A significant percentage of breast tumors are resistant to apoptotic stimuli. This resistance has been correlated with decreased expression of the proapoptotic protein bax. A major regulator of bax expression is the tumor suppressor p53. Unlike other well characterized p53 response elements, like the p21-5' element, which consist of two consensus p53 half-sites, the response element of the human bax promoter consists of three half-sites that cooperate in mediating p53-dependent transactivation. Within this unique response element are six GC-rich base pairs that mediate an interaction with Sp1 both in vitro and in cells. These bases were found to be required for p53-dependent activation, and mutations that inhibited Sp1 binding also blocked the ability of p53 to activate transcription through this element, suggesting a model in which p53 requires the cooperation of Sp1 or a Sp1-like factor to mediate transcriptional activation of the human bax promoter. In addition, I recently identified a novel p53 response element conserved in the first intron of both the human and the murine bax genes. This element is required for the p53-dependent transcriptional activation of both the human and murine bax genes, demonstrating that bax is a direct and evolutionarily conserved transcriptional target of p53.

Differential Activation of p53 Target Genes in Breast Cancer

Introduction:

In the past decade, there have been great advances in the field of breast cancer. These advances largely have been in the fields of education and early detection. Unfortunately, however, the treatment of breast cancer continues to be problematic in that a significant proportion of tumors are resistant to chemotherapy. Evidence suggests that this resistance is due to a defect in the normal programmed cell death or apoptotic pathway. A complete understanding of the apoptotic mechanism, therefore, is essential for designing the most therapeutic regimen for the treatment of breast cancer. The protein bax is a key regulator of the apoptotic process, and low levels of this protein correlate with a decreased response to treatment and a decreased survival period in breast cancer patients. A major regulator of bax transcription is the tumor suppressor protein p53, and the work I am conducting in this fellowship addresses the transcriptional regulation of the bax gene by p53. As such, I hope to understand the mechanism by which bax levels are reduced in breast tumor cells, and then to use this information to elevate the level of activation of the bax gene, causing breast tumors to become sensitive to apoptotic stimuli like chemotherapy. I believe that completion of the work proposed in this fellowship will enhance our understanding of both the origins of breast cancer and how tumors respond to treatment. In addition, I believe this work will identify novel targets for therapeutic intervention in breast tumors that are otherwise resistant to current treatment.

Body:

A significant percentage of breast tumors have been shown to be resistant to apoptotic stimuli such as chemotherapeutic drugs. This resistance has been correlated with a decreased expression of the proapoptotic protein bax. Low bax levels have been associated with a decreased treatment response and a shorter survival time in women with metastatic breast adenocarcinoma. In addition, overexpression of bax in tumor cell lines sensitizes the cells to drug-induced apoptosis. A major regulator of bax expression is the tumor suppressor p53. p53 is a well-characterized transcription factor that can bind DNA in a sequence specific manner and activate the transcription of particular genes, including bax. When compared to alternate p53 targets such as the cyclin dependent kinase inhibitor p21, several lines of evidence suggest that the bax gene is differentially regulated by p53. Preliminary data presented in the fellowship application demonstrated that the breast carcinoma MCF-7 and MDA-MB-453 cell lines both exhibited a defect in the ability of wild-type p53 to activate transcription through both the intact bax promoter as well as the p53 response element in isolation from the promoter. This defect was specific for bax as p53 was capable of activating transcription of other p53-dependent target genes, such as the cyclin-dependent kinase inhibitor p21. The goal of the work being conducted
Differential Activation of p53 Target Genes in Breast Cancer

in this fellowship is to understand the molecular mechanism by which wild-type p53 selectively fails to activate the transcription of the pro-apoptotic bax gene.

Work on this project began by identifying the minimal sequence within the bax promoter required to mediate p53-dependent transactivation. In contrast to other well characterized p53 response elements, which consist of two copies (half-sites) of sequences that closely resemble the palindromic decamer 5'-RRRCWWGYYY-3' (where R is a purine, Y is a pyrimidine, and W is an adenine or threonine) separated from each other by 0-13 bases, the minimal element from the bax promoter consists of three copies of this sequence, or three half-sites. Using this minimal sequence as a probe in electrophoretic mobility shift assays (EMSAs) with nuclear extract, a factor was identified that demonstrates marked sequence specificity for this p53 response element. This factor, referred to as BBF (Bax Binding Factor) in the original fellowship application, is specific for the p53-response element of bax as it fails to bind other well-characterized p53-response elements, including that of the cyclin-dependent kinase inhibitor p21 (Thornborrow and Manfredi, 1999). Five tasks were proposed in the original fellowship application to address the biological role of this binding factor in both breast tumor formation and resistance to treatment: 1) Identify additional wild-type p53 breast cancer cell lines that fail to activate transcription of the bax gene and fail to undergo p53-dependent apoptosis in response to DNA damage; 2) Explore a possible correlation between BBF levels and a cell line's ability to activate transcription of the bax gene and to undergo p53-dependent apoptosis; 3) Purify and clone BBF; 4) Determine the relevance of BBF to the apoptotic response in relevant breast cell model systems; 5) Examine the potential correlation between BBF levels, bax levels, and p53 status in breast tumor biopsy samples as compared to normal mammary epithelium.

Work on Task #3 successfully identified BBF as the transcription factor Sp1 (see Appendix 1). Mutational analysis demonstrated that the binding of Sp1 to the bax promoter is mediated by six base pairs (5'-GGCGGT-3') in the p53 half-site most proximal to the start site of transcription (Figure 4). Further, it was shown that the minimal response element capable of mediating p53-dependent transcriptional activation consists of the two distal p53 half-sites plus this adjacent six base pairs (Figure 8). This GC-rich region constitutes a "GC-box" capable both of binding members of the Sp family of transcription factors, including Sp1 in vitro (Figures 3 and 4), and of conferring Sp1-dependent transcriptional activation on a minimal promoter in cells (Figure 5). Mutations within this GC-box abrogated the ability of p53 to activate transcription without affecting the affinity of p53 for its binding site (Figures 6 and 8), demonstrating that these six bases are required for p53-dependent activation. In addition, a positive correlation was observed between the ability of p53 to activate transcription in cells and the ability of Sp1 to bind this response element in vitro (Figures 6 and 8). Mutations that inhibited Sp1 binding also blocked the ability of p53 to activate transcription through this element. Together, these results
suggest a model in which p53 requires the cooperation of Sp1 or a Sp1-like factor to mediate transcriptional activation of the human \textit{bax} promoter (Figure 9).

Two independent reports recently demonstrated that the murine \textit{bax} promoter is unresponsive to p53 in transient transfection assays (Igata et al., 1999, Schmidt et al., 1999), suggesting a lack of evolutionary conservation with respect to the ability of p53 to transcriptionally regulate \textit{bax} expression, and questioning the significance of the above studies done with the human \textit{bax} promoter. To assay for additional sequence elements that influence p53-dependent transcriptional activation, extended pieces of both the human and murine \textit{bax} genes were cloned (see Appendix 2). Sequence analysis of these two genes identified two regions conserved between human and mouse (Figure 1). The first region corresponds to the previously characterized p53 response element in the human \textit{bax} promoter at -113 to -83 from the start site of transcription. The second region of conservation is found in the first intron of both genes and resembles the p53 DNA-binding consensus sequence. Both regions in the human and murine \textit{bax} genes were capable of binding p53 in a sequence specific manner \textit{in vitro} (Figures 1 and 3) and of conferring p53 responsiveness upon a minimal promoter in cells (Figures 2 and 3). Further, it was found that the p53 response element in the first intron of the human and murine \textit{bax} genes is both required and sufficient for p53-dependent transcriptional activation in the context of a transient assay (Figures 2 and 4). These results demonstrate that \textit{bax} is a direct and evolutionarily conserved transcriptional target of p53.

