Upgrades to the Closed Bomb Facility and Measurement of Propellant Burning Rate

Tyler Wagner, John Ritter, and Barrie E. Homan
Weapons and Materials Research Directorate, ARL
**ABSTRACT**

Propellants are a class of materials designed to produce low molecular weight gases that can be used in guns, missiles, and pyrotechnics. The burn rate of a propellant is used to design such munitions systems. The preferred method for obtaining the burn rate is the constant volume closed bomb. The pressure-time history obtained in closed bomb experiments, coupled with a propellant’s thermochemistry and geometry, is used to calculate the linear burn rate. The hardware and software previously used to record the data needed to calculate the linear burn rate were outdated. The software that controlled the closed bomb experiments required modification in order to integrate the command set of the new Agilent oscilloscope. The new program sends user-defined commands, reads data from an external voltage source, and arranges that data in the proper format for XLCB, the burn rate data reduction code written in house using Visual BASIC in Microsoft Excel. The new code improves efficiency by creating buffers, eliminating extraneous subroutines. The new software has been tested for accuracy against the previous program using a split signal and closed bomb tests. This report presents a brief overview of closed bomb testing, a detailed account of the program and programming process, and results confirming the accuracy of the new program.

**SUBJECT TERMS**

Closed bomb, propellant characterization, burning rate

1. Introduction

Propellants are energetic materials used to create thrust. They are employed in a variety of fields, from ballistics and rocketry to pyrotechnics. Propellants generate thrust by producing gas pressure, which can be harnessed to accelerate a projectile. Propellants differ from high explosives because of their burn rate. If an explosive has a burn rate that is slower than the speed of sound in the material, the energy release is described as a deflagration. On the other hand, if the speed of the reaction is supersonic, the material is a high explosive and detonates. The speed of sound through a given material is directly proportional to the density of the material; in other words, sound moves faster through more dense materials.

In order to test propellants, a constant-volume sealed chamber equipped with a pressure transducer serves as a controlled environment in which burn rates can be measured. When a propellant is ignited in the chamber, the transducer reports a voltage, which is proportional to pressure. This pressure versus time data is then a measure of the rate at which gases are produced. The rate of change of pressure, along with propellant thermochemistry and geometry, is used to calculate the burn rate. In propellant testing, the sealed chamber used to conduct this experiment is often referred to as a “closed bomb” and is shown in figure 1.

Figure 1. A 200-cc closed bomb.
2. Background

The hardware and software that is needed to read the voltage-time data produced using the pressure transducer and execute the calculations to determine the burn rate of a propellant have evolved over time. An early version of the data reduction software written to perform these tasks was BRLCB created by Oberle and Kooker (1) in 1993. Since then, a new program, XLCB, has been created by Homan in 2001, which updated features of BRLCB and used the capabilities of Microsoft Excel (2). The XLCB program works in conjunction with the Wavebook data acquisition system and XLWavebook data acquisition program (3) to read data from the closed bomb and calculate propellant burn rates. Unfortunately, the data acquisition hardware used to capture the pressure data was antiquated. The previous hardware (IOTech, WaveBook 512) only works with Windows 98, which is no longer widely available. An update to the hardware/software system was required to ensure continued operation of the system and decrease the processing time necessary to make the required calculations. To perform this update, an Agilent oscilloscope was purchased and a program was written (XLAgilent) to acquire data using the new oscilloscope and integrate it into the XLCB data reduction program.

3. Approach

The first step in creating a new program to control the Agilent oscilloscope was to ensure the scope was functional and able to communicate with a laptop running Windows XP. To accomplish this, a program was written in Visual BASIC (4) to input commands into the scope. These commands control data acquisition settings, read voltage-time data from an external source, and display the voltage-time graph onscreen. The scope was connected to the laptop via a local area network (LAN) connection. An external voltage source was connected to the oscilloscope in order to simulate the voltage response produced by the pressure transducer in a closed bomb test. With an external voltage source, in this case a simple pulse generator, the user could define parameters, such as pulse width and voltage level, to ensure the program accurately read the voltage-time curve. Initially, the Agilent control program designed to control data acquisition from the closed bomb test procedure was written in three subroutines: Initialize, Acquire, and Capture. These subroutines are described in detail in section 4.
4. Program Operation

