobic residues, β5 subunit), trypsin-like (cleavage after basic residues, β2 subunit), and caspase-like or peptidyl-glutamyl peptide-hydrolyzing (cleavage after acidic residues, β1 subunit) activities (24, 25). Inhibition of the proteasomal chymotrypsin-like, but not trypsin-like, activity has been found to be associated with induction of apoptosis in tumor cells (26-31).

Dithiocarbamates are a well-defined class of metal-chelating compounds. These compounds have been previously used for treating bacteria, fungi and AIDS (32, 33). Pyrrolidine dithiocarbamate (PDTC; Figure 1A), a member of the dithiocarbamates, is an antioxidant that has been used as a therapeutic agent for treatment of inflammation, atherosclerosis and metal intoxication (34, 35). It has been shown that PDTC is able to inhibit NFκB activation and induce tumor cell apoptosis (36). Although the involved molecular mechanism remains unknown, it has been found that copper uptake is required for PDTC-mediated activities (37) and that PDTC is a copper-binding compound (38). PDTC and other dithiocarbamates have been found to induce apoptosis in conjunction with copper in different types of cancer cells (37, 39).

Tetrathiomolybdate (TM) is a copper chelator that was originally used for patients with Wilson’s disease (17, 18). TM has been found to be effective in impairing the growth of mammalian tumors in HER2/neu transgenic mice (40) and lung metastatic carcinoma in C57BL/6J mice (41). In a phase I clinical trial with patients suffering from metastatic cancers, TM therapy achieved stable disease in 5 of 6 patients who became copper-deficient (20). However, the disease advanced in some other patients before copper levels were sufficiently lowered (17, 18, 20). These reports support the idea of copper control as an anticancer strategy.

We have previously demonstrated that certain types of copper-binding compounds are potent proteasome inhibitors (42). Most recently, we have also found that PDTC, after interacting with copper, forms a proteasome inhibitor in human breast cancer cells (Daniel KG, Chen D, Orlu * et al, submitted). In the current study, we investigated the effects of the PDTC-Cu complex in human prostate cancer cells. We report that PDTC is capable of binding copper, spontaneously forming a new complex that has proteasome-inhibitory and apoptosis-inducing activities to human prostate cancer cells. In contrast, copper, PDTC or TM alone, or TM-copper complex had no effects under the same experimental conditions. We propose that targeting highly elevated copper could be tumor-specific and that formation of an active proteasome inhibitory complex between PDTC and copper is a novel strategy that has great potential for prostate cancer therapies.

3. MATERIALS AND METHODS

3.1. Chemicals, reagents, and radiopharmaceuticals

Cupric chloride (CuCl2), dimethyl sulfoxide (DMSO), pyrrolidine dithiocarbamate (PDTC), and ammonium tetrathiomolybdate (TM), 2-[4,8-Dimethylazolo-(2-yl)]-2,5-diphenyl-tetrazolium bromide (MTT), and Hoechst 33258 stain were all purchased from Sigma-Aldrich. The substrate for the chymotrypsin-like activity of the proteasome, Suc-Leu-Leu-Val-Tyr-AMC, was purchased from Calbiochem. Polyclonal antibody to poly(ADP-ribose) polymerase (PARP) was obtained from Boehringer, Mannheim. Monoclonal antibilibulin antibody, secondary antibodies, anti-rabbit IgG horseradish peroxidase, and anti-rabbit IgG horseradish peroxidase were from Santa Cruz Biotechnology Inc. Radiopharmaceutical 2-[18F]fluoro-2-deoxy-D-glucose ([18F]FDG), a tracer widely used for positron emission tomography (PET) imaging of cancers, is prepared by the method of Hamacher et al (43) using 1,3,4,6-tetra-O-acetyl-2-O-triflyl-β-D-manno-pyranose as the labeling precursor and [18F]fluoride is produced with a cyclotron housed at the PET Center, Children’s Hospital of Michigan.

3.2. Preparation of the PDTC-Cu complex

To prepare PDTC-Cu complex, equal molar amounts of PDTC and CuCl2, both dissolved in DMSO at 50 mM, were mixed by drop-wise addition of the CuCl2 solution into the PDTC solution. The mixture was kept at room temperature for 10 minutes to allow formation of the PDTC-Cu complex. The freshly prepared PDTC-Cu complex was used for experiments.

3.3. Cell culture, drug treatment and whole cell extract preparation

LNCaP human prostate cancer cell line was purchased from ATCC. Cell culture medium (RPMI 1640), antibiotics, and trypsin solution were purchased from Gibco. LNCaP cells were maintained in RPMI 1640 supplemented with 10% fetal calf serum, 100 units/mL of penicillin, 100 mg/mL of streptomycin and 10mM HEPES at 37 °C in a humidified incubator with an atmosphere of 5% CO2. Cells were treated with treated with nolar amounts of compounds, mixtures, or with an equivalent volume of solvent control as indicated in the figure legends. Whole cell extracts were prepared as described previously (44, 45). Briefly, cells were harvested, washed with cold PBS twice, and homogenized in a lysis buffer (50 mM Tris–HCl, pH 8.0, 150 mM NaCl, 1% NP-40, 0.5 mM phenylmethylsulfonyl fluoride, and 0.5 mM diithiothreitol) for 30 min at 4 °C. Afterwards, the lysates were centrifuged at 12,000 g for 15 min, and the supernatants were collected as whole cell extract.

3.4. Cell proliferation inhibition assay

The effects of each compound and their copper mixtures on LNCaP cells were determined using the MTT dye uptake method. Briefly, LNCaP cells (104 /well/ 0.1 ml) were seeded in triplicate in a 96-well plate and incubated at 37 °C in a humidified incubator with an atmosphere of 5% CO2 until 70-80% confluence. This was followed by an additional 24-h incubation with fresh medium containing different concentrations of each compound and their copper mixtures. The same
PDTC-copper complex as novel proteasome inhibitor and potential anti-cancer drug

amount of DMSO was added as the solvent control. Thereafter, 100 µL MTT solution (1 mg/ml in serum-free medium) replaced the medium in each well. After 4 h at 37 °C incubation, the MTT solution was replaced by 100 µL DMSO. When the blue crystals were dissolved, the optical density (OD) was measured in a Wallac Victor3™ multilabel plate reader (Perkin Elmer, USA) at a wavelength of 560 nm. The formula used to evaluate the result is as follows: inhibition of cell proliferation (%) = (OD of the experimental samples/OD of the control) × 100%.

3.5. Cellular and nuclear morphology analysis

LNCaP cells were treated as indicated (see figure legends). Afterwards, the cells were visualized by microscopic imaging with either phase contrast for cellular morphology or Hoeschst staining with fluorescence for nuclear morphology. Briefly, the cells were washed with PBS and fixed in 75% ethanol for at least 1 h at 4 °C followed by washing with PBS three times and staining in 50 µL of Hoeschst 33258 for 30 min at 4 °C in dark. Subsequently the cells were washed and resuspended in 50 µL PBS and mounted for viewing. Copper mixture-induced apoptosis was monitored by the extent of nuclear fragmentation. Nuclear fragmentation was visualized by Hoeschst 33258 staining of apoptotic nuclei using Zeiss Axiovision fluorescence microscope (Carl Zeiss Microscope Inc., Hallbergmoos, Germany).

3.6. In vitro proteasome activity assay

The cell-free chymotrypsin-like activity of the proteasome was determined by measuring the release of the AMC groups from a substrate as previously described (26). Briefly, after each treatment, whole cell extract (10 µg) of LNCaP cells was incubated in 100 µL of assay buffer (50 mM Tris–HCl, pH 7.5) and 40 µM fluorogenic peptide substrates, Suc-Leu-Leu-Val-Tyr-AMC (for the chymotrypsin-like activity) for 1 h at 37 °C. After incubation, production of hydrolyzed AMC groups was measured using a Wallac Victor3™ multilabel plate reader with an excitation filter of 380 nm and an emission filter of 460 nm. Changes in fluorescence were calculated against non-treated controls and plotted with statistical analysis using Microsoft Excel® software.

3.7. Western Blot Assay

To evaluate ubiquitinated protein accumulation and PARP cleavage induced by PDTC-Cu complex treatment, cell lysates (30 µg) from treated LNCaP cells were subject to SDS–PAGE analysis and then transferred to a nitrocellulose membrane. The Western blot analysis was performed using specific antibodies to ubiquitin and PARP as described previously (42, 45), followed by visualization via enhanced chemiluminescence (ECL) (Amersham Biosciences).

3.8. Cellular 18F-FDG uptake assay

To evaluate the effects of PDTC-Cu complex on cellular uptake of 18F-FDG, LNCaP cells (5x10^4 cells in 1 ml of RPMI1640/well) were seeded in triplicate in a 12-well cell culture plate 12 hours prior to treatment of cells with PDTC-Cu complex and other control reagents. Following treatment for 12 hours, LNCaP cells were incubated with 5 μCi (185 kBq) of 18F-FDG added to the cell culture medium for 1 hour at 37 °C in an atmosphere containing 5% CO₂. At end of incubation, the culture medium containing 18F-FDG was removed and the cells were washed with PBS three times. Subsequently, the cells were digested with 5% trypsin solution and collected in a tube for radioactivity count using a Packard RiaSfw multiwell gamma counter (Packard Instrument Co, Meriden CT). Radioactivity of the cells was calculated as percentage of inoculation dose (ID%) normalized to cell number (5x10^4/well), in reference to radioactivity of 5 μCi (185 kBq) or 18F-FDG.

3.9. Statistical analysis

All data were expressed as mean ±SD. Statistical analysis was performed with the paired, two-tailed T test using Microsoft Excel software and p values < 0.05 or < 0.01 were considered to represent statistical significance.

4. RESULTS

4.1. PDTC spontaneously reacts with copper to form a new complex.

In order to use endogenous elevated copper in prostate tumor tissues as a targeting mechanism for cancer therapy, it is prerequisite for a ligand to react spontaneously with copper to form a new complex. To test the reactivity of PDTC with copper, 50 mM of PDTC was added to a 50 mM of copper (II) chloride (Figure 1). The reaction of PDTC with copper results in a dramatic color change (Figure 1), indicating formation of a new metal complex. This result is consistent with a previous publication showing that PDTC is strong copper chelator (37). Therefore, PDTC may be capable of combining with endogenous copper in tumor tissues and forming an active proteasome-inhibitory complex.

4.2. The PDTC-Cu complex inhibits the chymotrypsin-like activity of the proteasome in intact LNCaP cells

Previously we reported that organic copper complexes inhibit the cellular proteasomal activity (42; Daniel KG, Chen D, Orlu S, Cui QC, Miller FR, Dou QP, submitted). We then investigated whether the PDTC-copper could inhibit the proteasome activity in human prostate cancer cell. Prostate cancer LNCaP cells were treated for 24 h with copper, PDTC, or PDTC-copper mixture, using TM and TM-copper mixture as controls. After treatment, the cells were collected and protein extracts were prepared for analysis of proteasome inhibition. Inhibition of the proteasome was measured by two assays: the chymotrypsin-like activity assay (Figure 2A), and the accumulation of ubiquitinated proteins by Western blotting (Figure 2B). We found that the prepared PDTC-copper mixture significantly inhibited the proteasome activity in LNCaP cells, as indicated by low levels of the...
PDTC-copper complex as novel proteasome inhibitor and potential anti-cancer drug

proteasomal chymotrypsin-like activity (Figure 2A) and accumulation of ubiquitinated proteins (Figure 2B, lane 5). Copper or PDTC alone does not inhibit the proteasome activity (Figure 2A, B, lanes 2, 3). We found that neither TM nor the TM-Cu mixture was able to inhibit the proteasome activity in the prostate cancer cells (Figure 2), further supporting that TM acts as a passive copper chelator and eliminator and TM-copper is an inactive complex (42). These data support the hypothesis that a PDTC-Cu complex is capable of proteasome inhibition.

4.3. PDTC-Cu mixture effectively inhibits proliferation of human prostate cancer cells

Since PDTC can form a complex with copper, as indicated by color change (Figure 1), and is able to inhibit the proteasomal activity in prostate cancer cells (Figure 2), we then tested whether the complex is able to inhibit proliferation of human prostate cancer cells. Prostate cancer LNCaP cells were treated with copper, PDTC, PDTC-copper mixture, TM or TM-copper mixture for 24 h. We found that the PDTC-copper mixture inhibited LNCaP cell proliferation in a dose-dependent manner (Figure 3). The PDTC-copper mixture showed 50% inhibition at 1 μM and greater than 90% inhibition at 5-10 μM (Figure 3). The IC₅₀ value of the PDTC-copper mixture was determined as 1 ±0.07 μM. In contrast, copper alone, PDTC alone, or TM and TM mixed with copper had no significant effect (Figure 3).

4.4. LNCaP cells treated with the PDTC-Cu complex undergo apoptosis

Having demonstrated that the PDTC-copper complex is capable of inhibiting cellular proliferation in prostate cancer cells (Figure 3), we then determined whether this mixture could induce prostate cancer cell apoptosis. Exponentially growing LNCaP cells were treated with copper, PDTC, TM or their mixtures for 24 h, followed by observing cellular and nuclear morphological changes by phase contrast or fluorescence microscope, respectively (Figure 4). The cells treated with the PDTC-copper mixture became spherical and detached (Figure 4A). By staining with Hoescht 33258, the most of the nuclei in the PDTC-copper-treated cells were brighter and denser, compared to those treated with copper, PDTC, TM alone or TM-copper (Figure 4B). These results suggested that the cells treated with the PDTC-copper mixture were undergoing apoptosis. Apoptosis induction was further verified by cleavage of PARP (Figure 2C). Treatment with the PDTC-copper mixture, but not others, induced lost of the intact PARP and appearance of a PARP cleavage fragment (Figure 2C). Taken together, PDTC, when combined with copper, forms an active complex that has the proteasome-inhibitory, proliferation-inhibitory and apoptosis-inducing activities.

4.5. Reduction of 18F-FDG uptake by LNCaP cells after treatment with PDTC-Cu complex

To prepare for evaluation of anti-tumor activity of the PDTC-Cu complex in vivo with 18F-FDG PET imaging, we tested effects of the PDTC-Cu complex on 18F-FDG uptake by LNCaP cells following treatment with the PDTC-Cu complex in vitro (Figure 5). Cellular 18F-FDG uptake was dramatically reduced in LNCaP cells treated with 10 μM of the PDTC-Cu complex (ID% 0.05), in comparison to LNCaP cells treated with 10 μM PDTC (ID% 20%), 10 μM copper chloride (ID% 74%), 3% DMSO (ID% 0.94), or no treatment (ID% 1.02) (Figure 5).

5. DISCUSSION

In regards to the current anti-cancer chemotherapies, most drugs used in clinics are toxic to some extent. This is mainly due to their inability to distinguish normal cells from tumor cells. In order to eliminate toxicity, it is necessary to identify some specific properties or features of cancer cells different from normal cells. An increased understanding of the tumor-specific differences will facilitate the development of novel anti-cancer drugs that selectively kill cancer cells with limited toxicity or no toxicity to the normal cells.

One such difference is the ubiquitin-proteasome pathway. In cancer cells, dysregulation of this system plays a critical role for tumor progression, drug resistance and altered immune surveillance (46). Previously we reported that proteasome inhibitors induce apoptosis selectively in tumor cells but not in normal cells (47). Bortezomib, the first proteasome inhibitor as a potential anticancer drug, is currently being tested in phase III clinical trials (48, 49). Another attractive tumor-specific feature is high levels of copper found in many types of human cancers including prostate, breast, colon, lung, and brain (3-11). Molecular processes of angiogenesis include: the requirement of copper, but not other trace metals, as an essential cofactor, stimulation of endothelial growth by tumor cytokine production (i.e., vasoendothelial growth factor), degradation of extracellular matrix proteins by metalloproteinases, and migration of endothelial cells mediated by integrins (12-21).

It has been shown that cancer cells are more sensitive to proteasome inhibition than normal cells (27, 47, 50-52). We hypothesize that an inactive or nontoxic organic ligand could bind with elevated copper found in tumor tissues and result in a complex capable of proteasome inhibition. After the ligand binds with endogenous tumor cellular copper, the formed complex would inhibit the proteasome activity, leading to inhibition of the processes of angiogenesis in tumor tissues and induction of apoptosis in the tumor cells.

In search for new proteasome inhibitors of high potency and low toxicity, we found that several organic copper complexes possessing potent proteasome-inhibitory and apoptosis-inducing activities in tumor but not in normal cells (42). Since PDTC, an antioxidant used to treat inflammation, atherosclerosis and metal intoxication (34, 35), could form a copper complex (37), we hypothesized that PDTC-Cu complex may also possess proteasome-inhibitory activity. Indeed, this hypothesis was
PDTC-copper complex as novel proteasome inhibitor and potential anti-cancer drug

supported by the most recent study using human breast cancer cells (Daniel KG, Chen D, Orlu S, Cui QC, Miller FR, Dou QP, submitted). In the current study, we have also demonstrated that PDTC can form a new complex with copper, and the complex can inhibit proteasomal activity and cellular proliferation and induce apoptosis in prostate cancer LNCaP cells.

