Received 25 July 2002; accepted 28 August 2002; published XX Month 2002.

[1] Secondary circulation, referring to the motion relative to a basic flow (geostrophic and hydrostatic balanced), occurs often in the ocean such as deep convection and circulations driven by fronts and eddies. It affects the general circulation and the mass, heat, salt, and energy balance. The oceanic secondary circulation is difficult to measure directly, but is easy to be identified by pseudo-vorticity using routine observations. A C-vector method, commonly used in atmospheric mesoscale moist frontogenesis, is applied to oceanography for identifying frontal secondary circulation in Fram Strait using Conductivity-Temperature-Depth data collected during a large-scale hydrographic survey on R/V Valdivia cruise-54 of the eastern Greenland Sea and Fram Strait from 16 March to 5 April 1987. Possible application of this method to large-scale motion is also discussed. 1. Introduction

[2] Fram Strait (Figure 1) is the only deep connection between the Arctic Ocean and the rest of the world ocean through the Greenland Sea, Iceland Sea, and Norwegian Sea (GIN Sea). Water masses in Fram Strait are imported from the neighboring Atlantic and polar oceans, and are encountered in various stages of modification. The North Atlantic Water (NAW) is relatively warmer and saline (T > 2°C, S > 34.9 ppt). The Polar Water (PW) is cooler and fresher (T < 0°C, S < 34.7 ppt) [van Aken et al., 1991]. Analyzing 1984 marginal ice zone experiment observations in Fram Strait, Gascard et al. [1988] found that the West Spitsbergen Current and the East Greenland Current are two main generators for eddies in Fram Strait.

[3] In the transition, different water masses interface and form frontal zones that not only separate water bodies with different hydrographic characteristics but also the regional biological systems. The different water masses encountered in the GIN Sea and Fram Strait often form fronts. The Arctic front or frontal zone is oriented more or less meridionally. It separates the warm and salty NAW in the Norwegian and West Spitsbergen currents from the cooler and fresher Arctic Water (AW) [Dietrich, 1969]. After analyzing hydrographic data along 74°45′N in February 1989 during cruise VA78 of R/V Valdivia, van Aken et al. [1991] identified four Arctic fronts south of Fram Strait. The physical-biological effect arises from the significant vertical component of the 3D ageostrophic flow (or called the secondary circulation) associated with the fronts, where vertical upward motion may act as a fertilizer of the upper water column. A better knowledge of the secondary circulation is therefore crucial. However, direct measurement of the secondary circulation in the ocean is difficult.

[4] Use of vorticity for depicting 3D secondary circulation is popular in meteorology. For example, vertical vorticity component can be used to describe gyres and eddies and horizontal vorticity component can be used to depict the vertical circulation. The Q-vector concept proposed by Hoskins et al. [1978] and related analysis methods on the base of quasi-geostrophic theory have been very useful in understanding and diagnosing the frontal secondary circulation. However, the barotropic part of the rotational ageostrophic flow is excluded in the Q-vector equation. To overcome this weakness, Xu [1992] proposed a C-vector to explain atmospheric mesoscale moist frontogenesis. However, the C-vector analysis hasn’t been applied to physical oceanography yet. This study shows the usefulness of the C-vector in diagnosing three-dimensional oceanic secondary circulations from observational data.

2. C-Vector

[5] Let (x, y) be the horizontal coordinates and z the vertical coordinate. With the Boussinesq approximation, the geostrophic velocity (ug, vg) is related to the density through the thermal wind relation,

\[ f \frac{\partial u_g}{\partial z} = -\frac{\partial b}{\partial y}, \quad f \frac{\partial v_g}{\partial z} = \frac{\partial b}{\partial x}, \quad b = -g \frac{\partial \rho}{\partial z} \]  

where \( \rho \) = \( \rho - \rho_0 \) and (\( \rho_0 \)) are the in-situ density and characteristic density. The variable b is usually called the buoyancy. The total flow, \( \mathbf{V} = (u, v, w) \), is decomposed into geostrophic and ageostrophic parts: \( \mathbf{V} = \mathbf{V}_g + \mathbf{V}_{ag} \). If the advection of momentum and buoyancy is dominated by the geostrophic advection (i.e., quasi-geostrophic system),

\[ \mathbf{V} \cdot \nabla \mathbf{V} \approx \mathbf{V}_g \cdot \nabla \mathbf{V}_g, \quad \mathbf{V} \cdot \nabla b \approx \mathbf{V}_g \cdot \nabla b, \]  

the ageostrophic velocity is determined by

\[ -f v_{ag} = \frac{1}{\rho_0} \frac{\partial X}{\partial z} \left( \frac{\partial}{\partial h} + V_g \cdot \nabla \right) u_g, \]

the secondary circulation is determined by three forcing
where
where (X, Y) and B are the vertical turbulent momentum and
buoyancy fluxes (downward positive), and N is the Brunt-
Veisala frequency.

