Targeting neuropilin-1 in prostate cancer bone metastasis

Our studies have demonstrated myeloid cell leukemia (Mcl-1) as a novel downstream target of NRP1 signaling in metastatic prostate cancer cells. During the third year of the supporting period, we correlated Mcl-1 overexpression with PCa bone metastasis, and elucidated a signaling mechanism by which NRP1 regulates Mcl-1 expression. These findings provide an excellent rationale to develop NRP-1-targeted therapy treating bone metastatic PCa.

These studies were published recently at Molecular Cancer (2010, 9: 9).

Introduction

Overexpression of neuropilin-1 (NRP1) has been associated with progression of prostate cancer (PCa) and other solid tumors [1-3]. However, since NRP1 is not a typical "signaling receptor" for its lacking sequences predicted to have kinase receptor activities, it remained elusive for the role of NRP1 in those cancer cells not expressing the "classics" vascular endothelial growth factor receptors (VEGFRs), i.e., VEGF-R1 and VEGF-R2 [4]. Our studies during the third year were to elucidate the NRP1 signaling mechanism in bone metastatic PCa cells.

Body

1. Clinical significance of Mcl-1 in PCa progression and bone metastasis

During the first two years of the supporting period, we identified myeloid cell leukemia-1 (Mcl-1) as a novel downstream target of NRP1 signaling in bone metastatic prostate cancer cells. However, only limited information are available on Mcl-1 expression profile in PCa [5]. To explore the clinical significance of Mcl-1 in PCa metastasis, we investigated the expression of pattern of Mcl-1 in human tumor specimens in collaboration with Dr. Adeboye Osunkoya at the Department of Pathology, Emory University School of Medicine, and Drs. Haiyen Zhau and Leland Chung at the Cedars-Sinai Medical Center. We defined tumors with Gleason score 2-6 as well-differentiated (n=2), Gleason score 7 as intermediately-differentiated (n=26) and Gleason score 8-10 as poorly-differentiated (n=43). Figure 1 showed Mcl-1 immuno-intensity was increased from normal tissues to well-differentiated cancer and further elevated in high grade PCa, though the difference between Gleason score 7 and 8-10 tumors is not statistically significant ($p = 0.93$). Our results, for the first time, revealed a remarkable increase in Mcl-1 immunointensity in bone metastasis compared to primary tumors, indicating that Mcl-1 overexpression is positively correlated to PCa progression towards metastatic status in clinical situation.

2. c-Met is required for NRP1 signaling in bone metastatic PCa cells

![Figure 1. IHC staining of Mcl-1 in human PCa tissue microarray consisting of normal adjacent tissues, primary PCa and bone metastases.](image1)

![Figure 2. c-MET signaling is required for VEGF\textsubscript{165} induction of Mcl-1 in ARCaPM cells.](image2)

(a) Effects of c-MET inhibition on Mcl-1 expression. ARCaPM cells were transfected with c-MET siRNA or control siRNA (30 nM) for 72 h. (b) Effects of recombinant HGF treatment (10 ng/ml) on Mcl-1 expression at RNA (0, 2, 4 and 6 h) and protein levels (72 h). (c) ARCaPM cells were transfected with c-MET siRNA or control siRNA for 48 h, serum-starved overnight, and treated with VEGF\textsubscript{165} (10 ng/ml) for 2 h. (d) ARCaPM cells were treated with PHA-665752 (0.5 μM) or dimethyl sulfoxide (DMSO) for 2 h, before treatment with VEGF\textsubscript{165} (10 ng/ml) or PBS for 2 h.
We identified a tyrosine kinase receptor c-Met as an interacting protein with NRP1 on the plasma membrane in bone metastatic PCa cells. Transient transfection of c-MET siRNA reduced Mcl-1 protein expression, and abrogated the induction of Mcl-1 by VEGF treatment, suggesting that c-MET is involved in the regulation of Mcl-1 expression in PCa cells. Blockade of c-Met signaling using a pharmacological inhibitor PHA-665752 significantly attenuated VEGF induction of Mcl-1 in ARCaP cells (Figure 2). These data indicated that c-MET signaling is required for VEGF regulation of Mcl-1 in PCa cells. We further revealed that c-Src and Stat3 are downstream components of NRP1 signaling pathway in PCa cells (Figure 3).

Figure 3. Src kinase-Stat3 signaling mediates VEGF induction of Mcl-1 expression in ARCaP cells. (a) Effects of NRP1 inhibition on phosphorylation of Src kinases and Stat3. ARCaPM cells were transfected with NRP1 siRNA or control siRNA for 72 h. (b) Effects of VEGF on the phosphorylation of Src kinases and Stat3. ARCaPM cells were treated with VEGF (10 ng/ml) for the indicated time, and immunoblotting was performed on total lysates (left) and nuclear extracts and cytoplasmic proteins (right). (c) Effects of Src kinases on VEGF regulation of Mcl-1. ARCaPM cells were treated with PP2 (10 μM) or DMSO for 2 h before treatment with VEGF or PBS. (d) Effects of Stat3 depletion on VEGF induction of Mcl-1. ARCaPM cells were transfected with Stat3 siRNA or control siRNA for 48 h, serum-starved overnight, then treated with VEGF (10 ng/ml) or PBS for 2 h.

Figure 4. Expression of NRP1 and p-c-MET is associated with bone metastatic status of human PCa specimens and the ARCaP model. IHC analyses of NRP1 expression in human normal/benign, cancerous and metastatic prostatic tissue specimens (a) and primary and bone metastatic tissue specimens from ARCaP model (b), and of p-c-MET expression in human PCa progression (c) and ARCaP xenografts (d). Arrows indicate positively-stained cells.