Once we verified that PDTC could spontaneously bind with copper and form a new complex (Figure 1), we then tested the complex in LNCaP cells to determine whether or not the complex was a proteasome inhibitor. We examined both cellular proteasome activity (Figure 2A) and accumulation of ubiquitinated proteins (Figure 2B). We found that the cells treated with PDTC-copper mixture had significantly reduced chymotrypsin-like activity (Figure 2A) and accumulation of ubiquitinated proteins (Figure 2B), indicating that proteasome inhibition had occurred. In contrast, copper, PDTC alone, TM alone, or TM mixed with copper was incapable of inhibiting the proteasome (Figure 2A and B).

We then tested whether or not the complex was capable of inhibiting proliferation of human prostate cancer cells. The results showed that only PDTC-copper mixture could inhibit proliferation of LNCaP cells in dose-dependent manner, but not copper, PDTC alone, TM alone, or TM-copper mixture (Figure 3).

Afterward we verified the association between PDTC-copper induced inhibition of proteasomal activity and proliferation, we then determined apoptosis-inducing activities of each compound in prostate cancer cells. Our result demonstrated that LNCaP cells treated with PDTC-copper mixture underwent apoptosis, as showed by PARP cleavage (Figure 2C) and cellular (Figure 4A) and nuclear (Figure 4B) morphological changes. However, LNCaP cells treated with copper, PDTC alone, TM alone, or TM-copper mixture failed to undergo apoptosis (Figs. 2C, 4A and B).

Positron-emission tomography (PET) is a sensitive, quantitative, non-invasive molecular imaging technology, which can be used to evaluate response of tumors to anticancer drugs. We tested effects of PDTC-Cu complex on 18F-FDG uptake by LNCaP cells. As expected, 18F-FDG uptake was dramatically reduced in LNCaP cells treated with PDTC-Cu complex (Figure 5), which suggests that the therapeutic effects of PDTC-Cu complex against prostate cancer may be monitored in vivo with 18F-FDG-PET imaging. Slight inhibition of 18F-FDG uptake was observed in the cells treated with PDTC alone, which is probably related to anti-tumor effects of small amount of PDTC-Cu complex formed with trace amount of intracellular copper. Unexpectedly, slight reduction of 18F-FDG uptake was also observed in LNCaP cells treated with 10 μM copper chloride (Cu), which may be related to inhibition of glucose transporter activity in LNCaP cells or other unknown mechanisms. These results demonstrated that it would be feasible to evaluate anti-tumor activity of PDTC-Cu complex in vivo non-invasively with 18F-FDG-PET imaging.

The data presented here supports the novel concept of using accumulated copper in prostate cancer cells and tissues as a selection method for chemotherapy. Non-toxic organic compounds such as PDTC can spontaneously bind with tumor cellular copper and form a proteasome inhibitor and an apoptosis inducer. PDTC has been previously explored for use in other diseases and we believe our data support further investigation of this and other similar compounds in an anticopper/anti-cancer strategy.

Abstract

Introduction A physiological feature of many tumor tissues and cells is the tendency to accumulate high concentrations of copper. While the precise role of copper in tumors is cryptic, copper, but not other trace metals, is required for angiogenesis. We have recently reported that organic copper-containing compounds, including 8-hydroxyquinoline-copper(II) and 5,7-dichloro-8-hydroxyquinoline-copper(II), comprise a novel class of proteasome inhibitors and tumor cell apoptosis inducers. In the current study, we investigate whether clioquinol (CQ), an analog of 8-hydroxyquinoline and an Alzheimer's disease drug, and pyrrolidine dithiocarbamate (PDTC), a known copper-binding compound and antioxidant, can interact with copper to form cancer-specific proteasome inhibitors and apoptosis inducers in human breast cancer cells. Tetrathiomolybdate (TM), a strong copper chelator currently being tested in clinical trials, is used as a comparison.

Methods Breast cell lines, normal, immortalized MCF-10A, premalignant MCF10AT1K.c12, and malignant MCF10DOS.com and MDA-MB-231, were treated with CQ or PDTC with or without prior interaction with copper, followed by measurement of proteasome inhibition and cell death. Inhibition of the proteasome was determined by levels of the proteasomal chymotrypsin-like activity and ubiquitinated proteins in protein extracts of the treated cells. Apoptotic cell death was measured by morphological changes, Hoechst staining, and poly(ADP-ribose) polymerase cleavage.

Results When in complex with copper, both CQ and PDTC, but not TM, can inhibit the proteasome chymotrypsin-like activity, block proliferation, and induce apoptotic cell death preferentially in breast cancer cells, less in premalignant breast cells, but are non-toxic to normal/non-transformed breast cells at the concentrations tested. In contrast, CQ, PDTC, TM or copper alone had no effects on any of the cells. Breast premalignant or cancer cells that contain copper at concentrations similar to those found in patients, when treated with just CQ or PDTC alone, but not TM, undergo proteasome inhibition and apoptosis.

Conclusion The feature of breast cancer cells and tissues to accumulate copper can be used as a targeting method for anticancer therapy through treatment with novel compounds such as CQ and PDTC that become active proteasome inhibitors and breast cancer cell killers in the presence of copper.

Introduction

Copper is an essential trace metal for animals. The amount of copper in an organism is tightly regulated [1,2]. Angiogenesis, the growth of a tumor blood supply, is essential for tumor growth, invasion, and metastasis [3-6]. It has been shown that tumors, without a blood supply, do not grow larger than 1 to 2
Molecular processes of angiogenesis that require copper as an essential cofactor include stimulation of endothelial growth by tumor cytokine production (i.e., vasoendothelial growth factor), degradation of extracellular matrix proteins by metalloproteinases, and migration of endothelial cells mediated by integrins [3-12]. Consistently high levels of copper have been found in many types of human cancers, including breast, prostate, colon, lung, and brain [13-21]. Three anti-copper drugs have been tested in clinical trials [8,9], particularly tetramethylthioketone (TM), a copper chelator, which was originally used for patients with Wilson’s disease [8,11]. TM has been found to be effective in impairing the growth of mammary tumors in HER2/neu transgenic mice [22] and lung metastatic carcinoma in C57BL/6J mice [23]. In a phase I clinical trial with patients suffering from metastatic cancers, TM therapy achieved stable disease in five of six patients who were copper-deficient [11]. However, the disease advanced in some other patients before copper levels were sufficiently lowered [8,9,11]. These reports support the idea of copper control as an anticancer strategy.

Apoptosis, an evolutionarily conserved form of cell death, is the process by which a cell will actively commit suicide under tightly controlled circumstances [24]. Apoptosis occurs in two physiological stages, commitment and execution [25,26]. Activation of effector caspases leads to apoptotic execution probably through the proteolytic cleavage of important cellular proteins [27], such as poly(ADP-ribose) polymerase (PARP) [28], and the retinoblastoma protein [29-31]. Other hallmarks of apoptosis include cellular shrinkage, membrane blebbing, and DNA fragmentation [25-27].

The ubiquitin/proteasome system plays an important role in the degradation of cellular proteins. This proteolytic system involves two distinct steps, ubiquitination and degradation [32,33]. The eukaryotic proteasome contains at least three known activities, which are associated with its β subunits. These are the chymotrypsin-like (cleavage after hydrophobic residues, β5 subunit), trypsin-like (cleavage after basic residues, β2 subunit), and caspase-like or peptidyl-glutamyl peptide-hydrolyzing (cleavage after acidic residues, β1 subunit) activities [34,35]. Inhibition of the proteasomal chymotrypsin-like activity has been found to be associated with induction of apoptosis in tumor cells [36-41].

Most recently, we discovered that several organic-copper (but not zinc or nickel) compounds, such as bis-8-hydroxyquinoline-copper(II), potently and specifically inhibited the chymotrypsin-like activity of the proteasome in vitro and in human tumor cell culture [42]. Inhibition of the proteasome activity by organic copper compounds occurs very rapidly in tumor cells (15 minutes), followed by induction of apoptosis. Neither proteasome inhibition nor apoptosis were found in human normal or non-transformed cells under the same treatment. Most importantly, proteasome inhibition and apoptosis were also detected in copper-containing tumor cells treated with 8-hydroxyquinoline (8-OHQ; Fig. 1a). None of these events occurred in cells treated with either inorganic copper, ligand-treated cells that did not contain copper, or pretreatment with the closely related nickel followed by addition of the ligand [42]. We also found that 5,7-dichloro-8-hydroxyquinoline (S-DCHQ; Fig. 1a) synthesized to contain copper was a potent proteasome inhibitor and apoptosis inducer [42].

Clioquinol (5-chloro-7-iodo-8-hydroxyquinoline; CQ; Fig. 1a) belongs to the quinoline class of compounds and is structurally similar to 5,7-DCl-8-OHQ. This class of compounds possesses an established toxicology profile with the US Pharmacopoeia [43]. During the 1950s to the 1970s, CQ was used as an antibiotic [44,45]; however, it was withdrawn due to association with subacute myelo-optic neuropathy possibly due to overdose and/or a reversible vitamin B12 deficiency [44,46-48]. Recently, interest in CQ has reemerged due to studies involving its use, in combination with B12, for treatment of Alzheimer’s disease [43,49,50]. Regardless of its being a controversial compound, CQ can still serve as a model compound from which analogs could be developed that exploit its copper binding potential but avoid its negative associations. CQ is a lipophilic compound that is capable of forming stable complexes with copper(II) ions [51]. In a phase II clinical trial, CQ, at a starting concentration of 3.3 mg/kg, the same order of magnitude of treatment used in mice, was found to be well-tolerated and suitable for further study [49]. Examination of CQ in animal studies has continued to further characterize its effects [52].

Figure 1

(a) Chemical structures of compounds referenced in the text: 5,7-DCl-8-OHQ, 5,7-dichloro-8-hydroxyquinoline; 8-OHQ, 8-hydroxyquinoline; CQ, clioquinol; PDTC, pyridoxine dithiocarbamate. (b) 50 mM of PDTC, CQ, or tetramethylthioketone (TM) were mixed in a 1:1 molar ratio with CuC12. All solutions were made in dimethylsulfoxide. In each case the appearance of intensified color indicated formation of a copper complex.

Copper complex formation as indicated by color change. (a) Chemical structures of compounds referenced in the text: 5,7-DCl-8-OHQ, 5,7-dichloro-8-hydroxyquinoline; 8-OHQ, 8-hydroxyquinoline; CQ, clioquinol; PDTC, pyridoxine dithiocarbamate. (b) 50 mM of PDTC, CQ, or tetramethylthioketone (TM) were mixed in a 1:1 molar ratio with CuC12. All solutions were made in dimethylsulfoxide. In each case the appearance of intensified color indicated formation of a copper complex.
Dithiocarbamates are a class of metal chelating compounds. These compounds have previously been used in the treatment of bacterial and fungal infections, and have been considered for use in the treatment of AIDS [53,54]. Pyrrolidine dithiocarbamate (PDTC; Fig. 1a) is a synthetic antioxidant and inhibitor of NF-κB that is capable of binding copper [55,56]. PDTC and other dithiocarbamates have been found to induce apoptosis in conjunction with copper in different types of cancer cells [55,57]. Previously we found a synthetic PDTC containing copper was a potent proteasome inhibitor and apoptosis inducer [42].

Here we show that CQ and PDTC are capable of binding copper, spontaneously forming new complexes that have proteasome-inhibitory and apoptosis-inducing activities to cancer but not normal/non-transformed breast cells, and that premalignant or cancer breast cells cultured to contain elevated copper are sensitive to treatment with CQ or PDTC alone. In contrast, TM-copper or TM alone had no effects in the same experiments. We propose that targeting highly elevated copper can be tumor-specific and that formation of an active anticancer proteasome inhibitory complex between CQ or PDTC and tumor cellular copper is a novel strategy that has great potential for breast cancer therapies.

Materials and methods

Chemicals and reagents

CQ, PDTC, disulfiram (tetraryl thiram disulfide), tetramethyl thirau disulfide, methyl propyl disulfide, allyl disulfide, isopropyl disulfide, TM, CuCl₂, dimethylsulfoxide (DMSO), bisbenzimid Hoechst No. 33358 stain, cholera toxin, hydrocortisone, 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyl-tetrazolium bromide (MTT), epidermal growth factor, and insulin were purchased from Sigma-Aldrich (St. Louis, MO, USA). F12 medium, DMEM, horse serum, penicillin, and streptomycin were purchased from Santa Cruz Biotechnology Inc (Santa Cruz, CA, USA). Mouse monoclonal antibody to human ubiquitin was purchased from Boster Biological Technology (Manassas, VA, USA). Mouse monoclonal antibody to human PARP was from Roche Applied Science (Indianapolis, IN, USA). Mouse monoclonal antibody to human ubiquitin was from Santa Cruz Biotechnology Inc (Santa Cruz, CA, USA).

Cell culture and lysates preparation

MCF10A (normal-MCF10), MCF10AT1K.cl2 (premalignant-MCF10), and MCF10dics.com (malignant-MCF10) cells were cultured as described previously [58]. Briefly, normal-MCF10 and premalignant-MCF10 cells were cultured in 1:1 F12/DMEM prepared as follows: 500 ml of media was supplemented with 5.26% (v/v) horse serum, 100 units/ml of penicillin, 100 μg/ml of streptomycin, 52.55 μg of cholera endotoxin, 5 mg insulin, 10 ml of 1 M NaHCO₃, 10 μg of epidermal growth factor, and 250 μg hydrocortisone. Malignant-MCF10 cells were cultured in 1:1 F12/DMEM media supplemented with 5.26% (v/v) horse serum, 10 ml of 1 M NaHCO₃, 100 units/ml of penicillin, and 100 μg/ml of streptomycin. MDA-MB-231 cells were purchased from the American Type Culture Collection (Manassas, VA, USA) and cultured in DMEM media containing 10% (v/v) fetal bovine serum and 100 units/ml of penicillin, 100 μg/ml of streptomycin. All cells were maintained at 37°C in a humidified incubator with an atmosphere of 5% CO₂. For copper enrichment experiments, premalignant-MCF10 or MDA-MB-231 cells were cultured in media further supplemented with 25 μM CuCl₂ for 3 days to 2 weeks. Whole cell extracts were prepared as described previously [29]. Briefly, cells were harvested, washed with PBS twice, and homogenized in a lysis buffer (50 mM Tris-HCl (pH 8.0), 150 mM NaCl, 0.5% NP40 (v/v), 0.5 mM phenylmethylsulfonyl fluoride, and 0.5 mM dithiothreitol) for 30 min at 4°C. Afterwards, the lysates were centrifuged at 12,000 g for 30 minutes, and the supernatants were collected as whole cell extracts.

Color change and precipitate formation reactions

CQ, PDTC, TM, and CuCl₂ were dissolved in DMSO to a final concentration of 50 mM. Then CuCl₂ was mixed with each in a 1:1 ratio and qualitatively examined for color change and precipitate formation. After mixing, solutions were heated and vortexed repeatedly until clear. For the visual studies, solutions were examined for color change and precipitation as indicators of complex formation. In cellular studies, however, stock concentrations were kept lower (10 and 20 μM) prior to dilution during mixing in order to prevent precipitation.

Cell proliferation assay

The MTT assay was used to determine the effects of these agents on overall proliferation of cells. Cells were plated in a 96-well plate and grown to 70–80% confluency, followed by addition of each compound at an indicated concentration for 24 h. MTT (1 mg/ml) in PBS was then added to wells and incubated at 37°C for 4 h to allow for complete cleavage of the tetrazolium salt by metabolically active cells. Next, MTT was removed and 100 μl of DMSO was added, followed by colorimetric analysis using a multilabel plate reader at 560 nm (Victor²; PerkinElmer, Waltham, MA, USA). Absorbance values plotted are the mean from triplicate experiments.

Cellular and nuclear morphology analysis

A Zeiss (Thornwood, NY, USA) Axiovert 25 microscope was used for all microscopic imaging with either phase contrast for cellular morphology or fluorescence for nuclear morphology with Hoechst staining. For fluorescent nuclear morphology analysis, Hoechst stain was used as follows. Cells, either attached in plates or collected as a detached fraction, were washed once with ice cold PBS. Cells were then fixed in ethanol for 1 h and afterwards washed with ice cold PBS. Cells were stained with 50 μM Hoechst and kept in the dark at 4°C for 30 minutes and then visualized using fluorescence microscopy. Punctate and bright staining, or granular and bright staining nuclei were considered apoptotic.
Copper pretreatment and ligand post-treatment
To simulate the in vivo copper status of cancer cells, premalignant-MCF10 and MDA-MB-231 cells were cultured in media containing 25 μM copper as done previously with prostate PC-3 cells [42]. MDA-MB-231 cells were cultured for a minimum of 48 h and premalignant-MCF10 cells were cultured for a minimum of 2 weeks. After copper enrichment culturing, cells were washed with PBS and then treated for the indicated hours using standard cell media containing TM (25 μM), CO (1 to 100 μM), or PDTC (1 or 10 μM).