The studies characterizing the novel p53 response element in the first intron of both the human and murine \textit{bax} genes are a digression from the original Statement of Work. These experiments, however, are essential to validate the significance of the work done with the human \textit{bax} promoter. As such, I propose the addition of a new task to my statement of work. Prior to continuing with the original tasks, it is important to determine the relevance of both the promoter and intronic response elements to the p53-dependent upregulation of endogenous \textit{bax} expression in response to physiological stresses like DNA damage. To this end, I will utilize the ML-1 cell line which is known to respond to DNA damage with a p53-dependent upregulation of \textit{bax}. Both \textit{in vivo} footprinting and chromatin immunoprecipitation will be used to assay for occupancy of both the promoter and intronic p53 response elements following damage. Once it is established that either one or both of these elements is required for p53-dependent upregulation of \textit{bax} expression, then subsequent questions concerning the potential role of coactivating elements as well as possible mechanisms of p53 action, including roles in chromatin remodeling and/or transcriptional elongation, can be addressed.

In addition to the above research accomplishments, I have continued to enhance my academic training and educational experience. While my course work is complete, I continue to participate in a weekly journal club, research seminar, and student club, each focussing on issues that are particularly relevant to the topics of tumor formation and progression. Also, I have had
Differential Activation of p53 Target Genes in Breast Cancer

the opportunity to attend international scientific meetings, including the 91st Annual Meeting of the American Association for Cancer Research and the 10th International p53 Workshop, both of which have allowed me to interact with renowned scientists in the field of tumor biology, and to learn of the latest developments in the field. To be properly prepared for a successful career in the battle against breast cancer one should be familiar with both the history of research as well as the most current techniques used in the field. I believe that the work I am conducting is so intimately connected to both the origins and the treatment of breast cancer that it will provide me with the broad foundation of knowledge and technical skill that will allow me to continually identify important clinical aspects of breast cancer that can benefit from further scientific research. As an M.D./Ph.D. student at the Mount Sinai School of Medicine I am receiving specialized training that will allow me to traverse both the clinical and basic science worlds. To this point, I participate in a program in which I spend one afternoon a week doing patient care work. The research I am conducting in the laboratory is an essential compliment to my clinical training that will continue to provide me with the skills to decrease the gap between benchtop discoveries and bedside cures. The experience of designing my research project and scrutinizing my experimental data is helping me to develop the analytical skills and experience necessary for a productive future battling breast cancer.

Key Research Accomplishments:

- Identified minimal p53 responsive element in the human bax promoter.
  - Found the response element to be unique in that it consists of three p53 half-sites instead of the typical two.

- Demonstrated that p53 requires Sp1 or an Sp1-like cofactor to mediate transcriptional activation of the human bax promoter.

- Identified a novel p53 response element perfectly conserved in the first intron of both the human and murine bax genes.
  - Demonstrated that this element is both required and sufficient for the p53-dependent transcriptional activation of bax.

Reportable Outcomes:

Differential Activation of p53 Target Genes in Breast Cancer

Conclusions:

Low levels of bax protein correlate with a decreased response to treatment and a decreased survival period in breast cancer patients. A major regulator of bax transcription is the tumor suppressor protein p53. The work conducted during this fellowship has analyzed in detail the interaction of p53 with the bax gene, and demonstrated that p53 requires both a cofactor to function through the bax promoter and a newly identified intronic response element to function in the context of the bax gene. Both of these observations suggest novel mechanisms to explain the defect in p53-dependent bax expression and apoptosis observed in many breast tumors. I believe that completion of the work proposed in this fellowship will enhance our understanding of both the origins of breast cancer and how tumors respond to treatment. In addition, I believe this work may identify novel targets for therapeutic intervention in breast tumors that are otherwise resistant to current treatment. Perhaps more significantly, this fellowship has allowed me to obtain an exceptional education that will form the basis for a continuing career in the battle against breast cancer.

An important regulator of the proapoptotic BAX is the tumor suppressor protein p53. Unlike the p21 gene, in which p53-dependent transcriptional activation is mediated by a response element containing two consensus p53 half-sites, it previously was reported that activation of the BAX element by p53 requires additional sequences. Here, it is demonstrated that the minimal BAX response element capable of mediating p53-dependent transcriptional activation consists of two p53 half-sites plus an adjacent 6 base pairs (5'-GGGGCGT-3'). This GC-rich region constitutes a "GC box" capable both of binding members of the Sp family of transcription factors, including Sp1 in vitro, and of conferring Sp1-dependent transcriptional activation on a minimal promoter in cells. Mutations within this GC box abrogated the ability of p53 to activate transcription without affecting the affinity of p53 for its binding site, demonstrating that these 6 bases are required for p53-dependent activation. In addition, a positive correlation was observed between the ability of p53 to activate transcription in cells and the ability of Sp1 to bind this response element in vitro. Mutations that inhibited Sp1 binding also blocked the ability of p53 to activate transcription through this element. Together, these results suggest a model in which p53 requires the cooperation of Sp1 or a Sp1-like factor to mediate transcriptional activation of the human BAX promoter.

The BCL-2 family of proteins are key mediators of the apoptotic response. One member of this family is the proapoptotic BAX. Preceding apoptosis, cytosolic BAX translocates to the mitochondria and homodimerizes. Homodimeric BAX then is thought to cause the release of cytochrome c (1-3) which stimulates apoptosis (4). BAX exists in equilibrium with two of its homologs, BCL-2 and BCL-XL. Unlike BAX, these two homologs exert antiapoptotic effects by heterodimerizing with BAX in the mitochondria, blocking its ability to release cytochrome c (5, 6). Thus, an important determinant of the apoptotic response of a cell is the balance between the levels of BAX and BCL-2/BCL-XL. In this regard, regulation of the level of expression of BAX protein is key.

An important regulator of BAX gene expression is the tumor suppressor protein p53 (7, 8). The p53 protein has been implicated in several growth-related pathways, including apoptosis and cell cycle arrest (9, 10). The ability of p53 to function as a sequence-specific DNA-binding protein appears to be central to its role as a tumor suppressor (11, 12). At its amino terminus, the protein contains a potent transcriptional activation domain (13) that is linked to a central core domain that mediates sequence-specific DNA binding (14-16). Both of these domains have been shown to be important for p53-mediated growth suppression (17).

A DNA consensus sequence through which p53 binds and activates transcription has been identified. This sequence consists of two palindromic decamers of 5'-RRRCWWGYYY-3' (where R is a purine; Y is a pyrimidine; and W is an adenine or thymine) separated by 0-13 base pairs, forming four repeats of the pentamer 5'-RRRCW-3' alternating between the top and bottom strands of the DNA duplex (18, 19). Through sequences similar to this consensus, p53 has been shown to activate the transcription of many genes, including BAX, p21, mdm2, gadd45, IGF-BP3, and cyclin G (8, 20-26). When compared with alternate p53 targets, studies demonstrate that the BAX gene is differentially regulated by wild-type p53 in a cell type-specific manner (7, 27, 28). In the mouse, p53-dependent regulation of BAX expression following ionizing radiation is seen in the prostate, thymus, spleen, small intestine, and lung, as well as sympathetic, Purkinje, and olfactory cortical neurons. In the kidney, heart, liver, and brain, however, no p53-dependent regulation of BAX is observed (7, 27). Furthermore, the myeloid leukemia ML-1, Burkitt's lymphoma WMN and AG876, and lymphoblastoid NL2 and FWL cell lines induce BAX following ionizing radiation, whereas the fibroblast AG1522 and WI38, colorectal carcinoma RKO, and osteosarcoma U2-OS cell lines fail to do so (28). In addition, several tumor-derived p53 mutants have been identified that are capable of activating transcription through the promoter of the p21 gene but not through the BAX promoter (29-32). This correlates with an inability of these mutants to trigger apoptosis (29, 31, 32), suggesting that a failure in the ability of p53 to transactivate the BAX gene may play an important role in tumor formation and progression. Supporting this, Yin et al. (33) demonstrated that BAX is an obligatory downstream effector for the p53-mediated apoptosis that attenuates choroid plexus tumor growth in the TgT121 mouse model. Thus, a complete understanding of the transcriptional regulation of the BAX promoter by p53 may yield important information relevant to our understanding of tumorigenesis.

