Acoustic and Seismic Sensor Placement (ASSP) Application Programming Interface (API) Version 1.0

David Marlin
Computational and Information Sciences Directorate, ARL

and

Shane Thomas
Physical Science Laboratory, New Mexico State University
In this report, an Acoustic and Seismic Sensor Placement (ASSP) application programming interface (API) for acoustic sensor placement is described. The API is implemented in both C++ and Java, with functionality for the later provided through the former via the Java Native Interface (JNI). This API is based on the Sensor Performance for Battlefield Environments (SPEBE) API, but the classes are not extensions of the SPEBE API. Instead, they include SPEBE objects as encapsulated data, accessible only through the methods. This serves the dual purpose of allowing a more natural interface dedicated to sensor placement, while at the same time protecting the user from inadvertent misuse of the more general SPEBE API. The ASSP interface includes classes to define the environment, including atmospheric, elevation, and ground characterization, define sensor locations and characteristics, compute the detection probability of these sensors for specified source type, and manage the resulting data as both a regularly-spaced grid and as a set of detection-probability contours.

Summary

The Sensor Performance Evaluator for Battlefield Environments (SPEBE) application programming interface (API) provides an outstanding suite of computational tools for modeling the performance of acoustic sensors in a wide range of operational environments and development situations. This includes the development of acoustic sensor placement decision aids to assist mission planners in determining the optimum distribution of sensors for a given detection objective. Unfortunately, the use of the SPEBE API requires a detailed knowledge of the SPEBE architecture and significant expertise in acoustic propagation, acoustic signatures and sensors, and meteorology.

The purpose of the Acoustic and Seismic Sensor Placement (ASSP) API is to present the programmer with a subset of SPEBE capabilities tailored to the specific needs of an operational decision aid. The objectives of the API are to simplify the process of setting up and generating required calculations while at the same time reducing the possibility of error resulting from improper configuration and sequencing of SPEBE calculations. To accomplish both objectives, the API encapsulates the SPEBE objects rather than extending the SPEBE classes. This allows the ASSP API complete flexibility in its class design while simultaneously preventing the direct manipulation of SPEBE methods and data.

The API is based on five classes centered on definition of the acoustic and seismic environment, estimation of the effects of this environment on acoustic and seismic propagation, definition of acoustic and seismic sensor configurations, prediction of acoustic and seismic detection probabilities, and representation of the resulting data. These classes are described in detail in this report.
INTENTIONALLY LEFT BLANK.
1. Introduction

The Acoustic and Seismic Sensor Placement (ASSP) Application Programmer Interface (API) provides the tools to develop acoustic sensor placement decision aids*. It is built upon the Sensor Performance Evaluator for Battlefield Environments (SPEBE) API1, tailored to the specific needs of acoustic sensor placement planning. While the SPEBE API provides a general set of classes to invoke all the acoustic propagation and sensor performance modeling capabilities of SPEBE, ASSP provides a smaller set of classes, of reduced complexity, designed specifically to support sensor placement planning. Thus, the user of the ASSP API can concentrate on the development of the sensor placement decision aid without the need to master the full range of the SPEBE API, which requires far more expertise in acoustics and meteorology.

The API is implemented in both C++ and Java, with the functionality of the Java implementation provided through the C++ implementation via the Java Native Interface (JNI).

At the heart of sensor placement planning is the calculation of probability of detection (PD), which is dependent upon the propagation environment, type and locations of sensors, and acoustic and seismic signatures of sources and backgrounds. Thus, the API is set up to streamline the description of the environment, sources, backgrounds, and sensors, to invoke PD calculations, and to represent the resulting data as both regularly spaced grids and contours.

This is done via the five ASSP classes, which are not extensions of the SPEBE API classes, but rather encapsulate them and provide the methods necessary to manage them internally. The five classes are organized to facilitate the sensor placement tasks, and insulate the user from the more general, and therefore complex, classes of the SPEBE API.

1.1 Four Steps of Detection-Probability Prediction

The overall process of sensor detection-probability prediction can be divided into four steps:

1. Definition of the propagation environment, including the following:
   - coordinates, time zone, and terrain elevations of the region of interest
   - predominant ground characterization of the region of interest
   - predominant meteorological conditions in the region of interest

*It was originally developed to support the Networked Sensors for the Future Force (NSFF) Advanced Technology Demonstration, hence the name SPEBE4NSFF.

2. Estimation of acoustic and seismic propagation effects, depending on the environmental characterization and the target and sensor heights (but not the specific type of target or sensor)

3. Definition of the sensor configuration, including number, type, and location of a set of sensors

4. Prediction of detection probabilities, depending on the following:
   - the environment defined in step 1
   - the propagation effects defined and generated in step 2
   - the sensor set defined in step 3
   - the specific type of target of interest (but not its location)
   - the selection of active sensors within the sensor set

1.2 Five Classes of ASSP

ASSP includes five classes: four to perform the four steps defined above, and a fifth to encapsulate the detection probability data generated by step 4. The data can be retrieved from the fifth class either as a two-dimensional (2-D) grid or as a set of contours. The five classes (in order of the steps) are as follows:

1. **SPEBE_Environment**
2. **SPEBE_PropagationTable**
3. **SPEBE_SensorSet**
4. **SPEBE_PDCalculator**
5. **ResultGrid**

Refer to the documentation in section 3 of each class for a more detailed description of the class and its methods.