Cellular copper measurement
Premalignant-MCF10 cells were cultured for 2 weeks in culture media with or without 25 μM CuCl₂. Cells were collected and counted to determine total cells in the sample. Samples were spun down, washed with PBS, and provided to Quantum Labs (Wixom, MI, USA) for graphite furnace analysis to determine total copper in each sample.

Western blot analysis
Cells were treated as indicated (see Figure legends). Afterwards, cells were harvested and lysed. Cell lysates (50 μg) were separated by SDS-PAGE and transferred to a nitrocellulose membrane, followed by visualization using the enhanced chemiluminescence kit (Amersham Biosciences, Piscataway, NJ, USA). Western blot analysis was performed using specific antibodies to ubiquitin and PARP as described previously [36]. Proteasome inhibition was measured as accumulation of ubiquitinated proteins and apoptosis by cleavage of PARP [36].

Analysis of the proteasome chymotrypsin-like activity in whole cell extracts
Whole cell extracts (10 μg) of cells treated as indicated were incubated for 60 minutes at 37°C in 100 μl of assay buffer (50 mM Tris-HCl, pH 7.5) with 40 μM of fluorogenic substrate for the proteasomal chymotrypsin-like activity. After incubation, production of hydrolyzed 7-amino-4-methylcoumarin (AMC) groups was measured using a Victor 3 Multi-label Counter with an excitation filter of 380 nm and an emission filter of 460 nm (PerkinElmer, Boston, MA, USA). Changes in fluorescence were calculated against non-treated controls and plotted with statistical analysis using Microsoft Excel™ software.

Results
CQ and PDTC spontaneously react with copper to form a new complex
In order to use endogenous elevated tumor copper as a targeting mechanism for breast cancer therapy (Fig. 2), it is necessary that the ligand under consideration be capable of reacting spontaneously with copper to form a new complex. Complex formation reactions, particularly those involving metal, can result in dramatic color changes and/or precipitate formation. To test the reactivity of CQ and PDTC with copper, 50 mM of each was added to a 50 mM solution of copper (II) chloride (Fig. 1). The reaction of CQ and PDTC with copper, in DMSO, results in a dramatic color change (Fig. 1), indicating a chemical reaction has occurred and a metal complex has formed. These results are consistent with previous publications showing that both CQ and PDTC are strong copper chelators [51,55]. Therefore, these ligands may be capable of combining with endogenous tumor copper and forming a reactive complex.

The CQ-copper mixture has been further examined by the advanced photon source (APS) of Argonne National Laboratories (Argonne, IL, USA). The result is consistent with formation of a new complex between CQ and copper in solution (unpublished data). Furthermore, samples of a PDTC-copper mixture will be analyzed by the APS to confirm complex formation and the resulting structure. The details of these studies will be presented in a future manuscript.

CQ and PDTC combine with copper to form proteasome-inhibitory complexes
As both compounds can form a complex with copper, as indicated by color change (Fig. 1), we then tested whether these
Inhibition of proteasome activity and apoptosis induction in MDA-MB-231 breast cancer cells by clioquinol (CQ) + copper and pyrrolidine dithiocarbamate (PDTC) + copper. MDA-MB-231 breast cancer cells were treated with 20 μM copper (Cu), CQ, CQ + copper (CC), tetraethyl thiuram disulfide (TM), TM + copper (TC), or 10 μM PDTC (P), or PDTC + copper (PC) using DMSO (DM) as a control. Cells were collected after 24 h treatment and analyzed for proteasome inhibition. (a) Proteasome activity as measured in released fluorescence units (RFUs) by release of 7-amino-4-methylcoumarins (AMCs) from substrate specific for chymotrypsin-like activity. (b) Western analysis for accumulation of ubiquitinated proteins as an indicator of proteasome inhibition. Treatment with PDTC + copper (PC; 10 μM) or CQ + copper (CC; 20 μM) results in reduced release of AMCs and ubiquitinated protein accumulation, suggesting proteasome inhibition. (c) Western analysis for cleavage of poly(ADP ribose) polymerase (PARP) as an indication of apoptosis. Treatment with CQ + copper (20 μM) or PDTC + copper (10 μM) results in cleavage of PARP, indicating that these complexes are capable of inducing apoptosis.

Although we have shown that copper alone can inhibit the activity of a purified proteasome [42], it is still possible that dithiocarbamates could be oxidized by copper to thiuram disulfides [59], which could be responsible for the observed proteasome inhibition. We therefore tested the effects of two thiuram disulfides and three disulfides on the proteasome activity. In the absence of copper, disulfiram (tetraethyl thiuram disulfide) and tetramethyl thiuram disulfide are incapable of inhibiting the proteasomal activity of MDA-MB-231 cell extract at micro-molar concentrations (data not shown). In addition, none of the tested disulfides, methyl propyl disulfide, allyl disulfide, and isopropyl disulfide, could inhibit the proteasome activity under the cell-free conditions (data not shown). This result suggests that complex formation between PDTC and copper, rather than general oxidation of PDTC to thiuram disulfide, is the likely mechanism of proteasome inhibition. Furthermore, we have found and reported that production of H$_2$O$_2$ does not occur in this system and that reductants do not block copper-mediated proteasome-inhibitory activity, supporting the idea that mechanisms other than oxidation are involved in proteasome inhibition [42]. This suggests that general oxidation or oxidation of dithiocarbamates is not sufficient to result in proteasome inhibition at these concentrations in these systems.

**CQ and PDTC when mixed with copper block proliferation of breast cancer MDA-MB-231 in a dose-dependent manner**

After finding that CQ-copper and PDTC-copper mixtures could inhibit proteasome activity (Fig. 3a,b), we measured the effects of each compound on breast cancer cell proliferation (Fig. 4). We found that, associated with proteasome inhibition, the CQ-copper and PDTC-copper complexes inhibited cellular proliferation in a dose-dependent manner. CQ-copper showed 40% inhibition at 10 μM and increased to approximately 80% inhibition at 30 μM (Fig. 4). The PDTC-copper mixture inhibited proliferation by 40% at 1 μM and greater than 90% inhibition at 10 μM (Fig. 4). In contrast, copper, CQ,
Anti-proliferative effects of clioquinol (CO) + copper and pyrrolidine dithiocarbamate (PDTC) + copper. MDA-MB-231 cells were treated for 24 h with the following: copper (Cu; at 30 μM); CO (CO; at 30 μM); PDTC (P; 10 μM); tetrathiomolybdate (TM; 30 μM); CO + copper (CC; 10, 20, 30 μM); PDTC + copper (PC; 1, 5, 10 μM); TM + copper (TC; 10, 20, 30 μM); or dimethylsulfoxide (DMSO) as a control. After 24 h the media was removed and cells were treated with 3-[4,5-dimethylthiazol-2-yi]-2,5-diphenyl-tetrazolium bromide (MTT) solution. Measurement of MTT conversion by absorbance at 560 nm showed that MDA-MB-231 cells responded in a dose-dependent manner to CO-copper and PDTC-copper complexes. This suggests that these organic-copper complexes act as anti-proliferative agents.

PDTC, or TM alone or TM mixed with copper had no significant effect (Fig. 4). The ranking of these compounds with respect to their ability to inhibit breast cancer cell proliferation matches well with their ability to inhibit the cellular proteasome activity (Figs. 4 versus 3a). Due to the nature of the MTT assay and the inability to separate apoptosis from growth arrest, both possible outcomes of the proteasome inhibition, IC_{50} values of these complexes were not measured. These data suggest that CQ and PDTC can spontaneously combine with copper to form an anti-proliferative complex.

CQ and PDTC combine with copper to form a product toxic to malignant-MCF10 and MDA-MB-231 and premalignant-MCF10 cells, but non-toxic to normal-MCF10 breast cells
We found that the same CQ-copper and PDTC-copper complexes capable of proteasome inhibition (Fig. 3a, b) also demonstrated apoptosis induction, as shown by cleavage of PARP (Fig. 3c). In the absence of copper, neither CQ nor PDTC was able to induce apoptosis at these concentrations (Fig. 3c, lanes 6 and 7 versus lanes 3 and 4). TM, in the presence or absence of copper, does not induce apoptosis, further supporting TM's action as passive chelation and elimination of copper. These data support the idea that CQ and PDTC, but not TM, can combine spontaneously with copper to form a proteasome-inhibitory and apoptosis-inducing complex.

To determine whether the CQ-copper and PDTC-copper complexes have differential effects on normal and tumor breast cells, the MCF10 series of cells [58] were then treated with CQ alone, copper alone, or the product of a 1:1 mixture of each at 20 μM (Fig. 5). The 20 μM CQ-copper complex induces apoptotic nuclei within 24 h for both premalignant- and malignant-MCF10 cells (10% and 65%, respectively; Fig. 5b, c). The malignant-MCF10 cells fully detached, suggesting that these cells were more sensitive to the complex than the premalignant cells. However, the normal-MCF10 cells demonstrated no apoptotic nuclei after 24 h of treatment with the CQ-copper complex (<2%; Fig. 5a).

We then tested the effects of the PDTC-copper mixture. The three breast cell lines were treated with PDTC alone, copper alone, or their mixture at 5 μM for 24 h. Again, both the premalignant (63%; Fig. 5b) and the malignant-MCF10 (75%; Fig. 5c) cells showed a dramatic induction of apoptotic nuclei after treatment with the mixture, while the normal-MCF10 cells (<2%; Fig. 5a) showed no apoptosis induction from the mixture. As a control, neither CQ alone, PDTC alone, nor copper alone had effect on any of these cell lines (<2% in all the cases; Fig. 5). These data suggest that CQ and PDTC can spontaneously bind with copper and that the resulting complex is an apoptosis inducer to premalignant and cancerous, but not normal/non-transformed, breast cells, suggesting that such a complex if formed in a normal cell would not be toxic, but would be toxic in tumor cells.

CQ and PDTC in complex with copper do not inhibit proteasome activity in normal breast MCF10A cells
To better understand the mechanism of resistance in normal breast cells to apoptosis induction by these organic-copper complexes, we treated both normal- and malignant-MCF10 cells with CQ-copper and PDTC-copper complexes and measured changes in the proteasome activity levels. Both cell lines were treated with 20 μM Cu, CQ, TM, CQ-copper, and...
**Figure 5**

Induction of apoptosis by clioquinol (CQ) + copper and pyrrolidine dithiocarbamate (PDTC) + copper complexes in premalignant- and malignant-MCF10 cells. CQ and PDTC were mixed in a 1:1 molar ratio with CuCl₂. Normal-, premalignant, and malignant-MCF10 cells were treated with CQ alone (CQ), copper alone (Cu), or CQ + copper (CQ+Cu) at 20 µM, or PDTC alone or PDTC + copper (PDTC+Cu) at 5 µM for 24 h. Dimethylsulfoxide (DMSO) was used as a control. After treatment, cells were stained with Hoescht for determination of apoptotic nuclei. Nuclei that were punctate or granular and bright were considered apoptotic. (a) The normal MCF10 cell line showed no apoptosis induction from the ligand, copper, or mixture (<2% in all cases). However, both (b) the premalignant MCF10AT1Kc12 and (c) the malignant MCF10DCIS.com cells showed a dramatic induction of apoptotic nuclei after treatment with the mixture. (b) The percentages of apoptotic nuclei in MCF10AT1Kc12 cells were: CQ+Cu, 100%; PDTC+Cu, 63%; and others <2%. (c) The percentages of apoptotic nuclei in MCF10DCIS.com cells were: CQ+Cu, 65%; PDTC+Cu, 75%; and others <2%.

**Figure 6**

Clioquinol (CQ) + copper and pyrrolidine dithiocarbamate (PDTC) + copper fail to inhibit proteasome activity in normal MCF 10 (MCF-10A) cells. Normal MCF-10A and malignant mCF-10 (DCIS) breast cells were treated with 20 µM of copper (Cu), CQ, CQ + copper (CC), tetrathiomolybdate (TM), TM + copper (TC), or 5 µM PDTC or PDTC + copper (PC). Dimethylsulfoxide (D) was used as a control. After 24 h, cells were collected and lysed. Lysates were analyzed for chymotrypsin-like activity and showed as released fluorescence units (RFUs). The complexes were capable of eliminating proteasome activity in DCIS cells but not in MCF-10A cells. This strongly suggests that these metal complexes do not inhibit proteasome activity in normal breast cells.

TM-copper, or 5 µM PDTC and PDTC-copper (Fig. 6). We found that PDTC-copper and CQ-copper both strongly inhibited proteasome activity in malignant but not in normal cells (Fig. 6). Again, TM or the TM-copper mixture had no effects on either of the cell lines (Fig. 6). These data suggest that these organic-copper complexes do not inhibit the proteasome and, therefore, do not induce apoptosis in normal breast cells, further protecting normal cells from toxicity.

**Premalignant-MCF10 cells accumulate copper when cultured in copper-enriched conditions**

A difficulty with examining the effectiveness of copper targeting in cell culture models is that cultured cancer cells seem to possess low to trace levels of copper [42]. This differs from the in vivo situation where cancer cells and tissues can contain micromolar concentrations of copper. In one study, the serum copper in breast cancer patients was approximately 2 µg/100 ml (equivalent to 0.3 µM) [60], while another study showed that the plasma copper levels in the malignant prostates were 124 µg/100 ml (equivalent to 19.5 µM) [16].

To simulate the in vivo situation, premalignant-MCF10 breast cells were cultured in media enriched with 25 µM CuCl₂ for at least 2 weeks (see Materials and methods). Afterwards, cells were collected and subject to graphite furnace analysis to determine copper content (Table 1). The results of the analysis show that these cells can accumulate at least 16 times more copper when cultured in copper-enriched media (referred to here as copper-enriched cells) than when in a normal culture and an individual enriched cell has at least an order of magnitude more copper than a standard culture cell. Given a volume of 10 ml, this would be equivalent to 6 µM. Previously, we pretreated prostate cancer PC-3 cells with 100 µM CuCl₂ for 48 h, which resulted in cellular copper levels being increased to 0.2 µM [42]. These data show that, in our enrichment system, premalignant-MCF10 cells can accumulate similar copper concentrations to those found in patients.

*C is theoretical content assuming no more than 0.1 µg total copper, which is the minimal detection limit. Because cells grown in media without copper enrichment had no detectable copper, the number reported is the highest possible content per cell based on the minimum detection. ND, not detected.

Copper-enriched breast pre-malignant and cancer cells are sensitive to treatment with CQ or PDTC alone

Fundamental to the strategy we are presenting is the ability of a normally non-toxic ligand to bind with endogenous tumor cellular copper (Fig. 2). Studies in various cancer cells and tissues have found that patients can have copper concentrations in the micromolar ranges in those tissues [16,60]. Similarly, when premalignant-MCF10A cells are cultured in copper they can contain micromolar concentrations of copper (Table 1). We therefore tested the effects of CQ or PDTC alone in copper-enriched breast premalignant or cancer cells.

We first treated the copper-enriched premalignant-MCF10 cells with CQ alone. CQ at 1 to 10 µM caused apoptotic morphological changes of these copper-containing cells (Fig. 7a). Consistent with the morphology study, after 24 h treatment with CQ, these copper-enriched cells underwent extensive apoptosis, measured by the appearance of the PARP cleavage fragment (Fig. 7c). In contrast, premalignant-MCF10 cells that did not contain elevated copper were highly resistant to 25 µM of CQ (Fig. 7c, lanes 1 and 2). Similarly, copper-enriched premalignant-MCF10 cells were also sensitive to treatment with PDTC, but not TM (data not shown; Fig. 7b, d, e).

We also found that copper-enriched breast cancer MDA-MB-231 cells adopt apoptotic morphology after post-treatment with CQ or PDTC, but not TM (Fig. 7b). In the same experiment, lysates of these cells were subjected to western analysis. Both CQ and PDTC were capable of inducing proteasome inhibition and apoptosis in copper-pretreated MDA-MB-231 cells, as measured by accumulation of ubiquitinated proteins and cleavage of PARP, respectively (Fig. 7d, e). This is dramatically different from the behavior of these compounds in the absence of copper or in non-copper enriched cells (Fig. 7d, e versus Fig. 3b, c). In contrast, TM neither inhibited the proteasome activity nor induced apoptosis in these copper-enriched cells (Fig. 7b, d, e). These data support the idea that CQ and PDTC can spontaneously bind with copper in copper-enriched breast cancer cells and form an apoptosis-inducing complex and that cells containing trace or undetectable amounts of copper are resistant to this effect. It is possible, therefore, that CQ and PDTC act as apoptosis inducers through proteasome inhibition in a copper-dependent manner and can do so in cancer cells that contain copper in concentrations similar to those found in patients' tissues and serum.

