**Abstract**

Bone is the most common metastatic site for prostate cancer which affects approximately 70% of patients with advanced disease. Despite this clinical importance, the exact molecular mechanism of the bone-specific metastasis has not been clearly defined. The growth of the tumor cells in the bone is generally slow and they often become dormant until an appropriate microenvironment is established for their re-growth. According to the recent cancer stem cell theory, which still remains a hypothesis, recurrent tumor must arise from a dormant tumor stem cell. However, the precise mechanism of dormancy is virtually unknown, and identifying the responsible factors and understanding the underlying mechanism are crucial for developing a novel therapeutic approach. Our recent preliminary data suggest that BMP7 (bone morphogenetic protein 7) which is secreted from bone stromal cells is able to induce senescence to prostate tumor cells and that this induction is mediated by activation of the tumor metastasis suppressor gene, NDRG1 (N-myc downstream regulated gene 1). Therefore, we hypothesize that a prostatic tumor stem cell becomes dormant in the bone through the BMP7-mediated activation of p38 and NDRG1.

INTRODUCTION
Bone is the most common metastatic site for prostate cancer which affects approximately 70% of patients with advanced disease (1). Despite this clinical importance, the exact molecular mechanism of the bone-specific metastasis has not been clearly defined. The growth of the tumor cells in the bone is generally slow and they often become dormant until an appropriate microenvironment is established for their re-growth. According to the recent cancer stem cell theory, which still remains a hypothesis, recurrent tumor must arise from a dormant tumor stem cell (2). However, the precise mechanism of dormancy is virtually unknown, and identifying the responsible factors and understanding the underlying mechanism are crucial for developing a novel therapeutic approach. Our recent preliminary data suggest that BMP7 (bone morphogenetic protein 7) which is secreted from bone stromal cells is able to induce senescence to prostate tumor cells and that this induction is mediated by activation of the tumor metastasis suppressor gene, NDRG1 (N-myc downstream regulated gene 1). Therefore, we hypothesize that a prostatic tumor stem cell becomes dormant in the bone through the BMP7-mediated activation of p38 and NDRG1.

BODY
Task 1. To clarify the signaling pathway of BMP7-induced senescence in tumor stem cell.
(a) Examine whether BMP7 blocks Wnt pathway by activating p38-NDRG1 axis.
(b) Test whether BMP7 blocks Wnt pathway by increasing the binding of NDRG1 to LRP6.
(c) Examine whether the BMP7-induced senescence is dependent on Wnt signaling.
(d) Examine whether BMP7-induced MET (mesenchimal-epithelial-transition) is dependent on Wnt signal and whether it is prerequisite for senescence.

To accomplish Task 1 (a)-(c), we first examined the effect of BMP7 and Wnt on the growth of prostate cancer cells. As shown in Figure 1, BMP7 significantly suppressed the growth, while Wnt3a significantly promoted the prostate cancer cell growth. Furthermore, up-regulation of NDRG1 counteracted the effect of Wnt3a on the cancer cell growth, suggesting that the balance of BMP and Wnt signalings may determine whether the tumor cells stay in growth arrest or proliferate. Next, we isolated cancer stem cells (CSCs, CD24+/CD44+/CD133+) from PC3mm cells that were labeled with the luciferase gene. Our result of serial dilution assay for tumor initiating ability in animals indicates that the CSC population was significantly more tumorigenic than non-stem cells (CD24+/CD44-/CD133-) (Figure 2A). We also found that BMP7 was able to activate p38, NDRG1 and p21 (Figure 2B-2D) in CSCs, and that the induction of NDRG1 and p21 was mediated by p38 (Figure 2C and 2D). In addition, BMP7 significantly inhibited the sphere forming ability of CSCs; however, these cells regained the growth ability after withdrawal of BMP7 from the medium (Figure 2E). Furthermore, BMP7 was also able to induce senescence in CSCs (Figure 2F; ++) with concomitant activation of NDRG1 and p21 (Figure 2G; ++ and 2H; ++). Of note, the BMP7-mediated induction of senescence as well as the activation of NDRG1 and p21 was reversed after withdrawal of BMP7 (Figure 2F; +/-, 2G; +/−, and 2H; +/-). Similarly, up-regulation of NDRG1 in CSCs by using PC3mm cell line which had tetracycline-inducible

![Figure 1. NDRG1 counteracts the effect of Wnt on cancer cell growth.](image) PC3mm/Tet-NDRG1 cells were cultured for 96 h with or without BMP7, Wnt3a or tetracycline, and the cell viability was measured by MTS assay. **; P<0.01, ***; P<0.001 versus -, ###; P<0.01 versus Wnt. n = 3.
NDRG1 significantly suppressed the sphere formation and induced senescence, while de-induction of NDRG1 by withdrawal of tetracycline reversed this effect (Figure 2I and 2J). These results suggest that BMP7 was able to induce reversible senescence in CSCs through activation of p38, p21 and NDRG1.

Figure 2. BMP7 induces reversible senescence in cancer stem-like cells (CSCs) through activation of p38, p21 and NDRG1. (A) CSCs isolated from PC3mm were injected subcutaneously into nude mice, and the growth of tumor was monitored by bioluminescence imaging (BLI). (B) The CSCs were treated with the HS5 (bone stromal cells)-CM or BMP7, and the expression of p-p38, NDRG1 and β-Tubulin was examined by Western blot. (C and D) The CSCs were treated with or without BMP7 and/or SB203580 (SB), and the expression of NDRG1 (C) and p21 (D) were examined by qRT-PCR. n = 3, *; P<0.05, ***; P<0.001. (E) Effect of BMP7 on the sphere forming ability of CSCs was measured. (--/--): no treatment throughout. (/+/--): no treatment for 5 days, treated with BMP7 for 4 days, and no treatment thereafter. (+/+/--): treatment for 9 days, and no treatment thereafter (n = 5, *, P<0.001 versus (--/--), #: P<0.001 versus (--/--)). (F) CSCs were cultured in the presence (+/+), absence (-/-) or withdrawal after treatment (+/-) of BMP7, and SA-β-gal staining was performed. n = 6, ***; P<0.001. Scale bar represents 10 μm. (G and H) The CSCs were treated with BMP7, and the expression of NDRG1 (G) and p21 (H) was measured by Western Blot (upper panel).
To accomplish Task 1 (d), we examined whether BMP7 activates MET program in prostate cancer cells. We found that BMP7 significantly reduced vimentin (mesenchymal marker) expression while it significantly augmented E-cadherin (epithelial marker) expression (Figure 3A, B). Moreover, up-regulation of NDRG1 induced similar MET effect (Figure 3C, D), suggesting that BMP7-NDRG1 axis induced MET in prostate cancer cells.

Therefore, we now have identified that BMP7-p38-NDRG1 axis plays critical roles in inducing senescence and MET in CSCs.

To accomplish Task 1, we also examined the effect of Wnt pathway on BMP7-induced senescence, and cancer stem cell population. We found that BMP7 significantly suppressed the Wnt 3-mediated self-renewal of CSCs (Figure 4 A, B). In addition, BMP7 was able to induce senescence in cancer cells even in the presence of Wnt ligand (Figure 4 C).

**Figure 2. BMP7 suppresses Wnt-induced CSCs growth.** PC3mm cells were treated with BMP7 and recombinant Wnt3a for 48h, and the CSC population (A), cell proliferation (B) and senescence (C) were measured by FACS, MTS and SA-β-gal staining.

**Figure 3. BMP7 induces MET.** (A and B) PC3mm cells were cultured with BMP7 or control vehicle for 48 h and the expression of vimentin (A) and E-cadherin (B) were examined by qRT-PCR. (C and D) PC3mm/Tet-NDRG1 cells were cultured with or without tetracycline for 48 h and the expression of vimentin (C) and E-cadherin (D) were examined by qRT-PCR.

Task 2. To examine the effect of BMP7 on tumor stem cell *in vivo*
(a) Co-inject tumor stem cell and bone marrow stromal cell into nude mouse using calcium-phosphate scaffold and examine the effect of BMP7 on the tumor growth.
(b) Examine the effect of BMP7 on dormancy by injecting tumor stem cell via intracardiac followed by directly injecting BMP7 intravenously.