1.3 Miscellaneous

There are several enumerated types associated with the five classes. Refer to section 5.1 or particular class documentation for details.

There are also a few dll housekeeping functions which must be performed, including initialization and termination. Refer to section 5.2 for details.
**Attention**: Use of this library requires the definition of the ABFAHome environment variable, which must point to the directory in which ASSP is installed.

Class constructors and methods that take filename arguments will throw char* exceptions if ABFAHome isn’t defined or files aren’t found.

Each of the five classes had a destructor, which frees a number of internal arrays allocated within the *dll*. It is important to *delete* all objects when they are no longer needed. Failure to adhere to this practice may result in memory failure and crashes.

The source and sensor types described in section 5.1 can be easily expanded or modified. Currently they are a minimal set used for the initial development of the API.

### 1.4 Some Examples

#### 1.4.1 Initialization and Shutdown

Every session must begin with the call

```c
SPEBE_Initialize();
```

and should end with the call

```c
SPEBE_Shutdown();
```

#### 1.4.2 Environment Definition

```c
// instantiate a new SPEBE_Environment, and set up the domain, ground type, seismic type, meteorology
SPEBE_Environment* theEnvironment = new SPEBE_Environment();
theEnvironment->SetDomain(33.0265, 33.1265, -106.239, -106.139, "f:\", 6);
theEnvironment->SetGroundType(Sand);
theEnvironment->SetSeismicType(Desert);
theEnvironment->SetMeteorology(temp, rh, windSpd, windDir, year, day, time, cloudCover);
```

#### 1.4.3 Propagation Table Management

```c
// instantiate a new SPEBE_PropagationTable, and generate a propagation table for an UGS3 sensor and Tracked source
SPEBE_PropagationTable* thePropTable = new SPEBE_PropagationTable(theEnvironment,
    "d:\spebe4nsff\spebe4nsff_develop\debug", "NSFF_Test");
thePropTable->GenerateTable(Human, Tracked);
```
1.4.4 Sensor Definition

```cpp
// instantiate a SPEBE_SensorSet for two Human and one Acoustic
// sensors, and set their coordinates
SPEBE_SensorSet* theSensors = new SPEBE_SensorSet(3, Human);
theSensors->ChangeSensorType(1, Acoustic);
theSensors->SetSensorLocation(0, 33.045, -106.255);
theSensors->SetSensorLocation(1, 33.045, -106.260);
theSensors->SetSensorLocation(2, 33.046, -106.260);
```

1.4.5 Detection Probability Calculations

```cpp
// instantiate a SPEBE_PDCalculator for the propagation tables
// and sensors defined above, for a Tracked target, in
// LightBattle background noise,
// activate all sensors, and calculate their detection probability
SPEBE_PDCalculator* thePDCalculator = new
    SPEBE_PDCalculator(thePropTable,
    theSensors, Tracked, LightBattle);
thePDCalculator->Activate(0);
thePDCalculator->Activate(1);
thePDCalculator->Activate(2);
ResultGrid* theResults3 = thePDCalculator->GetPD();

// deactivate one sensor and calculate the new detection probability
thePDCalculator->Deactivate(2);
ResultGrid* theResults2 = thePDCalculator->GetPD();
```

2. Class List

Table 1 shows the Acoustic Sensor Placement Decision Aid API Class List, which includes the classes, structs, unions, and interfaces with brief descriptions.
3. Class Descriptions

3.1 ResultGrid Class

The ResultGrid class encapsulates the 2-D gridded data returned by SPEBE sensor performance calculations, such as detection probability. It also generates contour plots of the encapsulated data to keep track of the computational grid coordinates, so that the data can be referenced to its location within the computational grid for contour generation. See also PerformanceCalculator.

Table 2 provides the public member functions for the ResultGrid class.
Table 2. Public member functions ResultGrid class.

<td>Return minimum value within the grid.</td>
</tr>
</tbody>
</table>

### 3.1.1 Constructor & Destructor Documentation

**ResultGrid::ResultGrid**

( ResultGrid * theArray )

This function is a copy constructor.

**Parameters:**

- *theArray* - the ResultGrid to be copied
ResultGrid::ResultGrid( double * theData, 
    int numRows, 
    int numCols, 
    CDomain * theDomain, 
    const char * arrayName )

This function instantiates a new ResultGrid with data contained in a linear double*array.
Note: This function assumes the data points are located on the computational grid defined in theDomain. If they are not, the results are unpredictable.

Parameters:
- *array - the returned data to be incorporated into the ResultGrid
- *theDomain - the CDomain object associated the data returned by the m-file
- *arrayName - the name to be associated with the data array

3.1.2 Member Function Documentation

void ResultGrid::GenerateContours( double contourValue )

This function generates a set of contours for the encapsulated data for the specified contourValue.

Parameters:
- contourValue - the contour value

double* ResultGrid::GetContourEasting( int contour )

This function returns the eastings of a specified contour generated by GenerateContours.

Parameters:
- contour - specifies the desired contour

Returns: An array of eastings for the points in the specified contour

double* ResultGrid::GetContourLat( int contour )

This function returns the latitudes of a specified contour generated by GenerateContours.

Parameters:
- contour - specifies the desired contour

Returns: An array of latitudes for the points in the specified contour
int ResultGrid::GetContourLength( int contour )

This function returns the length of a specified contour generated by ResultGrid::GenerateContours.