Discussion

A difficulty facing most cancer chemotherapy is the inability to discriminate between normal and malignant cells. Anti-angiogenesis and proteasome inhibition may be effective approaches to cancer therapy due to the dependence of cancer on these activities [9,37,61]. Unique among the trace metals, copper is required for angiogenesis [8-11]. Furthermore, it is well documented that cancer cells and tissues accumulate high concentrations of copper [13,18,21,62-64]. We previously reported that certain types of organic-copper complexes are capable of proteasome inhibition that is not a result of oxidative effects [42]. Therefore, the capability of organic copper to inhibit the proteasome, the necessity of copper for angiogenesis, and the accumulation of copper by cancer cells and tissues allows for a novel therapeutic strategy focusing on elevated copper as a selection mechanism against cancer cells and tissues (Fig. 2).

Our previous study [42] Additional file: 1 only briefly looked at an isolated system and examined the phenomenon of organic ligands binding to copper to form proteasome inhibitors and apoptosis inducers. The current study confirms and significantly expands our original findings. Specifically, this study examines a complete breast cancer system, including normal, premalignant and malignant cells. Furthermore, this study examines compounds that have clinical relevance and expands the copper enrichment studies. Several different approaches have been used in the analysis.

CQ and PDTC are two copper-binding compounds [51,53]. CQ has been investigated for use in Alzheimer's disease in regards to its ability to bind to copper found in amyloid plaques [43,47-50]. PDTC is a synthetic copper-binding antioxidant that has been studied for use in AIDS [53,54]. Previously, we have seen that 5,7-DICl-8-OHQ (an analog of CQ) and PDTC when in complex with copper possessed strong proteasome-inhibitory and apoptosis-inducing abilities [42]. We report here the ability of CQ and PDTC to spontaneously react with copper, and inhibit the proteasome, which is followed by apoptosis, in breast cancer but not normal cells.
Induction of apoptosis in premalignant-MCF10 breast cells and proteasome inhibition and apoptosis induction in breast cancer MDA-MB-231 cells cultured to contain elevated copper and post-treated with clioquinol (CQ) and pyrrolidine dithiocarbamate (PDTC). (a,c) Premalignant-MCF10 (KCL2) cells were cultured in media containing 25 μM copper for two weeks. (b,d,e) MDA-MB-231 cells were cultured in 25 μM copper for 48 h. After culturing, cells were washed with PBS and treated with media containing: (a) 1, 10, or 50 μM CQ; (b-e) 25 μM CQ; 25 μM tetrathiomolybdate (TM); or (b,d,e) 10 μM PDTC. An equivalent volume of DMSO (DM) was used as control. KCL2 and MDA-MB-231 cells were examined for (ab) apoptotic morphology and (ce) PARP cleavage. (d) MDA-MB-231 cells were also examined by western blot for accumulation of ubiquitinated proteins. (a,c) KCL2 cells containing clinically relevant levels of copper were sensitive to treatment by CQ alone, which induced apoptosis. (c) KCL2 cells cultured under standard conditions were resistant to treatment by 25 μM CQ. Similarly, MDA-MB-231 cells cultured to contain elevated copper were sensitive to CQ or PDTC and underwent proteasome inhibition as measured by accumulation of (d) ubiquitinated (Ub) proteins and apoptosis as evidenced by morphology and (b,e) poly (ADP ribose) polymerase (PARP) cleavage. These data suggest that KCL2 and MDA-MB-231 cells cultured to contain clinically relevant levels of copper are sensitive to treatment with CQ or PDTC alone, but not TM.

Our strategy revolves around the idea that a normally inactive or nontoxic organic ligand could bind with copper found in tumor tissues, resulting in a complex capable of proteasome inhibition. It has been shown that cancer cells are more sensitive to proteasome inhibition than normal cells [37,61,65-67]. To that end, we first verified that these two ligands directly interact with copper and form a new metal complex as indicated by dramatic color change (Fig. 1).

Once we verified that these two compounds spontaneously bind with copper and form a new complex we tested these complexes in MDA-MB-231 breast cancer cells to determine whether or not these complexes were proteasome inhibitors. We examined both cellular proteasome activity (Fig. 3a) and accumulation of ubiquitinated proteins (Fig. 3b). We found that treatment with ligand-copper mixtures significantly reduced chymotrypsin-like activity (Fig. 3a) and resulted in accumulation of ubiquitinated proteins (Fig. 3b), indicating proteasome inhibition had occurred. In contrast, ligand alone, copper alone, or TM mixed with copper did not inhibit the proteasome (Fig. 3). Previously we found that copper-mediated accumulation of ubiquitinated proteins is transient [42]. Therefore, the ubiquitinated protein pattern induced by CQ-copper and PDTC-copper shown in Fig. 3b should be considered transient and relevant only to the time point under consideration.

After determining that these organic-copper complexes could inhibit proliferation in MDA-MB-231 cells (Fig. 4), we examined the apoptosis-inducing abilities of the complexes. The organic-copper complexes were capable of inducing apoptosis strongly in malignant-MCF10 and MDA-MB-231, moderately in premalignant-MCF10, and did not induce apoptosis in normal-MCF10 cells (Figs. 5 and 3c). As a control, CQ, PDTC, TM or copper alone, or TM mixed with copper, were incapable of inducing apoptosis (Figs 5 and 3c). Therefore, the primary concerns of the strategy presented were fulfilled: the compound alone shows no toxic effects, the
compound when mixed with copper becomes toxic, and the toxicity is limited to cancer cells and is associated with proteasome inhibition.

As these complexes have minimal to no effect on our normal cell line and seem to inhibit tumor cellular proteasome activity, we surmise that their toxicity to cancer cells stems from their proteasome inhibitory activity, to which normal cells are resistant. This was verified by examining proteasome activity in breast normal MCF10 cells compared to malignant-MCF10 cells (Fig. 6). We found that normal-MCF 10 cells did not suffer proteasome inhibition when treated with CQ or PDTC in complex with copper, although the concentrations tested inhibited the proteasome activity in malignant-MCF10 cells (Fig. 6), further supporting the argument that these complexes may be non-toxic to normal cells but are toxic to cancer cells through the mechanism of tumor-specific proteasome inhibition.

In a living organism, cancer cells and tissues accumulate high concentrations of copper [13,18,21,62-64]. To simulate this in vivo situation, premalignant-MCF10 and cancer MDA-MB-231 breast cells were cultured in copper-enriched media for either 2 weeks (premalignant-MCF10) or 72 h (MDA-MB-231). Afterwards, premalignant-MCF10 cells were collected and subjected to graphite furnace analysis to determine copper content. We found that premalignant-MCF10 cells were capable of accumulating concentrations of copper similar to those found in patient tissues (Table 1) and contained at least 16 fold more copper than cells cultured in standard media.

Once we had established cultures of premalignant-MCF10 cells enriched with copper, we then treated those cells with CQ or PDTC alone. Both CQ (25 μM) and PDTC (1 μM) induced apoptosis after treatment (Fig. 7a, c; data not shown). In cells cultured in enriched copper conditions, the compounds at similar concentrations had no effect (Figs 5 and 3c). Similarly, the breast cancer cell line MDA-MB-231, when cultured in elevated copper, is sensitized to apoptosis induction associated with proteasome inhibition with CQ and PDTC alone (Fig. 7b, d, e). This further supports our proposal that the compounds studied can use the increased copper load in cancer cells to form a proteasome inhibitor and an apoptosis inducer, whereas in the absence of this copper load these compounds have minimal to no effect at these concentrations.

The data presented here supports the novel concept of using accumulated copper in breast cancer cells and tissues as a selection method for chemotherapy. Non-toxic organic compounds such as CQ or PDTC can spontaneously bind with copper and form a proteasome inhibitor and an apoptosis inducer that has no effect on normal cells. Cancer cells, containing elevated copper, are sensitive to treatment with these organic compounds. Normal cells, containing trace amounts of copper, are resistant to these effects (Fig. 2). Both CQ and PDTC have been previously explored for use in other diseases and we believe these data support further investigation of these and other similar compounds in an anticopper/anticancer strategy. Most recently, another group also reported the anticancer activity of CQ [52]. Our data presented here may have provided a mechanistic interpretation for their findings.

The exact mechanisms of the copper-ligand combination are unclear at this time. However, it is apparent that cells cultured to contain elevated copper become sensitive to treatment with the ligands alone. We have future plans to work with the APS at Argonne National Laboratory to determine the final state of the ligand-copper complexes in cells. This should assist in further understanding why copper-enriched cells are sensitive to treatment with ligands that bind copper to form proteasome-inhibiting complexes. It should be noted that the system we have presented in this report is limited by looking at immortalized breast cancer cells rather than true normal primary cell lines. Future experiments should examine not only normal primary lymphocytes in culture but also animal studies to further confirm the effect on normal cells and tissues. Additional studies on cells that naturally contain elevated copper such as kidney, liver, and hematopoietic cells are also warranted.

Conclusion
A unique feature of cancer cells is to accumulate high concentrations of copper [13,18,21,62-64]. We believe a potential strategy for cancer chemotherapy could involve the use of organic ligands that act as copper sensors and bind with the elevated copper in cancer cells and tissues. These complexes would act as proteasome inhibitors and apoptosis inducers to tumor cells. Because normal cells contain only trace amounts of copper, the organic ligands should form far fewer complexes with copper in them, thus exposing the normal cells to a minimal dose and reducing toxicity. We propose that treatment with copper-binding compounds such as CQ and PDTC will result in these compounds behaving as tumor 'sensors' using copper as a selection criteria. Therefore, this approach may convert the proangiogenic co-factor copper into a cancer-specific killing agent.

Abstract

Disulfiram (DSF), a member of the dithiocarbamate family capable of binding copper and an inhibitor of aldehyde dehydrogenase, is currently being used clinically for the treatment of alcoholism. Recent studies have suggested that DSF may have antitumor and chemosensitizing activities, although the detailed molecular mechanisms remain unclear. Copper has been shown to be essential for tumor angiogenesis processes. Consistently, high serum and tissue levels of copper have been found in many types of human cancers, including breast, prostate, and brain, supporting the idea that copper could be used as a potential tumor-specific target. Here we report that the DSF-copper complex potently inhibits the proteasomal activity in cultured breast cancer MDA-MB-231 and MCF10DCIS.com cells, but not normal, immortalized MCF-10A cells, before induction of apoptotic cancer cell death. Furthermore, MDA-MB-231 cells that contain copper at concentrations similar to those found in patients, when treated with just DSF, undergo proteasome inhibition and apoptosis. In addition, when administered to mice bearing MDA-MB-231 tumor xenografts, DSF significantly inhibited the tumor growth (by 74%), associated with in vivo proteasome inhibition (as measured by decreased levels of tumor tissue proteasome activity and accumulation of ubiquitinated proteins and natural proteasome substrates p27 and Bax) and apoptosis induction (as shown by caspase activation and apoptotic nuclear formation). Our study shows that inhibition of the cellular proteasome activity can be achieved by targeting tumor cellular copper with the nontoxic compound DSF, resulting in selective apoptosis induction within tumor cells. (Cancer Res 2006; 66(21): 1-9)

Introduction

Copper is an essential trace metal for animals. The amount of copper in an organism is very tightly regulated (1-3). Many critical enzymes and transcription factors require copper for their activities (1-3). Angiogenesis, the growth of a tumor blood supply, is essential for tumor growth, invasion, and metastasis (4, 5). Tumors without an additional blood supply do not grow larger than 1 to 2 mm³ (6). Molecular processes of angiogenesis include stimulation of endothelial growth by tumor cytokine production (i.e., vascular endothelial growth factor) and the requirement of copper (but not other trace metals) as an essential cofactor (3-6). Consistently, high serum or tissue levels of copper were found in many types of human cancers including breast, prostate, colon, lung, and brain (7-13), although the involved mechanisms remains unknown. The above information suggests that copper could be used as a novel selective target for cancer therapies. Along this line, therapies with the strong copper chelator tetrathiomolybdate (1M) are well tolerated and copper elimination can stabilize advanced kidney cancer (14, 15), showing the clinical feasibility of this approach.

The proteasome-mediated degradation pathway has been considered as an important target for anticancer drug development. The proteasome inhibitor bortezomib (Velcade, PS-341) has been used in clinical trials and its antitumor activity has been reported in a variety of tumor models (16-18). The ubiquitin/proteasome-mediated proteolytic system controls the turnover of critical regulatory proteins involved in several cellular processes such as cell cycle and apoptosis (19-21). This degradation pathway includes two distinct steps: ubiquitination and degradation. Ubiquitination is the step after which the target protein can be selectively recognized from other proteins by the 26S-proteasomal complex. Degradation of proteins occurs on the large 26S-proteasomal complex in an ATP-dependent manner (19-21). The eukaryotic proteasome contains at least three known catalytic activities: chymotrypsin-like, trypsin-like, and caspase-like or peptidyl-glutamyl peptide-hydratolyzing-like activities (22). Our laboratory and others have reported that inhibition of the proteasomal chymotrypsin-like activity is associated with induction of apoptosis in tumor cells (23-25).

Disulfiram (DSF; Fig. 1A) is a member of the dithiocarbamate family comprising a broad class of molecules possessing an R₆R₇NC(S)SR₈ functional group, which gives them the ability to complex metals and react with sulfhydryl groups (26-28). DSF, an irreversible inhibitor of aldehyde dehydrogenase, is one of the two drugs approved by the Food and Drug Administration (FDA) for treatment of alcoholism (28). Clinical trials have shown the efficacy of DSF with no toxicity (28). Several studies have shown that DSF and its metabolites can potentiate the effect of some anticancer drugs (29, 30). However, the precise mechanisms are still unknown.

We have reported that certain classes of copper-containing compounds act as potent proteasome inhibitors (3, 25). Because DSF can also bind copper (31, 32), we hypothesized that the DSF-copper complex is a proteasome inhibitor. We report here that, indeed, DSF is capable of binding copper and forming a new complex, which has proteasome inhibitory and apoptosis-inducing activities when tested in cultured human breast cancer, but not...
Figure 1. The effects of DSF-copper (DSF-Cu) complex on purified 20S proteasome and breast cancer cellular proteasome. A, inhibition of the chymotrypsin (CT)-like activity of purified rabbit 20S proteasome by CuCl₂ (Cu) and DSF-copper. Left, chemical structure of DSF. To determine whether DSF-copper can inhibit the proteasome activity directly, purified 20S rabbit proteasome was incubated with the peptide substrate for the proteasomal chymotrypsin-like activity in the presence of CuCl₂, DSF, and DSF-copper at indicated concentrations, as described in Materials and Methods. B, DSF-copper inhibits the proteasome activity and induces PARP cleavage in breast cancer cells. MDA-MB-231 cells were treated with 20 µmol/L of copper (Cu), DSF, TM, DSF-copper complex, or TM-copper complex (TM-Cu) for 24 hours, followed by preparation of cell extracts for the proteasomal activity and Western blot assays. DMSO (DM) was used as vehicle control. Top, proteasomal chymotrypsin-like activity in cell extracts. *** P < 0.001. Columns, mean of three experiments; bars, SD. Bottom, SDS-PAGE and Western blot analysis for accumulated ubiquitinated proteins (Ub-Prs) and PARP cleavage. C, MTT assay. MDA-MB-231 cells were treated with 20 µmol/L of copper, DSF, or TM, or 5 to 20 µmol/L of DSF-copper, or 10 to 20 µmol/L of TM-copper for 24 hours, followed by MTT assay as described in Materials and Methods. *** P < 0.001; ** P < 0.01. Columns, mean of three experiments; bars, SD. D, DSF-copper induces apoptosis in breast cancer cells. As described in (B), treated MDA-MB-231 cells were used for determination of cellular and nuclear apoptotic changes. Left, cellular morphologic changes (spherical and detached cells). Right, apoptotic nuclear changes were shown by Hoechst 33258 staining (punctuated, granular, and brighter nuclei).
activity) for 2 hours at 37°C. After incubation, production of hydroxylated AMC groups was measured with a Wallac Victor3 multilabel counter with an excitation filter of 365 nm and an emission filter of 460 nm.

**Proteasomal chymotrypsin-like and caspase-3 activity assays in cell extracts.** Whole-cell extracts (10 μg) of cells treated as indicated or tumor tissue extracts (10 μg) from human breast tumor xenografts were incubated for 1 hour at 37°C in 100 μl of assay buffer (50 mmol/L Tris-HCl, pH 7.5) with 20 μmol/L fluorogenic substrate Suc-LLVY-AMC (for the proteasomal chymotrypsin-like activity in cell extracts) or Z-GGL-AMC (for specific chymotrypsin-like activity in tumor tissues) or Ac-DEVD-AMC (for caspase-3 in tumor tissues) as previously described (34).

