14. ABSTRACT
In prior work, the synthesis of α, β and γ-Re2Si2O7 powders (Re= Y and Ho) at temperatures from 1000° to 1400°C h in air was reported, along with the Vickers hardness of dense γ-Y2Si2O7 and γ-Ho2Si2O7 polymorphs. Dense γ-Y2Si2O7 and γ-Ho2Si2O7 pellets were made by a pressureless sintering technique at 1400°C/8h. Using the pressureless sintering technique, densification of α and β-Y2Si2O7 powder compacts at their phase formation temperature (1000°C - 1200°C) was not successful and prevented the determination of their hardness values. In this work, the field assisted sintering technique (FAST) was used to form dense α, β and γ-Y2Si2O7 pellets at a pressure of 20KN and temperatures of 1050°C to 1200°C. Subsequently, their Vickers hardness was measured. SCS-0 fibers were also incorporated into α, β and γ-Re2Si2O7 matrices and densified at 1050°C to 1200°C/1 h using the FAST approach. Fiber push-out experiments were conducted, and the average sliding stress values were determined.

Abstract

In prior work, the synthesis of α, β and γ-Re$_2$Si$_2$O$_7$ powders (Re= Y and Ho) at temperatures from 1000° to 1400°C h in air was reported, along with the Vickers hardness of dense γ-Y$_2$Si$_2$O$_7$ and γ-Ho$_2$Si$_2$O$_7$ polymorphs. Dense γ-Y$_2$Si$_2$O$_7$ and γ-Ho$_2$Si$_2$O$_7$ pellets were made by a pressureless sintering technique at 1400°C/8h. Using the pressureless sintering technique, densification of α and β-Y$_2$Si$_2$O$_7$ powder compacts at their phase formation temperature (1000°C - 1200°C) was not successful and prevented the determination of their hardness values. In this work, the field assisted sintering technique (FAST) was used to form dense α, β and γ-Y$_2$Si$_2$O$_7$ pellets at a pressure of 20KN and temperatures of 1050°C to 1200°C. Subsequently, their Vickers hardness was measured. SCS-0 fibers were also incorporated into α, β and γ-Re$_2$Si$_2$O$_7$ matrices and densified at 1050°C to 1200°C/1 h using the FAST approach. Fiber push-out experiments were conducted, and the average sliding stress values were determined.

1. Introduction

The application of SiC/SiC ceramic matrix composites (CMCs) is limited by mechanical property degradation in oxidizing environments. Several methods are used to minimize the oxidation of BN or carbon fiber-matrix interphases in SiC/SiC CMCs; however, an ideal solution would be to replace BN or carbon with a material that does not oxidize. The rare-earth disilicates are attractive candidates.

Among the rare earth disilicates, yttrium disilicate (Y$_2$Si$_2$O$_7$) is the most thoroughly studied. It has five polymorphs and is refractory, melting at 1775°C. Its γ-polymorph (γ-Y$_2$Si$_2$O$_7$) is a “quasi-ductile” ceramic and has comparable mechanical properties to LaPO$_4$ (monazite), which has been demonstrated to function as a weak fiber-matrix interphase in oxide-oxide CMCs. Both are soft (Vickers hardness ~6 GPa) and machineable. However, monazite decomposes in the reducing atmospheres typically used for processing SiC-SiC CMCs, and the rare earth disilicate La$_2$Si$_2$O$_7$ forms by reaction between SiO$_2$ and LaPO$_4$ under reducing conditions. An alternate oxide coating, therefore, that is stable in reducing environments is needed. In addition to its softness, γ-Y$_2$Si$_2$O$_7$ is thermochemically compatible with SiC and SiO$_2$, and it has a thermal expansion coefficient (~4x10^{-6}°C^{-1}) that is similar to SiC. This combination of properties induced the investigation of Re$_2$Si$_2$O$_7$ as a possible fiber-matrix interphase for SiC/SiC CMCs.

The rare-earth disilicates are commonly prepared by a variety of methods, including conventional solid-state reaction of mixed oxides (Re$_2$O$_3$ and SiO$_2$), calcination of rare-earth disilicate sol-gel precursors, and hydrothermal processing. In our prior work, the formation of α, β, and γ-Re$_2$Si$_2$O$_7$ powders (Re= Y and Ho) at temperatures between 1000° - 1400°C/air was reported. Precursors to Y$_2$Si$_2$O$_7$ and Ho$_2$Si$_2$O$_7$ were made by adding colloidal silica to solutions of yttrium and holmium nitrate.
LiNO$_3$ was added to decrease the formation temperature of the $\gamma$-polymorphs. Dense $\gamma$-Y$_2$Si$_2$O$_7$ and $\gamma$-Ho$_2$Si$_2$O$_7$ pellets were made by pressureless sintering at 1400°C/8h and hardness measurements were completed using the Vickers indentation method. Densification of $\alpha$ and $\beta$-Y$_2$Si$_2$O$_7$ powder compacts at their phase formation temperatures of 1000°C - 1200°C using pressureless sintering was not successful; therefore, their hardness values were not measured. In this work, dense $\alpha$, $\beta$ and $\gamma$-Y$_2$Si$_2$O$_7$ pellets were made using the field assisted sintering technique (FAST) and hardness measurements were completed using the Vickers indentation method. Further, SCS-0 fibers were incorporated into $\alpha$, $\beta$, $\gamma$-Re$_2$Si$_2$O$_7$ matrices and densified at 1050-1200°C/1 h using the FAST approach. Fiber push-out experiments were conducted and the measured sliding stress values are reported and discussed.