Parameters:

• contour - specifies the desired contour

Returns: The number of points in the specified contour

double* ResultGrid::GetContourLong( int contour )

This function returns the longitudes of a specified contour generated by GenerateContours.

Parameters:

• contour - specifies the desired contour

Returns: An array of longitudes for the points in the specified contour

double* ResultGrid::GetContourNorthin( int contour )

This function returns the northing of a specified contour generated by GenerateContours.

Parameters:

• contour - specifies the desired contour

Returns: An array of northerings for the points in the specified contour

double ResultGrid::GetGridMax( void )

This function returns the maximum value within the grid.

Returns: The maximum grid value

double ResultGrid::GetGridMin( void )

This function returns the minimum value within the grid.

Returns: The minimum grid value
double ResultGrid::GetGridXY( int xx, int yy )

This function returns the value of the specified grid point.

**Parameters:**
- \( xx \) - X index of specified grid point
- \( yy \) - Y index of specified grid point

**Returns:** The value of the grid point with the specified indices

int ResultGrid::GetNumContours( void )

This function returns the number of contours generated by ResultGrid::GenerateContours.

**Returns:** The number of contours

int ResultGrid::GetNumGridX( void )

This function returns the number of grid points in the X (east-west) dimension.

**Returns:** The number of points in the X dimension

int ResultGrid::GetNumGridY( void )

This function returns the number of grid points in the Y (north-south) dimension.

**Returns:** The number of points in the Y dimension

### 3.2 SPEBE_Environment Class

The **SPEBE_Environment** class describes the general propagation environment of the region-of-interest, which encompasses the following:

- **Domain** (**SetDomain**)
  - coordinates of lower-left and upper-right corners of region-of-interest
  - time zone of lower-left corner
  - terrain elevations of region-of-interest
- Predominant ground type of region (**SetGroundType**, see also **SPEBE_GroundType**)
- Predominant seismological characteristics of region (**SetSeismicType**, see also **SPEBE_SeismicType**)
- Predominant meteorology of region (**SetMeteorology**, see also **TranslateCloudCover**).
Modify the enums `SPEBE_GroundType` and `SPEBE_SeismicType`, and the private methods `GetGroundFileName` and `GetSeismicFileName`, as necessary, to modify ground and seismic types.

A list of the public member functions for `SPEBE_Environment` class is given in table 3 and a list of the static member function for `SPEBE_Environment` class is given in table 4.

Table 3. Public member functions for the `SPEBE_Environment` class.

### 3.2.1 Constructor & Destructor Documentation

**`SPEBE_Environment::SPEBE_Environment(void)`**

This function creates a default environment, using the default files located under the directory defined in the ABFAHome environment variable.

**Warning:** These files are located in the Defaults subdirectory and are read-only. They should not be modified in any way.

**`SPEBE_Environment::SPEBE_Environment(const char * envPath, const char * envName)`**

This function creates the environment saved from a previous `SPEBE_Environment`.

**Parameters:**

- `envPath` - the directory path in which the environment file is located; don’t include final `\`. If NULL, the ABFAHome directory will be used.
- `envName` - the name of the environment file; don’t include a file type

**`SPEBE_Environment::~SPEBE_Environment(void)`**

This function is the destructor.

Note: Always delete a `SPEBE_Environment` object when it is no longer needed.

### 3.2.2 Member Function Documentation

**`void SPEBE_Environment::SaveEnvironment(const char * envPath, const char * envName)`**

This function saves environment to a file.

**Parameters:**

- `envPath` - the directory path in which the environment file is to be stored; don’t include final `\`. If NULL, the ABFAHome directory will be used.
- `envName` - the name of the environment file; don’t include a file type
void SPEBE_Environment::SetDomain( double lowerLeftLat,  
               double upperRightLat,   
               double lowerLeftLon,    
               double upperRightLon,   
               int timeZone )  

This function defines domain: region coordinates and timezone with a flat earth elevation model.

Note: All coordinates are in signed decimal:

- + for east/north, - for west/south
- left of decimal represents degrees, right of decimal represents fraction of a degree

Parameters:

- lowerLeftLat - Latitude of the lower-left corner of the region-of-interest (in signed decimal)
- upperRightLat - Latitude of the upper-right corner of the region-of-interest (in signed decimal)
- lowerLeftLon - Longitude of the lower-left corner of the region-of-interest (in signed decimal)
- upperRightLon - Longitude of the upper-right corner of the region-of-interest (in signed decimal)
- timeZone - the difference between local time of the lower-left corner and Greenwich Mean Time (GMT)
void SPEBE_Environment::SetDomain( double lowerLeftLat, double upperRightLat, double lowerLeftLon, double upperRightLon, const char * DTEDDirectory, int timeZone )

This function defines domain: region coordinates, Digital Terrain Elevation Data (DTED) directory for elevations, and timezone.

Note: All coordinates are in signed decimal:

• + for east/north, - for west/south

• left of decimal represents degrees, right of decimal represents fraction of a degree

Parameters:

• lowerLeftLat - Latitude of the lower-left corner of the region-of-interest (in signed decimal)

• upperRightLat - Latitude of the upper-right corner of the region-of-interest (in signed decimal)

• lowerLeftLon - Longitude of the lower-left corner of the region-of-interest (in signed decimal)

• upperRightLon - Longitude of the upper-right corner of the region-of-interest (in signed decimal)

• DTEDDirectory - a directory containing DTED data, including a file named DMED and a DTED subdirectory. This can be a DTED CD or directory on hard drive, flash disk, etc.