**Cell proliferation assay.** MDA-MB-231 cells were seeded in triplicate in a 96-well plate and grown until 70% to 80% confluence, followed by treatment with indicated agents for 24 hours. After that, the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay was done as previously described (34).

**Cellular and nuclear morphologic analysis.** A Zeiss Axiovert 25 microscope was used for all microscopic imaging with either phase contrast for cellular morphology or fluorescence for nuclear morphology after Hoechst 33258 staining as previously described (34). Punctuated, granular, and brightly stained nuclei were considered apoptotic.

**Western blot analysis.** The cell or tissue extracts were separated by SDS-PAGE and transferred to a nitrocellulose membrane. Western blot analysis was done using specific antibodies against ubiquitin, p27, Bax, or actin (Santa Cruz Biotechnology Inc. Santa Cruz, CA) or poly(ADP-ribose) polymerase (PARP; Biomol International), followed by visualization with the enhanced chemiluminescence reagent (Amer sham Biosciences, Piscataway, NJ).

**Human breast tumor xenograft experiments.** Five-week-old female athymic nude mice were purchased from Ta c onc Research Animal Services (Hudson, NY) and housed under pathogens-free conditions according to Wayne State University animal care guidelines. The protocols of animal experiments were reviewed and approved by Institutional Laboratory Animal Care and Use Committee of Wayne State University, MDA-MB-231 cells (5 x 10^6) were injected s.c. at one flank of the mice. Tumor size was measured every other day. Tumor volume (V) was determined by the equation: $V = (L \times W^2) / 2$, where L is the length and W is the width of the tumor. When xenografts reached volumes of ~200 mm^3, the mice bearing tumors were randomly assigned to control or DSF groups (n = 10), and administered daily using either solvent control (PBS/cremophore/ DMSO/ethanol, 7.5:1.5:0.5:0.5) or 50 mg/kg/d DSF. When the control tumors reached ~1,500 mm^3 (on day 29), the experiment was terminated and the mice were sacrificed. The tumors were removed and photographed and the tumor tissues were used for multiple assays to measure proteasome inhibition and apoptotic cell death.

**Terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling assay.** Tumor tissues were paraffin embedded and stained according to the instruction of the manufacturer. Briefly, after deparaffinization and hydration, the tissue was incubated with Working Strength TdT Enzyme, Working Strength Stop/Wash Buffer, conjugated with antidigoxigenin, and then stained with peroxidase substrate. Finally, the tissue was mounted under a glass coverslip in Perm mount and viewed under a microscope.

**Immunohistochemistry.** Tumor tissues were paraffin embedded. After deparaffinization and hydration, the slide was blocked its endogenous peroxidase by 3% hydrogen peroxide, incubated with primary antibody p27 (1:200 Novocastro Laboratories Ltd., Newcastle upon Tyne, United Kingdom), then with biotinylated secondary antibody, antimouse immunoglobulin G (H+L), followed by incubation in ABC reagent (Avidin and Biotinylated horseradish peroxidase Complex, DAKO Labs, Cambridgeshire, United Kingdom). Finally, the slide was mounted with 3,3'diaminobenzidine and visualized under a microscope.

**H&E staining assay.** Paraffin-embedded sample slides were deparaffinized and hydrated, and then stained with hematoxylin for 1 minute. After rinsing, the slides were then stained with eosin for 1 minute, followed by more rinse, and coverslips were mounted onto slides with Permount.

**Statistical analysis.** Statistical analysis was done with Microsoft Excel software. Student’s t test for independent analysis was applied to evaluate differences between treatment and control.

**Results**

The DSF-copper complex inhibits the chymotrypsin-like activity of purified 20S proteasome and 26S proteasome in breast cancer cells. It has been shown that DSF is able to bind copper (31, 32). Indeed, when a solution of DSF was mixed with a solution of CuCl₂ at 1:1 ratio, dramatic color change was observed, from light blue to dark green (data not shown). This indicates that a chemical reaction has occurred that involves formation of a DSF-copper complex.

We have previously reported that certain copper complexes act as proteasome inhibitors in cancer cells (3, 25, 34). To examine whether the complex of DSF-copper is capable of inhibiting the proteasome activity, we incubated CuCl₂, DSF alone, or the DSF-copper mixture at various concentrations with a purified rabbit 20S proteasome. The results showed that both CuCl₂ and DSF-copper could inhibit the chymotrypsin-like activity of the purified 20S proteasome with an IC₅₀ value of ~7.5 μmol/L for both (Fig. 1A). In a sharp contrast, DSF alone at even 20 μmol/L had little effect (Fig. 1A). This is consistent with our hypothesis that DSF is able to carry the copper ion into tumor cells and prevent copper from interacting with many nonspecific proteins, and that it is the copper ion that is responsible for inhibiting the proteasome molecule (see below).

To further evaluate this hypothesis, human breast cancer MDA-MB-231 cells were treated with 20 μmol/L copper alone, DSF alone, the DSF-copper complex, TM, or the TM-copper complex (as a comparison). Cells treated with DMSO were used as control. After 24-hour treatment, the cells were collected and lysates were prepared for measurement of proteasome inhibition by decreased levels of the proteasomal chymotrypsin-like activity and accumulation of ubiquitinated proteins. The proteasomal chymotrypsin-like activity was decreased by 99.5% in the breast cancer cells treated with the DSF-copper complex, compared with the vehicle control-treated cells (Fig. 1B, top). In contrast, neither copper nor DSF alone has such potent effect (Fig. 1B, top). As previously observed (34), neither TM nor the TM-copper complex can inhibit the proteasomal chymotrypsin-like activity (Fig. 1B, top). Consistent with the inhibition of the proteasomal chymotrypsin-like activity, significantly increased levels of polyubiquitinated proteins were detected in the lysates prepared from the cells treated with the DSF-copper complex, compared with the control or DSF alone-treated cells (Fig. 1B, bottom). Copper alone, TM alone, or the TM-copper complex had some effect, but much less than that of the DSF-copper complex (Fig. 1B, bottom). Collectively, these results show that the DSF-copper complex potently inhibits the proteasome activity in intact breast cancer cells.

The growth-inhibitory and apoptosis-inducing effects of the DSF-copper complex in breast cancer cells are associated with inhibition of cellular proteosomal chymotrypsin-like activity. It has been shown that inhibition of the proteasomal chymotrypsin-like activity is associated with induction of tumor cell growth arrest and/or apoptosis (23–25). To determine whether proteasome inhibition by the DSF-copper complex (Fig. 1B) causes suppression of cell proliferation, MDA-MB-231 cells were treated for 24 hours with copper, DSF, DSF-copper complex, TM, the TM-copper complex, or equal volume of the vehicle DMSO. We found that the DSF-copper complex inhibited proliferation of MDA-MB-231...
cells in a concentration-dependent manner, by 55%, 65%, and 85%, respectively, when used at 5, 10 and 20 μmol/L (Fig. 1C). In contrast, all the other treatments at up to 20 μmol/L had very little inhibitory effect on MDA-MB-231 cell proliferation (Fig. 1C).

To determine whether inhibition of growth is due to induction of apoptotic cell death, aliquots of the breast cancer MDA-MB-231 cells after each treatment (Fig. 1B) were subjected to Western blot analysis for measurement of PARP cleavage, an indicator of caspase activation and apoptosis induction (35). PARP cleavage was detected in the breast cancer cells treated with only the DSF-copper complex but not with others (Fig. 1B, bottom), showing that the DSF-copper complex induced apoptosis in breast cancer cells.

To further confirm the apoptosis-inducing ability of the DSF-copper complex, we measured apoptosis-associated cellular and nuclear morphologic changes in the same experiment. Cellular morphology changes (i.e., spherical and detached changes) were visualized by phase-contrast microscope imaging and apoptotic nuclear changes (i.e., punctuated or granular and bright nuclei) were determined after Hoechst dye staining. The apoptotic cellular (Fig. 1D, left) and nuclear changes (Fig. 1D, right) were observed only in the cells treated with the DSF-copper complex, but not with other agents or DMSO. These results further support the conclusion that the DSF-copper complex can induce apoptosis in breast cancer cells.

If proteasome inhibition is responsible for apoptosis induction by the DSF-copper mixture, we would expect that the proteasomal activity would be inhibited before the apoptotic events occur. To test this idea, we did a kinetic experiment in which MDA-MB-231 cells were treated with 15 μmol/L of CuCl₂, DSF, or DSF-copper for different hours. The results showed that proteasome inhibition by DSF-copper started at as early as 0.5 hour, before the time point, the levels of proteasome activity were decreased by ~30% (Fig. 2A) and accumulation of ubiquitinated proteins was significantly increased (Fig. 2B). Importantly, cell death was not observed after 0.5 hour of treatment with DSF-copper, as shown by lack of PARP cleavage (Fig. 2B) and lack of cellular morphologic change (Fig. 2C). From 0.5 to 2 hours, proteasome activity was continuously inhibited while apoptosis had not started yet (Fig. 2). Apoptosis started at 6 hours in the cells treated with DSF-copper and further increased afterwards (Fig. 2B and C). As a comparison, neither CuCl₂ nor DSF alone was able to induce any of these events (Fig. 2). The results clearly show that the apoptosis induced by DSF-copper treatment is a consequential event of the proteasome inhibition.

The nontoxic effect of the DSF-copper complex in normal, immortalized breast cells. The ability to induce apoptosis in tumor, but not normal, cells, is an important criterion for novel anticancer drugs. To determine whether the DSF-copper complex could inhibit the proteasome activity and induce apoptosis selectively in breast cancer over normal cells, we used a pair of normal and malignant breast cell lines, MCF-10A and MCF10DCIS.com. MCF-10A cells are normal, immortalized breast cells, whereas MCF10DCIS.com cells are malignant, which are derived from MCF-10A cells (33). Both MCF-10A and MCF10DCIS.com cell lines were treated with 20 μmol/L of copper, DSF, the DSF-copper complex, TM, the TM-copper complex, or DMSO for 24 hours, followed by measurement of proteasome inhibition and apoptosis. We found that the DSF-copper complex, but not others, strongly inhibited the proteasomal chymotrypsin-like activity in breast malignant MCF10DCIS.com cells (97%; Fig. 3A), similar to that observed in breast cancer MDA-MB-231 cells (Fig. 1B). In sharp contrast, when lysates of nontransformed MCF-10A cells treated with the DSF-copper complex were analyzed, no proteasome inhibition was detected (Fig. 3A). Other treatments had little or no effects on either MCF10DCIS.com or MCF-10A cells (Fig. 3A).

To determine whether failure of the DSF-copper complex to inhibit the proteasome activity in MCF-10A cells is associated with lack of apoptosis induction in these normal, immortalized breast cells, apoptosis-associated cellular and nuclear morphologic changes were then measured in the aliquots of both cell lines in the same experiment. The MCF10DCIS.com cells treated with the DSF-copper complex, but not others, were fully detached (Fig. 3B) and also showed the apoptotic nuclear changes (Fig. 3C). However, the normal, immortalized MCF-10A cells showed only little, if any, such cell death–related detachment or apoptotic nuclei after
treatment with the DSF-copper complex or others (Fig. 3B and C). Our data suggest that the DSF-copper complex could inhibit the proteasomal activity and induce apoptosis selectively in malignant cells but not in normal, immortalized breast cells.

The effects of DSF in copper-enriched breast cancer cells. Fundamental to the strategy we are using is the ability of the normal nontoxic ligand DSF to bind with endogenous tumor cellular copper. Cancer cells contain high level of copper in vivo (7–13). However, we found that the cultured cancer cells possess low to trace levels of copper (25, 34). To mimic the in vivo situation, human breast cancer MDA-MB-231 cells were cultured in medium containing 25 μmol/L CuCl₂ for 3 days. Cellular copper concentrations increased severalfold up to micromolar range (25, 34), similar to the copper concentrations found in patients (0.3–20 μmol/L; refs. 9, 10). Then the CuCl₂-precultured MDA-MB-231 cells were incubated with normal growth medium (without detectable copper) and treated with 20 μmol/L of DSF or TM for 24 hours, followed by measurement of proteasome inhibition and apoptosis.

![Figure 3](image-url)

Figure 3. The differential effects of DSF-copper complex in normal and malignant breast cells. Normal, immortalized human breast MCF-10A cells and malignant MCF10DCIS.com (DCIS) cells were treated with 20 μmol/L of copper, DSF, DSF-copper complex, TM, or TM-copper complex for 24 hours. DMSO was used as vehicle control. A, the inhibition of chymotrypsin-like activity was shown in malignant MCF10DCIS.com cells, but not in normal MCF-10A cells treated with the DSF-copper complex. *** P < 0.001. Columns, mean of three experiments; bars, SD. B, cellular spherical and detached changes (indicating apoptosis) were observed only in malignant MCF10DCIS.com cells, but not in normal MCF-10A cells, after treatment with the DSF-copper complex. C, punctuated, granular, and brighter nuclei (apoptotic nuclei) were observed in MCF10DCIS.com cells, but not in normal MCF-10A cells, treated with the DSF-copper complex after staining with Hoechst 33258.

![Figure 4](image-url)

Figure 4. The proteasome-inhibitory and apoptosis-inducing effects of DSF in copper-enriched MDA-MB-231 cells. MDA-MB-231 cells were cultured in medium containing 25 μmol/L CuCl₂ for 3 days and then maintained in normal growth medium (without additional copper). This was followed by treatment with 20 μmol/L of DSF or TM or vehicle DMSO for 24 hours and preparation of cell extracts. A, the proteasomal chymotrypsin-like activity was inhibited only in the cells treated by DSF (***, P < 0.001). No proteasome inhibition was seen in TM-treated cells. Columns, mean of three experiments; bars, SD. B, Western blot analysis showed accumulation of ubiquitinated proteins and cleavage of PARP in cells treated with DSF, but not with TM.

The proteasomal chymotrypsin-like activity was inhibited by 67% in the cells treated with DSF compared with the control (Fig. 4A). In addition, accumulation of ubiquitinated proteins and cleavage of PARP were observed in the extract of the cells pretreated with CuCl₂ and posttreated with DSF (Fig. 4B). In contrast, when the copper-enriched cells were treated with TM, neither proteasome inhibition nor apoptosis induction was observed (Fig. 4). Therefore, DSF is able to induce proteasome inhibition and apoptosis in MDA-MB-231 cells containing increased copper levels (Fig. 4), but not in those with undetectable copper (Fig. 1).

The proteasome-inhibitory, apoptosis-inducing, and antitumor effects of DSF in human breast tumor xenografts. Our data described above clearly showed that the DSF-copper complex is a proteasome inhibitor and an apoptosis inducer in cultured human breast cancer (but not normal, immortalized) cells (Figs. 1-3) and that DSF alone can do so in breast cancer cells containing increased cellular copper (Fig. 4). It has been shown that treatment with the strong copper chelator TM inhibits growth of human breast, prostate, and lung tumors in various mouse models (36–38), indicating that human tumor xenografts in mice also contain high levels of copper. If so, DSF alone treatment should be able to induce proteasome inhibition and apoptosis in human tumor xenografts, leading to tumor growth inhibition. To test this idea, human breast cancer MDA-MB-231 cells were implanted s.c. to female nude mice. When tumors became palpable (~ 200 mm³), the mice were randomly grouped (total 10 mice per group from two experiments) and injected i.p. daily with either vehicle control or 50 mg/kg DSF. The injections were kept for 29 days until the control tumors reached ~ 1,600 mm³. During the
treatment, the tumor sizes in these two groups were measured and shown in Fig. 5A (left). At the end of the experiment, the mice were sacrificed. The tumors were removed from the mice and photographed (Fig. 5A, right). We found that DSF significantly inhibited tumor growth by 74% (P < 0.01) compared with the solvent control (Fig. 5A). Therefore, the data show that DSF possesses potent antitumor effects in vivo.

To investigate whether the observed antitumor effects of DSF are associated with proteasome-inhibitory and apoptosis-inducing activities in vivo, samples of the control- or DSF-treated tumors were subjected to multiple assays. The proteasomal chymotrypsin-like activity was inhibited significantly (by 87%) in tumor tissues from mice treated with DSF when compared with the control (Fig. 5B), indicating that DSF inhibits the proteasomal activity in MDA-MB-231 tumors. Consistently, accumulation of ubiquitinated proteins and natural proteasome target proteins, p27 (39) and Bax (40, 41), was found in tumors treated with DSF versus control by Western blot analysis (Fig. 5D). Increased accumulation of p27 protein in tumors by DSF treatment was further confirmed by immunohistochemistry assay (Fig. 6A). Accompanying proteasome inhibition, apoptosis was induced in the MDA-MB-231 xenografts. It is unique that copper, but not other trace metals in the body, is a cofactor essential and requisite for the tumor angiogenesis inhibition, apoptosis was induced in the MDA-MB-231 xenografts. We found that DSF significantly inhibited detected by H&E staining (Fig. 6C). The results clearly show that DSF was able to target the proteasome in vivo, resulting in accumulation of natural tumor suppressor proteins (such as p27 and Bax) and induction of apoptotic cell death within the tumor, which may be responsible for the observed potent antitumor activity of DSF (Fig. 5A).