The Agilent program began with the Initialize subroutine, which established a connection between the computer and the oscilloscope, using the Virtual Instrument Systems Architecture Communications (VISA COM) library (5) as the primary medium for communication. The program then wrote strings of commands to the scope declaring data collection settings, such as voltage range, time base, and trigger level. At first, these settings were inherent in the code of the program and could only be changed by rewriting the code. Eventually, all of the necessary variables were integrated into one of the XLAgilent user forms such that values could be entered or changed by the user without looking at the code. The Acquire subroutine sent additional commands to the scope determining the input channel, acquire type, and counts. The last and most intricate part of the Agilent program, the Capture subroutine, recorded and displayed the data. To verify the data were successfully collected, three measures of displaying the data were written into the program. The first used the instrument-Web interface (6) to graph the data, scaling the graph based on the data collection settings entered earlier. A screen capture of this interface receiving a signal from the pulse generator is shown in figure 2, with the pertinent values labeled. The next measure to ensure data were present generated a message box, displaying the voltage-time data. Finally, a new Excel spreadsheet was created into which the data were automatically inputted and graphed.
To integrate the new XLAgilent program into XLCB, an understanding of the Wavebook command library was needed. XLWavebook used VBdaq command notation. Initially, VBdaq commands were replaced with equivalent VISA COM commands. However, the VISA COM library used by the Agilent system did not correlate to every command given by VBdaq. As a result, a bridge was constructed referring XLWavebook to the new XLAgilent program. This seemed to be an adequate solution until updates were made to the user form in which data acquisition settings were entered. Following the updates, XLAgilent would not read certain values from the user form, some values were extraneous, and some values were missing altogether. Rather than developing a mechanism to force the program to look back and forth from XLWavebook to XLAgilent, the commands from the Initiate and Acquire subroutines were combined into a new subroutine. This subroutine was placed in the Configuration user form of XLAgilent, shown in figure 3, where it could directly take the values entered into the user form, reformat them, and send them as commands to the oscilloscope. Later the Capture subroutine was integrated into the main code of XLAgilent, but changed slightly so that instead of creating a new Excel spreadsheet, it would input data values into the proper spreadsheets in XLCB for reduction. In this way, the Agilent program initially written with the three subroutines was
completely incorporated into XLAgilent without replacing any VBdaq code. The VBdaq code could now be removed as well as the three test measures to verify data were being collected, improving speed and efficiency.

In order to incorporate the Initialize and Acquire subroutines, many changes had to be made to the Configuration user form and the code governing it. Even after such changes were incorporated into the user form, the XLAgilent subroutines had problems accessing the values entered in the user form. To solve this problem, a registry was created, from which the values needed to send commands to the scope could be drawn. The registry also saved previously entered values, so they would appear at the beginning of the next closed bomb test.

The performance characteristics of the Wavebook and the oscilloscope also differ, which needed to be accounted for in the software. For example, the Wavebook can only record frequencies up to 1 MHz, whereas the oscilloscope can handle frequencies up to 100 MHz. The Wavebook and oscilloscope also process different dynamic ranges, providing the oscilloscope with a longer data collection range, as shown in figure 4. One of the key changes made in the Configuration user form was the use of a gain versus voltage range. The gain used by the Wavebook correlates to volts per division in the oscilloscope, but the Agilent commands have no function to set this value. Instead, this value is calculated internally using the vertical voltage range and the offset voltage. Both values were the same, but changes needed to be made to the user form to accommodate these program differences.
5. Discussion

Since it is dangerous to enter the closed bomb room if a shot has not been fired, the Wavebook program implemented a wait function as a fail-safe, which would not allow the code to continue until data were recorded, thus allowing the user to know if the propellant was successfully ignited inside the bomb. The new program provided a similar fail-safe using an error message. If the user pressed “OK” on a message box querying if a shot was performed and the propellant had not ignited, then an error message popped up essentially telling the user that no data were collected. However, this was eventually deemed an inadequate fail-safe. This difference between the Wavebook and the Agilent oscilloscope was inherent in the triggering code. The Wavebook included VBdaq code that would wait for data. Once the Wavebook had the desired amount of data recorded, it would proceed with the rest of the program code. The Agilent scope had no such command. To remedy this problem XLAgilent was programmed with a status byte register (STB) query and a While loop, which continues until the trigger bit (TRG) is returned as True. TRG is bit zero with a value of one, while the rest of the bits produce even values. A simple While loop was created to query for the status byte until an odd number appeared. The program waits indefinitely for an odd number, which is only generated by a trigger, serving the same role as the VBdaq wait function.