• timeZone - the difference between local time of the lower-left corner and GMT

void SPEBE_Environment::SetGroundType( SPEBE_GroundType groundType )

This function specifies the predominant ground type.

Parameters:

• groundType - The ground type, chosen from SPEBE_GroundType
void SPEBE_Environment::SetMeteorology( double temp,
    double relativeHumidity,
    double windSpeed,
    double windDirection,
    int year,
    int dayOfYear,
    int timeOfDay,
    double cloudCover[3] )

This function specifies the meteorological conditions for the domain.

Parameters:

• temp - surface temperature in degrees Celsius
• relativeHumidity - the surface relative humidity in percent
• windSpeed - the surface wind speed in meters per second
• windDirection - the surface wind direction in degrees (counterclockwise from east?)
• year - the full four digit Gregorian calendar year
• dayOfYear - the day of the year starting from 1 for January 1
• timeOfDay - the time of day in 24-h format starting at midnight = 0.
• cloudCover - a three-element array giving the fractional cloud cover at low, medium, and high elevation. See TranslateCloudCover.

void SPEBE_Environment::SetSeismicType( SPEBE_SeismicType seismicType )

This function specifies the predominant seismological characteristics.

Parameters:

• seismicType - The seismic type, chosen from SPEBE_SeismicType
void SPEBE_Environment::TranslateCloudCover( double cloudCover[3], const char * observation ) [static]

This function extracts cloud cover from an observation string.

**Parameters:**

- *observation* - a National Weather Service local observation string
- *cloudCover* - a three-element array, allocated in the calling program, returning the fractional cloud cover at low, medium, and high elevation.

### 3.3 SPEBE_PDCalculator Class

The **SPEBE_PDCalculator** class generates detection probabilities for a *fixed*

- environment (region and weather: **SPEBE_Environment**);
- background noise level (**SPEBE_NoiseType**);
- target type (**SPEBE_TargetType**), height, and direction; and
- set of sensors (**SPEBE_SensorSet**).

The **SPEBE_PDCalculator** allows individual sensors to be activated and deactivated, and returns detection probabilities for the set of activated sensors, or for any specified sensor regardless of its activation state. Note: All sensors are initially *activated*.

**Attention:** SPEBE_PDCalculator works on a snapshot of the constructor arguments, as does the **SPEBE_PropagationTable**. Thus, any changes to the **SPEBE_SensorSet**, such as location of a particular sensor, will require instantiation of a new **SPEBE_PDCalculator**. Likewise, any changes to the environment require a new **SPEBE_PropagationTable** and in turn a new **SPEBE_PDCalculator**.

The public member functions for the **SPEBE_PDCalculator** class are listed in table 5.
Table 5. Public member functions for the **SPEBE_PDCalculator** class.

<table>
<thead>
<tr>

</tr>
<tr>
<td>void Deactivate (int rcvrIndex)</td>
<td>Deactivates the specified sensor.</td>
</tr>
</tbody>
</table>

### 3.3.1 Constructor & Destructor Documentation

**SPEBE_PDCalculator::SPEBE_PDCalculator** (SPEBE_PropagationTable *table, SPEBE_SensorSet *sensorSet, SPEBE_TargetType targetType, SPEBE_NoiseType noiseType)

This function constructs a PDCalculator for the specified SPEBE_PropagationTable, SPEBE_SensorSet, SPEBE_TargetType, and SPEBE_NoiseType, using the default target height.

**Parameters:**

- **table** - The **SPEBE_PropagationTable** describing the propagation environment and file prefix for the propagation tables to be used in the detection probability calculations.
- **sensorSet** - The **SPEBE_SensorSet** describing the set of sensors for which detection probability calculations will be performed.
- **targetType** - The target type, chosen from **SPEBE_TargetType**
- **noiseType** - The background noise type, chosen from **SPEBE_NoiseType**
This function constructs a PDCalculator for the specified SPEBE_PropagationTable, SPEBE_SensorSet, SPEBE_TargetType, and SPEBE_NoiseType, using a specified target height.

**Parameters:**

- `table` - The SPEBE_PropagationTable describing the propagation environment and file prefix for the propagation tables to be used in the detection probability calculations.
- `sensorSet` - The SPEBE_SensorSet describing the set of sensors for which detection probability calculations we be performed.
- `targetType` - The target type, chosen from SPEBE_TargetType
- `targetHeight` - The target height, in meters
- `noiseType` - The background noise type, chosen from SPEBE_NoiseType

This function is the destructor.

Note: Always delete a SPEBE_PDCalculator object when it is no longer needed.

### 3.3.2 Member Function Documentation

**void SPEBE_PDCalculator::Activate( int rcvrIndex )**

This function returns the detection probability grid for the specified sensor and target height, regardless of active or inactive state, and activates the specified sensor.

**Parameters:**

- `rcvrIndex` - the receiver to be activated; indexing starts at zero.
**void SPEBE_PDCalculator::Deactivate( int rcvrIndex )**

This function deactivates the specified sensor.