**Discussion**

Many anticancer agents are unable to distinguish tumor from normal cells, which is perhaps responsible for their observed toxicity. Therefore, specific and selective targeting of chemotherapeutic drugs to the cancer, but not normal, cells could be of great benefit for cancer patients. Proteasome inhibition and antiangiogenesis have been found to be novel approaches to cancer therapy due to the fact that the cancer cells are much more dependent on these activities/processes than normal cells (3–6, 19–21, 42–44). It is unique that copper, but not other trace metals in the body, is a cofactor essential and requisite for the tumor angiogenesis processes (3–6). Furthermore, it is well documented that cancer

![Figure 5. Proteasome-inhibitory, apoptosis-inducing, and antitumor effects of DSF in vivo. Female athymic nude mice were xenografted by s.c. injection of MDA-MB-231 cells (5 x 10⁶) at one flank. When tumor size reached to ~200 mm³, the mice were divided into two groups and treated with either the control vehicle solvent (Sol) or DSF (50 mg/kg/d; n = 10). Tumors were collected after 29-day treatment, and the prepared tissue extracts were used for proteasome activity, caspase-3 activity, and Western blotting assays. A, left, tumor growth chart. cells and tissues accumulate high levels of copper in vivo (7–13). Previously, we reported that certain types of organic-copper complexes are capable of proteasome inhibition and apoptosis induction in cancer cells (25, 34). Therefore, the capability of copper-containing complexes to inhibit the proteasome, the necessity of copper for angiogenesis, and the accumulation of copper by cancer cells and tissues allow for a novel therapeutic strategy focusing on elevated copper as a selective mechanism against cancer cells and tissues (3–6, 25, 34).

DSF has been approved by the Food and Drug Administration for the treatment of alcoholism in 1951 by inhibition of aldehyde dehydrogenase (28, 45). It was reported that DSF itself had little effect, but in the presence of Cu(II), it was converted back to the two-electron oxidized form of diethyldithiocarbamate, which is the active form in inducing apoptosis (32). DSF is adsorbed as its bis(diethyldithiocarbamate)-copper(II) complex (28), suggesting that a heavy metal-thiolate chelator may be the active drug facilitating mixed DSF formation. It was also reported that DSF could reduce melanoma growth in mice and hepatic tumor in a patient but the involved in vivo molecular target was unclear (46). In addition, DSF can effectively protect normal cells in kidney, gut, and bone marrow from the damage of cisplatin and radiation in vivo and increase the therapeutic index (47, 48).

Previously, we have reported that complexes of clioquinol with copper and pyrrolidine dithiocarbamate with copper possessed strong proteasome-inhibitory and apoptosis-inducing abilities (25, 34). In the current study, we showed that when complexed with copper, DSF was a potent inhibitor of the proteasomal chymotrypsin-like activity in cultured breast cancer cells but not in normal, immortalized breast cells (Figs. 1–3). Inhibition of the tumor cellular proteasome activity occurred much earlier than apoptosis induced by DSF-copper (Fig. 2). Furthermore, DSF alone was a potent proteasome inhibitor in copper-elevated breast cancer cells (Fig. 4) and tumor xenografts (Figs. 5 and 6). DSF potently inhibited breast tumor growth in mice (Fig. 5A), associated with in vivo proteasome inhibition, as shown by decreased chymotryptic activity and accumulation of ubiquitinated proteins, p27 and Bax, and by apoptotic cell death, as shown by caspase-3 activation, PARP cleavage, TUNEL positivity, and condensed nuclei (Figs. 5 and 6). This finding further supports the conclusion that inhibition of the chymotryptic-like activity of the proteasome by a specific inhibitor was sufficient to induce apoptosis (23–25).

Our strategy revolves around the idea that an inactive or nontoxic organic ligand (such as DSF) could bind with elevated copper, found in tumors in vivo, resulting in formation of a complex capable of proteasome inhibition. We first verified that DSF would directly interact with copper and form a new metal complex, which was indicated by dramatic color change after mixing both of them (data not shown). Once we verified that DSF spontaneously binds with copper and forms a new complex, we then tested whether the complex was a proteasome inhibitor using purified rabbit 20S proteasome. The data showed that, indeed, both DSF-copper and CuCl₂, but not DSF, inhibited the chymotryptic activity of the purified 20S proteasome (Fig. 1A), showing that copper is responsible for inhibiting the proteasome molecule. This is consistent with the hypothesis that DSF is able to carry the copper ion into tumor cells and prevent copper from interacting with many nonspecific proteins.

Then we tested whether DSF–copper, DSF, or CuCl₂ could inhibit cellular proteasome activity using cultured breast cancer MDA-MB-231 cells. Another copper chelator, TM, was used as a comparison in this experiment. We examined levels of both cellular proteasome activity and ubiquitinated proteins (Fig. 1B) and found that the cells treated with the DSF–copper complex had significantly reduced chymotrypsin-like activity and increased ubiquitinated protein levels (Fig. 1B), indicating that proteasome inhibition had occurred. In contrast, copper, DSF, TM, or the TM–copper complex was incapable of inhibiting the proteasome (Fig. 1B). We also measured effects of these agents on MDA-MB-231 cell proliferation, PARP cleavage, and cellular and nuclear morphologic changes, and found that only the DSF–copper complex inhibited cell proliferation (Fig. 1C), induced cleavage of PARP (Fig. 1B), and caused cell death–associated morphologic and nuclear changes (Fig. 1D).

The following arguments support the idea that proteasome inhibition by DSF-copper is the cause, not the consequence, of apoptotic cell death. First, when MDA-MB-231 cells were treated with DSF-copper, the proteasome activity was inhibited at as early as 0.5 hour, about 5 hours before apoptosis induction (Fig. 2). Second, accumulation of tumor suppressor proteins p27 or Bax was also found in DSF-copper–treated tumors undergoing apoptosis (Figs. 5 and 6).

After determining that the DSF-copper complex could inhibit proteasome activity and cell proliferation and induce apoptosis in MDA-MB-231 cells (Fig. 1), we then examined the possibility that DSF-copper complex could specifically and selectively inhibit proteasome activity and induce apoptosis in breast cancer, but not normal, cells. Indeed, our results showed that the DSF-copper complex was a potent proteasome inhibitor and apoptosis inducer.
Cancer Res 8. Rizk 7. Kuo 6. Ryan 4. Fox SB, Gasparini G, Harris AL. Angiogenesis: Balibrea JL. Serum and tissue trace metal levels in lung 21. Dou QP, Li B. Proteasome inhibitors as potential chymotrypsin-like activity in tumors (Fig. 5B), accumulation of inhibition of MDA-MB-231 tumor growth in nude mice (Fig. 5A). with 18 U.S.C. Section 173t solely to indicate this fact. Our data showed that DSF treatment caused a significant dsf treatment caused a significant increase in cellular copper presented here have further confirmed their finding and also induction (Fig. 4). Although the strong metal chelator TM should but not normal, cells. Cancer cells and tissues, which contain elevated copper and more dependent on proteasome activity for induction (Fig. 4). Most recently one group bind to copper in cancer cells, the resulted complex seems inactive in such functions (Fig. 4). To answer the question of whether DSF can react with copper in tumor tissue and possess antitumor activity, we tested effect of DSF in mice bearing human breast tumor MDA-MB-231 xenografts. Our data showed that DSF treatment caused a significant inhibition of MDA-MB-231 tumor growth in nude mice (Fig. 5A). Also importantly, the antitumor activity of DSF was associated with its proteasome-inhibitory and apoptosis-inducing abilities because DSF treatment resulted in the inhibition of proteasomal chymotrypsin-like activity in tumors (Fig. 5B), accumulation of proteasome target proteins p27 (Figs. 5D and 6A) and Bax (Fig. 5D), and induction of apoptosis (i.e., increase in caspase-3/caspase-7 activity, PARP cleavage, TUNEL positivity, and condensed nuclei; Figs. 5 and 6). A previous study has suggested the antitumor activity of DSF in melanoma and hepatic tumor, which could be potentiated by Zn2+ supplementation (46). We have found that a DSF-zinc complex is also a proteasome inhibitor although its potency is weaker that of the DSF-copper complex.1 Our results presented here have further confirmed their finding and also showed the requirement of proteasome inhibition for the antitumor activity of DSF.

The data presented here support the novel concept of using accumulated copper in breast cancer cells and tissues as a selective approach for chemotheraphy. The nontoxic copper-binding ligands such as DSF can spontaneously bind with copper and form a proteasome inhibitor and an apoptosis inducer in breast cancer, but not normal, cells. Cancer cells and tissues, which contain elevated copper and more dependent on proteasome activity for their survival, should be very sensitive to treatment with DSF and other copper-binding compounds. In contrast, normal cells and tissues, containing trace amounts of copper and having basal level of proteasome activity, should be resistant to these effects. DSF has been previously explored for use in clinic for alcoholism, and our data suggest the potential use of DSF and other similar compounds in cancer therapies.

Activation of the cellular apoptotic program is a current strategy for the prevention and treatment of human cancer including breast cancer. The beta-lactam antibiotics have played an essential role in treating bacterial infections without causing toxic side effects for the past 60 years. We hypothesize that active N-thiolated beta-lactams can target a tumor-specific protein(s) and selectively induce apoptosis in human breast cancer but not normal cells.

To test this hypothesis, we designed and synthesized numerous new N-thiolated beta-lactams analogs, evaluated potencies of these synthetic beta-lactams to inhibit proliferation and induce apoptosis in human breast cancer cells, and investigated whether these beta-lactams can induce apoptosis selectively in breast tumor vs. normal cells and the involved molecular mechanisms.

We tested a library of lactam compounds and found that many of them are able to inhibit proliferation and induce apoptosis in human breast cancer cells in a time- and concentration-dependent manner. These active beta-lactams are capable of inducing DNA strand breakage, inhibiting DNA replication, and inducing p38 MAP kinase activation. Consistent with the idea that these beta-lactam antibiotics are potent anti-cancer agents, the active analogs are also capable of inhibiting colony formation potential of breast cancer cells. Furthermore, the active beta-lactams have much reduced effects on human normal or non-transformed cells. Our findings also yielded several important structure-activity relationships (SARs). The N-methylthio group is necessary for the apoptosis-inducing activity. Also observed is the inverse relationship between the number of carbon atoms off the N-thio group and apoptotic activity. Substitutions to C3 reveal that as the substituents increase in size or in polarity, the efficacy of the compound decreases. Therefore, the overall size of the beta-lactam is important, possibly indicating steric hindrance with the cellular target or permeability to the cell membrane. We also found that the stereochemistry of the beta-lactams play in important role in their potency. The 3R,4S enantiomers are more efficacious than the 3S,4R isomers, which may indicate a more favorable configuration for target interaction.

Our future studies will focus on the biochemical target of N-thiolated beta-lactams, whether the N-thiolated beta-lactams can induce apoptosis selectively in breast tumor vs. normal breast cells, and whether the in vivo apoptosis-inducing ability of the N-thiolated beta-lactams is related to their cancer-preventive and anti-tumor activities using nude mice bearing human breast tumors. These studies should provide strong support for proof-of-concept of the potential use of these N-thiolated beta-lactams in breast cancer prevention and treatment.

Re: 2006 AACR International Conference on Frontiers in Cancer Prevention Research
November 12-15, 2006, Boston, MA

Temporary Abstract Number #423
Title: Disulfiram, a clinically used anti-alcoholism drug and copper-binding agent, induces apoptotic cell death in breast cancer cultures and xenografts via inhibition of the proteasome activity.

Dear Dr. Dou:

Your above-referenced abstract has been scheduled for presentation in a Poster Session at the 2006 AACR International Conference on Frontiers in Cancer Prevention Research and will be published in the Program and Proceedings. Presentation information pertaining to your abstract is below:

Session Title: Poster Session A
Session Subtitle: New Molecular Targets/Mechanisms of Drug Action
Session Date and Start Time: 11/13/2006 at 4:00 PM
Session Location: Exhibit Hall A
Permanent Abstract Number: A92

Please note that the permanent number assigned to your abstract corresponds to the poster board number for your presentation. Refer to the printed Program (distributed onsite) for the exact location of your presentation.

For additional information about the conference, visit the conference home page:

Poster Session presenters at the AACR Frontiers in Cancer Prevention Research conference must register for the full meeting at the rate appropriate to their membership status and obtain their own hotel accommodations. Registration and housing information are included below:

PLEASE NOTE: The deadline for hotel reservations at the reduced conference rate is 5:00 PM EDT today, Thursday, October 19. Room reservations may be made after the October 19 deadline, but they are subject to availability and group room rates are not guaranteed.

Online Registration Information

Housing Information

Thank you for your participation in the 2006 AACR International Conference on Frontiers in Cancer Prevention Research.
Sincerely,

Scott M. Lippman, M.D.

Program Committee Chairperson

PLEASE NOTE: This document is your official notice of acceptance and scheduling. No separate letter will be mailed.
Disulfiram, a clinically used anti-alcoholism drug and copper-binding agent, induces apoptotic cell death in breast cancer cultures and xenografts via inhibition of the proteasome activity.

Short Title: Disulfiram/Cu inhibits proteasome

Author Block: D. Chen, Q. C. Cui, H. Yang, Q. Dou; Wayne State Univ., Karmanos Cancer Inst., Detroit, MI.

Abstract:
Disulfiram (DSF), a member of the dithiocarbamate family capable of binding copper and an inhibitor of aldehyde dehydrogenase, is currently being used clinically for the treatment of alcoholism. Recent studies have suggested that DSF may have antitumor and chemosensitizing activities although the detailed molecular mechanisms remain unclear. Copper has been shown essential for tumor angiogenesis processes. Consistently, high serum and tissue levels of copper have been found in many types of human cancers, including breast, prostate and brain, supporting the idea that copper could be used as a potential tumor-specific target. Here we report that the DSF-copper complex potently inhibits the proteasomal activity in cultured breast cancer MDA-MB-231 and MCF10DCIS.com, but not normal, immortalized MCF-10A, cells, prior to induction of apoptotic cancer cell death. Furthermore, MDA-MB-231 cells that contain copper at concentrations similar to those found in patients, when treated with just DSF, undergo proteasome inhibition and apoptosis. In addition, when administered to mice bearing MDA-MB-231 tumor xenografts, DSF significantly inhibited the tumor growth (by 74%), associated with in vivo proteasome inhibition (as measured by decreased levels of tumor tissue proteasome activity and accumulation of ubiquitinated proteins and natural proteasome substrates p27 and Bax) and apoptosis induction (as shown by caspase activation and apoptotic nuclei formation). Our study demonstrates that inhibition of the proteasomal activity can be achieved by targeting tumor cellular copper with the non-toxic compound DSF, resulting in selective apoptosis induction within tumor cells.

Nominee of Team Award (Cancer Control Program), 2002

Kenyon G. Daniel, Ph.D. a Winner of the 2004 Outstanding Dissertation Award from University of South Florida (Major Professor: Q. Ping Dou), 2004

Invited Visiting Professor in the Department of Urology at the University of California San Francisco and San Francisco VA Medical Center (April 28, 2005), with seminar presentation, "Searching for novel polyphenol proteasome inhibitors for cancer prevention and treatment"

Training Grant (Kristin Landis; Mentor: Q. Ping Dou). Wayne State University, 2005-2007

First Place, Oral Presentation (Kristin Landis; Mentor: Q. Ping Dou). Wayne State University School of Medicine, Graduate Student Research Day, September 22, 2005. "Molecular Studies for the Regulation of Green Tea Polyphenol Biological Function by the Polymorphic Gene Product Catechol-O-Methyltransferase"

Awardee (Kristin Landis; Mentor: Q. Ping Dou) for the Honors Recognition Program for Wayne State University School of Medicine, Wayne State University, 2005

Invited Visiting Professor in the Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, Beijing, China (April 19-20, 2006), with seminar presentation, "Cancer Prevention and the Role of Environmental Factors”. Received Honorary Professor Title.

Invited Visiting Professor in the Institution of Environmental Sciences, Shandong University, Jinan, Shandong, China (April 24-25, 2006), with seminar presentations, “Nutrient-Gene-Environment Interactions and Molecular Prevention of Cancer” and “Discovery of Novel Small Molecules from Nature and Laboratories for Cancer Therapies”

The First Place Poster Award (Huanjie Yang, Di Chen, Quizhi Cindy Cui, Xiao Yuan, and Q. Ping Dou). The 6th Annual Symposium, Michigan Prostate Research Colloquium,
Q. Ping Dou, Ph.D.