2. Experimental

2.1 Precursor Synthesis and Characterization

Precursors to Y$_2$Si$_2$O$_7$ and Ho$_2$Si$_2$O$_7$ were made by adding colloidal silica to solutions of yttrium and holmium nitrate, as reported previously. For the Y$_2$Si$_2$O$_7$ precursor, 12.7 g of Y(NO$_3$)$_3$•6H$_2$O were dissolved in 50 mL of deionized water to make a solution of pH ~1. The sol pH was determined using a pH/ion meter (Corning Inc., Corning NY). Silica (2.0 – 2.8 g) was added in the form of a sol with a pH of 10. For the Ho$_2$Si$_2$O$_7$ precursor, 14.7 g of Ho(NO$_3$)$_3$•5H$_2$O were added to 50 mL of deionized water and 2 g of silica was then added. In some cases, 0.12 g of LiNO$_3$ was added to the Y and Ho-derived precursor. The mixtures were dried in an oven for 72 h to form SiO$_2$/Y(OH)$_3$ and SiO$_2$/Ho(OH)$_3$ and then heated at 1050°C in air. The subsequent powders were characterized by X-ray diffraction (XRD) with Cu-K$_\alpha$ radiation (Model Rotaflex, Rigaku Co., Tokyo, Japan).

2.2 Formation and Densification of Pellets

SiO$_2$/Y(OH)$_3$ and SiO$_2$/Ho(OH)$_3$ dispersions with and without Li dopant were dried and then heat treated at 1050°C/1 h. Heat treated powders without Li formed $\alpha$-Y$_2$Si$_2$O$_7$ and $\alpha$-Ho$_2$Si$_2$O$_7$, while heat treated powders doped with Li formed $\beta$-Y$_2$Si$_2$O$_7$ and $\beta$-Ho$_2$Si$_2$O$_7$. Powders in the $\alpha$ and $\beta$ phases were ball milled in isopropanol using alumina milling media. Polyvinyl butyral resin (3 vol%) was added as a binder. After milling, the powder samples were characterized by XRD to confirm the retention of the $\alpha$ and $\beta$ phases. The milled slurry was separated and dried at 120°C for 18 h. The dried powder was uniaxially pressed into pellets and densified by the FAST approach at a pressure of 20KN and at temperatures of 1050°C, 1100°C and 1200°C. The dense pellets were ~20 mm in diameter and ~3 mm in height, with relative densities greater than 90%. Density measurements were gathered using the Archimedes method.

2.3. Indentation and Characterization

The hardnesses of the sintered pellets were measured by Vickers indentation at loads in the range of 50 g to 1000 g using a Buehler (Lake Bluff, IL) Hardness Tester 1600-2007. Indented samples were examined with FEI (Hillsboro, Oregon) scanning electron microscopes (SEM, Models Sirion and Quanta) with an X-ray energy dispersive spectroscopy (EDS) system operating at 5-20 kV. Foils for transmission electron microscopy (TEM, Philips CM200, FEI, Hillsboro, Oregon) were cut from areas below the Vickers indentations using an FEI (Hillsboro, Oregon) Focused Ion Beam (FIB) Dual Beam DB 235 workstation equipped with Omniprobe (Dallas, Texas) AutoProbe™ 200 micromanipulator.

2.4 Fiber Push-Out

SCS-0 fibers were sandwiched between two green pellets and densified at 1050 °C, 1100°C, and 1200°C for 1 h in vacuum using the FAST approach with a force of 20 kN. An approximately 0.4 mm thick cross sectional specimen was prepared for push-out studies; in this case, the fibers ran perpendicular...
to the polished surface. A fiber push-out testing apparatus (Process Equipment, Inc., Troy, OH) was used to obtain load displacement curves. The sliding stress was calculated based on a fiber diameter of 140 μm and using the minimum load, which corresponds to the load where fiber sliding stopped.