Here is presented a detailed analysis of the p53 response element located in the promoter of the human BAX gene. The minimal BAX response element capable of mediating p53-dependent transcriptional activation is found to consist of two p53 half-sites plus an adjacent 6 base pairs (5'-GGGGCGT-3') that...
demonstrate sequence-specific binding to the transcription factor Sp1. Mutational analysis of this "GC box" shows it to be required for p53-dependent activation, and a positive correlation between the ability of p53 to activate transcription in cells and the ability of Sp1 to bind this response element in vitro is observed. These results are consistent with a model in which p53 requires the cooperation of Sp1 or a Sp1-like factor to mediate transcriptional activation of the human BAX gene. This presents the intriguing possibility that regulation of this cofactor may represent a novel basis for the cell type-specific control of the proapoptotic BAX by wild-type p53.

EXPERIMENTAL PROCEDURES

Cells-The osteosarcoma Saos-2 cell line was maintained in a humidified tissue culture incubator at 37 °C with 5% CO2. Cells were grown in Dulbecco’s modified Eagle’s medium, containing 10% heat-inactivated fetal bovine serum, 100 unit/ml penicillin, and 100 μg/ml streptomycin. Drosophila SL2 cells were cultured at 25 °C in Schneider’s Drosophila medium, containing 10% heat-inactivated fetal bovine serum, 100 unit/ml penicillin, and 100 μg/ml streptomycin.

Oligonucleotides—For use in electrophoretic mobility shift assays and for subsequent cloning into luciferase reporter plasmids, complementary single-stranded oligonucleotides were annealed to produce double-stranded oligonucleotides with the following indicated sequences: BAX -113/-77, AATTCGGTACCGGAA- CACATCATCTCAACCAACTTTCAACAGAGTGAATATGCGGTATTT- GATT, BAX -113/-83, AATTCGGTACCACCTCAACCGAATTAGAAGACGC- TGGTACGCAATT, BAX -112/-83, AATTCGGTACCACCTCAACCGA- ATT, BAX -113/-92, AATTCGGTACCCTCAACATTAGAAGACGC-TGGTACGCAATT, BAX -112/-92, AATTCGGTACCCTCAACATTAGAAGACGC-TGGTACGCAATT, BAXGG-85/-84AA, Buffer C (20 ml HEPES, pH 7.6, 25% glycerol, 420 mm NaCl, 1.5 mm MgCl2, 0.2 mm EDTA, 0.5 mm DTT) per 109 cells, 1 μg of Drosophila SL2 cells were transfected using Cellfectin (Life Technologies, Inc.) 60-mm dishes were seeded with 2 x 105 cells 24 h prior to transfection. The extract was centrifuged at 4300 x g for 12 min. The supernatant was removed, and the pellet was resuspended in 20 ml of buffer containing 10% fetal bovine serum. The DNA to be transfected was added to 1 μl of serum-free medium, containing (8 μg) of Cellfectin’s reagent, mixed gently, and incubated at room temperature. This mixture was then added directly to the cells. 48 h post-transfection cells were lysed by sonication (6 x 20 s pulse). Total protein and luciferase activity was determined as above.

p53-dependent Transactivation of bax

The abbreviations used are: PCR, polymerase chain reaction; DTT, dithiothreitol; EMSA, electrophoretic mobility shift assays.
All three potential p53 half-sites are required for the p53-dependent transcriptional activation of the human BAX promoter. Previously it was demonstrated that in isolation the p53 response element from the human BAX promoter required p53-dependent transcriptional activation through this promoter (Fig. 1B). Consistent with the above results, removal of the first and second half-sites in combination (pBAXA-113/-93) also abolished the ability of p53 to activate transcriptionally the promoter (Fig. 1B). There was no significant difference between the p53-dependent transactivation of either a reporter construct lacking sequences 5' to the p53 response element (pBAXA-127/-93) or the full-length promoter construct (pBAXA-315/+51) (Fig. 1A). Deletion of a larger fragment, including the p53 response element (pBAXA-76/+51), produced a reporter construct that was unresponsive to wild-type p53 (Fig. 1A). Furthermore, targeted deletion of the promoter region containing the p53 response element (pBAXA-126/-77) also produced a reporter plasmid that was unresponsive to wild-type p53 (Fig. 1A). These results show that -113 to -83 is the only region, within the 366-base pair promoter fragment investigated, that affects the ability of p53 to activate transcription.

The role of each of these half-sites in the p53-dependent activation of bax is illustrated in Fig. 1. All three potential p53 half-sites are required for the p53-dependent transcriptional activation of the human BAX promoter. It was previously demonstrated that in isolation the p53 response element from the human BAX promoter required sequences from three adjacent half-sites to confer p53-dependent transcriptional activation on a minimal promoter (37). To confirm the requirement of all three half-sites in the context of the BAX promoter, luciferase reporter plasmids with various deletions in the BAX promoter, luciferase reporter plasmids with various pBAXA -315/+51 to 7-fold with pBAXA -127/-104, whereas removal of the second (pBAXA-103/-93) or the third half-site (pBAXA-92/-83) completely abolished the ability of p53 to activate transcriptionally the promoter (Fig. 1B). Consistent with the above results, removal of the first and second half-sites in combination (pBAXA-113/-93) also abolished the ability of p53 to activate transcriptionally the promoter (Fig. 1B).
p53-dependent Transactivation of bax

Fig. 2. The first two potential p53 half-sites constitute a bona fide p53 response element. Saos-2 cells were transfected as described under “Experimental Procedures” with 1 μg of the indicated pTATA reporter constructs in the presence of either 10 ng of pCMV (white bars) or 10 ng of pCMV-p53** (gray bars). 24 h post-transfection cells were lysed and assayed for total protein and luciferase activity as described under “Experimental Procedures.” The indicated values are the average of three independent experiments performed in duplicate. Error bars correspond to 1 S.D. The numbers above each bar indicate the fold activation for each reporter construct observed with pCMV-p53** as compared with pCMV. The sequence of the BAX promoter from −113 to −83 is given at the top of the figure. Potential p53 half-sites are indicated by the solid bars above and below the sequence. Bases that deviate from the DNA-binding consensus sequence are indicated by asterisks. The three potential half-sites are indicated by the brackets labeled 1–3, respectively, and are represented graphically as the light gray, white, and dark gray boxes, respectively. The vertical arrow above the BAX sequence indicates the 1-base pair insert between the first and second half-sites.

These results demonstrate that, as was observed with the isolated response element (37), p53 requires sequences from all three potential half-sites to mediate transcriptional activation of the BAX promoter.