**Parameters:**

- *rcvrIndex* - the receiver to be deactivated; indexing starts at zero.

**ResultGrid * SPEBE_PDCalculator::GetPD( int rcvrIndex )**

This function returns the detection probability grid for the active sensors, as determined by Activate and Deactivate, and specified target height returns the detection probability grid for the specified sensor, regardless of active or inactive state.

**Parameters:**

- *rcvrIndex* - the requested receiver; indexing starts at zero.

**Returns:** A ResultGrid object containing the requested detection probability data

**ResultGrid * SPEBE_PDCalculator::GetPD( void )**

This function returns the detection probability grid for the active sensors, as determined by Activate and Deactivate. **NOTE:** All sensors are initially deactivated.

**Returns:** A ResultGrid object containing the requested detection probability data

### 3.4 SPEBE_PropagationTable Class

The **SPEBE_PropagationTable** class generates and manages the propagation tables for a given environment (**SPEBE_Environment**). These tables are used by the **SPEBE_PDCalculator** to calculate detection probabilities. If you want to avoid errors leading to invalid results, make sure you read and understand the documentation for this class.

In addition to generating the propagation tables for a given environment and specified target and sensor types (**SPEBE_TargetType**, **SPEBE_SensorType**), **SPEBE_PropagationTable** saves them under a unique filename in a specified path. If no path is given in the constructor, then the path given by the environment variable ABFAHome will be used.

Two propagation models are available for the calculations: a simple but fast spherical spreading model with ground impedance and a full-wave, split-step parabolic equation. The spherical spreading will account for ground reflection and the spreading of the acoustic wavefront as it expands away from the source, but it will ignore refractive effects of the atmosphere. While this model is very fast, it may give poor results in many cases because the refraction effects are
generally significant. The parabolic equation will include all the effects of the spherical spreading model along with refraction, thus giving much more accurate results. However, it requires considerably more time to complete the calculations.

The spherical spreading model gives reasonable results for a source more than a few hundred meters above the ground, because most of the refractive effects are close to the ground. For sources closer to the ground, the parabolic equation will give much better results. To use the parabolic equation below a specified height, call EnableHiFi(double height). This will automatically invoke the spherical spreading above the specified height and the parabolic equation below that height. To use the spherical spreading model exclusively, regardless of height, call DisableHiFi(void).

In either case, for each table generated, a source and sensor height label will be appended to the file prefix specified in the constructor, and the table will be saved in the file of that name, in the directory specified in the constructor. Thus, a set of tables will be generated and stored in files, depending on the environment and types of sources and sensors specified.

Only the source and sensor heights are important, so a new table may not be generated for each call to GenerateTable, depending upon the heights of the specified source and sensor types and the heights associated with any tables that may have already been generated.

You do not have to explicitly generate any propagation tables (but you do need to instantiate a SPEBE_PropagationTable object). The SPEBE_PDCalculator will generate tables as needed. However, you can generate them if you prefer, so that once you start making detection probability calculations, you won't have any long delays as new tables are generated.

Note: SPEBE_PropagationTable uses a snapshot of the specified SPEBE_Environment. If any changes are made to the environment after instantiation of the SPEBE_PropagationTable, they will not be incorporated. Thus, a new SPEBE_PropagationTable must be instantiated for the modified environment. The intent is that a given SPEBE_PropagationTable represents a given environmental state, and different environmental states should be associated with different filenames.

Attention: Propagation tables are permanently saved for reuse. If propagation table files with the specified prefix, in the specified directory, already exist, they will be reused. This allows tables generated in a previous session to be reused without recomputing, but also calls for careful use of file prefix naming and table housekeeping. Be sure to read the warnings at the bottom of this section.
Reusing Tables and/or File Prefixes

To reuse tables at a later session, use one of two options:

- First option:
  1. Before terminating a session, save the `SPEBE_PropagationTable` (which includes the associated environment) using `SPEBE_PropagationTable::SaveEnvironment(void)`.
  2. In the new session, generate a new `SPEBE_PropagationTable` using `SPEBE_PropagationTable::SPEBE_PropagationTable(char* tablePath, char* tablePrefix)` with the same `tablePath` and `tablePrefix` as was used in the previously saved `SPEBE_PropagationTable`.

- Second option:
  1. Before terminating the session, save the `SPEBE_Environment` used to generate the `SPEBE_PropagationTable`, using `SPEBE_Environment::SaveEnvironment(char* envPath, char* envName)` with any desired `envPath` and `envName`.
  2. In the new session, generate a new `SPEBE_Environment` using `SPEBE_Environment::SPEBE_Environment(char* envPath, char* envName)` with the same `envPath` and `envName` used to save in the previous session.
  3. Then, generate a new `SPEBE_PropagationTable` using `SPEBE_PropagationTable::SPEBE_PropagationTable(SPEBE_Environment* theEnvironment, char* tablePath, char* tablePrefix)` using the `SPEBE_Environment` just generated, and the same `tablePath` and `tablePrefix` used by the `SPEBE_PropagationTable` in the previous session.

**Warning:** The second option will give invalid results if changes were made to the `SPEBE_Environment` after the `SPEBE_PropagationTable` was instantiated.

In general, if a `SPEBE_PropagationTable` is instantiated with a previously used `tablePath` and `tablePrefix`, and a `SPEBE_Environment` that does not represent the environmental state of the previously generated table files, the results will be invalid.