3. Results and Discussion

3.1 Densification of \( \gamma_2 \)Si\(_2\)O\(_7\) and Ho\(_2\)Si\(_2\)O\(_7\)

As reported previously, heat treatment of SiO\(_2\)/Y(OH)\(_3\) and SiO\(_2\)/Ho(OH)\(_3\) dispersions without Li at 1050°C formed \( \alpha \)-Y\(_2\)Si\(_2\)O\(_7\) and \( \alpha \)-Ho\(_2\)Si\(_2\)O\(_7\) powders.\(^2\) Alternately, with Li doping, SiO\(_2\)/Y(OH)\(_3\) and SiO\(_2\)/Ho(OH)\(_3\) dispersions heat treated at 1050°C formed \( \beta \)-Y\(_2\)Si\(_2\)O\(_7\) and \( \beta \)-Ho\(_2\)Si\(_2\)O\(_7\). The \( \alpha \) and \( \beta \) powders formed at 1050°C were uniaxially pressed into pellets and densified by the FAST process at a pressure of 20KN and at temperatures of 1050°C, 1100°C and 1200°C. Table 1 and Figure 1 summarize the XRD results after densification. X-ray diffraction studies showed that \( \alpha \)-Y\(_2\)Si\(_2\)O\(_7\) pellets, densified at 1050°C, retained the \( \alpha \) phase, whereas \( \alpha \)-Y\(_2\)Si\(_2\)O\(_7\) pellets densified at 1100°C transformed to \( \beta \)-Y\(_2\)Si\(_2\)O\(_7\). In the case of Li-doped \( \beta \)-Y\(_2\)Si\(_2\)O\(_7\) and \( \beta \)-Ho\(_2\)Si\(_2\)O\(_7\) pellets, densification at 1200°C formed \( \gamma \)-Y\(_2\)Si\(_2\)O\(_7\) and \( \gamma \)-Ho\(_2\)Si\(_2\)O\(_7\). (Table 1, Figure 1). The relative densities of the pellets were determined from the measured and the theoretical densities shown in parentheses. The relative densities were calculated as the percentage of the measured to the theoretical density. The \( \alpha \), \( \beta \) and \( \gamma \) dense pellets formed by the FAST approach had relative densities > 90%.

3.2 Hardness

SEM micrographs of \( \alpha \), \( \beta \), and \( \gamma \)-Y\(_2\)Si\(_2\)O\(_7\) pellets after Vickers indentation are shown in Figure 2. In addition to the pure rare-earth disilicate, SEM/EDS showed silica as a second phase in all cases. SEM/EDS showed silica-rich dark regions with almost no yttrium in the EDS spectrum and a grey region with very similar yttrium and silica intensities.\(^2\) The experimental hardness values were obtained from Vickers indentation and these values represent the sum of the hardnesses of the pure rare earth disilicate and silica. The hardness of pure rare earth-silicate was calculated using the rule of mixtures, assuming that the hardness of pure silica is 1GPa. Results of the experimental measurements and the theoretical determined hardness values for dense \( \alpha \), \( \beta \), \( \gamma \)-Y\(_2\)Si\(_2\)O\(_7\) and \( \gamma \)-Ho\(_2\)Si\(_2\)O\(_7\) pellets are summarized in Table 2. The measured Vickers hardness values were very similar for \( \alpha \), \( \beta \), \( \gamma \)-Y\(_2\)Si\(_2\)O\(_7\) and \( \gamma \)-Ho\(_2\)Si\(_2\)O\(_7\) (~7GPa) and were consistent with our previous reported \( \gamma \)-Y\(_2\)Si\(_2\)O\(_7\) hardness value of ~ 6GPa for samples densified using a pressureless sintering technique at 1400°C/8h.

3.3 Deformation Behavior under Indentation

As mentioned previously, the mechanical properties of $\gamma$-$Y_2Si_2O_7$ are comparable to monazite, which is soft and deforms plastically by multiple dislocation glide and twinning systems.\textsuperscript{23-25} To study deformation mechanisms that may operate in $\alpha$, $\beta$ and $\gamma$-$Y_2Si_2O_7$, TEM foils were machined beneath indented regions of sintered $Y_2Si_2O_7$ using FIB. A cross-sectional TEM image of an indent made on sintered $\gamma$-$Y_2Si_2O_7$ is shown in Figure 3. It shows extensive fracture and plastic deformation. Preliminary studies of the $\alpha$ and $\beta$-$Y_2Si_2O_7$ polymorphs also indicated extensive deformation (Figure 4). More detailed studies of these features are in progress.