Basic and Clinical Advances in Prostate Cancer Research, University of Michigan Medical School, Towsley Center, Dow Auditorium, Ann Arbor, MI 48109, May 6, 2006.

“Celastrol, A Triterpene Extracted From The Chinese Thunder Of God Vine, Is A Potent Proteasome Inhibitor And Suppresses Human Prostate Cancer Growth In Nude Mice”.

**Honorary Professorship**, Wuhan Botanical Garden/ Wuhan Institute of Botany, The Chinese Academy of Sciences, Wuhan, Hubei, China (October, 2006), with seminar presentation, “Discovery of Novel Small Molecules for Cancer Therapies”.

**Nominee of the 2007 AACR Landon Prize for Basic Research.**

First Place, Oral Presentation (Kristin Landis; Mentor: Q. Ping Dou). Wayne State University School of Medicine, Graduate Student Research Day, September 21, 2006. “A Novel Pro-drug of Green Tea Catechin (-)-EGCG as a Potential Anti-Breast Cancer Agent”.

**Co-Session Chairman.** The 3rd International Symposium on Persistent Toxic Substances, Beijing, China, October 22-25, 2006

**SERVICE:**

**Professional Consultation**

- Tours for University of Pittsburgh Cancer Institute
- Tours for Drug Discovery Program Moffitt Cancer Center & Research Institute
- Advisor for Project LINK (Leaders In New Knowledge) Students
- Advisor for Moffitt Summer Interns
- Advisor for Undergraduate Student Honor’s Thesis Research
- Member, the Scientific Advisory Board, Torrey Pharmaceuticals, LLC, San Diego, CA, 2000-present
- Graduate student recruitment faculty for Cancer Biology Program Karmanos Cancer Institute and Wayne State University, April 3, 2004, April 2, 2005
- Presentation to Cancer Biology Program Candidates, Karmanos Cancer Institute and Wayne State University, March 25, 2006 (Kristin Landis and Vesna Minic from Dr. Dou’s laboratory)
- Preferred Consultant, MEDACorp, Boston, Massachusetts, 2004-present
- Speaker (Kristin Landis from the laboratory of Q. Ping Dou), “Friends Raising Funds” program, March 5th, 2006, the Powerhouse Gym, West Bloomfield, MI.
- Invited Speaker, “Green Tea and Cancer Prevention”, “The Day of Wellness” Program, September 16, 2006, the Grosse Pointe War Memorial, Grosse Pointe, MI.
- Moderator, Population Studies and Prevention Program Scientific Retreat, Lung Cancer session, Karmanos Cancer Institute and Wayne State University, September 15, 2006
- Invited Speaker, Green Tea and its Role in Cancer Prevention. Dow and Towsley Foundation Visit, Karmanos Cancer Institute Research, Detroit, MI, October 11, 2006

**Journal/Editorial Activity**

**Editorial Board Memberships**

- Invited member of the Editorial Board of the *Oncology Reports*, 1996-present
- Invited member of the Editorial Board of *Frontiers In Bioscience*, 1997-present
- Invited member of the Editorial Board of *LifeXY (Currently International Archives of Biosciences)*, 2001-present
- Invited panel evaluator of *Current Drugs*, 2001-present
- Invited member of *The Science Advisory Board*, 2002-present
Q. Ping Dou, Ph.D.

Invited managing editor of *Frontiers In Bioscience*, 2003-present
Invited managing editor of *Frontiers In Bioscience* for a special issue of “Potential Molecular Targets for Chemoprevention”, 2004-present

*Reviewer for Journal Manuscripts*

- The Pittsburgh Undergraduate Review
Reviewer for Grant Applications

Competitive Medical Research Fund (Ad Hoc Reviewer), University of Pittsburgh School of Medicine, 1996
Competitive Medical Research Fund, University of Pittsburgh School of Medicine, 1997
Central Research Development Fund, University of Pittsburgh, 1997
National Science Foundation, 1998
Merit Review Subcommittee for Oncology, the Veterans Affairs Medical Research Programs, US Department of Veterans Affairs, 1999-2005
Member, Cancer Study Section, The Tobacco-Related Disease Research Program, University of California, San Francisco, CA, 2004-present
Invited Reviewer, Biotechnology and Biological Sciences Research Council Research Grant, United Kingdom, 2004, 2006
Invited Reviewer, the Strategic Research Initiative Awards, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI, 2005
Invited Reviewer, the Seed Money Grants, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI, 2006
Invited Reviewer, the European Commission’s Research Program on "Combating Cancer" - Apoptosis, Brussels, Belgium, 2006

Other Professional Related Service

Faculty reviewer for applications to University of Pittsburgh and University of Pittsburgh Cancer Institute
Faculty reviewer for applications to Moffitt Cancer Center & Research Institute and University of South Florida
Faculty reviewer for applications to Karmanos Cancer Institute and Wayne State University (2003-)
Faculty reviewer for Deputy Director/Associate Center Director Candidates to Karmanos Cancer Institute and Wayne State University (2004)
Faculty reviewer for Lambert – Webber Endowed Chair, Division Chief, Hematology and Oncology, Department of Internal Medicine, Wayne State University, Program Leader, Developmental Therapeutics, Karmanos Cancer Institute (2005)

National and International Boards and Committees

Ad Hoc Reviewer, National Science Foundation, 1998
Ad Hoc Reviewer, Merit Review Subcommittee for Oncology, the Veterans Affairs Medical Research Programs, US Department of Veterans Affairs, 1999-2001
Member, Department of Veterans Affairs (VA) Medical Research Service Merit Review Subcommittee for Oncology, 2001-2005
Member, the Scientific Advisory Board, Torrey Pharmaceuticals, LLC, San Diego, CA, 2000-present
Council Member, Gerson Lehrman Group’s Council of Healthcare Advisors, New York, NY, 2004-present
Member, Cancer Study Section, The Tobacco-Related Disease Research Program, University of California, San Francisco, CA, 2004-present
Invited Reviewer, Biotechnology and Biological Sciences Research Council Research Grant, United Kingdom, 2004, 2006
Q. Ping Dou, Ph.D.

Preferred Consultant, MEDACorp, Boston, Massachusetts, 2004-present
Judge, Cell Biology & Cell Signaling Section, 2nd Annual Research Symposium, Henry Ford Health System Academic Affairs, Detroit, MI, April 15, 2005
Invited Reviewer, the European Commission’s Research Program on "Combating Cancer" - Apoptosis, Brussels, Belgium, 2006

State and Local Boards and Committees

Department of Pharmacology, University of Pittsburgh School of Medicine
Comprehensive Examination Committee, Department of Pharmacology, University of Pittsburgh School of Medicine, 1993-1998
Committee of Graduate Studies, Department of Pharmacology, University of Pittsburgh School of Medicine, 1994-1998
Chairman of Graduate Evaluations, Department of Pharmacology, University of Pittsburgh School of Medicine, 1994-1998
NIH Predoctoral Training Grant Selection Committee, 1995
Director of Departmental Seminar Program, 1997

University of Pittsburgh School of Medicine
Competitive Medical Research Fund Review Committee (Ad Hoc Reviewer), University of Pittsburgh School of Medicine, 1996-1997
The Graduate Progress Evaluation Committee, University of Pittsburgh School of Medicine, 1997
Central Research Development Fund, University of Pittsburgh, 1997

University of South Florida and Moffitt Cancer Center & Research Institute
Member, Search Committee for Assistant Professor position in Molecular, Epidemiology Program of Cancer Control Division at Moffitt Cancer Center & Research Institute, 2001
Member, Rb Club, Moffitt Cancer Center & Research Institute, 2001-2002
Member, The Summer Intern Program Committee at Moffitt Cancer Center & Research Institute, 2002
Member, Preliminary Data Club, Moffitt Cancer Center & Research Institute, 2002-2003
Member, Proteomics Task Force Committee, Moffitt Cancer Center & Research Institute, 2002
Member, Search Committee for Structural Biology Faculty position in Drug Discovery Program at Moffitt Cancer Center & Research Institute, 2003
Member, Search Committee for the Cancer Prevention Faculty position in Molecular Epidemiology Program of Cancer Control Division at Moffitt Cancer Center & Research Institute, 2003
Member, Search Committee for Chemistry Faculty position in Drug Discovery Program at Moffitt Cancer Center & Research Institute, 2003
Member, SPARK (Summer Program for the Advancement of Research Knowledge) Selection Committee at Moffitt Cancer Center & Research Institute, 2003

Wayne State University and Karmanos Cancer Institute
Graduate student recruitment faculty for Cancer Biology Program Karmanos Cancer Institute and Wayne State University, April 3, 2004
Graduate student recruitment faculty for Cancer Biology Program Karmanos Cancer Institute and Wayne State University, April 2, 2005
Invited Reviewer, the Strategic Research Initiative Awards, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI, 2005
Invited Judge, the 2nd Annual Research Symposium, Henry Ford Health System, Detroit, MI, 2005
Invited Reviewer, the Seed Grants, Barbara Ann Karmanos Cancer Institute, Wayne State University School of Medicine, Detroit, MI, 2006
Co-Director and Member of a P01 Group, “AR-mediated cell cycle-dependent anti-apoptotic events in prostate cancer”, Wayne State University and Henry Ford Health System, Detroit, MI, 2004-present
Speaker (Kristin Landis from the laboratory of Q. Ping Dou), "Friends Raising Funds" program, March 5th, 2006, the Powerhouse Gym, West Bloomfield, MI.
Member, HFHS/WSU Prostate Journal Club, 2003-
Co-Director and Member of a P01 Group, “AR-mediated cell cycle-dependent anti-apoptotic events in prostate cancer”, Wayne State University and Henry Ford Health System, Detroit, MI, 2004-present

Dr. Dou has the following responsibilities:
(1) Assist the Program Leader in the entire Population Studies and Prevention program and provide leadership in the Prevention sub-program, particularly with respect to basic science research, molecular targeting and chemoprevention;
(2) Participate in Population Studies and Prevention leadership meetings;
(3) Participate in updating and maintaining strategic planning for the Prevention sub-program;
(4) Facilitate inter- and intra-programmatic interactions between the Prevention faculty members and members of Population Studies, Communication & Behavioral Oncology, and other cancer center programs;
(5) Organize and lead the monthly Prevention group meetings;
(6) Recruit new members into the Prevention sub-program and mentor junior faculty;
(7) Advocate for shared facilities that meet the needs of the Prevention members;
(8) Develop the Prevention sub-program into an independent program in the next five years.

TEACHING:

Years at Wayne State University: Since August 1, 2003
Years at Other Universities:
Harvard Medical School, 1 year
University of Pittsburgh, 5 years
University of South Florida, 5 years

Courses Taught at Wayne State University
2003- CB 7250: CANCER CONTROL. 3 credits. 20 students
2004 CB 7230: BREAST CANCER. 2 credits. 10-12 students (December 8, 2004, 10:00 AM- 12:00 PM, 1140 Scott Hall).

Courses Taught at University of South Florida
Q. Ping Dou, Ph.D.

1999-2001 BCH 6411: Molecular Biology. Lecture. 3 credits. 25-30 students
2001- Cancer Biology I Course Lecture. 3 credits. ~10 students

Courses Taught at University of Pittsburgh
1993-1998 MS MIC 2355: Advanced Molecular Genetics. Lecture and Paper Discussion. 3 credits. 8-16 students
1993-1998 PHL 3510: Receptors and Signal Transduction. Lecture and Paper discussion. 3 credits. 10-15 students
1993-1998 2563: Cancer Pharmacology. Lecture. 3 credits. ~5 students
1993-1998 Medical Student Program: Problem-Based Learning Sessions. 8-10 students
1995 Medical Student Program: Pharmacology Conference. ~20 students
1997 Medical Student Program: Neoplasia and Neoplastic Disease. 16 students
1996-97 The Pennsylvania Governor’s School Program. 6-8 students
1997 Foundations of Biomedical Science. Small group conference. 3 credits. ~8 students

Undergraduate and Graduate/Medical Student Supervision
1994 Chen Yu, Harvard University, ASPET undergraduate
1995 Peggy Lin, Penn State-Jefferson
1995 Bill Wang, California University of PA
1995 Vivian Lui, Department of Pharmacology, University of Pittsburgh School of Medicine, one lab rotation
1996 Toni A. Termin, Saint Vincent College, ASPET undergraduate
1996 Kirk E. Dineley, Department of Pharmacology, University of Pittsburgh School of Medicine, two lab rotations
1996-1999 Cheryl Fattman, Department of Pharmacology, University of Pittsburgh School of Medicine. Ph.D., Dissertation Title: “Molecular mechanisms for apoptosis-associated the retinoblastoma protein (RB) internal cleavage”. Graduation with Honor (Mentor: Q. Ping Dou). Currently working as a postdoctoral fellow in Department of Pathology, University of Pittsburgh School of Medicine
1997 Lachelle Sussman, University of New York at Buffalo, ASPET Undergraduate, University of Pittsburgh School of Medicine, one lab rotation
1997 Kristin S Morrow, Department of Biology University of South Florida, master graduate student
1998- Yaser S. Bassel, University of South Florida College of Medicine, medical student
1998- Jason A. Evangelista, University of South Florida College of Medicine, medical student
1998- Joseph J. Kavanagh, University of South Florida College of Medicine, medical student
1998- Alexander Paloma, University of South Florida College of Medicine, medical student
1998- Gregory A. Russell, University of South Florida College of Medicine, medical student
1999-2002 David M. Smith, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine, one lab rotation and Ph.D. student in my lab (graduated in 2002). Dissertation Title: “Mechanistic Studies on Tumor Cell Cycle Disruption and Apoptosis by
Q. Ping Dou, Ph.D.

Green Tea Polyphenols and N-Thiolated beta-Lactams”. Currently working as a postdoctoral fellow in Dr. Fred Goldberg’s laboratory at Harvard Medical School

1999 Lisa Smith, Department of Biology University of South Florida, undergraduate student (currently a graduate student in University of North Carolina)
1999 Jessica Hu, Harvard University, undergraduate student
1999 Daniel Lorch, University of Florida, undergraduate student
1999 Sun Hee Rim, Hillsborough High School, student
1999 Alvin Jones, Land O’Lakes High School, student
1999 Kristie Main, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine, one lab rotation
1999-2000 Kenyon Daniel, Department of Biology University of South Florida, undergraduate student. Research for Honor’s Thesis
2000 Lisa Smith, Moffitt Summer Intern, Department of Biology University of South Florida, undergraduate student (current graduate student at University of North Carolina)
2000-2002 Marie Bosley, Project LINK (Leaders In New Knowledge) Student and a Moffitt Summer Intern, Department of Biology University of South Florida, undergraduate student
2000 John (Chilu) Chen, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine, one lab rotation
2001 Jonathan S. Anderson, Moffitt Summer Intern, Zoology, University of Florida, undergraduate student
2001 Kyleen Charlton, Moffitt Summer Intern, Boston College, undergraduate student
2001-2002 Priyanka Kamath, Volunteer, Hillsborough High School, high school student
2000-2004 Kenyon Daniel, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine, one lab rotation and Ph.D. student in my lab (graduated in 2004). Dissertation Title: “Strategies for Cancer Therapy Through Regulation of Apoptotic Proteases”. Currently working as a postdoctoral fellow in my laboratory at Karmanos Cancer Institute, Wayne State University
2001-2004 Deborah Kuhn, Cancer Biology Ph.D. Program (IOP), University of South Florida College of Medicine, one lab rotation and Ph.D. student in my lab (graduated in November of 2004). Dissertation Title: “Novel Approaches to Targeting Tumor Cell Apoptotic Signaling Pathways”. Currently working as a postdoctoral fellow in University of North Carolina.
2002 Naveen Kumar, Moffitt Summer Intern, New York University, undergraduate student
2002 Randy Hill, Moffitt Summer Intern, University of Wisconsin, undergraduate student (currently a graduate student in University of Wisconsin)
2002 Seth Pross, Moffitt Summer Intern, Hillsborough High School, high school student (currently a graduate student in University of Pennsylvania)
2002-2003 Audrey Burns, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine, one lab rotation and Ph.D. student in my lab
2002-2003  Sam Falsetti, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine, one lab rotation and Ph.D. student in my lab
2002  Jennelle McQuown, Cancer Biology Ph.D. Program (IOP), University of South Florida College of Medicine, one lab rotation
2002-2003  Daniel Urbizu, Project LINK (Leaders In New Knowledge) Student, Department of Biology University of South Florida, undergraduate student
2003-  Thomas Lendrihas, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine, one lab rotation
2003  Seth Pross, Moffitt Summer Intern, University of Pennsylvania, undergraduate student
2003  Shuojing Song, Moffitt Summer Intern, C. Leon King High School, high school student (currently an undergraduate of MIT)
2003  R. Hope Harbach, Summer Student, Department of Chemistry, Eckerd College, undergraduate student
2003  Daniel Urbizu, Summer/Project LINK (Leaders In New Knowledge) Student, Department of Biology University of South Florida, undergraduate student
2003  Marina Si Chen, Summer Research Volunteer, King High School, high school student
2003  Sydnor M. Richkind, Summer Research Volunteer, Hillsborough High School, high school student (currently a graduate student in University of Florida)
2004-present  Kristin Landis, Cancer Biology Program, Wayne State University, one lab rotation and Ph.D. student in my lab
2004  Marina Si Chen, Summer Research Hourly Technician, Emory University, undergraduate student
2005-present  Vesna Minic, Cancer Biology Program, Wayne State University, one lab rotation and Ph.D. student in my lab
2005-  Joan McCallum, Cancer Biology Program, Wayne State University, one lab rotation in my lab
2006-  Mike Frezza, Cancer Biology Program, Wayne State University, one lab rotation and Ph.D. student in my lab
2006-  Benchamart Moolmuang, Cancer Biology Program, Wayne State University, one lab rotation in my lab
2006  Andy Yang, Summer Research Student, Webster Thomas High School, New York
2006  Marina Si Chen, Summer Research Hourly Technician, Emory University, undergraduate student
2006  Justin Shaya, Summer Research Student, West Bloomfield High School, MI

Theses/ Dissertation or Comprehensive Examination Committees

Ph.D. Dissertation Committees
1995  Kirti G. Goyal, Molecular Genetics and Biochemistry, University of Pittsburgh School of Medicine (Advisor: Dr. Leaf Huang)
1997  Jie-Gen Jiang, Pathology, University of Pittsburgh School of Medicine (Advisor: Dr. Reza Zarnegar), graduated in 12/97
1997-1998  Marni Brisson, Pharmacology, University of Pittsburgh School of Medicine (Advisor: Dr. Leaf Huang)
Q. Ping Dou, Ph.D.