3. Clinical significance of NRP1-c-Met pathway in PCa progression and bone metastasis

During the revision of our manuscript submitted to Molecular Cancer, we responded to the reviewers’ critiques and re-evaluated the expression profile of NRP1 and p-c-MET in human tumor specimens and ARCaP.
xenografts. Figure 4 showed that expression of both NRP1 and p-c-MET increased significantly from well-differentiated and intermediate to poorly-differentiated primary PCa. Importantly, bone metastatic PCa specimens displayed a higher expression of NRP1 and p-c-MET than primary PCa. The results were further observed in ARCaP tumors. These data indicated that activation of the NRP1-c-Met signaling is associated with PCa bone metastasis.

4. Establishment of ARCaP<sub>M</sub> cells stably expressing NRP1 short-hairpin RNA (shRNA)

To explore the targeting potential of NRP1 in treating PCa bone metastasis, we established two sublines of ARCaP<sub>M</sub> that express specific shRNA against human NRP1 (obtained from Origene, Inc.) (Figure 5). In vivo experiments will be performed using intracardiac and intratibial procedures.

5. Genentech NRP1 monoclonal antibodies moderately inhibited proliferation of bone metastatic PCa cells

In collaboration with Genentech, we evaluated the in vitro effects of two NRP1 monoclonal antibodies on the proliferation of ARCaP<sub>M</sub> cells. Figure 6 showed that at the concentration of 20 μg/ml, both antibodies inhibited proliferation moderately, with a higher degree when NRP1<sup>Δ1</sup> was used [6]. We will test the in vivo effects of these antibodies with the intention of co-targeting tumor and vasculature to achieve more efficacious inhibition of tumor growth in animal models.

Key Research Accomplishments

1. We demonstrated that Mcl-1 expression is positively associated with PCa progression, particularly bone metastasis.

2. We elucidated a novel signaling pathway by which NRP1 regulates Mcl-1 expression through a c-MET-dependent mechanism in bone metastatic prostate cancer cells. We further validated the implication of this pathway in clinical PCa specimens.

3. These novel findings resulted in a highly-accessed publication in the journal Molecular Cancer (http://www.molecular-cancer.com/content/9/1/9/abstract).

4. We established ARCaP<sub>M</sub> cells stably expressing NRP1 shRNAs. Genentech NRP1 mAb showed moderate efficacy in suppressing PCa cell proliferation in vitro.

Reportable Outcomes Publication/manuscript/abstract

New collaboration

We established new collaboration with Dr. Adeboye Osunkoya at the Department of Pathology, Emory University School of Medicine

Conclusion

During the third year of the supporting period, we correlated Mcl-1 overexpression with PCa bone metastasis, and elucidated a signaling mechanism by which NRP1 regulates Mcl-1 expression. These findings provide an
excellent rationale to develop NRP-1-targeted therapy treating bone metastatic PCa. These studies have recently been published as a highly-accessed paper in the journal of Molecular Cancer.

Vascular endothelial growth factor regulates myeloid cell leukemia-1 expression through neuropilin-1-dependent activation of c-MET signaling in human prostate cancer cells

Shumin Zhang1, Haiyen E Zhau2, Adeboye O Osunkoya1, Shareen Iqbal1, Xiaoqian Yang2,4, Songqing Fan5, Zhengjia Chen6, Ruoxiang Wang1, Fray F Marshall1, Leland WK Chung2, Daqing Wu1*

Abstract

Background: Myeloid cell leukemia-1 (Mcl-1) is a member of the Bcl-2 family, which inhibits cell apoptosis by sequestering pro-apoptotic proteins Bim and Bid. Mcl-1 overexpression has been associated with progression in leukemia and some solid tumors including prostate cancer (PCa). However, the regulatory mechanism for Mcl-1 expression in PCa cells remains elusive.

Results: Immunohistochemical analyses revealed that Mcl-1 expression was elevated in PCa specimens with high Gleason grades and further significantly increased in bone metastasis, suggesting a pivotal role of Mcl-1 in PCa metastasis. We further found that vascular endothelial growth factor (VEGF) is a novel regulator of Mcl-1 expression in PCa cells. Inhibition of endogenous Mcl-1 induced apoptosis, indicating that Mcl-1 is an important survival factor in PCa cells. Neuropilin-1 (NRP1), the "co-receptor" for VEGF165 isoform, was found to be highly expressed in PCa cells, and indispensable in the regulation of Mcl-1. Intriguingly, VEGF165 promoted physical interaction between NRP1 and hepatocyte growth factor (HGF) receptor c-MET, and facilitated c-MET phosphorylation via a NRP1-dependent mechanism. VEGF165 induction of Mcl-1 may involve rapid activation of Src kinases and signal transducers and activators of transcription 3 (Stat3). Importantly, NRP1 overexpression and c-MET activation were positively associated with progression and bone metastasis in human PCa specimens and xenograft tissues.

Conclusions: This study demonstrated that Mcl-1 overexpression is associated with PCa bone metastasis. Activation of VEGF165-NRP1-c-MET signaling could confer PCa cells survival advantages by up-regulating Mcl-1, contributing to PCa progression.