Thus, exercise caution when reusing previously generated tables, or when reusing an old `tablePath` and `tablePrefix` to generate new files.

In particular, if a file directory and prefix are to be reused to generate new tables, then the old tables must first be deleted. It is also advisable to delete old tables that are no longer needed.

The public member functions for the `SPEBE_PropagationTable` class are listed in table 6.
Table 6. Public member functions for the SPEBE_PropagationTable class.

3.4.1 Constructor & Destructor Documentation

SPEBE_PropagationTable::SPEBE_PropagationTable(SPEBE_Environment * environment, const char * tablePath, const char * tablePrefix)

This function constructs a new **SPEBE_PropagationTable** for the specified environment, tablePath, and tablePrefix.

**Parameters:**

- *tablePath* - the directory path in which the propagation tables will be placed; don’t include final slash “\”
- *tablePrefix* - the file prefix to be used in naming the propagation tables; don’t include a file type

SPEBE_PropagationTable::SPEBE_PropagationTable(const char * tablePath, const char * tablePrefix)

This function constructs a new **SPEBE_PropagationTable** from a previously saved **SPEBE_Environment** and **SPEBE_PropagationTable** using **SaveEnvironment**.

**Parameters:**

- *tablePath* - the directory path in which the environment and table files are located; don’t include a final directory slash “\”
- *tablePrefix* - the file prefix of the previously saved **SPEBE_PropagationTable**; don’t include a file type

SPEBE_PropagationTable::~SPEBE_PropagationTable()

This function is the destructor.

Note: Always delete a **SPEBE_PropagationTable** object when it is no longer needed.
3.4.2 Member Function Documentation

```cpp
void SPEBE_PropagationTable::DisableHiFi( void )
```

This function disables the use of high-fidelity propagation modeling for near-ground sources.

**Warning:** This must be enable or disabled PRIOR to the generation of any propagation tables. If it is changed after propagation tables have been generated, then the tables will not be regenerated, i.e., the new value will be ignored.

```cpp
void SPEBE_PropagationTable::EnableHiFi( double height )
```

This function enables the use of high-fidelity propagation modeling for near-ground sources.

**Warning:** This must be enable or disabled PRIOR to the generation of any propagation tables. If it is changed after propagation tables have been generated, then the tables will not be regenerated, i.e., the new value will be ignored.

**Parameters:**

- `height` - Specify the height below which the high-fidelity will be used.

```cpp
void SPEBE_PropagationTable::GenerateTable( SPEBE_SensorType sensorType, double targetHt )
```

This function constructs and saves a table for the given sensor type and target height. The table will be saved in the directory specified in the constructor. The filename prefix will be prepended to a coded height string to arrive at the final filename.

**Warning:** If the file already exists, it will not be generated again. This results in efficient use of tables for calculations, but requires care in the use of file prefixes. See comments under the description of the class.

**Parameters:**

- `sensorType` - The sensor type, chosen from `SPEBE_SensorType`
- `targetHt` - The target height
void SPEBE_PropagationTable::GenerateTable( SPEBE_SensorType sensorType, 
SPEBE_TargetType targetType 
)

This function constructs and saves a table for the given sensor and target types, using the default target height. The table will be saved in the directory specified in the constructor. The filename prefix will be prepended to a coded height string to arrive at the final filename.

**Warning:** If the file already exists, it will not be generated again. This results in efficient use of tables for calculations, but requires care in the use of file prefixes. See comments under the description of the class.

**Parameters:**

- `sensorType` - The sensor type, chosen from `SPEBE_SensorType`
- `targetType` - The target type, chosen from `SPEBE_TargetType`

const char * SPEBE_PropagationTable::GetTableFileName( SPEBE_SensorType sensorType, double targetHt )

This function gets the full name of the propagation table file for the specified sensor type and target height. Note: These are `.mat` files and are managed by the API internally. Thus, their direct manipulation is not required.

**Parameters:**

- `sensorType` - The sensor type, chosen from `SPEBE_SensorType`
- `targetHt` - The target height

const char * SPEBE_PropagationTable::GetTableFileName( SPEBE_SensorType sensorType, 
SPEBE_TargetType targetType 
)

This function gets the full name of the propagation table file for the specified sensor and target type, using the default target height. NOTE: These are `.mat` files and are managed by the API internally. Thus, their direct manipulation is not required.

**Parameters:**

- `sensorType` - The sensor type, chosen from `SPEBE_SensorType`
- `targetType` - The target type, chosen from `SPEBE_TargetType`
void SPEBE_PropagationTable::SaveEnvironment( void )

This function saves the SPEBE_PropagationTable and associated SPEBE_Environment under the same tablePrefix as the tables for later reuse.

Note: Individual propagation tables are saved automatically as they are generated. This method saves the SPEBE_PropagationTable and associated SPEBE_Environment for reuse.

3.5 SPEBE_SensorSet Class

The SPEBE_SensorSet class manages a set of sensors chosen from SPEBE_SensorType. A sensor set is instantiated with a specified number of sensors of identical type. Coordinates of each sensor are then set individually. If any sensor is of a different type, it can be changed individually using ChangeSensorType; the assumption is that in most cases there will be a predominant type.