Cross derivatives among (3)–(5) lead to the definition of
psuedovorticity [Xu, 1992],

where

are components of C-vector. Thus, the pseudovorticity of
the secondary circulation is determined by three forcing
factors: (a) geostrophic forcing (i.e., distinct water masses
across the front), −f∂(u_{x}, v_{y})/∂(y, z), −f∂(u_{y}, v_{x})/∂(z, x), −f∂(u_{z}, v_{x})/∂(x, y), (b) turbulent momentum flux (X, Y), and
(c) buoyancy flux (B). In the upper ocean, the last two
factors are mainly caused by the surface wind stress and
buoyancy flux. As pointed by Xu [1992], the C-vector is the
ageostrophic vortex line (Figure 2) whose horizontal
components (C_{x}, C_{y}) represent the secondary circulation in
vertical cross-section.

Observations show generally well-mixed upper ocean
by turbulent motion. The transition between the turbulent
mixed layer and the stratified water below is a thin
entrainment zone with large gradients of density and velocity. All
turbulent fluxes are usually assumed to vanish below the
ocean mixed layer. The mixed layer depth h is defined as the
depth above which temperature, salinity, or velocity (geo-

Figure 1. Geography of East Fram Strait, coordinate system, and CTD stations of R/V Valdivia cruise 54 in Fram
Strait from March 16 to April 5, 1987.

f\mu_{y} = \frac{1}{\rho_{0}} \frac{\partial Y}{\partial z} \left( \frac{\partial}{\partial t} + V_{e} \cdot \nabla \right) v_{y},

N^{2}w_{y} = \frac{\partial B}{\partial z} - \left( \frac{\partial}{\partial t} + V_{e} \cdot \nabla \right) b,

where (X, Y) and B are the vertical turbulent momentum and
buoyancy fluxes (downward positive), and N is the Brunt-
Veisala frequency.

Cross derivatives among (3)–(5) lead to the definition of
psuedovorticity [Xu, 1992],

\frac{\partial}{\partial t} (N^{2}w_{y}) - \frac{\partial}{\partial z} (f^{2}u_{x}) = 2C_{x}, \quad (6a)

\frac{\partial}{\partial z} (f^{2}u_{x}) - \frac{\partial}{\partial x} (N^{2}w_{y}) = 2C_{y}, \quad (6b)

\frac{\partial}{\partial x} (f^{2}u_{x}) - \frac{\partial}{\partial y} (f^{2}u_{y}) = 2C_{z}, \quad (6c)

where

\begin{align*}
C_{x} &= -f \frac{\partial (u_{x}, v_{y})}{\partial (y, z)} + \frac{1}{2} \frac{\partial}{\partial z} \left( f \frac{\partial X}{\partial z} + \frac{\partial B}{\partial y} \right), \quad (7a) \\
C_{y} &= -f \frac{\partial (u_{y}, v_{x})}{\partial (z, x)} + \frac{1}{2} \frac{\partial}{\partial x} \left( f \frac{\partial Y}{\partial x} + \frac{\partial B}{\partial y} \right), \quad (7b) \\
C_{z} &= -f \frac{\partial (u_{z}, v_{x})}{\partial (x, y)} - f \frac{\partial}{\partial z} \left( f \frac{\partial X}{\partial z} + \frac{\partial Y}{\partial y} \right) - \frac{1}{2} \frac{\partial}{\partial z} B \frac{\partial Y}{\partial y}, \quad (7c)
\end{align*}

are components of C-vector. Thus, the pseudovorticity of
the secondary circulation is determined by three forcing
factors: (a) geostrophic forcing (i.e., distinct water masses
across the front), −f∂(u_{x}, v_{y})/∂(y, z), −f∂(u_{y}, v_{x})/∂(z, x), −f∂(u_{z}, v_{x})/∂(x, y), (b) turbulent momentum flux (X, Y), and
(c) buoyancy flux (B). In the upper ocean, the last two
factors are mainly caused by the surface wind stress and
buoyancy flux. As pointed by Xu [1992], the C-vector is the
ageostrophic vortex line (Figure 2) whose horizontal
components (C_{x}, C_{y}) represent the secondary circulation in
vertical cross-section.