To accomplish Task 2, we isolated tumor stem cells from PC3mm labeled with luciferase gene and these cells were seeded onto CaP scaffolds with HS5 (bone stromal cells), and then these constructs were implanted into the upper back of nude mice. Recombinant human BMP7 was peritumorally injected daily after implantation. Tumor growth was monitored weekly by bioluminescent imaging. We found that BMP7 treatment significantly suppressed the tumor growth (Figure 4A and B). To further examine the effect of BMP7 on the tumor growth in bone, CSCs were injected into tibiae of mice with HS5 cells that had either scrambled shRNA (control) or shRNA for BMP7 (shBMP7). We found that the control HS5 was able to suppress tumor growth and activated p38 and NDRG1; however, HS5 with shBMP7 significantly abrogated such an effect on CSCs and failed to suppress tumor-induced osteolysis in the tibiae (Figure 4C). These results suggest that BMP7 secreted from the bone stromal cells is indeed capable of inducing growth arrest of CSCs through activation of p38 and NDRG1 in the bone environment. We also assessed the effect of NDRG1 in the suppression of tumor growth by co-injecting HS5 and CSCs in which NDRG1 expression was knocked down by shRNA (shNDRG1), into mice tibiae. We found that knockdown of NDRG1 in CSCs enabled these cells to grow significantly greater than that of control CSCs even when they were co-injected with HS5 (Figure 4D). These results indicate that the BMP7-NDRG1 axis plays a critical role in the growth suppression of metastasized prostate tumor cells in bone, and also strongly suggest the potential therapeutic utility of BMP7 for metastatic disease.
To directly address the possibility of using BMP7 for therapy of bone metastatic disease, 100 μg/kg of BMP7 was administrated daily. BLI of representative mice in each group six weeks after implantation (A). Normalized BLI signals after six weeks (B). *: control vehicle, n=6, BMP7: 100 g/kg BMP7 treatment, n=10. **; P=0.0225 by Mann-Whitney test. (C) CSCs isolated from PC3mm were co-injected into tibiae of nude mice with control (scramble, n=11) or BMP7-knocked down (shBMP7, #1: n=14, #2: n=10) HS5 cells. Left panel: bioluminescence imaging (BLI) and x-ray radiography of bone lesions from representative mice in each group four weeks after inoculation. Osteolytic lesions are indicated by arrow heads. Center panel: Normalized BLI signals after four weeks. *; P<0.05 by Mann-Whitney test. Right panel: Representative images of immunohistochemical staining of tumors in the tibiae for p-p38 and NDRG1. Scale bar represents 50 μm. (D) CSCs isolated from PC3mm/shNDRG1 (n=12) or PC3mm/scramble (n=12) were co-injected with HS5 into tibiae of nude mice. Left panel: BLI and x-ray radiography of representative mice in each group four weeks after inoculation. Osteolytic lesions are indicated by arrow heads. Center panel: BLI after four weeks. **; P<0.01, by Mann-Whitney test. Right panel: H&E staining of the tibiae from representative mice four weeks after inoculation. Asterisk indicates tumor. Scale bar represents 200 μm.

**Figure 4. BMP7 suppresses tumor growth of CSCs in vivo.** (A and B) CSCs from PC3mm were seeded onto CaP scaffolds with HS5 and these constructs were implanted into nude mice, and then BMP7 was administrated daily. Scale bar represents 200 μm.

To directly address the possibility of using BMP7 for therapy of bone metastatic disease, 100 μg/kg of BMP7 was administrated daily through i.v. after intracardiac injection of CSCs from PC3mm or C4-2B cells to the mice. As shown in Figure 5A, BMP7 treatment significantly suppressed the bone metastasis compared to the control. Importantly, withdrawal of BMP7 treatment significantly abrogated its suppressive effect and induced recurrent metastatic growth in the bones. These results suggest that BMP7 suppresses bone metastasis by inducing senescence in disseminated CSCs in the bone. To further verify the inhibitory effect of BMP7 in the bone, CSCs were inoculated directly into mouse tibiae followed by BMP7 treatment. We found that tumor growth in tibiae was indeed significantly suppressed by BMP7 treatment compared to control (Figure 5B), suggesting that direct injection of BMP7 can block the growth of CSCs in the bone. Moreover, withdrawal of BMP7 treatment led the tumor to regain the ability to further proliferate in the bone. Of note, the tumor cells in tibiae exhibited feature of cellular senescence during BMP7 treatment (Figure 5B: BMP7), whereas SA-β-gal staining was strongly decreased after withdrawal of BMP7 (Figure 5B: Withdrawal). These results again suggest that BMP7 plays a critical role in balancing the dormancy and recurrence of CSCs in bone metastasis of prostate cancer.
Task 3. To examine whether serum level of BMP7 and Wnt ligand correlates with bone metastasis in patients with prostate cancer

To accomplish Task 3, we first analyzed the BMP7 and Wnt3a expression in benign prostate tissue from healthy donors and prostate cancer tissues from patients using an existing data base. We found that BMP7 was significantly down-regulated in prostate cancer tissues compared to benign tissues. On the other hand, Wnt3a was significantly up-regulated in the prostate cancer tissues (Figure 6).

Figure 5. BMP7 suppresses tumor growth but withdrawal induces tumor recurrence of CSCs in vivo. (A) Kaplan-Meier bone metastasis-free survival curve of mice after intracardiac injection with CSCs isolated from PC3mm (upper panel) or C4-2B (lower panel) followed by treatment with vehicle or BMP7. Control: control vehicle treatment (PC3mm: n = 9, C4-2B: n = 10), BMP7: continuous treatment with BMP7 (PC3mm: n = 15, C4-2B: n = 10), BMP7 withdrawal: BMP7-treatment (2 weeks for PC3mm and 3 weeks for C4-2B) followed by withdrawal of BMP7 (PC3mm: n = 9, C4-2B: n = 10). ***; P=0.0008, **; P=0.0012 versus control, ###; P<0.0001, #; P=0.0289 versus BMP7 by Log-rank test. (B) Upper panel: After injection of CSCs into mouse tibiae, BMP7 was administered daily through i.v. (●): control vehicle treatment, n = 13. (●): continuous treatment with BMP7, n = 10. (●):10-day-treatment followed by withdrawal of BMP7, n = 10. *; P<0.05 versus control (●), ###; P<0.001 versus BMP7 treatment (●). Lower panel: Representative SA-β-gal staining of tumors in the tibiae of mice at the end point. Data represent the mean ± SEM of at least two independent experiments.

Figure 6. Expression of BMP7 and Wnt3a in clinical cohorts. Upper panels: The expression levels of BMP7 and Wnt3a were examined in Oncomine data base. Lower panels: The expression levels of BMP7 and Wnt3a were examined in GSE6919 cohort (P<0.0001).
KEY RESEARCH ACCOMPLISHMENTS

1. We found that NDRG1 counteracts the growth promoting effect on prostate cancer cells by Wnt.
2. We found that BMP7 induces senescence by activating p38, p21 and NDRG1 in CSCs.
3. We found that BMP7-induced senescence is reversible.
4. We found that BMP7 induces MET in prostate cancer cells.
5. We found that BMP7 significantly suppresses the growth of CSCs on CaP scaffold model.
6. BMP7 suppresses tumor growth but withdrawal induces tumor recurrence of CSCs in vivo.
7. BMP7 and Wnt3a are inversely correlated in clinical cohorts and tumor samples.

REPORTABLE OUTCOMES

Peer reviewed publications

Abstract/presentation

Employment

Fei Xing, Ph.D. (postdoctoral fellow) has been partly supported by the current grant from May 2012

Training Accomplishments

1. I published this work in high impact journal (Journal of Experimental Medicine, IF=13)
2. I submitted the abstract and attended the 2013 annual meeting of American Association for Cancer Research with this project.
3. I submitted the abstract and attended the 2013 AACR Tumor Invasion and Metastasis meeting with this project.
4. I submitted a NIH R21 grant (PQC6) entitle : “Mechanism of tumor dormancy in bone microenvironment” as a Co-I with my mentor.
5. I did oral presentations of this project in the journal club of UMMC cancer institute.
6. I attended multiple workshops of grant writing in UMMC.
7. I attended work in progress meeting of cancer institute every week and discussed grant applications with other principle investigators.
8. Because of my outstanding performance I was promoted to instructor of UMMC cancer institute.
CONCLUSIONS

We have shown that BMP7 secreted from bone stromal cells induces senescence through activation of p38, p21 and NDRG1. We have also shown that this senescence is reversible and the CSCs regain the ability to proliferate upon withdrawal of BMP7. Therefore, we are now in a strong position to pursue the rest of tasks. In the next fiscal year, we will address two important points. First, we will clarify whether BMP7 blocks the Wnt pathway and whether the Wnt pathway interferes with the BMP7-induced senescence and MET. Secondly, we will compare the expression level of BMP7 and Wnt ligand in sera of prostate cancer patients with or without metastatic disease. The results of this research will provide us with strong rationale for using BMP7 as an anti-recurrence agent to treat prostate cancer patients with metastatic disease. Because the previous recipient of this fellowship (Dr. Aya Kobayashi) left the lab and went back to her own country, Dr. Fei Xing assumed this grant from May 2012. However, Dr. Xing and his mentor (Dr. Watabe) moved to University of Mississippi Medical Center on Aug. 1, 2012. Accordingly, the progress of this project was somewhat delayed and we requested 6 months extension of the fellowship.