Background

Acquisition of apoptosis resistance is characteristic of invasive tumor cells. Elevated expression of anti-apoptotic proteins is associated with tumor progression clinically and experimentally [1]. Myeloid cell leukemia-1 (Mcl-1), a member of the Bcl-2 family, sequesters pro-apoptotic proteins Bim and Bid, thereby inhibiting mitochondrial outer membrane permeabilization, a central control point of apoptosis [2,3]. Mcl-1 overexpression is associated with progression in leukemia [4] and some solid tumors including prostate cancer (PCa) [5-7]. Mcl-1 was elevated in primary PCa with high Gleason grades and metastatic tumors compared to that in prostatic intraepithelial neoplasia (PIN) or lower grade tumors, suggesting a pivotal role of Mcl-1 in PCa progression [5].

Angiogenesis favors tumor cell survival, thereby contributing to progression [1]. Vascular endothelial growth factor (VEGF) is a critical pro-angiogenic factor that induces proliferation and migration of endothelial cells within tumor vasculature [8]. VEGF is expressed as several alternately spliced isoforms. VEGF165 is pre-dominant, with optimal bioavailability, and responsible for VEGF biological potency, whereas VEGF121 is less potent but freely diffusible. VEGF binds two highly-
related receptor tyrosine kinases, VEGF-R1 and VEGF-R2 [8]. Neuropilin-1 (NRP1) was originally identified as a receptor for the semaphorin 3 subfamily mediating neuronal guidance and axonal growth [9]. It was subsequently found to specifically bind VEGF165 but not VEGF121 on endothelial cells and tumor cells [9,10]. NRP1 lacks a typical kinase domain, primarily functioning as a “co-receptor” to form ligand-specific receptor complexes. In response to VEGF165, NRP1 couples with VEGF-Rs to signal in endothelial cells. Though VEGF-R1 and VEGF-R2 are usually absent or expressed at very low levels in PCa cells [11], aberrant upregulation of NRP1 has been frequently observed in high grade and metastatic PCa and other solid tumors [9,12-16]. Ectopic expression of NRP1 in PCa cells induced cell migration, increased tumor size and microvessel density, and inhibited apoptosis [17]. These observations suggested that NRP1 may be critical for PCa progression. Nonetheless, the mechanism by which NRP1 transmits VEGF signaling in PCa cells lacking VEGF-Rs remains unclear.

Previously we reported that serum VEGF levels correlate to bone metastatic status in PCa patients, and activation of VEGF signaling in PCa cells is associated with invasive phenotypes in experimental models [18]. In this study, we correlate Mcl-1 overexpression to PCa progression towards bone metastasis, and provide evidence that VEGF regulates Mcl-1 expression through NRP1-dependent activation of c-MET in PCa cells.

Results
Elevated Mcl-1 expression is associated with PCa progress and bone metastasis
To investigate the clinical significance of Mcl-1 in PCa progression, immunohistochemical (IHC) analyses were performed to determine the expression of Mcl-1 in a human PCa tissue microarray with matched normal adjacent tissue and bone metastatic bone specimens (Figure 1a). We defined tumors with Gleason score 2-6 as well-differentiated (n = 2), Gleason score 7 as intermediatedifferentiated (n = 26) and Gleason score 8-10 as poorly-differentiated (n = 43). Mcl-1 immunointensity was increased from normal tissues to well-differentiated cancer and further elevated in high grade PCa, although the difference between Mcl-1 intensity in intermediate-and poorly-differentiated cancers was not statistically significant (p = 0.93). Intriguingly, Mcl-1 staining in bone metastatic tumors (n = 6) was remarkably increased compared to that in either intermediate- or poorly-differentiated PCa (p < 0.002). These data correlated elevated Mcl-1 expression to clinical PCa progression, particularly bone metastasis.

Mcl-1 is a survival factor in human PCa cells
We have established several lines of human PCa models that closely mimic the clinical progression of PCa bone metastasis, including the ARCaP model [19,20]. When inoculated either orthotopically or intracardially, ARCaPM cells are capable of metastasizing spontaneously to bone and soft tissues, forming mixed osteoblastic and osteolytic lesions in mouse skeleton [19,21,22]. The ARCaPM-C2 subclone, derived from metastatic bone tumors after two rounds of intracardiac injection of ARCaPM cells in athymic mice, forms predictable metastases to bone, adrenal gland and other soft tissue with higher propensity and shorter latency [21,22] (Figure 1b). Reverse transcription-PCR (RT-PCR) and immunoblotting analyses found that Mcl-1 was substantially expressed by ARCaPM cells, and further increased in ARCaPM-C2 cells (Figure 1c). Similarly, increased Mcl-1 expression was observed in metastatic C4-2 and C4-2B cells [23] when compared to their parental, androgen-dependent human PCa cell line LNCaP (Additional file 1, Figure S1a). These results suggested a possible association between Mcl-1 expression and invasive phenotypes of PCa cells.

To examine the function of Mcl-1 in PCa cell survival, a Mcl-1 small-interfering RNA (siRNA) was transfected into ARCaPM cells. siRNA treatment efficiently inhibited Mcl-1 expression and significantly reduced ARCaPM cell viability by ~36% after 72 h (Figure 1d). Annexin V staining by fluorescence-activated cell sorting (FACS) analysis showed that the Mcl-1 siRNA induced apoptosis in 24.4-2.3% of ARCaPM cells (Figure 1e). These results indicated that Mcl-1 may be an important survival factor in PCa cells.