Observations show generally well-mixed upper ocean
by turbulent motion. The transition between the turbulent
mixed layer and the stratified water below is a thin
entrainment zone with large gradients of density and velocity. All
turbulent fluxes are usually assumed to vanish below the
ocean mixed layer. The mixed layer depth h is defined as the
depth above which temperature, salinity, or velocity (geo-

Figure 2. C-vector and the secondary circulation.
surface mixed layer is depth-independent [see (8a)]. Since $B_{-b}$ is computed from the surface turbulent fluxes ($\tau_x$, $\tau_y$) and $B_0$ (bulk models), the atmosphere may control the scale of the horizontal variability of $B_{-b}$ and $B_0$. The atmosphere has most of its energy in scales of several hundreds of kilometers and longer, it is reasonable to assume that

$$\frac{\partial}{\partial z} \left( \frac{\partial \tilde{B}}{\partial y} \right) = 0, \quad \frac{\partial}{\partial z} \left( \frac{\partial \tilde{B}}{\partial x} \right) = 0, \quad (10)$$

across the Arctic front, and therefore the horizontal C-vector components are computed from the geostrophic forcing only. The geostrophic forcing has been recognized as the major factor to cause the atmospheric frontal secondary circulation [Hoskins et al., 1978; Xu, 1992]. It may also be important for oceanic frontal secondary circulation.

3. Data

[9] Conductivity-Temperature-Depth (CTD) data, collected during a large-scale hydrographic survey on RV VALDIVIA cruise-54 of the eastern Greenland Sea and Fram Strait from 16 March to 5 April 1987 [Quadsafel and Ungewiss, 1988], are used to illustrate the advantage of using the C-vector method in analyzing oceanic secondary circulation. The major task of this cruise was to map the vertical distribution of temperature, salinity, and dissolved oxygen in the Greenland Sea as a measure of the large-scale circulation and transport. A secondary objective was to search active convection events. Along seven sections a total of 73 CTD profiles were taken (Figure 1). Four of these sections crossed the Arctic Front that separates the Greenland Sea gyres from the warm and saline northward flowing Norwegian Atlantic Current and the West Spitsbergen Current. The sections were designed to form three closed boxes to allow calculation of transport budgets. Usual station spacing was 56 km except along Fram Strait section at 78° 25′N and across the Hovgaard Fracture Zone, where the spacing was decreased to less than 28 km. All CTD profiles were run to within 5 m of the bottom.

4. Potential Density

[10] The potential density excess referred to 500 db computed from the CTD data shows the existence of multi-frontal zones in Fram Strait. For example, three Arctic fronts are identified from the north cross section (Stations 44 to 51) (Figure 3): (a) eastern front occurring near the west coast of Spitsbergen (Stations 49–51), (b) shallow western front (above 160 m depth) occurring near 0° longitude (Stations 44–46) in the Hovgaard Fracture Zone, and (c) a deep mid-front (Stations 47–48) in the north Knipovich Ridge. In the south cross-section in Fram Strait (Stations 26–41, Figure 4), only two fronts can be identified with a strong and shallow front in the Boreas Basin (Stations 34–36) and a weak deep front near the west coast of Spitsbergen (Stations 26–30).

[11] Usually, upward (downward) bending of isopycnals is used to identify upward (downward) motion. For example, in Figure 3 the isopycnals bend upward near Stations 46–47, 49, and downward near Stations 45 (to 250 m depth), 48 (surface to 1000 m depth), and 51. Since such identification is very qualitative, it is hard to sketch the secondary circulation pattern and strength. Is it possible to get quantitative information using the same density data? The answer is ‘yes’ because the secondary circulation can be represented by the horizontal component of the C-vector (i.e., horizontal pseudovorticity).