1997-1998 Donald Schwartz, Pharmacology, University of Pittsburgh School of Medicine (Advisor: Dr. John Lazo)
1996-1998 Robert Rice, Pharmacology, University of Pittsburgh School of Medicine (Advisor: Dr. John Lazo)
1996-1999 Cheryl Fattman, Pharmacology, University of Pittsburgh School of Medicine (Advisor: Dr. Q. Ping Dou)
1999-2002 David M. Smith, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine (graduated; Ph.D. Advisor: Dr. Q. Ping Dou)
2000-2004 Kenyon Daniel, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine (Graduated; Ph.D. Advisor: Dr. Q. Ping Dou)
2001-2005 Deborah Kuhn, Cancer Biology Ph.D. Program (IOP), University of South Florida College of Arts and Sciences (Advisor: Dr. Q. Ping Dou). Graduated in November, 2004.
2002-2003 Audrey Burns, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine (Advisor: Dr. Q. Ping Dou)
2002-2003 Sam Falsetti, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine (Advisor: Dr. Q. Ping Dou)
2003 Bonnie Goodwin, Department of Biochemistry & Molecular Biology, University of South Florida College of Medicine (Advisor: Dr. Duane Eichler)
2004 Kristin Landis, Cancer Biology Program, Wayne State University (Advisor: Dr. Q. Ping Dou)
2005 Vesna Minic, Cancer Biology Program, Wayne State University (Advisor: Dr. Q. Ping Dou)
2006- Mike Frezza, Cancer Biology Program, Wayne State University (Advisor: Dr. Q. Ping Dou)

Comprehensive Examination Committees
1994 Xiang Gao, Pharmacology, University of Pittsburgh School of Medicine
1995 Jeff Phillips, Pharmacology, University of Pittsburgh School of Medicine
1995 Chialin Cheng, Pharmacology, University of Pittsburgh School of Medicine
1995 Cheryl Fattman, Pharmacology, University of Pittsburgh School of Medicine
1996 Marni Brisson, Pharmacology, University of Pittsburgh School of Medicine
2003 Deborah Kuhn, Cancer Biology Ph.D. Program, University of South Florida College of Arts and Sciences

Research Associates and Others
2006-present Guoqing Shi, Ph.D., Visiting Scholar
2006-present Nivedita Tiwari, M.S., Sr. Research Assistant
2005-present Huanjie Yang, Ph.D., Post-Doctoral Fellow
2004-present Cindy (Qiuzhi) Cui, Technician
2004-present Marciana Norris, Administrative Assistant (Supervisor: Dr. Q. Ping Dou)
2003-present Di Chen, Ph.D., Research Associate
2005-present Jaiwei Ren, Technician

2006 Lihua Li, M.D., Visiting Scholar
2005-2006 Haiyan Pang, Ph.D., Research Associate
2005 Alejandro Diez, M.D., Physician Intern
2004-2005 Shirley Adanta Orlu, Research Assistant
2005-2005 Yezhou Sun, Student Assistant
2004-2005 Kenyon Daniel, Ph.D., Post-Doctoral Fellow
2003-2004 MaryAnn Sparkman, Administrative Assistant (Supervisor: Dr. Q. Ping Dou)
2003-2004 Mohammad Bhuiyan, Ph.D., Research Associate
2000-2003 Aslamuzzaman Kazi, Ph.D., Research Associate
2002 Robin Shear, Research Volunteer
2000-2002 Sherry Zhong, Research Assistant
2001-2002 Puja Gupta, Research Volunteer
2000-2001 Hongwei Wang, Research Assistant
2000-2001 Kenyon Daniel, Research Assistant
1998-2000 Sangkil Nam, Ph.D., Research Associate
2000 Gen Wang, Ph.D., Research Associate
1999-2000 Xiaoxia Zhang, M.S., Research Assistant
1998-2000 Gui Gao, Ph.D., Research Associate
1998-2000 Benyi Li, M.D., Research Associate
1998-1999 Roland Cooper, Ph.D., Research Associate
1998 Jieliu Tang, Ph.D., Research Associate
1994-1998 Bing An, Research Associate
1996-1998 Terence F. McGuire, Ph.D., Instructor
1997-1998 Yibing Peng, M.S., Research Assistant
1995-1996 Jia-Rui Jin, Visiting Scholar
1995 Leilei Zhang, Visiting Scholar

GRANT SUPPORT:

Completed support

American Cancer Society Institutional Research Grant. Cyclins, transcription and defective growth control in cancer. Principal Investigator: Qing Ping Dou. 10/01/93-06/30/95.

NIH R01. Molecular Biology of G1/S Regulation in Murine Cells. 07/01/93-06/30/96. Subcontract (Principal Investigator: Arthur B. Pardee)

NIH Shannon Award. Functions of RB-protease(s) in apoptosis. Principal Investigator: Qing Ping Dou. 09/15/95-08/31/97 (replaced by R29 on 04/14/96).

Q. Ping Dou, Ph.D.

NIH R29. Functions of RB-protease(s) in apoptosis. Principal Investigator: Q. Ping Dou (50%). 04/15/96-02/28/01.

NIH R01. Growth Inhibition by IL-2 of IL2R+ oral carcinomas. Principal Investigator: Q. Ping Dou (10%). 04/01/98-03/31/01. (a subcontract from University of Pittsburgh)

Department of the Army Advanced Cancer Detection Center Research Grant (Moffitt). Significance of Bax-Dependent Apoptosis in Prevention and Detection of Human Prostate and Lung Cancer. Principal Investigator: Q. Ping Dou. 10/01/00-9/30/01.

Administrative Supplement from Moffitt Cancer control. Co-Principal Investigator: Q. Ping Dou.

Administrative Supplement from Moffitt Foundation. Co-Principal Investigator: Q. Ping Dou.

Agreement from University of North Taxes. Co-Principal Investigator: Q. Ping Dou.

NIH R03. Tea Targeting Proteasome: A Role in Cancer Prevention. Principal Investigator: Q. Ping Dou (10%). 07/01/01-06/30/03.

Supplement for Correlative Studies Related to estrogen Receptor Negative (ER-negative) Breast Cancer (Moffitt CCOP Research Base). PI: Krischer; Co-Investigator: Q. Ping Dou.

U10 CA81920. A Clinical Trial of the Action of Isoflavones in Breast Neoplasia: Administration Prior to Mastectomy or Lumpectomy - A Pilot Study. PI: Krischer; Co-Investigator: Q. Ping Dou. 12/01/01-11/30/03

U10 CA81920. The Specific Role of Isoflavones in reducing Prostate Cancer Risks. PI: Krischer; Co-Investigator: Q. Ping Dou. 12/01/01-11/30/03

U10 CA81920. A Randomized Pilot Clinical Trial of the Action of Isoflavones and Lycopene in Localized Prostate Cancer: Administration Prior to radical Prostatectomy. PI: Krischer; Co-Investigator: Q. Ping Dou. 12/01/01-11/30/03

Approved but not funded

American Cancer Society. Induction of an RB-associated phosphatase and cancer cell apoptosis (Score: the second decile). Principal Investigator: Q. Ping Dou. 01/01/97-12/31/99.

American Institute for Cancer Research. Tea polyphenols target proteasome-mediated Bax degradation pathway: Significance in prostate cancer prevention and treatment (Score: 2.92). Principal Investigator: Q. Ping Dou. 02/01/00-01/31/03.
Present support

NIH R01. Roles of polymorphic COMT, tea polyphenols and proteasome in cancer prevention. 20% Effort (PI: Q. Ping Dou). 04/01/06-03/31/11.

NIH R01. N-Thiolated β-Lactams. Co-Principal Investigator: Q. Ping Dou (5%) (PI: Ed Turos). 03/01/02-02/28/07. Total Direct Costs (to Dou lab)

DOD Breast Cancer Research Program-Concept Award. Examination of potential anti-tumor activity of N-thiolated β-lactam antibiotics in nude mice bearing human breast tumors. 5% Effort (PI: Q. Ping Dou). 10/01/04-09/30/06.

NIH R03. The Proteasome as Molecular Target of Grape Polyphenols. 5% Effort (PI: Q. Ping Dou). 12/01/04-11/30/06.

Wayne State University President’s Research Enhancement Program Proposal. Enhancing chemo- and photodynamic therapy in breast cancer using nanotechnology. (Co-I: Q. Ping Dou; PI: Jayanth Panyam). 06/01/06-05/31/08.

VA Merit. Ubiquitin Protease System in Malignant Pleural Mesothelioma. 10% Effort. (Co-I: Q. Ping Dou; PI: Anil Wali). 09/01/06-08/31/10.

NIEHS P50 ES012395. Center for Urban African American Health. 3.0% Effort (Co-I: Q. Ping Dou; PI: John Flack). 06/01/05-05/31/07.

T32-CA09531-19 NIH Training Grant. “Training Program in the Biology of Cancer" (Ms. Kristin R. Landis-Piwowar; Mentor: Q. Ping Dou) 09/01/05-8/31/07.

NCI/NIH the Cancer Center Support Grant (PI: Ruckdeschel). Population Studies & Prevention Program (Program PI: Schwartz; Co-I: Q. Ping Dou, 5%) 10/01/05-9/31/10.

CellQuest, Inc. CellQuest, A Musaceas Plant Extract: Implications in cancer prevention. Principal Investigator: Q. Ping Dou. 10/01/02-09/30/06. (Approved)

Karmanos Cancer Institute Startup funds. Principal Investigator: Q. Ping Dou. 08/01/03 -.
Pending support

NIH R01. Elucidation of molecular mechanisms for the ubiquitin-proteasome pathway in malignant pleural mesothelioma (Co-I: Q. Ping Dou; PI: Anil Wali). 10/01/05-9/30/10.

NIH R21. Molecular Study on Novel NCI Potential Anti-tumor Drugs. 15% Effort (PI: Q. Ping Dou). 04/01/05-03/31/07.

NIH R03. Targeting tumor endogenous copper with clioquinol. 5% Effort (PI: Q. Ping Dou). 07/01/05-06/30/07.

NIH R21. Dual-agent nanoparticles to overcome drug resistance. 5% Effort (Co-PI: Q. Ping Dou; PI: Jayanth Panyam). 07/01/05-06/30/07.

Alliance For Cancer Gene Therapy. Dual-agent nanoparticles to overcome drug resistance. 5% Effort (Co-PI: Q. Ping Dou; PI: Jayanth Panyam). 07/01/05-06/30/07.

Total Direct Costs: $449,991; Total Indirect Costs: $44,999

DOD Breast Cancer Research Program-Concept Award. Determination of potential anticancer activity of synthetic acetylated EGCG analog prodrugs in nude mice bearing human breast tumor xenografts. 5% Effort (PI: Q. Ping Dou). 07/01/05-06/30/06.

DOD Breast Cancer Research Program-Concept Award. Synchronized Gene Silencing and Drug Delivery to Overcome Drug Resistance in Breast Cancer. 5% Effort (Co-PI: Q. Ping Dou; PI: Jayanth Panyam). 07/01/05-06/30/06.

NIH R01. Synthesis and evaluation of prodrugs of green tea polyphenol EGCG analogs. 20% Effort (PI: Q. Ping Dou). 12/01/05-11/30/10.

DOD Prostate Cancer Research Program-Idea Development Award. MOLECULAR TARGETS OF NOVEL NCI POTENTIAL ANTICANCER DRUGS IN HUMAN PROSTATE CANCER CELLS. 20% Effort (PI: Q. Ping Dou). 10/01/05-09/30/08.

The Michigan Technology Tri-Corridor Fund, Fiscal Year 2005 Competition. DUAL-AGENT NANOPARTICLES TO OVERCOME DRUG RESISTANCE. 5% Effort (Co-PI: Q. Ping Dou; PI: Jayanth Panyam). 07/01/05-06/30/07.

(to Dou Lab)
Q. Ping Dou, Ph.D.

DOD Breast Cancer Research Program/IDEA Award. The potential use of the anti-alcoholism drug disulfiram in breast cancer prevention and treatment. 15% Effort (PI: Q. Ping Dou). 01/01/06-12/31/08.

DOD Prostate Cancer Research Program/Physician Research Training Award. Novel organic copper complex PDC-Cu for molecular therapy of prostate cancer facilitated by PET imaging (PI: Fangyu Peng; Mentor: Q. Ping Dou). 10/01/05-09/30/10.

Susan Komen Foundation. Nanoparticle-mediated combination photodynamic and chemotherapy to overcome refractory tumors. 5% Effort (Co-PI: Q. Ping Dou; PI: Jayanth Panyam). 05/01/06-04/30/08.

Wilson Foundation. Targeting tumor endogenous copper with the antibiotic clioquinol: A novel approach for cancer-specific killing with no or low toxicity. 15% Effort (PI: Q. Ping Dou). 01/01/06-12/31/07.

VA Merit. Ubiquitin Protease System in Malignant Pleural Mesothelioma. 10% Effort. (Co-I: Q. Ping Dou; PI: Anil Wali).

NIH R01. Copper as a novel target for determining fate of AR and prostate cancer cells. 20% Effort (PI: Q. Ping Dou). 07/01/06-06/30/11.

NIH R21 (resubmission). Dual-agent nanoparticles to overcome drug resistance. 5% Effort (Co-PI: Q. Ping Dou; PI: Jayanth Panyam). 07/01/06-06/30/08.

NIH R01. The Chinese Thunder of God Vine: Active Components & Biological Targets in Cancer. 20% Effort (PI: Q. Ping Dou). 12/01/06-11/30/11.

DOD Breast Cancer Research Program-Concept Award. Chemosensitization of human breast cancer cells by an active compound purified from the Chinese medicine Thunder of God vine. 5% Effort (PI: Q. Ping Dou). 07/01/06-06/30/07.

NIH R01. Maspin in Hormone Refractory Prostate Cancer Intervention (Co-I: Q. Ping Dou, 5%; PI: Shijie Sheng). 12/01/06-11/30/11.
Q. Ping Dou, Ph.D.

NIH R01 (resubmission). Elucidation of molecular mechanisms for the ubiquitin-proteasome pathway in malignant pleural mesothelioma (Co-I: Q. Ping Dou; PI: Anil Wali). 12/01/06-11/30/11.

MICHIGAN ECONOMIC DEVELOPMENT CORPORATION (MEDC). Development of natural pharmaceuticals to protect against low-intensity radiation exposure. 5% Effort (Co-PI: Q. Ping Dou; PI: Michael C Joiner). 10/01/06-09/30/09.

DOD Prostate Cancer Research Program-Idea Development Award. Targeting the proteasome/ NFκB/ Androgen receptor-mediated survival pathway to chemosensitize human prostate cancer cells. 20% Effort (PI: Q. Ping Dou). 12/01/06-11/30/09.

NIH R21 (resubmission). Dual-agent nanoparticles to overcome drug resistance. 5% Effort (Co-PI: Q. Ping Dou; PI: Jayanth Panyam). 07/01/07-06/30/09.