VEGF regulates Mcl-1 expression in human PCa cells
Previously we reported that ARCaPM cells express high levels of endogenous VEGF, regulated by a cyclic AMP-response element binding protein (CREB)-hypoxia-inducible factor (HIF)-dependent mechanism in normoxic conditions [18]. In the present study, RT-PCR assay that could differentiate mRNA expression of VEGF165 and VEGF121 isoforms [18] was performed in ARCaPM and ARCaPM-C2 cells, showing a significant increase in the expression of both VEGF isoforms in ARCaPM-C2 cells, as confirmed at protein level by enzyme-linked immunosorbent assay (ELISA) (Figure 2a). Similarly, C4-2 cells express higher levels of VEGF when compared to LNCaP cells (Additional file 1, Figure S1b). These data suggested that VEGF expression is elevated in metastatic PCa cells.

VEGF potently stimulates endothelial cell proliferation and migration, an underlying mechanism for angiogenesis during tumor progression. However, neither exogenous human VEGF165 (Figure 2b) nor VEGF121 (Additional file 1, Figure S1c) significantly affected the proliferation of ARCaPM cells at a non-saturating range (5-100 ng/ml), suggesting that VEGF is not a potent mitogen in PCa cells. Intriguingly, VEGF165 was found
to rapidly induce Mcl-1 mRNA expression in a dose- and time-dependent manner, with the maximum accumulation of Mcl-1 mRNA after 2 h-incubation at the concentration of 10 ng/ml. Western blot analysis confirmed a remarkable increase of Mcl-1 protein in ARCaPM cells (Figure 2c) and LNCaP cells (Additional file 1, Figure S1d) treated with VEGF165. Conversely, when ARCaPM cells were transfected with a VEGF siRNA nucleotide that selectively inhibited expression of VEGF165 but not VEGF121, expression of Mcl-1, but not Bcl-2, was reduced after 72 h (Figure 2d). Notably, Mcl-1 expression was not affected by VEGF121 treatment (Additional file 1, Figure S1e). These results indicated that VEGF165 may specifically regulate Mcl-1 expression in PCa cells.

**Differential expression of VEGF-Rs in PCa cells**

Expression of VEGF-Rs was examined in several PCa cell lines with human umbilical vein endothelial cells (HUVEC) as a positive control (Figure 3a, and Additional file 1, Figure S1f). VEGF-R1 was undetectable in
PCa cells. Only very low expression of VEGF-R2 could be observed in ARCaPM-C2 cells. However, NRP1 was ubiquitously expressed in PCa cells at a level comparable to that in HUVEC, and higher in metastatic ARCaPM-C2, PC3, C4-2 and C4-2B cells. NRP2, the "co-receptor" for VEGF-C [8], was not detected in PCa cells. These data implied that NRP1 may be the major receptor mediating VEGF effects in PCa cells.

**NRP1 regulates both basal expression and VEGF induction of Mcl-1 in PCa cells**

The role of NRP1 in the regulation of Mcl-1 expression was investigated. ARCaPm cells cultured in serum-containing T-medium were transiently transfected with a NRP1 expression vector. Compared to the control, ectopic expression of NRP1 resulted in increased Mcl-1 at both the mRNA and protein levels (Figure 3b). Conversely, transfection with a NRP1 siRNA specifically inhibited NRP1 and reduced endogenous Mcl-1 expression in ARCaPM cells (Figure 3c). These data indicated that NRP1 may be required and sufficient for basal expression of Mcl-1 in PCa cells. Further, ARCaPM cells were transfected with NRP1 siRNA or control siRNA, and incubated with VEGF165 in serum-free T-medium for indicated time. Figure 3d showed that expression of NRP1 siRNA, but not control siRNA, abrogated VEGF165 induction of Mcl-1 in ARCaPM cells. These data indicated an indispensible role of NRP1 in mediating VEGF165 induction of Mcl-1 in PCa cells.

**c-MET signaling is required for VEGF regulation of Mcl-1 in PCa cells**

Since NRP1 does not contain typical kinase receptor sequences [24], we hypothesized that NRP1 may interact with certain tyrosine kinase receptor(s) to transmit VEGF autocrine signal in PCa cells lacking VEGF-Rs. Two recent studies independently demonstrated that NRP1 physically binds c-MET, and potentiates c-MET activation in PCa cells. Only very low expression of VEGF-R2 could be observed in ARCaPM-C2 cells. However, NRP1 was ubiquitously expressed in PCa cells at a level comparable to that in HUVEC, and higher in metastatic ARCaPM-C2, PC3, C4-2 and C4-2B cells. NRP2, the “co-receptor” for VEGF-C [8], was not detected in PCa cells. These data implied that NRP1 may be the major receptor mediating VEGF effects in PCa cells.

**Figure 2 VEGF165 regulates Mcl-1 expression in PCa cells**

(a) VEGF expression in ARCaPM and ARCaPM-C2 cells, as determined by RT-PCR and ELISA (conditioned medium). (b) Effects of recombinant VEGF165 on cell proliferation as determined by MTS assay. Top, ARCaPM cells were seeded in 96-well plates (1 x 10^3 cells/well) for 24 h, and serum-starved overnight. The cells were further incubated with varying concentrations of VEGF165 in serum-free T-medium for 72 h. Bottom, ARCaPM cells were incubated with PBS or VEGF165 (50 ng/ml) in serum-free T-medium for varying times. (c) VEGF165 effects on Mcl-1 expression. ARCaPM cells were treated with VEGF165 at indicated concentrations and times, and Mcl-1 mRNA expression was measured. For immunoblotting, ARCaPM cells were incubated with VEGF165 (10 ng/ml) for 72 h. (d) Effects of VEGF siRNA on Mcl-1 expression. ARCaPM cells were transfected with VEGF siRNA or control siRNA (80 nM) for 72 h.

response to HGF stimulation in human glioma and pancreatic cancer cells [25,26]. It is therefore plausible that c-MET may be involved in VEGF regulation of Mcl-1 in PCa cells. Indeed, HGF activation of c-MET signaling has been shown to transcriptionally increase Mcl-1 expression in primary human hepatocytes [27].