![Figure 3. Plastic deformation under an indent made on sintered $\gamma$-$Y_2Si_2O_7$ (cross-sectional TEM image): (a) overview, bright field; (b) multiple slip bands/active dislocation glide, bright field; (c) $(11\bar{1})$ staking faults, dark field](image)

3.4 Fiber Push-Out

Previous results showed that SCS-0 fibers in dense $\gamma$-Ho$_2$Si$_2$O$_7$ and $\gamma$-$Y_2Si_2O_7$ matrices debond and push-out with sliding stresses of 30-60 MPa,\textsuperscript{26-27} within the range reported for C, BN, and LaPO$_4$ coatings. Similar to the observation made for LaPO$_4$/alumina composites, SEM showed smearing of the $\gamma$-$Y_2Si_2O_7$ matrix. Furthermore, as with the plastic deformation observed for the LaPO$_4$/alumina interface, TEM observation was consistent with intense deformation at the SCS-0 fiber/matrix interface. These results indicate that the $\gamma$-$Y_2Si_2O_7$ may function as a weak interface for toughening SiC/SiC composites. However, the $\gamma$-$Y_2Si_2O_7$ matrix forms at relatively high temperatures (> 1400°C) and may
cause fiber damage during the coating processing. The α and β polymorphs form at relatively lower temperatures (<1200°C) and may therefore retain the fiber strength. The fact that the α and β polymorphs have similar hardnesses as the γ polymorph implies that the α and β-Y₂Si₂O₇ may work as well. Pushout measurements were done for SCS fibers in α and β-Y₂Si₂O₇ matrices to measure the interface sliding stress. SCS-0 fibers were sandwiched between two green α-Y₂Si₂O₇ pellets and densified at 1050 °C and 1100°C for 1 h using the FAST approach. For the SCS-0/α-Y₂Si₂O₇ composite densified at 1050°C, the Y₂Si₂O₇ matrix retained the α phase. Alternately, the α-Y₂Si₂O₇ matrix transformed to β-Y₂Si₂O₇ in composites densified at 1100°C.

Fiber push-out results for SCS fibers in the β-Y₂Si₂O₇ matrix are summarized in Figures 5 and 6. The push-out data is classified into 3 groups according to the extent of defocus of the optical micrographs after the fiber push-out. These groups consist of: a) pushed, b) pushed but with fiber damage and c) not pushed. The average sliding stress is plotted and tabulated in Figure 6. Fibers that pushed with damage (b) showed similar average sliding stresses to fibers that pushed (a). The average sliding stress was 11.7±3.3 GPa and 14.4±5.7 for fibers that pushed and pushed with damage, respectively. SEM investigation of fibers that pushed with damage showed push-out in the front and back-end of the pushed out specimen, confirming fiber sliding after push-out.

**Figure 5.** Optical micrographs of pushed SCS-0 fibers in the β-Y₂Si₂O₇ matrix

<td>-</td>
</tr>
</tbody>
</table>
The data for the pushed out fiber in the $\alpha$-$Y_2Si_2O_7$ matrix was very erratic and was classified into pushed and unpushed sets (Figure 7). The average sliding stress was 28.0±3.8. For fibers that pushed, SEM analysis showed fiber sliding in the front end, but the back-end showed very little or no sliding (Figure 8). In the worst case scenario, the matrix was observed to be pushing with the fiber, which indicates strong fiber/matrix bonding. CTE measurements of the $\alpha$, $\beta$, and $\gamma$ polymorphs of $Y_2Si_2O_7$ and Ho$_2$Si$_2O$_7 show a CTE of $\sim 8$ for the $\alpha$ phase. The $\beta$ and $\gamma$ phases have a similar CTE of $\sim 4$. The composites were formed at 1050°C-1200°C. During cooling, the $\alpha$-$Y_2Si_2O_7$, with a higher CTE, contracts to a greater extent and exerts a radial compressive stress on the fiber, which makes it more difficult to push. The compressive stresses will increase along the fiber length, thus making it more difficult for the fibers to push in the back ends.

4. Summary and Conclusions

Dense $\alpha$, $\beta$ and $\gamma$-$Y_2Si_2O_7$ pellets were formed using the FAST technique at a pressure of 20KN and temperatures of 1050°C to 1200°C. Vickers hardness values for $\alpha$, $\beta$, and $\gamma$-$Y_2Si_2O_7$ polymorphs were similar (−7GPa). TEM analysis of samples directly beneath the indentations suggested that both extensive dislocation slip and fracture were active. Preliminary results showed that SCS-0 fibers in dense $\beta$, $\gamma$-$Y_2Si_2O_7$ matrices debonded and pushed-out with sliding stresses of 15-60 MPa, within the range reported for C, BN, and LaPO$_4$ coatings. Fibers in the $\alpha$-$Y_2Si_2O_7$ matrix showed poor and erratic pushout.
behavior due to the radial compressive stresses that developed on the fibers as result of the differences in CTEs (fiber ~4 and matrix ~8).