So what?

Despite the significant improvement in recent therapeutic technologies, metastatic disease is still the ultimate cause of death in prostate cancer patients (3). Therefore, understanding the underlying mechanisms of dormancy and recurrence in bone metastasis is of paramount interest for developing an effective approach to treat and prevent recurrent prostate cancer. We believe that elucidation of such mechanisms will provide a paradigm shift in this research field and eventually lead to the development of a novel therapeutic approach to this devastating disease.

REFERENCES

Despite significant improvement in recent therapeutic technologies, >90% of the cancer deaths are still attributed to metastatic disease (Peinado et al., 2008). In the case of prostate and breast cancers, 20–50% patients who have localized cancer and have been “successfully” treated with surgery eventually experience recurrent disease after many years (Karrison et al., 1999; Weckermann et al., 2001; Pfitzenmaier et al., 2006). How metastatic tumor cells become dormant in the distant organs is virtually unknown. However, because recurrent disease is almost always fatal, it is of paramount importance to elucidate the underlying molecular mechanism of dormancy and recurrence to identify novel therapeutic targets. The dormant state of metastatic cell is thought to be controlled by both genetic changes in tumor cell and microenvironment of the metastasized organs (Aguirre-Ghiso, 2007).

According to the recent tumor stem cell theory, metastatic cells must have stem-like characteristics such as abilities of self-renewal and differentiation in addition to their invasive capability (Pantel and Alix-Panabières, 2007; Polyak and Weinberg, 2009). Therefore, only a fraction of primary tumor cells is able to establish colonization at the distant organ and also become dormant. However, because dormant lesions in most cases consist of a solitary or small number of tumor cells, they are clinically undetectable, which significantly hampers the progress of research in this field. This dormant state is thought to be maintained by virtue of the balance of local microenvironment such as stroma–tumor cell interaction and secreted growth factors and pro- and antiangiogenic factors, as well as local immune system (Derynck et al., 2001; Bhowmick et al., 2004; Aguirre-Ghiso, 2007). The most critical question is to identify such key players.
that modulate the tumor cell dormancy and to dissect the responsive signaling pathways.

Recently, others demonstrated, through a series of elegant experiments, that the signaling cascade that is controlled by the balance of two prominent pathways, p38 mitogen-activated protein kinase (MAPK) and extracellular signal-regulated kinase (ERK), is the key determining factor for tumor cell dormancy (Aguirre-Ghiso et al., 2001, 2003, 2004; Aguirre-Ghiso, 2007). p38 signaling is also known to be involved in the regulation of cell cycle arrest and plays a crucial role in the induction of senescence in response to a variety of stress, including oncogenic stress (Bulavin and Fornace, 2004; Bulavin et al., 2004; Dasari et al., 2006; Tront et al., 2006; Han and Sun, 2007; Sun et al., 2007; Wagner and Nebreda, 2009). A high ratio of ERK/p38 expression was indeed observed in metastatic lesions in an animal model of ovarian cancer, which supports the notion that the balance of ERK and p38 determines the fate of disseminated tumor cells whether to proliferate or stay in dormant state at the distant organ (Aguirre-Ghiso et al., 2004). However, extracellular factors in the microenvironment, either cell–cell interaction or secretory factors, that regulate p38 signaling and modulate the concomitant tumor cell dormancy and recurrence are yet to be determined.

In this study, we found that one of the TGF-β family members, BMP7 (bone morphogenetic protein 7), which is secreted from bone stromal cells, induces senescence through activation of p38 MAPK, cell cycle inhibitor, p21, and the tumor metastasis suppressor gene, NDRG1 (N-myc downstream-regulated gene 1) in prostate cancer stem-like cells (CSCs). Importantly, this BMP7-induced senescence was found to be reversible, indicating that BMP7 plays a critical role in tumor dormancy and recurrence. Our results also suggest that targeting BMP7 signaling may become effective therapeutics to prevent recurrence of metastatic prostate cancer.

RESULTS

A secretory factor from bone stromal cells suppresses the growth of prostate cancer cells

Bone stromal cells are considered to play a critical role in generating a niche for metastasized tumor cells by secreting various growth-inhibitory as well as growth-promoting factors in the microenvironment, which may contribute to tumor dormancy and recurrence (McAllister et al., 2008; Zhang et al., 2009). In an attempt to identify such factors, we first cultured PC3 mm, a metastatic prostate cancer cell line, in the presence of the conditioned medium (CM) of human BM stromal cells (HS5). We found that the CM of HS5 significantly promoted the expression of the key cell cycle inhibitors, p21 and p27 (Fig. 1 A). The up-regulation of p21 by the CM of HS5 was also observed in a panel of prostate cancer cell lines (Fig. 1 B). That modulate the tumor cell dormancy and to dissect the responsive signaling pathways.

Figure 1. CM of bone stromal cells induces senescence in prostate cancer cells. (A) The prostate cancer cell line PC3 mm was cultured in the presence of CM from human bone stromal cells (HS5), mouse BM stroma (MBMS), mouse embryonic fibroblasts (NIH3T3), or human lung fibroblasts (MRC5) or serum-free medium (−). Expression of p21, p27, and β-tubulin was examined by qRT-PCR (n = 3) and Western blot. (B) The prostate tumor cell lines LNCaP, C4, C4-2, C4-2B, PC3, DU145, and ALVA were cultured in the presence of the conditioned medium (CM) of human BM stromal cells (HS5). We found that the CM of HS5 significantly promoted the expression of the key cell cycle inhibitors, p21 and p27 (Fig. 1 A). The up-regulation of p21 by the CM of HS5 was also observed in a panel of prostate cancer cell lines (Fig. 1 B).

for 48 h, and SA–β-gal staining (blue-green) was performed (n = 4). The inset shows representative images of three independent experiments. Bar, 100 µm. (G) PC3 mm was cultured in the presence of CM of HS5, MRC5, or NIH3T3 or serum-free medium (−), and the expression of NDRG1 was measured by qRT-PCR (n = 3). **, P < 0.01; ***, P < 0.001. All experiments were performed three times independently, and representative data are shown. Results are shown as mean ± SEM.
Moreover, p38 MAPK, which has been shown to be a key regulator of tumor cell dormancy (Aguirre-Ghiso, 2007), was strongly activated in prostate cancer cell lines in the presence of the CM of bone stromal cells (Fig. 1, C and D). In fact, we found that the CM of HS5 significantly suppressed the growth of prostate cancer cell lines (Fig. 1 E and not depicted) and induced senescence-associated ß-galactosidase (SA-ß-gal) activity (Fig. 1 F) but not apoptosis of PC3 mm cells (not depicted), suggesting that the bone stromal cells secrete a growth-inhibitory factor. Interestingly, we also found that the CM of bone stromal cells significantly up-regulated the metastasis suppressor gene, NDRG1, which was previously shown to suppress tumor metastasis in prostate, breast, and colon cancers (Fig. 1, C and G; Guan et al., 2000; Bandyopadhyay et al., 2003, 2004). It should be noted that we previously showed a significant inverse correlation between NDRG1 expression and bone metastasis in prostate cancer patients (Bandyopadhyay et al., 2003). These results strongly suggest that a secretory factor of bone stromal cells induces cellular senescence by activating p38, NDRG1, and cell cycle inhibitors in tumor cells.