The First Two Potential p53 Half-sites Constitute a Bona Fide p53 Response Element—Each of the three potential p53 half-sites located in the BAX promoter from −113 to −83 closely resembles the consensus sequence of 5'-RRRCWWGYYY-3' (represented in Fig. 2 by the light gray, white, and dark gray boxes). The first, located at −113 to −104, deviates from the consensus at 2 bases (−113 and −104). The second half-site matches the consensus sequence at all 20 base pairs and is located at −102 to −93. The third half-site is located at −92 to −83 and deviates from the consensus at three bases (−84, −85, and −86)/see Fig. 2). These three half-sites can combine in different ways to produce a total of three possible p53 complexes binding sites (half-sites 1 and 2, 2 and 3, and 1 and 3). Previous studies demonstrated that in electrophoretic mobility shift assays (EMSA), double-stranded oligonucleotides representing both −113 to −93 (half-sites 1 and 2) and −102 to −83 (half-sites 2 and 3) are capable of binding p53 in a sequence-specific manner with similar affinities (37). When cloned upstream of the adenovirus E1b minimal promoter in the pTATA luciferase reporter plasmid, however, the combination of the first and second half-sites (−113 to −93) is unable to mediate p53-dependent transcriptional activation (37). To examine further the ability of p53 to interact with this sequence in cells, the −113 to −93 sequence was multimerized (as three copies) and cloned into the pTATA luciferase reporter plasmid. This reporter plasmid was cotransfected with either pCMV or a wild-type p53 expression vector in the Saos-2 cell line (Fig. 2). These three copies of this p53-binding site were capable of mediating a significant degree of activation in response to p53 (Fig. 2, compare 4-fold with pTATA-113/-93 to 142-fold with pTATA(−113/-93)3), demonstrating that the sequence from −113 to −93 is indeed a bona fide p53 response element capable of both binding p53 in a sequence-specific manner in vitro and mediating p53-dependent transcriptional activation in cells. Confirming previous results, p53 was able to activate transcription through the second and third half-sites (−102 to −83), but this activation was significantly reduced as compared with that mediated by all three half-sites combined (Fig. 2, compare 44-fold with pTATA-102/-83 and 153-fold with pTATA-113/-83). To test the ability of half-sites one and three to mediate p53-dependent transcriptional activation, a synthetic oligonucleotide corresponding to −113 to −83 of the BAX promoter, with −102 to −93 scrambled to remove any contribution of the second half-site, was cloned into the pTATA reporter plasmid. This construct failed to be activated by p53 (Fig. 2, pTATA-113/-83(sc−102/-93)). The third half-site in isolation (−92 to −83) also failed to mediate p53-dependent transcriptional activation (Fig. 2, pTATA-92/-83).

Sp1 Binds with Sequence Specificity to and Activates Transcription through the p53 Response Element from the Human BAX Promoter—We previously reported the identification of a nuclear factor, termed Binder of BAX (BoB1), that interacts with sequence specificity with the same region of the human BAX promoter that is required for p53-dependent transcriptional activation (37). These previous studies demonstrated that this factor binds to sequences within the region of −102 to −83. Analysis of this region using a MatInspector search of the TRANSFAC data base (38, 39) showed that it contains a sequence that potentially could bind the transcription factor Sp1. To test this, a synthetic oligonucleotide corresponding to −102 to −83 of the BAX promoter was used as a radiolabeled probe in an EMSA with HeLa cell nuclear extract (Fig. 3). As reported previously for Saos-2 (37), HeLa cell nuclear extract contains a factor that demonstrated marked sequence specificity for the labeled BAX probe. This factor was successfully competed by increasing amounts of unlabeled probe (Fig. 3, lanes 7–9) as well as by increasing amounts of oligonucleotide corresponding to the DNA-binding consensus sequence of Sp1 (Fig. 3, lanes 13–15). This binding was specific, as an oligonucleotide corresponding to the 5'- p53 response element from the human p21 promoter failed to compete for binding (Fig. 3, lanes 10–12). In addition, this factor was successfully bound by an anti-Sp1 antibody, as demonstrated by a "supershifted" complex (Fig. 3, lanes 2 and 3), whereas a control anti-p300 antibody failed to bind the factor (Fig. 3, lanes 4 and 5). Together, these data demon-
REPLACE TEXT
the Saos-2 cell line, substitution of bases −92 and −91 completely abolished the ability of p53 to activate transcription through this element (Fig. 6A, compare −113/−83 to GG−92/−91AA), whereas substitution of bases −85 and −84 did not (Fig. 6A). As observed in Figs. 1 and 2, removal of the third potential half-site (−92 to −83) inhibited the ability of p53 to mediate transcriptional activation through this element (Fig. 6C, compare −113/−83 and −113/−93), demonstrating the requirement for this Sp1-binding sequence in the p53-dependent transcriptional activation of this element.

Both of these mutant sequences were assayed for their ability to bind purified p53 in an EMSA. An oligonucleotide corresponding to −113 to −77 of the BAX promoter was used as a radiolabeled probe with purified p53 in an EMSA (Fig. 6B). Competitions were performed with increasing amounts of an oligonucleotide corresponding to −113 to −83 of the BAX promoter and the two mutant oligonucleotides. When compared with the wild-type oligonucleotide, both mutant oligonucleotides displayed a slightly decreased affinity for p53 (Fig. 6B, compare lanes 2–4 with lanes 5–7; Fig. 6C). Compared with one another, however, both mutant oligonucleotides demonstrated a comparable affinity for p53 (Fig. 6, A and B), suggesting that the differences in p53-dependent transcriptional activation observed in Fig. 6A are due to differences in the affinity of p53 for the two sequences. In contrast, the abilities of the two mutant sequences to bind Sp1 differed (Fig. 6, D and E). An oligonucleotide corresponding to −113 to −77 of the BAX promoter was used as radiolabeled probe with extract from SF9 cells expressing recombinant human Sp1 protein in an EMSA (Fig. 6D). Sp1 bound the probe and was recognized by an anti-Sp1 antibody (Fig. 6D, lanes 1–2). Sp1 binding was successfully competed by unlabeled BAX−113/−83 oligonucleotide as well as by the GG−85/−84AA mutated oligonucleotide (Fig. 6D, lanes 3–4 and 9–11, respectively; Fig. 6E). The GG−92/−91AA mutant, however, demonstrated a significant decrease in affinity for Sp1 (Fig. 6D, compare lanes 3–5 and 9–11 to lanes 6–8; Fig. 6E).

The results with the GG−85/−84AA mutant presented in Fig. 6 suggest that not all of the bases contained within the third potential half-site of the p53 response element are required for p53-dependent transcriptional activation. To iden-

FIG. 5. Sp1 can activate transcription through the p53 response element of the human BAX promoter. Drosophila SL2 cells were transfected as described under "Experimental Procedures" with 2 μg of the indicated pTATA reporter constructs in the presence of 0, 300, 600, or 900 ng of pPacSp1. Appropriate amounts of the vector pPacU were added to each transfection mixture to maintain a constant level of total plasmid DNA of 2.9 μg/sample. 48 h post-transfection cells were lysed and assayed for total protein and luciferase activity as described under "Experimental Procedures." The indicated values are the average of four independent experiments expressed as the fold activation for each reporter plasmid with pPacSp1 as compared with pPacU. Error bars correspond to 1 S.D.

To confirm that the bases from −86 to −83 are not required for p53-dependent transcriptional activation, two additional mutant oligonucleotides were synthesized. The first mutant was generated by replacing all 10 nucleotides from −92 to −83 (Fig. 8A, sc−92/−83). The 4 bases from −86 to −83 were substituted as indicated to generate the second mutant oligonucleotide (Fig. 8A, sc−86/−83). Each oligonucleotide was cloned into the pTATA vector and tested for its responsiveness to p53 in a cotransfection assay in the Saos-2 cell line (Fig. 8A). As observed with the reporter plasmid in which the sequence from −92 to −83 is removed entirely (pTATA−113/−93), the first mutant, in which all 10 bases of the third potential half-site (−92 to −83) are replaced, showed little to no response to p53 (Fig. 8A, compare pTATA−113/−93 to pTATA−113/−83 and pTATAsc−92/−83). In contrast, the second mutant, in which only the last 4 bases of the element (−86 to −83) are replaced, was efficiently activated by p53 (Fig. 8A, compare lanes 8–10 with lanes 323-fold with pTATA−113/−83 to 323-fold with pTATAsc−86/−83). This result demonstrates that the minimal p53 response element in the BAX promoter consists of sequence from −113 to −87, with −86 to −83 being dispensable for p53-dependent transactivation.