A c-MET siRNA construct was transfected into ARCaPM cells, which effectively inhibited endogenous c-MET (Figure 4a). c-MET siRNA treatment reduced Mcl-1 protein expression, suggesting that c-MET is involved in maintaining basal expression of Mcl-1 in PCa cells. Interestingly, however, recombinant HGF treatment did not significantly affect Mcl-1 expression at either RNA or protein levels (Figure 4b), indicating that HGF-dependent activation of c-MET signaling is not sufficient to induce Mcl-1 expression in these cells.
We further investigated whether c-MET signaling is required for VEGF\textsubscript{165} induction of Mcl-1. Indeed, VEGF\textsubscript{165} only induced Mcl-1 expression in ARCaPM cells transfected with control siRNA, not in those expressing c-MET siRNA (Figure 4c). PHA-665752, a c-MET selective inhibitor [28], was used to treat ARCaPM cells prior to addition of VEGF\textsubscript{165}. PHA-665752 significantly attenuated VEGF\textsubscript{165} induction of Mcl-1 in ARCaPM cells (Figure 4d). These data indicated that c-MET signaling is required for VEGF regulation of Mcl-1 in PCa cells.

**VEGF induces c-MET activation by a NRP1-dependent mechanism in PCa cells**

c-MET activation involves phosphorylation of several tyrosine residues including those at positions 1230, 1234, and 1235 [29]. To assess whether VEGF\textsubscript{165} could induce c-MET activation, and whether this process was mediated by NRP1, ARCaPM cells were transiently transfected with NRP1 siRNA or control siRNA before VEGF\textsubscript{165} treatment. VEGF\textsubscript{165} induced rapid phosphorylation of c-MET at Tyr1230/1234/1235 residues in ARCaPM cells transfected with control siRNA, but this effect was significantly attenuated by expression of NRP1 siRNA. Expression of total c-MET protein was not affected by siRNA treatment (Figure 5a). These data indicated that VEGF\textsubscript{165} activated c-MET signaling independent of HGF, and NRP1 may be indispensable in this process.

**VEGF promotes interaction between NRP1 and c-MET in PCa cells**

To explore whether VEGF could induce physical interaction between NRP1 and c-MET, an immunoprecipitation assay was performed in ARCaPM cells treated with VEGF\textsubscript{165} for varying times. First, endogenous NRP1 protein was immunoprecipitated (Figure 5b, upper). There was a constitutive association between c-MET and NRP1 in the absence of VEGF\textsubscript{165}. Upon VEGF\textsubscript{165} treatment, presence of c-MET in the NRP1 immunoprecipitates increased at 30 min and returned to baseline at 60 min. Phosphorylated c-MET (p-c-MET) significantly increased at 15 min following VEGF\textsubscript{165} treatment, reached a peak at 30 min and slightly decreased in 60 min. Reciprocal immunoprecipitation with anti-c-MET antibody confirmed an association of NRP1 with c-MET in the absence of VEGF\textsubscript{165}. The presence of NRP1 and p-c-MET in the protein complex exhibited a similar time course following VEGF\textsubscript{165} stimulation, with the peak at 30 min (Figure 5b, low).

Confocal microscopy was performed to determine whether VEGF\textsubscript{165} promotes NRP1 interaction with c-MET.
and activation of c-MET in ARCaPM cells. NRP1 and c-MET were found to be constitutively associated on plasma membrane, with the intensity of co-localization further increased at 30 min upon VEGF165 treatment (Figure 5c, left panel). Notably, there was a more significant increase in the intensity of co-localization of NRP1 and p-c-MET following VEGF165 stimulation (Figure 5c, right panel). The data independently supported a mechanism that NRP1 may be constitutively associated with c-MET on plasma membrane. Upon VEGF165 binding, NRP1 may further recruit c-MET and facilitate its activation, subsequently transmitting VEGF165 signal (Figure 6).

Role of Src kinases and signal transducers and activators of transcription 3 (Stat3) in VEGF induction of Mcl-1 in PCa cells

Activation of the Src kinase-Stat3 pathway is an important downstream event in c-MET signaling [30,31] (refer to Figure 6). Recently, a Stat3 cis-element was identified in human Mcl-1 promoter [32]. We investigated whether the Src kinase-Stat3 pathway is a downstream component in NRP1 signaling in ARCaPM cells (Figure 7a). Indeed, expression of NRP1 siRNA in ARCaPM cells significantly inhibited phosphorylation of Src kinases at Tyr416 (p-Src), as well as activation of Stat3 at Tyr705 (p-Stat3), without altering expression of endogenous Src kinases and Stat3.

Next we examined whether VEGF induces activation of Src kinase-Stat3 signaling in ARCaPM cells (Figure 7b). VEGF165 rapidly induced expression of both p-Src (Tyr416) and p-Stat3 (Tyr705) in a time-dependent manner in ARCaPM cells, with the peak at 60 min. Significantly, VEGF165 promoted rapid intracellular translocation of p-Stat3 (Tyr705) from the cytoplasm to the nucleus, indicating activation of Stat3-dependent gene expression. By contrast, nuclear presence of p-Stat3 (Ser727), which has been associated with HGF-induced Mcl-1 expression in primary human hepatocytes [27], was not affected. These data indicated that Src kinase-Stat3 pathway activation may be an important event following VEGF165 stimulation.