BMP7 up-regulates a metastasis suppressor gene, NDRG1, through activation of p38

The next critical question is the identity of the secretory factor from bone stromal cell. Because TGF-ß (Mundy, 2002; Massagué, 2008) and TGF-ß family members, BMPs (Celeste et al., 1990; Mundy, 2002) and FGF2 (fibroblast growth factor 2; Johnson et al., 1998; Mundy, 2002; Korah et al., 2004), are all known to exist in the bone microenvironment, we first examined the effect of a selective inhibitor of TGF-ß type 1 receptor, SB431542, and a general BMP inhibitor, Noggin, on the activation of NDRG1 and p38. The addition of Noggin to HS5-CM in our assay system significantly blocked the ability of CM to activate NDRG1 and p38, whereas SB431542 did not affect the CM-induced p38 activation, and recombinant human TGF-ß failed to activate NDRG1 (Fig. 2 A and not depicted). Moreover, p38 MAPK, which has been shown to be a key regulator of tumor cell dormancy (Aguirre-Ghiso, 2007), was strongly activated in prostate cancer cell lines in the presence of the CM of bone stromal cells (Fig. 1, C and D). In fact, we found that the CM of HS5 significantly suppressed the growth of prostate cancer cell lines (Fig. 1 E and not depicted) and induced senescence-associated ß-galactosidase (SA-ß-gal) activity (Fig. 1 F) but not apoptosis of PC3 mm cells (not depicted), suggesting that the bone stromal cells secrete a growth-inhibitory factor. Interestingly, we also found that the CM of bone stromal cells significantly up-regulated the metastasis suppressor gene, NDRG1, which was previously shown to suppress tumor metastasis in prostate, breast, and colon cancers (Fig. 1, C and G; Guan et al., 2000; Bandyopadhyay et al., 2003, 2004). It should be noted that we previously showed a significant inverse correlation between NDRG1 expression and bone metastasis in prostate cancer patients (Bandyopadhyay et al., 2003). These results strongly suggest that a secretory factor of bone stromal cells induces cellular senescence by activating p38, NDRG1, and cell cycle inhibitors in tumor cells.

BMP7 up-regulates a metastasis suppressor gene, NDRG1, through activation of p38

The next critical question is the identity of the secretory factor from bone stromal cell. Because TGF-ß (Mundy, 2002; Massagué, 2008) and TGF-ß family members, BMPs (Celeste et al., 1990; Mundy, 2002) and FGF2 (fibroblast growth factor 2; Johnson et al., 1998; Mundy, 2002; Korah et al., 2004), are all known to exist in the bone microenvironment, we first examined the effect of a selective inhibitor of TGF-ß type 1 receptor, SB431542, and a general BMP inhibitor, Noggin, on the activation of NDRG1 and p38. The addition of Noggin to HS5-CM in our assay system significantly blocked the ability of CM to activate NDRG1 and p38, whereas SB431542 did not affect the CM-induced p38 activation, and recombinant human TGF-ß failed to activate NDRG1 (Fig. 2 A and not depicted).
We then directly tested the effect of purified BMPs as well as FGF2 using both PC3 mm and DU145 cells and found that only BMP7 among these factors was able to activate all of p38, NDRG1, p21, and p27 (Fig. 2 B). The activation of p38 was also observed in a panel of prostate cancer cell lines (Fig. 2 C). Moreover, BMP7 significantly up-regulated the NDRG1 messenger RNA expression and promoter activity in a dose-dependent manner (Fig. 2 D and E). Furthermore, our results of Western blot analysis demonstrate that BMP7 is expressed at a much higher level in HS5 as well as other bone stromal cells including human BM-derived mesenchymal stem cells (MSCs [hBMSCs]) and human osteoblast cells (hFOB1.19) than in the prostate cancer cells (Fig. 2 F). These results suggest that the major sources of BMP7 at the metastatic sites are various prostate cancer cells (Fig. 2 F). These results suggest that the major sources of BMP7 at the metastatic sites are various prostate cancer cells (Fig. 2 F). These results suggest that the major sources of BMP7 at the metastatic sites are various prostate cancer cells (Fig. 2 F).

BMP7 induces reversible senescence through activation of p38, p21, and NDRG1

BMP7 was originally identified as an osteoinductive factor from bone (Celeste et al., 1990; Ozkaynak et al., 1990), and it has been shown to be involved in normal bone morphogenesis and to play an important role in bone regeneration (Dudley et al., 1995; Luo et al., 1995; Friedlaender et al., 2001; Ristiniemi et al., 2007). To further assess the growth inhibitory effect of BMP7 on tumor cells, we measured SA-β-gal activity in prostate cancer cells and found that BMP7 indeed induced growth arrest with features of cellular senescence and p21 expression (Fig. 3, A–C). Although this activation of p21 by BMP7 was not affected by dominant-negative Smad4 (Fig. 3 D), it was significantly suppressed by the p38 inhibitor (Fig. 3 E), suggesting that BMP7 up-regulates p21 through a non-Smad pathway. Furthermore, knock-down of p21 in PC3 mm cells abrogated BMP7-induced NDRG1 expression, whereas the status of phospho-p38 was not affected by p21 knockdown (Fig. 3 F), implying that BMP7 up-regulates NDRG1 through the activation of p38 and p21. Therefore, these results strongly suggest that the BMP7–p38–p21–NDRG1 axis plays a key role in tumor cell dormancy in the bone.

To gain further insight into BMP7-mediated cell growth arrest, we incubated PC3 mm cells with BMP7 for 8 d followed by withdrawal of this factor. BMP7 significantly suppressed the cell growth; however, cells regained the ability to grow upon withdrawal of BMP7 (Fig. 4 A). We also examined the effect of BMP7 withdrawal on Erk activity. In this experiment, epidermal growth factor (EGF) was used as an activator of Erk. We found that the phosphorylation of Erk was greatly suppressed in the presence of BMP7, whereas p38 phosphorylation was strongly enhanced (Fig. 4 B). Interestingly, withdrawal of BMP7 restored the Erk phosphorylation, whereas it reversed the phosphorylation of p38, suggesting that the p38/Erk ratio plays an important role in determining whether the tumor cells stay in dormant state or proliferate. Furthermore, we tested this reversibility of the BMP7 effect on senescence by SA-β-gal staining. PC3 mm cells were cultured with BMP7 for 48 h, and then they were incubated another 48 h either with (+/+) or without (+/−) BMP7. We found that BMP7 treatment (+/+) significantly increased senescent cells compared with

Figure 3. BMP7 up-regulates NDRG1 by activating p38 and p21. (A) Effect of 200 ng/ml BMP7 on senescence in PC3 mm was examined by SA-β-gal staining (n = 4). *, P < 0.05; **, P < 0.01; ***, P < 0.001. All experiments were performed three times independently, and representative data are shown. Results are shown as mean ± SEM.
Figure 4. BMP7 induces reversible senescence. (A) Effect of BMP7 on the growth of PC3 mm cells was measured by the MTT assay. Cells were treated with 200 ng/ml BMP7 continuously (green), with BMP7 between day 4 and 11 followed by BMP7 withdrawal (red), or with control vehicle (black; n = 5). (B) PC3 mm cells were cultured with 10 ng/ml EGF or 200 ng/ml BMP7 alone, or EGF with BMP7, or EGF with BMP7 followed by BMP7 withdrawal, and the expression of p-Erk, Erk, p-p38, p38, and β-tubulin was examined by Western blot. (C) Effect of BMP7 on growth arrest was examined by SA-β-gal staining (top) and cell cycle analysis (bottom). PC3 mm cells (left) and C4-2B cells (right) were cultured with (+/+) or without (−/−) BMP7 for 96 h.+/− cells were treated with BMP7 for 48 h followed by withdrawal of BMP7 and further incubation for 48 h (n = 3). (D) Effect of BMP7 on senescence was examined by SA-β-gal staining. DU145, LNCaP, C4, and ALVA were cultured with (+/+) or without (−/−) BMP7 for 96 h.+/− cells were treated with BMP7 for 48 h followed by withdrawal of BMP7 and further incubation for 48 h (n = 3). (C and D) The insets show representative images of three independent experiments. Bars, 50 µm. (E and F) PC3 mm cells that had either scrambled shRNA (scramble) or shRNA for NDRG1 (shNDRG1) were cultured with BMP7 or control vehicle, and the knockdown of NDRG1 was confirmed by qRT-PCR (n = 3; E). These cells were stained for SA-β-gal activity (n = 4; F). (G) Effect of NDRG1 on senescence was examined by SA-β-gal staining (bottom). PC3 mm cells stably expressing Tet-NDRG1 were cultured with (+/+) or without (−/−) tetracycline for 96- or 48-h treatment followed by 48-h withdrawal of tetracycline (+/−; n = 4). The expression of NDRG1 and β-tubulin was examined by Western blot (top). *, P < 0.05; **, P < 0.01; ***, P < 0.001. The experiment in A was performed twice, experiments in B–G were performed three times independently, and representative data are shown. Results are shown as mean ± SEM.
BMP receptor, BMPR2, has an inverse correlation with bone metastasis and recurrence