5. Horizontal Pseudovorticity

[12] Taking 2500 db as the reference level, the geostrophic current ($u_g$, $v_g$) is computed from density, and then the horizontal components of the C-vector are computed from ($u_g$, $v_g$). Figure 5 shows the $x$-component of the non-dimensional pseudovorticity ($C_x/f^2$) along the north cross section (Stations 44 to 51). Looking toward north the
positive (negative) values of $C_x/f^2$ imply a clockwise (anticlockwise) circulation. Two clockwise and two anticlockwise secondary circulations are identified. Among them, the clockwise secondary circulations are deeper than the anticlockwise secondary circulations (depth less than 60 m). Note that in this study, the geostrophic current is computed as 2500 db to be assumed as the level of no motion. This may affect the C-vector computation especially in large horizontally sheared barotropic current such as in Fram Strait [Fahrbach et al., 2001]. However, Figure 5 keeps almost the same as 2000 db is chosen as the reference level.

The most striking feature is the existence of a shallow (surface to 60 m), strong anticlockwise secondary circulation with a minimum value of $C_x/f^2$ around $-9.01$, located near the Knipovich Ridge (Stations 46–48). We may call it the Knipovich cell. Its upward and downward branches are connected to two clockwise secondary cells from the east (upward branch) and west (downward branch). Below the Knipovich cell between 340 and 1000 m depth, there is a very weak clockwise vorticity (a maximum value of $C_x/f^2$ around 0.01).

East of the Knipovich cell, a deep (surface to 1000 m), clockwise secondary circulation with a maximum pseudovorticity of 1.95 is identified near the West Spitsbergen slope (Stations 48–50). We may call it the West Spitsbergen cell. Its downward branch follows the slope. Its upward branch connects to the Knipovich cell. West of the Knipovich cell, a relatively shallow (to 250 m depth),

Figure 4. Potential density excess referred to 500 db along the south cross-section in Fram Strait (from Stations 26–41).

Figure 5. Nondimensional horizontal pseudovorticity, $C_x/f^2$, along the north cross-section in Fram Strait (from Stations 44–51).
clockwise secondary circulation with a maximum pseudovorticity of 3.16 is identified in the Hovgaard Fracture Zone (Stations 44–46). Downward branch connects to the Knipovich cell (Stations 46–48). The upward branch is located at Stations 44–45. We may call it the Hovgaard cell. Since the horizontal pseudovorticity ($C_{\theta}/f^2$) represents the secondary circulation around the x-axis. The larger the $C_{\theta}/f^2$, the stronger the secondary circulation is. Strong upwelling is identified between the Knipovich Ridge and the West Spitsbergen slope.

6. Possible Application to Large-Scale Motion

[15] For large-scale motion, the horizontal variability of $B_{\theta h}$ and $B_0$ cannot be assumed as zero, and (10) is not valid. However, Equation (9) is still valid since it does not depend on the horizontal scale. The C-vector for the large-scale motion can be written by

$$C_x = -f \frac{\partial (u_x, v_y)}{\partial (y, z)} + \frac{1}{2} \frac{\partial}{\partial z} \left( \frac{\partial B}{\partial y} \right),$$

$$C_y = -f \frac{\partial (u_x, v_y)}{\partial (z, x)} - \frac{1}{2} \frac{\partial}{\partial x} \left( \frac{\partial B}{\partial y} \right),$$

$$C_z = -f \frac{\partial (u_x, v_y)}{\partial (x, y)} \frac{f}{2} \frac{\partial}{\partial z} \left( \frac{\partial X}{\partial y} + \frac{\partial Y}{\partial x} \right) - \frac{\beta}{2} \frac{\partial Y}{\partial z},$$

where the thermohaline circulation can be represented by the horizontal components ($C_x$, $C_y$) and the wind-driven circulation can be represented by the vertical component $C_z$. The overturning streamfunction can be obtained from ($C_x$, $C_z$) by solving the Poisson equation with the C-vector components as the forcing terms.

7. Conclusions

[16] This paper illustrates the usefulness of the C-vector method in identifying the secondary circulations in Fram Strait frontal zone. However, this method might be used to diagnose the large-scale motion such as the thermohaline circulation represented by the horizontal components ($C_x$, $C_y$) and the wind-driven circulation represented by the vertical component $C_z$. The overturning streamfunction can be obtained from ($C_x$, $C_y$) by solving the Poisson equation with the C-vector components as the forcing terms.

[17] Acknowledgments. The author would like to thank Detlef Quadfasel and Manfred Ungewiss for providing the CTD data from R/V Valdivia cruise 54 for the GIN Sea and Fram Strait in March—April 1987 during the Maginal Ice Zone Experiment (MIZEEX)-1987. The Office of Naval Research, Naval Oceanographic Office, and Naval Postgraduate School sponsored this research.