Finally, we assessed the role of Src kinase-Stat3 signaling in VEGF165 regulation of Mcl-1. PP2, a selective inhibitor of Src kinases [33], was used to treat ARCaPM cells before VEGF165 stimulation. PP2 treatment effectively abrogated VEGF165 induction of Mcl-1 (Figure 7c). Similarly, Mcl-1 mRNA expression was rapidly induced by VEGF165 in ARCaPM cells transfected with control siRNA, but not in the cells expressing Stat3 siRNA (Figure 7d). Collectively these data suggested that Src kinase-Stat3 signaling may be required for VEGF induction of Mcl-1 in PCa cells (Figure 6).

NRP1 overexpression and c-MET activation are positively associated with human PCA progression and bone metastasis

To validate the clinical significance of NRP1-c-MET signaling in PCA progression, and avoid the potential bias from using human PCA cell lines, IHC analyses were performed to determine the expression of NRP1 and p-c-MET in human PCA tissue specimens. Prostatic tissue specimens of normal/benign glands, primary and bone metastatic tumors were analyzed. NRP1 expression was increased from normal/benign glands (0/5) or well-differentiated cancer (1/5) to poorly-differentiated cancers (5/5) and bone metastatic tissues (5/5) (Figure 8a). NRP1 staining was also determined in tumor specimens from the ARCaPM xenograft model in which ARCaPM cells were inoculated into athymic mice orthotopically, resulting in skeletal metastases with a short latency [21]. Consistently, NRP1 expression was significantly greater in bone metastatic tumors than in primary tumors (Figure 8b).

We and others have reported that c-MET overexpression is positively associated with PCA progression [34,35]. As shown in Figure 8c, p-c-MET was expressed at a low level in normal human prostatic tissue, but increased significantly from well-differentiated and intermediate to poorly-differentiated primary PCa. Importantly, bone metastatic PCa specimens displayed a higher expression of p-c-MET than primary PCa. p-c-MET expression was also remarkably increased in bone metastatic ARCaPM tumors (Figure 8d).

Discussion

Aberrant overexpression of Mcl-1 has been associated with poor prognosis and resistance to chemotherapy in a variety of human cancers [36]. Sensitizing tumor cells to apoptosis induction by selectively targeting Mcl-1, in combination with conventional chemotherapy, has
emerged as an attractive therapeutic strategy [3,37]. In this study, we presented evidence that elevated Mcl-1 expression is associated with clinical PCa progression, particularly bone metastasis. We further showed that activation of VEGF-NRP1-c-MET signaling is responsible for Mcl-1 expression, which may confer survival advantages allowing PCa cells to evade apoptosis and progress towards invasive states (Figure 6).

Only limited information are available on Mcl-1 expression profile in PCa. An early study found that Mcl-1 expression was increased in tumors (81%) compared with only 38% in PIN. The percentage of Mcl-1-positive cells was typically higher in Gleason grade 8-10 tumors and metastasis than lower grade tumors, but there was no significant difference in Mcl-1 immunointensity between high grade tumors (47%) and metastasis in lymph node (38%) and bone (50%) [5]. Our present study confirmed elevated Mcl-1 expression in high grade (≥7) PCa, though the difference between Gleason score 7 and 8-10 tumors is not statistically significant. Intriguingly, our results revealed a remarkable increase in Mcl-1 immunointensity in bone metastasis compared to primary tumors, indicating that Mcl-1 overexpression is positively correlated to PCa progression towards metastatic status in clinical situation.

Accumulating evidence suggests that the function of VEGF in tumor progression may not be limited to angiogenesis [38]. Numerous tumor cells express significant levels of VEGF-Rs, which could engage VEGF and initiate multiple signaling responses involved in cell proliferation, survival and migration. VEGF autocrine signaling confers a degree of self-sufficiency that may be crucial to metastasis as the microenvironment becomes increasingly hostile. Nonetheless, it remains controversial whether VEGF has significant autocrine effects in PCa cells, since the “classical” VEGF-Rs, i.e., VEGF-R1 and -R2, are undetectable in most established PCa cell lines [11,39,40]. Previously we reported that serum VEGF is positively associated with bone metastatic status in PCa patients, and recapitulated this close association in the ARCaP model [18]. In this study, we investigated whether VEGF could affect PCa cell behavior in an autocrine manner. Intriguingly, VEGF_{165} was found to be capable of inducing Mcl-1 expression within a non-saturating range, suggesting it may act as a survival factor in PCa cells. Moreover, NRP1 was found to be highly expressed by PCa cell lines and displayed a positive association with invasiveness, suggesting that it may be the primary receptor responsible for VEGF autocrine signaling.
effects in PCa cells. Gene transfer experiments supported an indispensible role of NRP1 in mediating VEGF$_{165}$ regulation of Mcl-1 in metastatic PCa cells. Importantly, a positive association between NRP1 expression and in vivo bone metastatic potential was found in ARCaP$_{M}$ xenografts and further confirmed in clinical PCa specimens. These data collectively support a novel role of NRP1 in PCa progression and metastasis, presumably by transmitting the VEGF autocrine survival signal and enabling PCa cells to evade apoptosis.