The results of our in vitro experiments suggest that BMP7-induced reversible senescence contributes to tumor dormancy and recurrence in bone environment. Therefore, we examined the possibility that the status of BMP receptors in patients is a determining factor in bone metastasis and recurrence of prostate cancer. To test this hypothesis, we first analyzed the expression profile of the BMP receptors in prostate cancer patients and their clinical status using the existing database (http://www-genome.wi.mit.edu/cancer/; Glinsky et al., 2004). Among these receptors, the expression of BMPR2 had significant positive correlation with the recurrence-free survival of patients (Fig. 5 A). To further investigate the role of BMPR2 in prostate cancer and its clinical relevance to bone metastasis, we performed immunohistochemical analysis for BMPR2 with a prostate tissue array that contains 41 primary prostate cancer samples. Consistently, there was a significant inverse correlation between BMPR2 expression and bone metastasis of prostate cancer patients (Fig. 5 B), suggesting that BMPR2 plays a critical role in tumor dormancy and recurrence in bone environment. To directly address this question, we first examined the status of BMPR2 expression in our experimental metastasis model in vivo. We isolated cancer cells from micrometastases in tibiae of mice after implanting PC3 mm cells through intracardiac injection. We then examined the expression of BMPR2 in these cells by Western blot and found that a comparable level of BMPR2 expression to the parental cells was maintained in these cells (not depicted). Next, we asked whether knockdown of BMPR2 can abrogate the BMP7-induced dormancy in bone metastasis. To this end, mice were inoculated with PC3 mm cells that either shRNA for BMPR2 (shBMPR2) or scrambled shRNA control (−/−) cells that were cultured in the absence of BMP7 throughout the period (Fig. 4 C, left). To our surprise, withdrawal of BMP7 (+/−) significantly reduced the senescent cells to the control level, suggesting that BMP7-induced senescence is reversible. In support of this observation, we performed cell cycle analysis and found that the BMP7 treatment (+/+ +) significantly increased the fraction of cells in the G1 phase compared with the control (−/−), whereas withdrawal of BMP7 (+/−) significantly decreased the cell population in the G1 state, suggesting that BMP7-induced G1 arrest in PC3 mm cells. We also observed the reversible senescence phenotype upon withdrawal of BMP7 in other prostate cancer cell lines (Fig. 4, C [right] and D).

Among the cell lines we tested in these experiments, PC3 mm and DU145 are androgen receptor (AR) negative, whereas LNCaP, C4, C4-2B, and ALVA are AR positive. Interestingly, the reversible senescence phenotype was observed in both AR-negative and positive cells, suggesting that the effect of BMP7 on recurrent growth is independent of the AR status of the cells. We then examined whether NDRG1, a downstream effector of BMP7 signaling, also plays a role in the induction of senescence in prostate cancer cells. When NDRG1 expression was knocked down by shRNA in PC3 mm (Fig. 4 E), the cells failed to enter senescence even in the presence of BMP7 (Fig. 4 F). In contrast, up-regulation of NDRG1 by adding tetracycline for a total of 96 h (+/+ +) to the PC3 mm cell line, which had the tetracycline-inducible NDRG1, significantly induced senescence; however, the 48-h withdrawal of tetracycline (+/−) after 48-h incubation significantly reversed this effect (Fig. 4 G). These results suggest that BMP7 induces reversible senescence in prostate cancer cells and that this effect is indeed mediated by NDRG1.

Figure 5. The expression of BMPR2 receptor is inversely correlated with recurrence and bone metastasis of prostate cancer patients. (A) The relation between recurrence-free survival and the expression (positive or negative) of the indicated BMP receptors was analyzed using an existing cohort data of prostate cancer patients (n = 21; Glinsky et al., 2004). *P = 0.0485 [Log-rank test]. (B, top) Representative images of immunohistochemical staining for BMPR2 on prostate cancer patient samples with or without bone metastasis. Bar, 50 µm. (bottom) The correlation between BMPR2 expression and bone metastasis (met) status was evaluated by Fisher’s exact test.
(control; Fig. 6 A) by intracardiac injection followed by BMP7 treatment. The progression of bone metastasis was monitored by bioluminescence imaging (BLI) using stably expressed luciferase reporter. We found that the BMP7 treatment significantly delayed the onset of bone metastasis of the control group; however, the knockdown of BMPR2 significantly attenuated the effect of BMP7 (Fig. 6 B). These results suggest that BMPR2 plays a direct role in BMP7-induced suppression of bone metastasis. We also confirmed that BMPR2 knockdown disrupted BMP7 signaling in vitro. As shown in Fig. 6 C, BMPR2 deficiency strongly abrogated activation of p38, NDRG1, and p21 by BMP7. Furthermore, by using a cell line with tetracycline-inducible shBMPR2, we found that the knockdown of BMPR2 significantly decreased the senescent cells even in the presence of BMP7 (Tet+/+, BMP7), whereas the withdrawal of tetracycline (i.e., the recovery of BMPR2 expression) ameliorated the effect of BMP7 on the induction of senescence (Tet+/−, BMP7; Fig. 6 D). Collectively, these results suggest that BMPR2 is a critical mediator of BMP7 signaling for tumor cell dormancy in bone metastasis.

BMP7 suppresses the growth of CSCs

According to the cancer stem cell theory, a dormant and recurrent tumor cell must retain stem cell–like properties (Pantel and Alix-Panabières, 2007; Polyak and Weinberg, 2009). Therefore, we intended to examine the effect of BMP7 on CSCs. We first isolated the CSC population (CD24−/CD44+/CD133+) from PC3 mm cells that were labeled with the luciferase gene. Our result of serial dilution assay for tumor-initiating ability in animals indicates that the CSC population was significantly more tumorigenic than non-stem cells (CD24+/CD44−/CD133−; Fig. 7 A). We also found that BMP7 was able to activate p38, NDRG1, and p21 (Fig. 7, B–D) and that the induction of NDRG1 and p21 was mediated by p38 (Fig. 7, C and D) in the CSCs. In addition, BMP7 significantly inhibited the sphere-forming ability of CSCs; however, these cells regained the growth ability after withdrawal of BMP7 from the medium (Fig. 7 E). Furthermore, we found that BMP7 was also able to induce senescence in CSCs (Fig. 7 F, +/+ with concomitant activation of NDRG1 and p21 (Fig. 7, G and H, +/+). Of note, the BMP7-mediated induction of senescence as well as the activation of NDRG1 and p21 was reversed after withdrawal of BMP7 (Fig. 7, F–H, +/+). Similarly, up-regulation of NDRG1 in CSCs significantly suppressed the sphere formation and induced senescence, whereas de-induction of NDRG1 by withdrawal of tetracycline reversed this effect (Fig. 7, I and J). These results suggest that BMP7 was also able to induce reversible senescence in CSCs through activation of p38, p21, and NDRG1.

BMP7 suppresses the growth of CSCs in a reversible manner in vivo

Our results strongly support a notion that BMP7 secreted from bone stromal cells plays a role in tumor dormancy by suppressing the growth of CSCs in the bone environment. To determine whether the BMP7 from bone stromal cells indeed induces tumor growth arrest and senescence in vivo, we next used an animal model of bone metastasis. CSCs that were labeled with luciferase were isolated and injected into tibiae of mice with H55 cells that had either scrambled shRNA (control) or shRNA for BMP7 (shBMP7). We found that the control H55 was able to suppress tumor growth and activated p38 and NDRG1; however, H55 with shBMP7 significantly abrogated such an effect on CSCs and failed to suppress tumor-induced osteolysis in the tibiae (Fig. 8 A). These results suggest that BMP7 secreted from the bone stromal cells is indeed capable of inducing growth arrest of CSCs through activation of p38 and NDRG1 in the bone.
of using BMP7 for therapy of bone metastatic disease, 100 µg/kg BMP7 was administrated daily i.v. after intracardiac injection of CSCs from PC3 mm or C4-2B cells to the mice. As shown in Fig. 8 C, BMP7 treatment significantly suppressed the bone metastasis compared with the control. Importantly, withdrawal of BMP7 treatment significantly abrogated its suppressive effect and induced recurrent metastatic growth in the bones. To ensure the responsiveness of tumors derived from CSCs to BMP7, we also examined the effect of BMP7 on bone derivatives that were isolated from mice tibiae and found that BMP7 was indeed able to induce reversible senescence in these bone derivatives (Fig. 8 D). These results suggest that BMP7 suppresses bone metastasis by inducing senescence in disseminated CSCs in the bone.