To confirm the bases from −92 to −83 are not required for p53-dependent transcriptional activation, a series of oligonucleotides was synthesized in which each of the 10 bases of the third potential half-site (−92 to −83) was individually replaced. These mutant oligonucleotides were then cloned into the pTATA luciferase reporter plasmid and tested for their responsiveness to p53 in a cotransfection assay in the Saos-2 cell line (Fig. 7). Consistent with the results in Fig. 6A, substitution of the bases at either −85 or −84 did not inhibit the ability of p53 to activate transcription through this element (Fig. 7, G−85T and G−84T). Furthermore, substitution of −86 and −83 also failed to affect significantly the ability of p53 to activate transcription (Fig. 7, compare −113/−83 to G−86T and C−83A). Substitution of the base at −87, however, significantly reduced the ability of p53 to activate transcription through this element (Fig. 7, compare −113/−83 to T−87G). Together, these results suggest that the minimal response element consists of sequence from −113 to −87, with −86 to −83 being dispensable for p53-dependent transactivation.

DISCUSSION

The data presented in this report demonstrate that the minimal p53 response element in the BAX promoter consists of the sequence from −113 to −87 from the start site of transcription. This sequence contains a p53-binding site (−113 to −93) that can function as a bona fide response element as demonstrated by its ability when tetramerized to confer p53-depend-

ent transcriptional activation on a minimal promoter (Fig. 2). Immediately adjacent to this p53-binding site are 6 base pairs that are GC-rich in nature (−92 to −87: 5'GGCCGT-3'). These 6 bases are required for p53-dependent transcriptional activation as deletion or mutation of this region in the context of either the promoter or the isolated response element completely abrogates the ability of p53 to activate transcription through this sequence (Figs. 1B, 2, 6A, and 8A). The addition of these bases to the −113/-93 sequence appears to have little effect on the affinity of p53 for this sequence (Fig. 8, B and C), consistent with a model in which these 6 bases function to recruit a co-activator as opposed to simply enhancing p53 binding. Furthermore, these 6 base pairs mediate sequence-specific binding to the Sp1 transcription factor (Figs. 3, 4, 6D, and 8D), and a positive correlation is seen between the ability of Sp1 to bind this element in vitro and the ability of p53 to mediate transcriptional activation through its response element in cells (Figs. 6 and 8). In addition, the results with electrophoretic mobility shift assays with the GG-92/-91AA mutant oligonucleotide (Fig. 6D) are not consistent with the published p53 DNA-binding consensus sequence of (RRRCWWGYYY)₂ (18, 19). This consensus allows for a purine in the first three posi-
FIG. 7. Mutational analysis shows that the BAX promoter sequence from −86 to −83 is not required for p53-dependent transcriptional activation. Saos-2 cells were transfected as described under "Experimental Procedures" with 1 μg of the indicated pTATA reporter constructs in the presence of either 10 ng of pCMV (white bars) or 10 ng of pCMV-p53* (gray bars). 24 h posttransfection cells were harvested and assayed for total protein and luciferase activity as described under "Experimental Procedures." The indicated values are the average of three independent experiments each performed in duplicate. Error bars correspond to 1 S.D. The GC-rich region that binds Sp1 is shown by the boxed sequence. Bases in the wild-type sequence that were mutated are shown in gray with the corresponding mutations indicated above.

**tions of each half-site. The GG−92/−91AA mutant contains a conservative substitution of purines (adenines) for purines (guanines) and, as such, does not represent a substantive change in terms of the p53 DNA-binding consensus sequence. This substitution, however, did produce a significant decrease in the ability of p53 to bind to this oligonucleotide in vitro (Fig. 6B), suggesting that, in these limited circumstances, the p53 DNA-binding sequence involves greater specificity than implied by the consensus.

Previous studies have suggested a connection between p53 and Sp1. The two proteins physically interact under certain circumstances (40–42), and, transcriptionally, p53 and Sp1 have been shown to function in a cooperative manner in some settings and an antagonistic manner in others (41, 43, 44). In addition to p53, Sp1 has been found to synergize with other transcription factors, including YY1 and SREBP (45–47). Studies with the Sp family of transcription factors, however, are complicated by the fact that there are at least 16 mammalian members of this family. Due to marked conservation in the DNA-binding domain, many of these family members have similar if not identical in vitro DNA binding characteristics (48, 49). Originally, this led to the misclassification of many GC boxes solely as Sp1-binding sites because of the ubiquitous nature of Sp1 and the fact that it was the first family member cloned. Given this, the possibility exists that the true in vivo cofactor required for the p53-dependent transactivation of the BAX promoter is an Sp1-related family member that is observed in *in vitro* assays by the sheer abundance of Sp1 in nuclear extracts from tissue culture cells. Consistent with this, antibodies used in a supershift EMSA identified other Sp family members as minor components of the Sp1-DNA complex. Furthermore, cotransfection assays in the Sp1-deficient *Drosophila* SL2 cell line failed to demonstrate cooperation between Sp1 and p53 in transcriptionally activating the p53 response element of the BAX promoter. The *Drosophila* assays, however, are difficult to interpret as the ability of p53 alone to activate transcription through a control plasmid was significantly impaired in the SL2 cell line. Complicating interpretation of the results in the *Drosophila* system is the recent identification of a *Drosophila* p53 homolog (50, 51) that may affect the ability of transiently expressed human p53 to function properly in this system.

Regardless of whether the cofactor required for the p53-dependent transactivation of the BAX promoter is Sp1 or a related family member, the requirement of this cooperating protein suggests a model for the observed cell type- and tumor type-specific regulation of the BAX gene by wild-type p53 (Fig. 9). In this model, cells that are permissive to p53-dependent up-regulation of the BAX gene express both p53 and the cofactor, and these proteins function together to activate transcriptionally the gene. In those cells that fail to show p53-dependent

Bases in the wild-type sequence that were mutated are shown in gray with the corresponding mutations indicated above. B, an electrophoretic mobility shift assay was performed using an oligonucleotide corresponding to the -113/-83 sequence from the human BAX promoter as radiolabeled probe. 50 ng of purified p53 was incubated with 3 ng of the probe alone (lane 1) or in the presence of a 500-, 1000-, or 1500-fold molar excess of either the unlabeled BAX -113/-83 oligonucleotide (lanes 2-4), the BAX -113/-93 oligonucleotide, the BAX sc -92/-83 oligonucleotide (lanes 5-7), or the BAX sc -86/-83 oligonucleotide (lanes 8-10). The arrow indicates the position of the p53-DNA complex. C, bands were quantitated by phosphorimaging. D, an electrophoretic mobility shift assay was performed using an oligonucleotide corresponding to the -113/-83 sequence from the human BAX promoter as radiolabeled probe. Extract from Sf9 cells expressing human recombinant Sp1 protein was incubated with 3 ng of the probe alone (lane 1) or in the presence of a 10-, 50-, or 100-fold molar excess of either the unlabeled BAX -113/-83 oligonucleotide (lanes 2-4), the BAX sc -92/-83 oligonucleotide (lanes 5-7), or the BAX sc -86/-83 oligonucleotide (lanes 8-10). The arrow indicates the position of the Sp1-DNA complex. E, bands were quantitated by phosphorimaging. BAX expression, one can propose three possible mechanisms to explain the apparent failure of wild-type p53 to activate the BAX gene (Fig. 9). First, the required cofactor may be absent, either due to mutation or due to cell type-specific limitations on its expression. Second, this factor may be inactivated by post-translational modification. Finally, another factor that cannot cooperate with p53 may compete with the cofactor for binding to its site in the BAX promoter. Data with the Sp family of transcription factors support each of these possibilities. Although several of the Sp family members, like Sp1, are ubiquitously expressed, other members of the family display high degrees of tissue specificity (48, 49). Even the ubiquitously expressed family members fluctuate in levels under particular cellular conditions (52-55). Sp1 mRNA, for example, varies up to 100-fold depending on the cell type and developmental stage of the mouse (56). Consistent with a model of post-translational modification, certain Sp family members, including Sp1 and EKLF, are phosphorylated, glycosylated, and acetylated (57-59). Finally, given the high level of conservation in the DNA-binding domain of the Sp family of transcription factors, it is not surprising that DNA binding competition can be observed between various members of this family. In certain cases, including Sp1/Sp3, BTEB1/AP-2rep, and BKLFEKLF, this competition has ramifications on gene expression (60-62).