NRP1 is not a typical “signaling receptor” since it lacks sequences predicted to have kinase receptor activities [24]. Direct interaction between NRP1 and VEGF-Rs or plexin A is essential to its function in prioritizing differential signals from VEGF$_{165}$ or semaphorin 3 in endothelial cells and nerve cells [24]. Recent studies found that

**Figure 8** Expression of NRP1 and p-c-MET is associated with bone metastatic status of human PCa specimens and the ARCaP$_{M}$ model

IHC analyses of NRP1 expression in human normal/benign, cancerous and metastatic prostatic tissue specimens (a) and primary and bone metastatic tissue specimens from ARCaP$_{M}$ model (b), and of p-c-MET expression in human PCa progression (c) and ARCaP$_{M}$ xenografts (d). Arrows indicate positively-stained cells.
the NRP1 intracellular domain, especially the C-terminal three amino acids (SEA-COOH), may be required for the interaction between NRP1 and its binding partners, including NRP1-interacting protein (NIP; or RGS-GAIP-interacting protein, GIPC) and VEGF-R2 [41,42]. However, the molecular effects and mechanism for NRP1-mediated signaling in tumor cells, especially in the absence of VEGF-Rs, remain elusive. It has been proposed that NRP1 may store or sequester VEGF165 and attract endothelial cells towards tumor, contributing to angiogenesis via juxtacrine or paracrine mechanisms [9,17]. In this study, we investigated whether NRP1 is required for VEGF165 autocrine signaling in PCa cells lacking VEGF-Rs. We presented evidence that NRP1 and c-MET are physically associated on plasma membrane, and in response to VEGF165 stimulation, their interaction may significantly facilitate further recruitment and activation of c-MET. Though the structural and molecular basis for interaction between the two receptors needs to be further investigated, this study indicates for the first time that c-MET activity can be modulated by VEGF, and the NRP1-c-MET interaction may be a critical component in transmitting the VEGF survival signal in PCa cells. It may be plausible to assign c-MET phosphorylation as an indicator for activation of NRP1 autocrine signaling in tumor cells. Using human PCa tissue specimens as the “gold standard”, we observed that NRP1 and p-c-MET were both significantly increased with progression of primary PCa, and further elevated in bone metastatic PCa, suggesting that activation of NRP1-c-MET signaling may be positively associated with clinical PCa progression. It is worth noting that these results need cautious interpretation since a limited number of patient specimens was examined, and the polyclonal antibody against p-c-MET has not been fully validated for immunohistochemical analysis in tissue sections.

In human primary hepatocytes, HGF transcriptionally induced Mcl-1 expression, but not Bcl-2 or Bcl-x(L) [27]. Our studies found that, however, HGF treatment did not significantly affect Mcl-1 protein expression in ARCaPM cells, suggesting HGF activation of c-MET signaling may not be sufficient to increase Mcl-1 expression. We postulated that VEGF165 may utilize a different mechanism to regulate Mcl-1 expression in PCa cells. An important observation supporting this hypothesis is that VEGF165 only rapidly induced Stat3 phosphorylation at Tyr705, but not altering Ser727 phosphorylation in ARCaPM cells. In hepatocytes, however, HGF triggered Ser727, but not Tyr705, phosphorylation of Stat3 [27]. It will be intriguing to investigate the role of NRP1-c-MET interaction in differentiating extracellular ligands, i.e., VEGF165 or HGF, and activating distinct downstream cascades leading to Mcl-1 expression in a highly cell context-dependent fashion.

Mcl-1 is a protein with very short half-life and is highly regulated at multiple levels in response to survival and differentiation signals. Rapid turnover of Mcl-1 protein can be initiated by stress (such as serum withdrawal) through caspase-mediated and proteasome-dependent degradation in tumor cells [3]. Previous study found that VEGF protects multiple myeloma cells against apoptosis by up-regulating Mcl-1 protein in a time-dependent manner, peaking at 6 h and returning to baseline after 24 h; change in Mcl-1 mRNA expression was not reported [43]. In ARCaPM cells, however, VEGF165 treatment rapidly induced Mcl-1 mRNA expression and significantly increased Mcl-1 protein level at 72 h. Though whether VEGF165 may also regulate Mcl-1 expression at other levels needs to be further investigated, the data presented here suggest that transcriptional activation, presumably mediated by Stat3, is an important mechanism for VEGF165 induction of Mcl-1 in PCa cells.

Interrupting NRP1 functions with mimetic peptides and monoclonal antibodies is being developed in xenograft models of human cancers [44,45]. NRP1 monoclonal antibody has been shown to effectively inhibit tumor vascular remodeling, rendering vessels more susceptible to anti-VEGF therapy [45]. If the VEGF165-NRP1-c-MET pathway is required for Mcl-1 expression and survival in PCa cells, it would be intriguing to evaluate whether targeting NRP1 could interrupt both NRP1-c-MET signaling in tumor cells (survival) and NRP1-VEGF-Rs signaling in endothelial cells (angiogenesis). Inhibition of NRP1 signaling may be a promising strategy alone or in combination with other therapeutic approaches for treating PCa.

**Methods**

**Cell culture**

Human PCa cell lines ARCaPM, ARCaPM-C2, PC3, LNCaP, C4-2 and C4-2B, were routinely maintained in T-medium (Invitrogen, Carlsbad, CA) with 5% fetal bovine serum (FBS). ARCaPM-C2 subclone was derived from ARCaPM bone metastatic tissues as described previously [21,22]. Where specified, ARCaPM cells were serum-starved overnight, and treated with recombinant human VEGF165, VEGF121, HGF (R&D Systems, Minneapolis, MN), c-MET inhibitor PHA-665752 (Calbiochem, San Diego, CA), or Src kinase inhibitor (PP2) (Calbiochem) in serum-free T-medium. HUVEC (The American Type Culture Collection, Manassas, VA) were maintained in endothelial basal growth medium (EBM-2) with 2% FBS. Cell proliferation was measured using the CellTiter 96 AQ proliferation assay according to the manufacturer’s instructions (Promega, Madison, WI). Viable cells were counted in triplicate using a hemacytometer and trypsin blue staining.
Immunohistochemical analysis