(middle) BLI after 4 wk. **, P < 0.01 by Mann-Whitney test. (right) H&E staining of the tibiae from representative mice 4 wk after inoculation. The asterisk indicates a tumor. (C) Kaplan-Meier bone metastasis–free survival curve of mice after intracardiac injection with CSCs isolated from PC3 mm (left) or C4-2B (right) followed by treatment with vehicle or BMP7. Control, control vehicle treatment (PC3 mm, n = 9; C4-2B, n = 10); BMP7, continuous treatment with BMP7 (PC3 mm, n = 15; C4-2B, n = 10); BMP7 withdrawal, BMP7 treatment (2 wk for PC3 mm and 3 wk for C4-2B) followed by withdrawal of BMP7 (PC3 mm, n = 9; C4-2B, n = 10). ***, P = 0.0008; and **, P = 0.0012 versus control; and ##, P = 0.0001; and #, P = 0.0289 versus BMP7 by Log-rank test. (D) Effect of BMP7 on senescence was examined by SA–β-gal staining. The bone derivatives of PC3 mm (PC3 mm–BM) were cultured with (+/+) or without (−/−) BMP7 for 96 h. +/+ cells were treated with BMP7 for 48 h followed by withdrawal of BMP7 and further incubation for 48 h (n = 3). ***, P < 0.001. (E, top) After injection of CSCs into mouse tibiae, BMP7 was administered daily i.v. Control, control vehicle treatment (n = 13); BMP7, continuous treatment with BMP7 (n = 10); withdrawal, 10-d treatment followed by withdrawal of BMP7 (n = 10). *, P < 0.05 versus control; and ##, P < 0.001 versus BMP7 treatment. (bottom) Representative SA–β-gal staining (blue-green) of tumors in the tibiae of mice at the end point. Experiments in A–C and E were performed twice, the experiment in D was performed three times independently, and representative data are shown. Results are shown as mean ± SEM. Bars: (A, D, and E) 50 µm; (B) 200 µm.
To further verify the inhibitory effect of BMP7 in the bone, CSCs were inoculated directly into mouse tibiae followed by BMP7 treatment. We found that tumor growth in tibiae was indeed significantly suppressed by BMP7 treatment compared with control (Fig. 8 E), suggesting that direct injection of BMP7 can block the growth of CSCs in the bone. Moreover, withdrawal of BMP7 treatment led the tumor to regain the ability to further proliferate in the bone. Of note, the tumor cells in tibiae exhibited features of cellular senescence during BMP7 treatment (Fig. 8 E, BMP7), whereas SA-β-gal staining was strongly decreased after withdrawal of BMP7 (Fig. 8 E, withdrawal). These results again suggest that BMP7 plays a critical role in balancing the dormancy and recurrence of CSCs in bone metastasis of prostate cancer.

**DISCUSSION**

Recurrent disease is the most daunting issue for cancer patients because virtually no treatment option is available and it is almost always fatal. Clinically, tumor dormancy is defined as asymptomatic or having minimum residual disease after treatment (Aguirre-Ghiso, 2007). The disseminated cancer cells often undergo dormancy for years to decades before recurrence; however, little is known about the underlying molecular mechanism of the pathological process, although several theories have been proposed, including balance of immunosurveillance, lack of angiogenesis, and induction of quiescence of tumor cells by microenvironmental factors (Aguirre-Ghiso, 2007; Steeg and Theodorescu, 2008). In this study, we have demonstrated that BMP7 secreted from bone stromal cells is capable of inducing senescence to the CSCs through activation of p38, p21, and NDRG1. Importantly, this senescence is reversible and the CSCs regain the ability to proliferate immediately upon withdrawal of BMP7 both in vitro culture and in our animal models. Consistent with these data, the expression of a BMP7 receptor, BMPR2, was significantly increased after BMP7 treatment. We found that tumor growth in tibiae was strongly decreased after withdrawal of BMP7 (Fig. 8 E, withdrawal). These results again suggest that BMP7 plays a critical role in balancing the dormancy and recurrence of CSCs in bone metastasis of prostate cancer.

BMP7 belongs to the TGF-β family, and it is involved in various functions of normal development including bone morphogenesis (Dudley et al., 1995; Friedlaender et al., 2001; Chen et al., 2004; Ristiniemi et al., 2007). Several lines of recent evidence suggest that BMP7 contributes to the inhibition of migration and invasion of cancer cells and this may be because of the ability of BMP7 to counteract epithelial–mesenchymal transition (EMT), which is a hallmark of the aggressive tumor phenotype (Zeisberg et al., 2003; Ye et al., 2007). We also found that BMP7 indeed up-regulated the expression of epithelial genes such as E-cadherin, whereas it suppressed mesenchymal genes such as fibronectin and vimentin in PC3 mm cells (unpublished data). In this context, it is noteworthy that EMT induced by Twist1 and/or Twist2 was shown to lead human epithelial cells to escape from oncogene-induced premature senescence (Ansieau et al., 2008). Similarly, another transcription factor Zeb1-mediated EMT has also been suggested to suppress cellular senescence (Liu et al., 2008). Therefore, this ability of BMP7 to counteract EMT may partly contribute to the BMP7-induced reversible senescence of the CSCs. Although BMP7 is expressed in a variety of normal tissues, aberrant expression of BMP7 in various epithelial tumors has also been reported (Mehler et al., 1997; Bobinic et al., 2005; Hruska et al., 2005; Buijs et al., 2007). The results of expression analysis for BMP7 in prostate and breast cancers are contradictory depending on the reports, which suggests intricate roles of this gene in tumor progression, similar to the role of TGF-β in tumorogenesis (Massagué, 2008). However, Morrissey et al. (2010) recently reported that BMP7 expression in primary human prostate cancer tissue was strongly down-regulated compared with normal prostate epithelium and that ectopic expression of BMP7 in prostate cancer cell lines significantly suppressed metastatic potential in vivo. Therefore, it is plausible that although BMP7 is necessary for the maintenance of normal differentiation of prostate gland tissue, the loss of expression of this gene promotes EMT and metastatic ability of CSCs. Importantly, our study showed that BMP7 is expressed at a much higher level in the bone stromal cells than in the prostate cancer cells. When the tumor cells reach the distant organs, BMP7 secreted in the microenvironment may again block EMT and promote differentiation of the tumor cells to become senescent and dormant. In addition, our results indicate that BMP7 also induced NDRG1, which was originally identified as a differentiation-related gene. However, questions still remain about what causes the change in BMP7 expression in clinical settings that allows the outgrowth of metastasis. One possible cause is aging as reported that the expression of BMP7 has been observed to be dramatically reduced in human articular cartilage during aging (Chubinskaya et al., 2002). Another possibility is that BMP7 expression is affected by androgen status, which is also associated with aging. The expression of BMP7 messenger RNA was indeed shown to be increased by androgen and decreased after orchidectomy (Thomas et al., 1998). Therefore, androgen ablation therapy as well as age-related decline in androgens may cause the change in expression of BMP7 that allows the recurrent growth of dormant cancer cells.

BMP7 has been shown to induce bone formation in animal models and enhance bone repair in clinical studies (Sampath et al., 1992; Ripamonti et al., 1996; Friedlaender et al., 2001; Ristiniemi et al., 2007). Our in vivo studies showed that BMP7 treatment inhibited the tumor-induced osteolysis, suggesting that osteoinductive function of BMP7 may also contribute to the tumor suppression in the bone by countering the osteolytic activity of cancer cells. The processes of bone resorption and bone formation are almost always coupled, and both resorption and formation have been shown to be activated in most bone metastases (Mundy, 2002). Although bone metastases of prostate cancer are frequently osteolytic, 20–60% of patients have metastases that are osteolytic or mixed osteolytic and osteoblastic (Niell et al., 1983;
Shimazaki et al., 1992; Cheville et al., 2002). Furthermore, it has been reported that the course of bone lesions showed a tendency to change from the osteolytic to osteoblastic type and relapse was often accompanied by an increase in the osteolytic type lesion (Shimazaki et al., 1992), suggesting that osteolysis plays an important role in bone metastasis of prostate cancer. Interestingly, androgen ablation, which is a standard treatment for prostate cancer, has been shown to increase osteoclastic bone resorption and bone loss (Smith et al., 2001, 2005; Guise et al., 2006). This excess fracture risk associated with hormone therapy may be related to the development of bone metastases of prostate cancer.