Abstract

Recent studies demonstrating that both the human and mouse bax promoters fail to respond to p53 have brought into question whether bax is a direct target of p53. Here, data are presented identifying an evolutionarily conserved p53 response element in the first intron of both the human and the murine bax genes. Electrophoretic mobility shift assays demonstrated that this sequence is capable of mediating sequence-specific binding to p53, and transfection assays showed that this element is both required and sufficient to mediate p53 dependent transcriptional activation of the bax gene from both species. These results demonstrate that bax is a direct and evolutionarily conserved transcriptional target of p53.

Introduction

Bax is an important mediator of apoptosis. Miyashita and Reed identified the human bax gene as a transcriptional target of p53 (1,2). Supporting this notion, a p53 response element in the promoter of the human bax gene has been demonstrated at -113 to -83 from the start site of transcription (2,3). The recent cloning of the murine bax promoter, however, has questioned the significance of this response element. Two independent reports have demonstrated that the murine bax promoter is unresponsive to p53 (4,5), suggesting a lack of evolutionary conservation with respect to the ability of p53 to transcriptionally regulate bax expression. To assay for additional sequence elements that influence p53-dependent transcriptional activation, extended pieces of both the human and murine bax genes were cloned. Here is presented data
demonstrating that both the human and murine bax genes are direct transcriptional targets of the tumor suppressor protein p53. Sequence analysis of these two genes identified two regions conserved between human and mouse. The first region corresponds to the previously characterized p53 response element in the human bax promoter at -113 to -83 from the start site of transcription. The second region of conservation is found in the first intron of both genes and resembles the p53 DNA-binding consensus sequence. Both regions in the human and murine bax genes are capable of binding p53 in a sequence specific manner in vitro and of conferring p53 responsiveness upon a minimal promoter in cells. Further, it is demonstrated that the p53 response element in the first intron of the human and murine bax genes is both required and sufficient for p53-dependent transcriptional activation.

Materials and Methods

Oligonucleotides and plasmids

With respect to the human bax gene, numbering is in reference to the start of transcription, while in the mouse gene numbering is from the start of translation. The following double-stranded oligonucleotides were used in electrophoretic mobility shift assays, and were cloned into pTATA (6) to produce vectors with corresponding names:

HuBax-113/-83, AATTCGGTACCTCACAAGTJTAGAGACAAGCCTGGGCGTGGGCGCTAGCGAATT;

MuBax-341/-315, AATTCCGTACCGATGACAAGCATATCCCGAGGTAAGCTTTTGGAGCTACGTAGCGAATT;

MuBax-324/-315, AATTCCGTACCGATGACAAGCATATCCCGAGGTAAGCTTTTGGAGCTACGTAGCGAATT;

Bak, AATTCCGTACCGATGACAAGCATATCCCGAGGTAAGCTTTTGGAGCTACGTAGCGAATT;

Sens-1, AATTCCGTACCGATGACAAGCATATCCCGAGGTAAGCTTTTGGAGCTACGTAGCGAATT.

Hu+408/+989 was generated by the PCR amplification of intron 1 (+408 to +989) of the bax gene from human genomic DNA, and subsequent cloning of this product into pTATA. The region in Hu+408/+989 corresponding to +657 to +676 was replaced with the NcoI restriction site to produce Hu+408/+989ΔIn. Mu+1/+541 was generated by the PCR amplification of +1 to +541 of the bax gene from murine genomic DNA, and subsequent cloning of this product into pTATA. The region in Mu+1/+541 corresponding to +183 to +202 was replaced with the SacI restriction site to produce Mu+1/+541ΔIn. HuBax was generated by PCR amplification of -571 to +1028 of the bax gene from human genomic DNA, and cloning of this product into the pGL3-Basic reporter plasmid. HuBaxΔPr and HuBaxΔIn were derived from HuBax by replacing the relevant sequences, -113 to -84 and +652 to +676 respectively, with the BglII restriction site. MuBax was generated by PCR amplification of -898 to +542 of the bax gene from mouse genomic DNA, and cloning of this PCR product into pGL3-Basic. MuBaxΔPr and MuBaxΔIn were derived from MuBax by replacing the relevant sequences, -339 to -304 and +183 to +202 respectively, with the BglII restriction site. The expression plasmids, pCMV-p53wt and p11-4mup53wt, previously have been described (7,8).
Transfections

2 x 10^5 Saos-2 cells were transfected using Lipofectamine Plus Reagent (GibcoBRL, Life Technologies). Total protein concentration and luciferase assays were quantitated 24 h post transfection.

Electrophoretic Mobility Shift Assay

Production of baculovirus-infected Sf9 cell extracts, purification of recombinant human p53 protein, and electrophoretic mobility shift assays were conducted as previously described (6).

Results

Cloning of the human and murine bax genes identifies a putative p53 response element in the first intron.

To identify sequence elements that participate in p53-dependent transcriptional activation of the human bax gene, a 1599 bp fragment (-571/+1028 from the start site of transcription) of this gene was PCR cloned from human genomic DNA (Figure 1A, Accession #AF339054). This sequence contains the previously identified p53 response element at -113/-83 (Figure 1A, upper box). Sequence analysis of the first intron revealed 20 bp at +657/+676 that matched the p53 DNA-binding consensus sequence at 18 of 20 bases (Figure 1A, lower box, mismatches indicated by asterisks). This sequence was confirmed in three independent PCRs of human
genomic DNA, and, subsequently, has been confirmed independently by the Human Genome Project (Accession #11425312).

To assess whether or not the two p53 response elements observed in the human bax gene are evolutionarily conserved, a 1440 bp fragment (-898 to +542 from the start site of translation) of the murine bax gene was PCR cloned from mouse genomic DNA (Figure 1B, Accession #AF339055). Sequence analysis of the murine gene identified partial conservation of the promoter response element at -339/-304 (Figure 1B, upper sequence, solid lines represent identities, dashed lines represent conservative substitutions). As with the human sequence, if one applies the p53 DNA-binding consensus sequence of 5’-RRRCWWGYYY-3’ to this region three potential p53 half-sites are identified (Figure 1B, upper boxes labeled 1-3). Of note is the Cytosine (C) at position -332 (Figure 1B, arrow). This base is consistent with the murine bax promoter sequence published by Schmidt et al. (5), but is not found in the sequence published by Igata et al. (4) nor is it found in their accompanying GenBank submission (Accession #AB029557). To confirm the presence of this base, this region was PCR cloned from mouse genomic DNA and sequenced on five independent occasions. In each case the C was present at position -332.