IHC staining of NRP1 and p-c-MET on human normal/benign prostatic glands, well- and poorly-differentiated primary PCa and bone metastatic PCa tissue specimens was performed as described previously [18] using goat anti-NRP1 antibody (C-19, Santa Cruz Biotechnology, Santa Cruz, CA; 1:100) and rabbit anti-p-c-MET (Tyr1230/1234/1235) antibody (44888G, Invitrogen; 1:100). IHC analysis of Mcl-1 expression was performed on a human PCa progression tissue microarray specimen (US BioMax, Inc., Rockville, MD) using rabbit anti-Mcl-1 antibody (S-19, Santa Cruz Biotechnology, 1:150). Matching normal serum was used as negative control. All IHC common reagents were obtained from Dako (Carpinteria, CA). Positive expression of NRP1, p-c-MET and Mcl-1 was defined as >15% positive staining in cell population.

Transfection

The vector harboring NRP1 cDNA (pCMV-NRP1) and the control (pCMV-XL4) (Origene, Rockville, MD) were transfected into ARCaPM cells for 48-72 h using lipofectamine 2000 (Invitrogen). Small interfering RNA (siRNA) nucleotides were transfected into ARCaPM cells according to the manufacturer’s instructions. VEGF siRNA, Mcl-1 siRNA, Stat3 siRNA and control siRNA-A were purchased from Santa Cruz Biotechnology. NRP1, p-c-MET and Mcl-1 was defined as >15% positive staining in cell population.

Western blot analysis

Total cell lysates were prepared using radioimmunoprecipitation (RIPA) buffer (Santa Cruz Biotechnology). Nuclear proteins were extracted using a Novagen kit (EMD Biosciences, San Diego, CA). Immunoblotting analysis followed standard procedure [18] with anti-Stat3, anti-p-Stat3 (Ser705), anti-Src and anti-p-Src (Tyr416) (Cell Signaling, Danvers, MA); anti-p-Stat3 (Tyr705) (Upstate, Charlottesville, VA); anti-Mcl-1, anti-NRP1 (C-19), anti-NRP2, anti-VEGF-R2, and anti-c-MET (Santa Cruz Biotechnology); anti-p-c-MET (Tyr1230/1234/1235) (Invitrogen); and anti-β-actin (Sigma, St. Louis, MO).

RT-PCR

Total RNA was prepared with Qiagen RNeasy Kit (Valencia, CA), and RT-PCR was performed using the SuperScriptIII® One-Step RT-PCR kit (Invitrogen) following the manufacturer’s protocol. The specific primer pairs are: 5’-GAGGAGGAGGAGCAAGTT-3’ (forward) and 5’-GTCCCGTTTTTGCTTACGA-3’ (reverse) (for Mcl-1); 5’-AGGACAGAGACTGCAAGTATGAC-3’ (forward) and 5’-AACATTCAAGACCTCTCTTGA-3’ (reverse) (for NRP1). The primers for VEGF, glyceraldehyde-3-phosphate dehydrogenase (GAPDH) [18] and Stat3 [46] were described previously. The primer pairs for human VEGF-R1, VEGF-R2 and NRP2 were purchased from R&D Systems.

ELISA

Subconfluent PCa cells were cultured in serum-free T-medium for 72 h before conditioned medium was collected. VEGF concentrations were analyzed using a Quantikine ELISA kit (R&D Systems) and normalized with total protein concentrations in CM.

Immunofluorescence and confocal imaging

Immunofluorescence was performed as described previously [47]. Goat anti-NRP1 antibody (C-19), rabbit anti-c-MET antibody (C-12, Santa Cruz Biotechnology), or rabbit anti-p-c-MET (Tyr1230/1234/1235) antibody was incubated with subconfluent ARCaPM cells at 4°C overnight. Either anti-goat Alexa Fluor® 546 or anti-rabbit Alexa Fluor® 488 secondary antibody (Invitrogen) was used at a dilution of 1:500. Cells were imaged on a Zeiss LSM 510 META [47]. In all cases, either a 63× or 100× Zeiss Plan-Apo oil objective was used (numerical aperture of 1.3 and 1.4, respectively). All images had contrast expansion performed in Adobe Photoshop.

Immunoprecipitation

The Immunoprecipitation Starter Pack (GE healthcare Bio-Sciences Corp., Piscataway, NJ) was used according to the manufacturer’s instructions. Total lysates (1 mg) were immunoprecipitated with rabbit anti-c-MET antibody (C-12), rabbit anti-NRP1 antibody (H-286, Santa Cruz Biotechnology), or normal rabbit IgG (R&D Systems). Protein A/G Sepharose 4 Fast Flow beads were added to precipitate proteins, then washed and eluted. The samples were further processed for western blot analysis.

Apoptosis analysis

Cells were stained with an Annexin V-PE apoptosis detection kit (BD Biosciences, San Jose, CA) following the manufacturer’s protocol, and measured using a fluorescence-activated cell sorting (FACS) caliber benchtop flow cytometer (Becton Dickinson, Franklin Lakes, NJ). The data were analyzed using FlowJo software (Tree Star, Inc., Ashland, OR).

Data analysis

Significance levels for comparisons of Mcl-1 expression in different Gleason score PCa were calculated by using the 2-sample t test. Treatment effects were evaluated using a two-sided Student’s t test. All data represent three or more experiments. Errors are S.E. values of averaged results, and values of p < 0.05 were taken as a significant difference between means.
