The Importance of Autophagy in Breast Cancer Development and Treatment

Beclin 1, the mammalian homologue of the yeast Atg6, is a key autophagy-promoting gene that plays a critical role in the regulative cell death and survival of various types of cells. However, recent studies have observed that the expression of beclin 1 is altered in certain diseases including cancers. The causes underlying the aberrant expression of beclin 1 remain largely unknown. We report that micro RNAs (miRNAs), a class of endogenous, 22-24 nucleotides non-coding RNA molecules able to affect stability translation of mRNA, may represent a previously unrecognized mechanism for regulating beclin 1 expression and autophagy. Demonstrated that beclin 1 is a potential target for miRNA miR-30a, and this miRNA could negatively regulate beclin 1 expression resulting in decreased autophagic activity. Treatment of tumor cells with the miR-30a mimic decreased, and with the antag increased, the expression of beclin 1 mRNA and protein. Dual luciferase reporter assay confirmed that the miR-30a binding sequence in the 3’-UTR of beclin 1 contribute to the modulation of beclin 1 expression by miR-30a. Furthermore, inhibition of beclin expression by the miR-30a mimic blunt activation of autophagy induced by rapamycin. Our study of the role of miR-30a regulating beclin 1 expression and autophagy reveals a novel function for miRNA in a critical cellular event with significant impact.

beclin 1; autophagy; microRNA; miR-30a; gene expression
INTRODUCTION

Autophagy, a conserved, programmed response to metabolic and environmental stress found in yeast, plants, worms, flies, mice, and man\(^1\), has been known to play a critical role in the regulation of survival and death of various types of cells\(^2\). Recent studies have implicated autophagy in a number of physiologic and pathophysiologic processes such as aging, cancers, and neurodegenerative diseases\(^3\). The process of autophagy involves formation of double-membrane vesicles (autophagosomes) that engulf organelles and cytoplasm, then fuses with the lysosome to form the autolysosome, where the contents are degraded and recycled for protein and ATP synthesis\(^4,5\). The formation of the autophagosome is mediated by a series of autophagy-promoting gene products that function at different stages of autophagy\(^6\). Beclin 1, the mammalian homologue of the yeast Atg6, is a key autophagy-promoting gene whose product is part of a lipid kinase (class III Phosphoinositide 3-kinase) complex that participates in the early stage of autophagosome formation\(^7,8\). Beclin 1 is a ~60-kDa coiled–coli protein also able to interact with bcl-2, an anti-apoptotic protein. Although ubiquitously expressed, it has been known that the expression of beclin 1 is altered in certain diseases. For example, in early Alzheimer disease beclin 1 expression is decreased\(^9\); in contrast, neurodegeneration causes up-regulation of beclin 1\(^10\). In several types of human cancers, the expressions of beclin 1, both protein and mRNA, were also found to be aberrant\(^11-13\). Yet, the causes underlying the altered expression of this key autophagy-promoting gene remains largely unknown. In the present study we sought to explore the role of microRNAs (miRNAs) in the regulation of expression of beclin 1. MiRNAs are a class of endogenous, 22 - 24 nucleotides RNA molecules with the ability to induce mRNA degradation, translational repression, or both, via pairing with partially complementary sites in the 3' UTR of the targeted genes\(^14-17\). It is estimated that over 1000 miRNAs exist in mammalian cells, and that 30% of all genes are regulated by miRNAs\(^18-20\). Because of their capacity to target numerous mRNAs, miRNAs can regulate the expression of genes in a number of pathways that are associated with tumor initiation, development and progression\(^21-23\). During this grant period, we discovered that the autophagy-promoting gene beclin 1 is a potential target for miR-30a, and this miRNA may play a regulatory role in autophagic response through modulating the expression of beclin 1.

BODY

Task 1 To determine the importance of autophagy in the life and death of breast cancer cells.

Task 2 To determine the role of autophagy in the sensitivity of breast cancer to treatment.

During the last grant period, we focused on the roles of miRNA in regulating autophagy. We first analyzed the miRNA expression profiling in tumor cells treated with HBSS (nutrient deprivation) or rapamycin. Nutrient deprivation and rapamycin treatment are known to
activate autophagy in various types of cells. Using a miRNA microarray (OSUCCC-microRNA version 4.0) analysis, we observed a differential expression of 13 miRNAs in T98G and MDA-MB-468 cells treated with HBSS or rapamycin, as compared with the untreated cells or the cells treated with vehicle. The heat map of these miRNA expression profiles of those samples is shown as supplemental data (Figure 1). We then conducted an in silico search for miRNA binding sites using the PicTar algorithm (http://pictar.bio.nyu.edu). Among those 13 miRNAs that were differentially expressed in the HBSS or rapamycin – treated cells, we found in the 3’ - UTR of beclin 1 the consensus sequences for miR-30a, implying that beclin 1 is a potential target for miR-30a. To verify the change of miR-30a expression following HBSS or rapamycin treatment, we performed qRT-PCR analysis of the endogenous miR-30a expression. Fig. 2 shows that there was a 10% and 35% reduction of miR-30a expression in cells subjected to nutrient depletion or rapamycin treatment, respectively. These results suggest a possible role for this miRNA in targeting beclin 1 in response to stresses.

To obtain experimental evidence supporting beclin 1 gene as a target for miR-30a, we next examined the effect of miR-30a on beclin 1 expression using a mimic and an antagonir of this miRNA. In these experiments, T98G, MDA-MB-468 and H1299 cells were transfected with a miR-30a mimic or an antagonir, and then the expressions of beclin 1 mRNA and protein were analyzed by qTR-PCR and Western blot, respectively. As shown in Fig. 3, transfection with the miR-30a mimic caused a 25-40% decrease in beclin 1 mRNA (Fig. 3A), and a 25-60% decrease in beclin 1 protein (Fig. 2B); by contrast, treatment with the miR-30a antagonir resulted in a 55-85% increase in beclin 1 mRNA (Fig. 2A) and a 10-25% increase in beclin 1 protein (Fig. 3B). Using the mimic and antagonir of miR-30a, these experiments demonstrated a suppressive role for this miRNA in beclin 1 expression.