Cellular senescence is generally viewed as an irreversible process and considered to serve as a barrier against tumorigenesis and metastasis; however, in this study, we have shown that BMP7 reversibly induced senescence and blocked proliferation of CSCs. The reversibility of senescence has been shown in several normal cells. Sage et al. (2003) previously reported that acute loss of retinoblasoma tumor suppressor reversed senescence in mouse embryonic fibroblasts, and they also showed that Ras oncogene–induced senescence was reversed by the loss of retinoblasoma. In addition, inactivation of tumor suppressor, p53, was also shown to reverse replicative senescence in mouse embryonic fibroblasts and human fibroblasts (Beauséjour et al., 2003; Dirac and Bernards, 2003). More recently, reactive oxygen species–induced senescence in primary human fibroblast was found to be reversed by knockdown of PLA2R (phospholipase A2 receptor; Augert et al., 2009). To our knowledge, our result is the first study to show the reversibility of senescence in CSCs, and we are proposing that BMP7-induced reversible senescence is at least a part of the underlying mechanism of tumor cell dormancy and recurrence. Therefore, it is conceivable that loss of BMP7 receptors may serve as one of the mechanisms for metastatic cells to escape from dormancy and promote metastatic recurrence. We indeed found that expression of BMPR2, one of the BMP7 receptors, was significantly correlated with recurrence-free survival and inversely correlated with bone metastasis of prostate cancer patients. We have also shown that when BMPR2 was knocked down in prostate cancer cells, they became irreversible to activation of p38 signaling and to concomitant induction of senescence in vitro. In support of our hypothesis, BMPR2 expression was also found to be frequently lost in aggressive bladder and colon cancers (Kim et al., 2004; Kodach et al., 2008a,b). Therefore, the BMP7-BMPR2 signaling is considered to play a critical role in metastatic tumor growth and dormancy.

Because the self-renewal of CSCs requires an appropriate niche at the metastasized site that provides specific growth-promoting factors, recurrent growth of such dormant cells is likely to be triggered by stem cell–related pathways such as Wnt, Notch, and Hedgehog (Visvader and Lindeman, 2008; Rosen and Jordan, 2009). Understanding the signaling pathway of BMP7–induced dormancy is an intriguing question, and elucidating the cross talk mechanism with recurrent signaling is clinically an important issue. BMPs exert their biological function through both Smad–dependent and -independent pathways (Derynck and Zhang, 2003; Miyazono et al., 2010).

In this study, we have shown that BMP7 induced senescence via a non–Smad pathway by activating p38 MAPK and p21. p38 is a bifunctional cell signaling molecule, and it is reported to both suppress and promote tumor cell proliferation in a context-dependent manner (Wagner and Nebreda, 2009). Interestingly, Ventura et al. (2007) recently reported that p38 was capable of coordinating self-renewal and differentiation of the normal lung stem and progenitor cells and that inactivation of p38 led to abnormal proliferation of lung epithelial cells followed by hypersensitivity to Kras–mediated tumor induction, suggesting an important tumor-suppressive role of p38 at an early stage of tumorigenesis. It should also be noted that p38–activating kinases, MKK4 and MKK6, have been shown to suppress metastasis of ovarian cancer, suggesting a diverse function of p38 in tumor progression (Hickson et al., 2006). Recently, several lines of evidence suggest that the balance of p38 and ERK is a critical factor to determine the state of dormancy and proliferation in several types of tumor cells (Aguirre-Ghiso et al., 2003, 2004). p38 was indeed shown to be able to arrest cell cycle by up-regulating the key negative cell cycle regulator, p21, which is also activated during cellular senescence (Han and Sun, 2007; Abbas and Dutta, 2009). In contrast, ERK is a major positive cell cycle regulator that is responsive to many extracellular mitotic stimuli by regulating G0–G1–S phase transition (Hoshino et al., 1999). How the balance of p38/ERK is controlled and what downstream signaling coordinates the direction to dormancy or recurrence are not yet clearly defined; however, our data indicate that the level of BMP7 expression in the metastatic microenvironment or status of BMP receptors of tumors may play a pivotal role in modulating p38 activation and in determining the fate of CSCs for dormancy and recurrence.

NDRG1 expression has been shown to be significantly down-regulated in a variety of carcinomas, including prostate, breast, colon, pancreas, and esophageal squamous cell carcinomas (van Belzen et al., 1997; Bandyopadhyay et al., 2003, 2004; Ando et al., 2006; Maruyama et al., 2006), and importantly, the expression of NDRG1 was shown to be inversely correlated with bone metastasis of prostate cancer patients (Bandyopadhyay et al., 2003). NDRG1 exerts both tumor-suppressor and metastasis-suppressor activities in a cell context–dependent fashion, and we indeed previously showed that NDRG1 was capable of directly suppressing metastasis without affecting the primary tumor growth in an animal model of prostate cancer (Bandyopadhyay et al., 2003). In this study, we demonstrated that NDRG1 was able to induce reversible cellular senescence in a p38- and p21-dependent manner in CSCs. Our results also indicate that the up-regulation of NDRG1 by BMP7 is mediated by p21. p21 has been shown to directly bind to c-Myc, E2F1, and STAT3 and inhibit their transcriptional activity (Kitaura et al., 2000; Abbas and Dutta, 2009). Importantly, both c-Myc and N-Myc have been shown to suppress NDRG1 expression (Li and Kretzner, 2003; Ellen et al., 2008). Therefore, NDRG1 activation by
BMP7 is likely to be mediated by inhibition of c-Myc by p21, although this possibility needs to be further tested. These results suggest that BMP7 induces cellular senescence in CSCs by activating NDRG1 via the p38 signaling pathway followed by mobilizing the intrinsic transcriptional network, which eventually leads to tumor dormancy.

The ultimate goal of treating patients with dormant tumors is to eradicate the residual cancer cells that are believed to be the cancer stem cells; however, confining such cells in the state of perpetual dormancy is another rational approach. Considering that the BMP7–p38–NDRG1 axis induces growth arrest of prostate CSCs, as we reported in this study, and given that BMP7 is already FDA approved for clinical use to heal bone fractures, BMP7 or a small molecule that mimics its function may serve as a potential anticancer agent to treat cancer patients with metastatic disease.

**MATERIALS AND METHODS**

**Cell culture.** PC3 mm was provided by I.J. Fidler (The University of Texas MD Anderson Cancer Center, Houston, TX). DU145, H5, NIH3T3, MRC5, and hFOB1.19 were obtained from the American Type Culture Collection. ALVA41 was provided by W. Rosner (Columbia University, New York, NY). LNCAp, C4, C4-2, and C4-2B were obtained from the University of Texas MD Anderson Cancer Center. The PC3 mm/Tet-NDRG1 cell line was established as previously described (Bandyopadhay et al., 2006). hBMSCs were isolated from human BM (Lonza) by depletion of red blood cells followed by enrichment of plastic adherent cells. The MSC population was characterized by flow cytometry for expression of negative (CD34+/CD45+) and positive (CD44+ and CD29+) surface markers, and their multipotent potential was confirmed by the capacity to differentiate into adipogenic and osteogenic lineages. hBMSCs were maintained in minimum essential medium with 20% fetal bovine serum, 100 µg/ml streptomycin, and 100 U/ml penicillin. hBMSCs were cultured in 1:1 DME medium/Ham’s F12 medium without phenol red supplemented with 10% fetal bovine serum, 100 µg/ml streptomycin, and 100 U/ml penicillin. hFOB1.19 was cultured in 1:1 DME medium/Ham’s F12 medium without phenol red supplemented with 10% fetal bovine serum, 100 µg/ml streptomycin, and 100 U/ml penicillin at 34°C, and it was differentiated into mature phenotype at 39°C for 24 h. Other cells were differentiated into mature phenotype at 39°C for 24 h. Other cells were transfected to PC3 mm using Lipofectamine, and cells were cultured with or without BMP7 or CM for 48 h and subjected to reporter assay. Luciferase activities were measured by using the Dual-Luciferase Reporter Assay System (Promega) and Lumimenter (Berthold Detection Systems). For each experiment, the Renilla expression plasmid, pHRG-TK (Promega), was cotransfected as an internal control, and the promoter activities were normalized accordingly.