An additional region of conservation between the mouse and human bax genes was identified in the first intron. This 43 bp region at +177/+219 in the murine bax gene was found to be 93% identical to the human bax sequence at +651/+693 (Figure 1B, lower sequence, solid lines represent identities, dashed lines represent conservative substitutions). Further, the putative
p53 response element at +657/+676 in the human bax gene is perfectly conserved in the mouse intron at +183/+202 (Figure 3, lower boxes). As with the promoter region, the sequence of the murine bax intron was confirmed by five independent PCRs.

*p53 requires the intronic response element to mediate transcriptional activation of the human bax gene.*

To determine whether the sequence from +657/+676 in the human bax gene constitutes a *bona fide* p53 response element, a synthetic oligonucleotide corresponding to this sequence was used as a radiolabeled probe in an Electrophoretic Mobility Shift Assay (EMSA) with purified p53 (Figure 1C). Purified p53 bound the labeled oligonucleotide containing the putative response element (Figure 1C, lane 1), and this binding was effectively competed by an excess of the same, unlabeled oligonucleotide (Figure 1C, lanes 5-7). An oligonucleotide corresponding to the p53 response element at -113/-83 also competed for p53 binding (Figure 1C, lanes 2-4). An unrelated control oligonucleotide, Sens-1, was unable to compete for p53 binding (Figure 1C, lanes 8-10), demonstrating that the binding of p53 to +657/+676 is sequence-specific.

To determine the significance of this 20 bp element to p53-dependent activation in cells, luciferase reporter plasmids containing different regions of the human bax gene were constructed (Figure 2A) and cotransfected with either pCMV or a wild-type p53 expression vector into the p53-negative osteosarcoma Saos-2 cell line (Figure 2). When cloned upstream of a minimal promoter, the first intron of the human bax gene (Figure 2A, Hu+408/+989) mediated a
significant degree of activation in response to p53 (Figure 2B, Hu+408/+989). Deletion of the putative p53 response element at +657/+676 (Figure 2A, Hu+408/+989ΔIn) abolished the ability of p53 to transcriptionally activate (Figure 2B, Hu+408/+989ΔIn), demonstrating that the first intron of the human bax gene can confer p53 responsiveness upon a minimal promoter and that the p53 response element at +657/+676 is required for this activity. To determine if this 20 bp element is sufficient to mediate p53-dependent transcriptional activation, an oligonucleotide corresponding to this sequence was cloned into the reporter (Figure 2A, HuBax+657/+676). When cotransfected with a wild-type p53 expression vector, this reporter plasmid mediated a significant degree of activation in response to p53 (Figure 2C, HuBax+657/+676). Thus, the 20 bp from +657/+676 is sufficient to confer p53-dependent transcriptional activation upon a minimal promoter. A reporter with no insert as well as a reporter containing an unrelated sequence from the human bak promoter failed to respond to wild-type p53 (Figure 2C, Empty and Bak).

To address the significance of this intronic p53 response element in the larger context of the human bax gene, a reporter plasmid was made in which the bax gene from -571 to +1028 was cloned in frame with luciferase (Figure 2A, HuBax). When transfected into Saos-2 cells, this reporter plasmid mediated a significant degree of transcriptional activity in response to a cotransfected p53 expression vector (Figure 2D, HuBax). There was no substantial difference between the p53 responsiveness of this reporter as compared to a reporter in which the previously characterized p53 response element at -113/-83 is deleted (Figure 2A,
HuBaxΔPr)(Figure 2D, compare 3.5-3.8 fold with HuBax to 2.8-3.3 fold with HuBaxΔPr).

Deletion of the intronic region containing the newly identified p53 response element (Figure 2A, HuBaxΔIn), however, produced a reporter that was unresponsive to wild-type p53 (Figure 2D, HuBaxΔIn), demonstrating that this element is required for p53 to mediate transcriptional activation of the human bax gene.

*Both p53 response elements are functionally conserved in the murine bax gene.*

To determine if there is functional conservation of the promoter response element, synthetic oligonucleotides corresponding to -113/-83 in the human bax gene and to -341/-302 in the murine bax gene were cloned upstream of a minimal promoter and cotransfected into cells with either an expression vector for human or murine wild-type p53 (Figure 3A). Both human and murine p53 effectively activated transcription through the p53 response element from the human bax promoter (Figure 3A, HuBax-113/-83, white and black bars respectively). Human and murine p53 also activated transcription through the murine bax sequence (Figure 3A, MuBax-342/-302, white and black bars respectively). The level of activation observed with the murine element, however, was significantly reduced as compared to that seen with the human sequence (Figure 3A, compare 98-fold and 95-fold with HuBax-113/-83 to 19-fold and 7-fold with MuBax-341/-302). Again, the reporter containing an unrelated sequence from the human bak promoter did not respond to p53 (Figure 3A, Bak).
To confirm that p53 is capable of binding the murine sequence from -341/-302, oligonucleotides corresponding to either this sequence (Figure 3B, upper panel) or the human sequence from -113/-83 (Figure 3B, lower panel) were used as radiolabeled probes in EMSAs. Purified p53 bound both radiolabeled probes (Figure 3B, lane 1), and was effectively competed by increasing amounts of unlabeled human and murine bax oligonucleotides (Figure 3B, lanes 2-4 and 5-7 respectively). An unrelated oligonucleotide, Sens-1, failed to compete for p53 binding with either probe (Figure 3B, lanes 8-10), demonstrating that the binding of p53 to both the human and murine bax promoter elements is specific.

The p53 response element from the human bax promoter has been shown to require sequence from three adjacent half-sites to effectively mediate p53-dependent transcriptional activation (3). To determine if this requirement for three half-sites is conserved in the murine response element, oligonucleotides corresponding to the first and second half-sites and the second and third half-sites were cloned into the pTATA luciferase reporter vector and assayed for their ability to confer p53 responsiveness upon a minimal promoter in cells (Figure 3C). As seen in Figure 4A, the murine sequence from -341/-302, containing all three potential p53 half-sites, was activated in response to p53 (Figure 3C, MuBax-341/-302). Similar to results observed with the p53 response element from the human bax promoter (3), neither the combination of the first and second nor the second and third half-sites was sufficient to mediate activation in response to p53 (Figure 3C, compare 13-fold with MuBax-341/-302 to 1.2-fold and 0.5-fold with MuBax-341/-315 and MuBax-324/-302 respectively). Together these results show that, in
addition to significant sequence conservation (Figure 3), there is functional conservation of the p53 response element in the human and murine bax promoters.

To address the significance of the promoter and intronic p53 response elements in the larger context of the murine bax gene, a reporter plasmid was made in which the bax gene from -898 to +542 was cloned in frame with luciferase (Figure 4A, MuBax). When cotransfected with a p53 expression vector into Saos-2 cells this reporter plasmid was transcriptionally activated (Figure 4A, MuBax). As observed with the human bax gene (Figure 2D), there was no significant difference between the p53-dependent transactivation of this reporter as compared to a reporter in which the p53 response element at -339/-304 is deleted (Figure 4A, compare MuBax to MuBaxΔPr). Deletion of the intronic region containing the newly identified p53 response element, however, produced a reporter construct that was unresponsive to wild-type p53 (Figure 4A, MuBaxΔIn). Also, the isolated intron from the murine bax gene conferred p53-responsiveness on a minimal promoter, while this same reporter with the p53 response element at +183/+202 deleted did not (Figure 4B). Together, these results demonstrate that this intronic element is required for p53 to mediate transcriptional activation of the murine bax gene, as was the case in the human gene.