To validate the predicted consensus sequences for miR-30a in the beclin 1 – 3’ UTR, and determine whether these miR-30a binding sequences directly contributed to the negative regulation of beclin 1 expression, we tested the effects of miR-30a on activity of a reporter gene using the vectors that either contained wild-type miR-30a targeting sequences (psiCHECKTM2-WT-BECN-3’-UTR) or deletion mutant (psiCHECKTM2-MT-BECN-3’-UTR) (Fig. 4B). As shown in Fig. 4C, co-transfection of T98G, MDA-MB-468 and H1299 cells with 50 nM or 100 nM of the miR-30a mimic resulted in a 40-80% reduction in the activity of the reporter gene vector containing the wild-type miR-30a targeting sequences (psiCHECKTM2-WT-BECN-3’-UTR), in comparison to that of the vector with the deletion mutant (psiCHECKTM2-MT-BECN-3’-UTR). In contrast, the non-targeting control RNA did not have any effect on the reporter activity of either of the vectors (Fig. 4C). These results demonstrated that the miR-30a binding sequences in the beclin 1 – 3’ UTR is the region required for the miR-30a - mediated inhibition of beclin 1 expression.

Beclin 1 plays an essential role in activating autophagy. To determine the functional consequence of modulation of beclin 1 expression by miR-30a, we tested the effect of the miR-30a mimic on autophagic response to rapamycin. Fig. 5 shows that treatment of T98G cells with rapamycin activated autophagy, as evidenced by the increases in LC3-II amount (Fig. 5A), in double membrane vacuoles in the cytoplasm (Fig. 5B), and in formation of GFP-LC3 aggregation (Fig. 5C). Notably, tumor cells transfected with the mimic of miR-30a showed a remarkable reduction in beclin 1 expression, and a blunted autophagic response to rapamycin,
as evidenced by the lower LC3-II levels (Fig. 5A), fewer double membrane vacuoles (Fig. 5B), and less GFP-LC3 aggregations (Fig. 5C), indicating that inhibition of beclin 1 expression by miR-30a leads to suppression of autophagic activity. To confirm that the effect of miR-30a on autophagy was mediated through beclin 1, we tested the effect of miR-30a on the resveratrol – induced autophagy in MCF-7 cells, which was reported to be beclin 1-independent \(^{26}\). Fig. 6 shows that miR-30a mimic had no effect on autophagy induced by resveratrol in MCF-7 cells.

**KEY RESEARCH ACCOMPLISHMENTS**

- We found that beclin 1 is a putative target for miR-30a.
- We showed that miR-30a negatively regulates beclin 1 expression.
- We demonstrated the effect and mechanism of miR-30a on autophagic activity.

Figure 3. Effect of miR-30a on the expression of beclin 1. (A) T98G, MDA-MB-468 and H1299 cells were transfected with a mimic or antagonim of miR-30a (100 nM) or a control RNA (100 nM). Forty-eight and 72 hours later, total RNAs were extracted from the treated cells and quantitative real-time RT-PCR analyses of beclin 1 mRNA were performed. Beclin 1 mRNA levels of the cells treated with a control RNA were arbitrarily set at 1, and beclin 1 mRNA levels of the cells treated with the miR-30a mimic were normalized to the control. Results shown are the mean ± SD of triplicate determinations from one of three identical experiments. (B) T98G, MDA-MB-468, and H1299 cells were treated as described in (A). Forty-eight hours later, cell lysates were prepared from the transfected cells. Equal amounts (25 μg proteins) of cell lysates were separated by 8% SDS-PAGE, and then transferred onto nitrocellulose membranes. The membranes were immunoblotted with a monoclonal anti-beclin 1 antibody. Detection of beclin 1 was performed using enzyme-linked chemiluminescence. α-tubulin was used as a loading control. Protein expression was quantified using the ImageJ software. Beclin 1/tubulin ratios of the samples treated with a control RNA was arbitrarily set at 1, and the beclin 1/tubulin ratios of the miR-30a mimic or antagonim-treated samples were normalized to the control. Results shown are the mean ± SD of triplicate determinations from one of three identical experiments.

Figure 5. Effect of miR-30a on autophagic response to rapamycin. (A) T98G cells transfected with a mimic of miR-30a or a non-targeting control RNA were treated with rapamycin (200 nM) in the presence or absence of lysosomal protease inhibitors E64D (10 μg/ml) and pepstatin A (10 μg/ml). At the end of treatment, formation of LC3-II was detected by immunoblotting with an anti-MAP-LC3 antibody. (B) T98G cells were treated as described in (A), and then were harvested by trypsinization, fixed and embedded in spur resin. Ninety nm thin sections were cut and examined at 80 Kv with a JEOL 1200EX transmission electron microscope. Arrows indicate autophagic vacuoles. Double membrane vacuoles per cell were determined by counting 20 cells for each sample and average numbers of double membrane vacuoles were shown. The bars are the mean ± S.D. (C) GFP-LC3-expressing T98G cells were treated as described in (A). At the end of treatment, cells were fixed with 4% formaldehyde for 15min and inspected at 60x magnification for numbers of GFP-LC3 puncta. LC3-GFP puncta per cell were determined by counting 20 cells for each sample and average numbers of puncta per cell were shown. The bars are the mean ± S.D.. Results shown are the representative of three identical experiments.