**Quantitative RT-PCR (qRT-PCR) analysis.** Total RNA was isolated from the cells and reverse transcribed. The cDNA was then amplified with a pair of forward and reverse primers for the following genes: NDRG1 (5’-CGGTTATGGCGGATCGATGCTGCAG-3’ and 5’-GGTTCAATGGCGGATCGATGCTGCAG-3’), p21 (5’-GAAAGACATGTGCGATGCTGCAG-3’ and 5’-GGTTCAACATGGCGGATCGATGCTGCAG-3’), BMP7 (5’-CAGCAATGGCTCAGCACG-3’ and 5’-CAACTGGGTTGATGCTTG-3’), BMP2 (5’-CAGCAATGGCTCAGCACG-3’ and 5’-CAACTGGGTTGATGCTTG-3’), and β-actin (5’-TGGACACCTCTCAACACCCGACGC-3’ and 5’-CGTATGGGGACAGCTTGTTTGTG-3’). The thermal cycling conditions consisted of an initial denaturation step at 95°C for 1 min followed by 35 cycles of PCR using the following profile: 94°C for 30 s, 58°C for 30 s, and 72°C for 30 s.

**Isolation of pG3-NDRG1 reporter plasmid.** Recombinant human NDRG1 plasmid was a gift from T. Commes, Université de Montpellier 2, Montpellier, France. pGL3-BM7, pBMPR2 (R&D Systems), and β-tubulin (Millipore).

**Western blot.** The cells were lysed by immunoblotting using antibodies specific for the following proteins: total and phospho-p38, p21, p27 (Cell Signaling Technology), NDRG1 (gift from T. Commes, Université de Montpellier 2, Montpellier, France), BMP7, BMPR2 (R&D Systems), and β-tubulin (Millipore).

**Sphere-forming assay.** CSCs were plated (500 cells/ml) in ultra-low attachment plates (Corning) with DMEM/F12 supplemented with 2% B27 (Invitrogen), 20 ng/ml EGF (Sigma-Aldrich), and 4 µg/ml insulin (Sigma-Aldrich). They were then incubated with or without 200 ng/ml BMP7 or tetracycline as described in the legend for Fig. 7 (E and I). The number of prostaphereses was counted, and data were represented as the means ± SEM.

**Reportor assay.** The promoter plasmids of pGL3-NDRG1 (promoter region 1,433 to 97) and p21 (WWP-luciferase; a gift from B. Vogelstein, Howard Hughes Medical Institute, Baltimore, MD) were used. They were transfected to PC3 mm using Lipofectamine, and cells were cultured with or without BMP7 or CM for 48 h and subjected to reporter assay. Luciferase activities were measured by using the Dual-Luciferase Reporter Assay System (Promega) and Lumimenter (Berthold Detection Systems). For each experiment, the Renilla expression plasmid, pHRG-TK (Promega), was cotransfected as an internal control, and the promoter activities were normalized accordingly.

**In situ apoptosis assay.** PC3 mm cells were cultured in the presence of CM of H85 or MCF7 for 48 h and fixed with 4% paraformaldehyde in PBS followed by permeabilization with 0.2% Triton-X 100/0.1% sodium citrate at 4°C. The cells were then washed extensively, and terminal deoxynucleotidyl transferase-mediated dUTP-biotin end labeling assay was performed using the In Situ Cell Death Detection kit/TMR Red (Roche). The reaction was stopped after 1 h, and the number of apoptotic cells in each well was counted under an SP5 spectral laser-scanning confocal microscope (Leica).

**Animal experiments.** All animal work was performed in accordance with a protocol approved by the Laboratory Animal Care and Use Committee of Southern Illinois University School of Medicine. Athymic nude mice (Harlan) with the ages of 4–5 and 7–8 wk were used for tumorigenic ability assay and other xenograft experiments, respectively. For tumorigenic ability assay, 103, 104, or 105 cells were injected subcutaneously into the mice, and primary tumor growth was monitored weekly by BLI. For intravenous inoculation, 2 × 104 CSCs with or without 2 × 104 bonestromal cells were injected into the tibiae of the mice. For recurrence assay, 100 µg/kg BMP7 or vehicle alone was subsequently injected daily into the tail vein. For metastasis experiments, 106 CSCs isolated from PC3 mm cells, 106 CSCs isolated from C4-2B cells, or 5 × 106 PC3 mm/shBMPR2 or PC3 mm/scrBMPR2 cells were injected into the left cardiac ventricle of the mice. To obtain bone derivatives of PC3 mm CSCs in micrometastases, 106 GFP/luciferase-expressing cells were injected into the left cardiac ventricle of the mice. 4 wk after the injection, metastasized cells in tibiae were flashed with a 26-gauge needle, and GFP-positive cells were sorted. Several independent bone...
derivatives were isolated and named as PC3 mm-BM. The progression of cell growth and development of metastases were monitored by BI. At the experimental endpoint, mice were sacrificed, and x-ray images of the tibial bone were also taken using a Faxitron instrument (model MX-20; Faxitron Biopics, LLC).

**Histological analysis.** All work was performed in accordance with the Springfield Committee for Research Involving Human Subjects. A prostate cancer tissue microarray was obtained from US Biomax, Inc. The tissue microarray slide contained 41 samples from prostate cancer patients for whom clinical data of their bone metastasis status had been collected. Formaldehyde-fixed and paraffin-embedded human prostate tissue specimens were obtained from the surgical pathology archives of the Akita Red Cross Hospital (Akita, Japan) and Iwate Medical School (Iwate, Japan). The sections were baked at 60°C for 1 h, deparaffinized in xylene, and rehydrated. Hind limb long bones of nude mice that were injected with cancer cells were excised and fixed in 10% neutral-buffered formalin. The bone was decalcified, embedded in paraffin, sectioned, and stained with hematoxylin and eosin (H&E). Histological services were provided by American Histolabs, Inc. Immunohistochemical staining of histological sections was performed according to the previously published protocol (Bandopadhyay et al., 2006) using the EnVision plus System (Dako) and antibodies specific to the following proteins: BMPR2 (Abcam), phospho-p38 (Cell Signaling Technology), and NDRG1 (gift from T. Commes).

**SA-β-gal staining.** Cells were treated with or without BMP7 or tetra-cycline as indicated in the figure legends, and SA-β-gal assay was performed using the SA-β-gal staining kit (Cell Signaling Technology) according to the manufacturer's instruction. For staining of CSCs, single cells were obtained by enzymatic digestion of the spheres after each treatment and then washed with PBS before being stained using the SA-β-gal staining kit. For staining of tibiae, samples were fixed in 10% neutral-buffered formalin, dealcified in 10% EDTA for 1 wk, and then washed in PBS before being stained using the SA-β-gal staining kit. After staining, tissues were embedded in paraffin and subsequently counterstained with H&E.

**Proliferation assay.** Cells were seeded into 96-well plates with 2,000 cells/well in regular growth medium. The cells were then cultured overnight to subsequently counterstained with H&E.

**Cell cycle analysis.** Cells were treated with or without BMP7 as indicated in the figure legends, and they were trypsinized, washed twice in PBS, and fixed in 70% ice-cold ethanol. The fixed cells were washed twice in PBS, treated with 50 µg/ml propidium iodide and 250 µg/ml R Nase A for 30 min at 37°C, and analyzed by flow cytometry using the C6 flow cytometer (Accuri Cytometers) and FCS Express software (De Novo Software).

**Statistical analysis.** Results were reported as mean ± SEM. For in vitro experiments, the Student's t test or one-way analysis of variance was applied. For in vivo experiments, group comparisons were performed using the non-parametric Mann-Whitney test or unpaired Student's t test. Kaplan-Meier curve comparison was performed with the log-log rank test. Tumorigrancy and statistical significance were evaluated with the ELDA software (Extreme Limiting Dilution Analysis; http://bioinf.wehi.edu.au/software/elda/index.html).