Note: Sensors cannot be added or deleted once the set is created; however, sensor types and coordinates can be changed. Also, specific sensors can be activated and deactivated for detection probability calculations (see SPEBE_PDCalculator).

Warning: If you change the type of any of the sensors, a new set of parameters will be set up for that sensor, including the coordinates. Thus, the coordinates of each sensor must be set after the type is specified.

The public member functions for SPEBE_SensorSet class are listed in table 7 and the static public member functions for this class are listed in table 8.

3.5.1 Constructor & Destructor Documentation

**SPEBE_SensorSet::SPEBE_SensorSet**( int numSensors, **SPEBE_SensorType** sensorType )

This function instantiates a specified number of specified sensor type. Once instantiated, particular sensor types can be changed using **ChangeSensorType**.

**Parameters:**

- **numSensors** - the number of sensors in the set.
- **sensorType** - The sensor type, chosen from **SPEBE_SensorType**

**SPEBE_SensorSet::SPEBE_SensorSet**( **SPEBE_SensorSet** *sensorSet )

This function is a copy constructor. Once instantiated, particular sensor types can be changed using **ChangeSensorType**.

**Parameters:**

- **sensorSet** - the existing **SPEBE_SensorSet** to be copied.
SPEBE_SensorSet::~SPEBE_SensorSet( void )

This function is the destructor.

**Parameters:** none

Note: Always delete a SPEBE_SensorSet object when it is no longer needed.

### 3.5.2 Member Function Documentation

#### void SPEBE_SensorSet::Chan

gegSensorTy

te( int sensorNumber, SPEBE_SensorType sensorType )

This function changes the sensor type of the specified sensor. Indexing starts with zero.

**Parameters:**

- *sensorNumber* - the particular sensor within the set to be changed; indexing starts at zero.
- *sensorType* - The sensor type, chosen from SPEBE_SensorType

#### int SPEBE_SensorSet::GetNumSensors( void )

This function indicates the number of sensors.

**Returns:** the number of sensors

#### double SPEBE_SensorSet::GetSensorHeight( SPEBE_SensorType sensorType ) [static]

This function indicates the specified sensor height.

**Parameters:**

- *sensorNumber* - the particular sensor within the set. Indexing starts at zero.

**Returns:** The specified sensor height

#### double SPEBE_SensorSet::GetSensorLat( int sensorNumber )

This function indicates the specified sensor latitude.

**Parameters:**

*sensorNumber* - the particular sensor within the set; indexing starts at zero.

**Returns:** The specified sensor latitude
double SPEBE_SensorSet::GetSensorLon( int sensorNumber )

This function indicates the specified sensor longitude.

Parameters:

• sensorNumber - the particular sensor within the set; indexing starts at zero.

Returns: The specified sensor longitude

SPEBE_SensorType SPEBE_SensorSet::GetSensorType( int sensorNumber )

This function indicates the sensor type of the specified sensor.

Parameters:

• sensorNumber - the particular sensor within the set to be changed; indexing starts at zero.

Returns: The specified sensor type

void SPEBE_SensorSet::SetSensorLocation( int sensorNumber, double lat, double lon )

This function sets the location of the specified sensor. Indexing starts with zero. NOTE: This must be called after ChangeSensorType if the sensor type is to be changed.

Parameters:

• sensorNumber - the particular sensor within the set to be changed; indexing starts at zero
• lat - the latitude of the sensor, in signed decimal
• lon - the longitude of the sensor, in signed decimal

3.6 SPEBE_TargetSet Class

The SPEBE_TargetSet class manages a set of targets, or acoustic/seismic sources, chosen from SPEBE_TargetType. A target set is instantiated with a specified number of targets of identical type. Coordinates of each target are then set individually. If any targets are of a different type, they can be changed individually using ChangeTargetType; the assumption is that in most cases there will be a predominant type.

Note: Targets cannot be added or deleted once the set is created; however, target types and coordinates can be changed. Also, specific targets can be activated and deactivated for detection probability calculations (see SPEBE_PDCalculator).
**Warning:** If you change the type of any of the targets, a new set of parameters will be set up for that target, including the coordinates. Thus, the coordinates of each target must be set after the type is specified.

The public member functions for the SPEBE_TargetSet Class are listed in table 9 and the static public member function is listed in table 10.

Table 9. Public member functions for the **SPEBE_TargetSet** class.

<table>
<thead>
<tr>

### 3.6.1 Constructor & Destructor Documentation

**SPEBE_TargetSet::SPEBE_TargetSet( int numTargets, SPEBE_TargetType targetType )**

This function instantiates a specified number of specified target types. Once instantiated, particular target types can be changed using `ChangeTargetType`.

**Parameters:**
- `numTargets` - the number of targets in the set.
- `targetType` - The target type, chosen from `SPEBE_TargetType`

**SPEBE_TargetSet::~SPEBE_TargetSet( void )**

This function is the destructor. **NOTE:** Always delete a `SPEBE_TargetSet` object when it is no longer needed.

### 3.6.2 Member Function Documentation

**void SPEBE_TargetSet::ChangeTargetType( int targetNumber, SPEBE_TargetType targetType )**

This function changes the target type of the specified target. Indexing starts with zero.

**Parameters:**
- `targetNumber` - the particular target within the set to be changed; indexing starts at zero.
- `targetType` - The target type, chosen from `SPEBE_TargetType`

**int SPEBE_TargetSet::GetNumTargets( void )**

This function indicates the number of targets in the set.