Figure 4. Voltage-time graphs (overlapped) for the JA2 test data performed on 15 July 2009.
Another improvement made to the overall program performance is how data are transferred to the Excel spreadsheet. Initially data were transferred one cell at a time. To make the program more efficient, a buffer was introduced. This buffer was already in place in the XLWavebook program, but had been commented out due to the limitations of the Wavebook. With a few modifications to the Capture subroutine, the data recorded by the oscilloscope were placed inside this buffer and could be found in one place, rather than the program going through a loop, which contained thousands of points, until all of the data were found.

6. Results

After the program was thought to be running without any problems, it was executed using a live closed bomb test with JA2, a nitrocellulose-based propellant. One problem that became apparent during calibration steps was that XLAgilent was outputting values in microseconds while XLCB was looking for data in seconds. This was remedied with a code change and testing resumed. After the first closed bomb shot, an error message appeared. The error was a formatting error, the one that appears when no data are recorded and the user tries to proceed. Per testing safety regulations, the closed bomb’s valve was vented, but no gas was released. The propellant had not ignited, and the program’s fail-safe had been confirmed. However, this fail-safe mechanism was ultimately replaced in favor of a mechanism that replicated the XLWavebook fail-safe. Failure to fire was attributed to an igniter issue, which was subsequently resolved. The test was carried out and the values recorded using the new program appeared to be accurate.

To confirm the accuracy of the initial test values, additional tests were performed using a split signal between the Wavebook system and the new Agilent system. The results of one of these tests are presented in figures 4–7. As shown, the data from the old Wavebook system is consistent with that of the new Agilent system, but problems have been encountered in reducing the data due to noise in the pressure-time curve. This is a hardware error rather than a software error and will be sorted out at a later date through additional testing. A grounding wire will most likely limit the noise and allow the data to be more accurately reduced. Even though noise was present in the data reduction, the heat loss observed on the Agilent system, calculated from the theoretical and observed maximum pressures, was 5.03% for the test shown in figure 4, which is acceptable. The heat loss calculated by the Wavebook was 5.83% and can be explained by the lack of noise and that the Wavebook does not accept negative values, while the Agilent system does. In either case 5–6% heat loss is reasonable for the test performed (I).

Notice that the voltage-time graphs align perfectly, indicating that the new program is sending the correct commands, receiving the trigger, and collecting data accurately. The remaining problem is the noise, which translates from the voltage-time graph to the pressure-time graph. The pressure derivative graph amplifies this noise, also making it apparent in the derived burn rate and vivacity graphs.

### 7. Conclusions

The new Agilent-based data acquisition system is working and is consistent with the outdated Wavebook system. The changes incorporated in the XLAgilent program allow it to interface with the Agilent oscilloscope, as well as improve efficiency and user compatibility. With future tests and hardware improvements, noise in the data collected using the Agilent system will be reduced, and both systems (Agilent and Wavebook) should produce identical test results. After further refinement and evaluation, the Agilent oscilloscope will replace the Wavebook as the closed bomb data acquisition system.
8. Addendum

Following recent tests, the XLAgilent program has been updated. The Agilent oscilloscope has an inherent high resolution acquisition function, which smoothes incoming raw data. At the slower sweep speeds at which the program runs, this function acquires extra samples with the desired frequency and averages them in order to reduce random noise. Noise was no longer an issue after the program’s acquisition mode was changed from “normal” to “high resolution.” As shown in figure 7, the waveform has been smoothed compared to that shown in figure 2. Calibration tests were performed again using a split signal, and the raw data from the Agilent oscilloscope now is identical to the data from the Wavebook. It is suspected that one of the Wavebook’s VBdaq functions also automatically limits noise by acting as a smoothing function. Now that matching results are being attained from the new Agilent system, the Wavebook system can be replaced by its more up-to-date counterpart.