Discussion

The p53-dependent regulation of Bax expression has been observed in numerous tissues and cell types of the mouse (1,9). Further, Bax has been shown both to be an obligatory downstream
effector for the p53-mediated apoptosis that attenuates choroid plexus tumor growth in the TgT121 mouse model (10), and to function as an effector of p53-dependent apoptosis and a suppressor of oncogenic transformation in mouse embryo fibroblasts (11). Studies showing that the mouse bax promoter is not p53 responsive, however, raised the question of whether bax is a direct transcriptional target of p53 in the mouse (4,5). In humans, Miyashita and Reed identified a p53 response element in the bax promoter (2). Yet, a recent study showed that a reporter containing 1 kb of human promoter sequence failed to respond to p53, further questioning a transcriptional link between p53 and bax (4).

The data presented in this report demonstrate the existence of a novel p53 response element in the first intron of the bax gene that is perfectly conserved between human and mouse (Figure 1). Further, it is shown that this element is both sufficient and necessary for p53 to mediate transcriptional regulation of the bax gene in both species (Figures 2 and 4). In addition, we have demonstrated partial conservation of the p53 response element of the human bax promoter in the murine promoter at -339 to -304 (Figures 1B and 3). These results demonstrate that both the human and murine bax genes can function as direct transcriptional targets of the tumor suppressor protein p53, and that this response appears to be mediated predominantly through a newly identified response element in the first intron. Thus, these results confirm and substantiate the important role of bax as a direct and evolutionarily conserved target of p53-dependent transcriptional activation.
Acknowledgments

We thank Bert Vogelstein (Johns Hopkins University) for the wild-type p53 expression plasmid. Ron Magnusson is thanked for help with the recombinant baculovirus infections. Lois Resnick-Silverman of the Manfredi laboratory is thanked for their help and support. This work was supported by grants from the National Cancer Institute (CA69161) and the Breast Cancer Program of the U.S. Army Medical Research and Materiel Command (DAMD-17-97-1-7336, DAMD-17-97-1-7337, and DAMD-17-99-1-9308).

Figure Legends

Figure 1. Cloning of the human bax gene reveals a potential p53 response element in the first intron. (A) The human bax gene from -571 to +1028 from the start site of transcription was PCR cloned (Accession# AF339054). This region is represented with the black boxes indicating the positions of exons 1 (+373 to +406) and 2 (partial sequence: +991 to +1028). The box labeled p53 RE at -113 to -83 indicates the location of the previously described p53 response element. The sequence of this element and surrounding bases are indicated above. The box labeled p53 RE at +657 to +676 indicates the location of the putative p53 response element located in the first intron. The sequence of this element and surrounding bases are indicated below. The horizontal lines indicate the positions of the p53 quarter sites. The asterisks indicate bases that deviate from the p53 DNA-binding consensus sequence. (B) The murine bax gene from -898 to +542 from the start site of translation was PCR cloned (Accession# AF339055). This region is schematically represented with the black boxes indicating the positions of exons 1 (+1 to +34) and 2 (partial sequence: +505 to +542). The white boxes labeled -339 to -304 and +177 to +219 indicate two regions of conservation between the mouse and human sequences. The nucleotide sequences of these two regions is listed. A solid line between the two sequences indicates perfect conservation at that base. Dashed lines indicate a conservative substitution. The boxes indicate the p53 response element half-sites. The asterisks indicate bases that deviate from the p53 DNA-binding consensus sequence. The arrow indicates a cytosine at position -332 that was not reported in the original cloning of the murine bax promoter. (C) An electrophoretic mobility shift
assay was performed using an oligonucleotide corresponding to the +657/+676 sequence from the human bax promoter as radiolabeled probe. 50 ng of purified p53 was incubated with 3 ng of the probe alone (lane 1) or in the presence of a 500-, 1000-, or 1500-fold molar excess of either the unlabeled HuBax-113/-83 oligonucleotide (lanes 2-4), the HuBax+657/+676 oligonucleotide (lanes 5-7), or the Sens-1 oligonucleotide (lanes 8-10). The arrow indicates the position of the p53-DNA complex.

Figure 2. The first intron of the human bax gene contains a p53 response element that is required for p53-dependent transcriptional activation. (A) Schematic representation of the HuBax, HuBaxΔPr, HuBaxΔIn, Hu+408/+989, Hu+408/+989ΔIn, and HuBax+657/+676 reporter plasmids. Exons are represented by black boxes, and p53 response elements are represented by white boxes. (B) Saos-2 cells were transfected with 1 μg of the indicated pTATA reporter plasmids in the presence of 0, 1, 5, and 10 ng of pCMV-p53wt. (C) Saos-2 cells were transfected with 1 μg of the indicated pTATA reporter plasmids in the presence of either 5 ng of pCMV (-) or 5 ng of pCMV-p53wt (+). (D) Saos-2 cells were transfected with 1 μg of the indicated pGL3 reporter plasmids in the presence of 0, 100, and 200 ng of pCMV-p53wt. Where appropriate, amounts of the vector pCMV were added to each transfection mixture to maintain a constant level of total plasmid DNA (B), (C), and (D). The indicated values are the average of three independent experiments each performed in duplicate. Error bars correspond to one standard deviation. The numbers above each bar indicate the fold activation for each reporter construct.
observed with pCMV-p53wt as compared with pCMV.

Figure 3. The p53 response element from the promoter of the human bax gene is conserved in the mouse. (A) Saos-2 cells were transfected with 1 μg of the indicated pTATA reporter plasmids in the presence of either 50 ng of pCMV (gray bars), 50 ng of pCMV-p53wt (white bars), or 50 ng of p11-4-mup53wt (black bars). The indicated values are the average of three independent experiments each performed in duplicate. The numbers above each bar indicate the fold activation for each reporter construct observed with pCMV-p53wt or p11-4-mup53wt as compared with pCMV. (B) An electrophoretic mobility shift assay was performed using an oligonucleotide corresponding to either the -113/-83 sequence from the human bax promoter (bottom panel) or the -341/-302 sequence from the murine bax gene (top panel) as radiolabeled probe. 50 ng of purified p53 was incubated with 3 ng of the probe alone (lane 1) or in the presence of a 500-, 1000-, or 1500-fold molar excess of either the unlabeled HuBax-113/-83 oligonucleotide (lanes 2-4), the MuBax-341/-302 oligonucleotide (lanes 5-7), or the Sens-1 oligonucleotide (lanes 8-10). The asterisks indicate the positions of the p53-DNA complexes. (C) Saos-2 cells were transfected with 1 μg of the indicated pTATA reporter plasmids in the presence of either 50 ng of pCMV (-) or 50 ng of pCMV-p53wt (+). The indicated values are the average of three independent experiments each performed in duplicate. The numbers above each bar indicate the fold activation for each reporter construct observed with pCMV-p53wt as compared with pCMV. The boxes, labeled 1, 2, and 3, indicate the p53 half-sites that are
partially conserved between mouse and human (see Figure 1B).

Figure 4. The first intron of the murine bax gene contains a p53 response element that is required for p53-dependent transcriptional activation. (A) Saos-2 cells were transfected with 1 μg of the indicated pGL3 reporter plasmids in the presence of either 100 ng of pCMV (black bars) or 100 ng of pCMV-p53wt (white bars). (B) Saos-2 cells were transfected with 1 μg of the indicated pTATA reporter plasmids in the presence of either 10 ng of pCMV (black bars) or 10 ng of pCMV-p53wt (white bars). (A) and (B) The indicated values are the average of three independent experiments each performed in duplicate. Error bars correspond to one standard deviation. Each reporter insert is diagramed with black boxes representing exons and white boxes indicating p53 response elements.