**Returns:** The number of targets

**double SPEBE_TargetSet::GetTargetHeight( SPEBE_TargetType targetType ) [static]**

This function indicates the specified target height.

**Parameters:**
- `sensorNumber` - the particular target within the set; indexing starts at zero.

**Returns:** The specified target height, in meters above ground
double SPEBE_TargetSet::GetTargetLat( int targetNumber )

This function indicates the specified target latitude.

**Parameters:**

- `sensorNumber` - the particular target within the set; indexing starts at zero.

**Returns:** The specified target latitude

double SPEBE_TargetSet::GetTargetLon( int targetNumber )

This function indicates the specified target longitude.

**Parameters:**

- `sensorNumber` - the particular target within the set; indexing starts at zero.

**Returns:** The specified target longitude

SPEBE_TargetType SPEBE_TargetSet::GetTargetType( int targetNumber )

This function indicates the specified target type.

**Parameters:**

- `sensorNumber` - the particular target within the set; indexing starts at zero.

**Returns:** The specified target type

void SPEBE_TargetSet::SetTargetDirection( int targetNumber, double dir )

This function sets the direction of the specified target. Indexing starts with zero. Note: This refers to the direction the target is pointing, not the direction of the target’s ground track. In the case of an aircraft flying with a crosswind component, the two will not be the same. This must be called after `ChangeTargetType` if the target type is to be changed.

**Parameters:**

- `targetNumber` - the particular target within the set; indexing starts at zero.
- `dir` - the direction the target is pointing, in degrees
This function sets the height of the specified target. Indexing starts with zero. Note: This must be called after `ChangeTargetType` if the target type is to be changed.

**Parameters:**

- `targetNumber` - the particular target within the set; indexing starts at zero.
- `height` - the height above ground of the sensor, in meters

This function sets the location of the specified target. Indexing starts with zero. Note: This must be called after `ChangeTargetType` if the target type is to be changed.

**Parameters:**

- `targetNumber` - the particular target within the set to be changed; indexing starts at zero.
- `lat` - the latitude of the sensor, in signed decimal
- `lon` - the longitude of the sensor, in signed decimal

### 4. Acoustic Sensor Placement Global Definitions

This section includes the definitions of several global enumerated types and functions.

The enumerated types are used by various class methods to specify predefined choices for ground, seismic, sensor, target, and noise types. Each determines a set of parameters defined in the data files that are included with the SPEBE and ASSP distribution.

The functions are associated with operation of the overall API rather than any specific class, and are therefore defined independently of the classes.
4.1 Global Enumerated Types

4.1.1 Enumeration Type Documentation

<table>
<thead>
<tr>
<th>Enum Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>enum SPEBE_GroundType</strong></td>
<td>This lists the ground types for environmental characterization. The types are Urban, Suburban, Asphalt, Gravel, Sand, Brush, Forest, ShortGrass, LongGrass, OpenWater, Ice, and Snow. See also SPEBE_Environment.</td>
</tr>
<tr>
<td><strong>enum SPEBE_NoiseType</strong></td>
<td>This lists the background noise types for detection probability calculations. The types are Rural, City, LightBattle, and IntenseBattle.</td>
</tr>
<tr>
<td><strong>enum SPEBE_SeismicType</strong></td>
<td>This lists the seismic types for environmental characterization. The types are Desert, SoilOverBedrock, and SiltOverWaterTable.</td>
</tr>
<tr>
<td><strong>enum SPEBE_SensorType</strong></td>
<td>This lists the sensor types for detection probability calculations and propagation table generation. The types are Human, Acoustic, and Seismic, where human refers to a person with International Standards Organization (ISO) Standard good hearing, acoustic refers to a generic three-element microphone array, and seismic refers to a generic geophone.</td>
</tr>
<tr>
<td><strong>enum SPEBE_TargetType</strong></td>
<td>This lists the target types for detection probability and propagation table generation. The types are Tracked, WheeledHeavy, WheeledLight, HelicopterLow, HelicopterHigh, T2_UAS, T3_UAS, and Personnel. T2_UAS refers to a Shadow surrogate Unmanned Arial System (UAS), T3_UAS refers to a Hunter surrogate UAS, and Personnel refers to the seismic signature of adult human footsteps.</td>
</tr>
</tbody>
</table>
4.2 Global Functions

4.2.1 Function Documentation

```c
void SPEBE_Initialize( void )
```

This function shows the initialization to be called once at the beginning of a session.

**Parameters:** *none*

```c
void SPEBE_Shutdown( void )
```

This is the function to be called once at the end of a session.

**Parameters:** *none*

---

5. Conclusion

This API was used by the U.S. Army Communications-Electronics Research, Development and Engineering Center (CERDEC), Command and Control Directorate (C2D), to provide acoustic sensor capability to graphical user interface (GUI)-based multimode sensor placement decision aid development projects. Much of the architecture and interface design was based on requirements provided by C2D, which in turn were derived from operational requirements for the deployment of acoustic sensors and sensor decision aids. It was implemented by C2D developers with general expertise in GUI and decision aid development but limited expertise in acoustic sensors. The relative ease with which these developers were able to integrate ASSP into their software demonstrates the success of the API as a tool to enable the development of acoustic sensor placement decision aids with minimal acoustics expertise.
