ABSTRACT

High quality fluoride and oxide single crystals for optical, piezoelectric and other applications have been grown by advanced crystal growth techniques. Corundite- and Perovskite-type fluoride single crystals – LiCaAlF$_6$, LiSrAlF$_6$, K$_2$MgF$_3$ and BaLiF$_3$ – have been grown for solid state UV laser applications, and as window materials for next generation optical lithography. La$_3$Nb$_3$Ga$_5$O$_{14}$ and La$_3$Ta$_3$Ga$_5$O$_{14}$ piezoelectric single crystals of size and quality comparable to La$_3$Ga$_2$SiO$_{14}$ (langasite), have been produced. The piezoelectric and device properties of the crystals were investigated. A search for new langasite-type materials was also performed. Promising new structural materials, Al$_2$O$_3$/RE$_3$Al$_2$O$_{12}$ (RE=rare earth) eutectic fibers, have been grown by the micro-pulling-down (μ-PD) technique. Undoped and doped β-Ga$_2$O$_3$ single crystals have been grown by the floating zone technique as promising transparent conductive oxides.

1. INTRODUCTION

The important role of oxide and fluoride crystals in various branches of science and technology demands a comprehensive and integrated treatment of the subject. We have carried out investigations focusing on the development of new materials for optical, piezoelectric and other applications, using advanced crystal growth techniques. Oxide crystals are of highest importance for modern electrical and electro-optical applications in several devices. Fluoride single crystals, because of their unique properties such as large band gap, also present many advantages as optical materials.

The recent crystal growth research described in this work involved the development of new, high-quality oxide and fluoride single crystals, and of novel crystal growth techniques. The growth of fluoride single crystals doped with Ce for ultra-violet (UV) laser applications is reviewed. Growth of new langasite (La$_3$Ga$_2$SiO$_{14}$) single crystals for piezoelectric applications, by the Czochralski (CZ) technique, is discussed. The micro-pulling-down (μ-PD) method and its application to the growth of structural materials are mentioned. Crystal growth of β-Ga$_2$O$_3$ for transparent conductive oxide (TCO) applications is also addressed.

2. FLUORIDES FOR UV OPTICAL APPLICATIONS

Coherent optical sources in the ultraviolet (UV) wavelength region are useful for many practical applications, such as medical procedures, semiconductor processing and remote sensing. Recently, Ce-doped LiCaAlF$_6$ (Ce:LiCAF) and LiSrAlF$_6$ (Ce:LiSAF) single crystals have been reported as leading candidates for tunable all-solid-state-lasers in the UV wavelength region. However, due to the limited size of the available crystals, it was difficult to obtain high energy output directly from a Ce:LiCAF laser. Furthermore, the growth of Ce:LiCAF itself was known to be difficult. Therefore, the growth of Ce:LiCAF single crystals was studied.

Crystal growth was performed in a CZ system with a resistive heater made of high-purity graphite. The starting material was prepared from commercially available $\text{AlF}_3$, $\text{CaF}_2$, $\text{SrF}_2$, and $\text{LiF}$ powders of high purity (>99.99%). The composition was 1 mol.% $\text{LiF}$ and $\text{AlF}_3$ enriched from a stoichiometric one, in order to compensate for the vaporization of $\text{LiF}$ and $\text{AlF}_3$. As dopants, $\text{CeF}_3$ and $\text{NaF}$ powders of high purity (>99.99%, Rare Metallic Co., Ltd.) were used. $\text{Na}^+$ was co-doped with $\text{Ce}^{3+}$ in order to maintain the charge neutrality. The concentration of $\text{Ce}^{3+}$ and $\text{Na}^+$ in the starting material was 1 mol.%. The pulling rate was 1 mm/h and the rotation rate was 10 rpm. Crystal growth was performed under high purity $\text{CF}_4$ gas (99.9999%).

Fig. 1 shows as-grown Ce:LiCAF and Ce:LiSAF single crystals with dimensions of 18 mm in diameter and 60 mm in length. Cracks, bubbles and inclusions were not observed. Under the modified growth conditions, foreign substances on the surface of the grown crystal, as observed in ref.5, were not formed. However, Ce:LiSAF showed a tendency to crack perpendicular to the growth axis after several days. On the contrary, Ce:LiCAF did not show cracks at any time. Therefore, LiCAF was chosen for the growth of large diameter crystals. The effective distribution coefficient ($k_{\text{eff}}$) of $\text{Ce}^{3+}$ in LiCAF and LiSAF has been determined to be 0.021 and 0.013, respectively. The $k_{\text{eff}}$ of $\text{Ce}^{3+}$ in LiCAF was larger than in LiSAF. This is because the ionic radius of $\text{Ce}^{3+}$ under 6-fold coordination (1.01 Å) is closer to that of $\text{Ca}^{2+}$ (1.00 Å) than to that of $\text{Sr}^{2+}$ (1.18 Å), the ions thought to be replaced by $\text{Ce}^{3+}$.

Fig. 2 shows an as-grown Ce:LiCAF single crystal of 2-inch diameter, free from cracks and inclusions. When crystals of this diameter were grown, the following two problems, not observed for crystals of 18 mm diameter, appeared: formation of inclusions, and cracks accompanied by the formation of an impurity phase at the bottom of the crystal.

Fig. 3 shows a crystal which contains inclusions. It should be noticed that the formation of these inclusions was related to a change of the crystal diameter, for example at the shoulder part of the crystal. Once they appeared at the shoulder part, they did not disappear during crystal growth. In order to avoid these inclusions, the diameter at the shoulder part had to be controlled precisely and extended smoothly, without rapid change of the diameter. Although the absorption spectrum for the inclusion free region did not show any absorption peaks, that of the region with inclusions had one small absorption peak around 3600 cm$^{-1}$. Since this peak indicates the existence of $\text{OH}^-$, it is thought that $\text{H}_2\text{O}$ based impurities were present in the inclusions.

Fig. 4 shows an as-grown crystal with one large crack along the growth axis and a white substance at the bottom of the crystal. This large, flat crack appeared during cooling after growth, in cases when white material was present. This white substance usually formed when the solidification fraction exceeded 70%. The XRD analysis showed that the white substance was composed of LiCAF and $\text{CaF}_2$ phases. This is because the melt composition shifted in the $\text{CaF}_2$-enriched direction during growth, since the vaporization pressure of $\text{LiF}$ and $\text{AlF}_3$ is very high$^7$. $\text{CeF}_3$ and $\text{NaF}$ might have accumulated in the residual melt due to the small $k_{\text{eff}}$. In order to avoid formation of this white substance, crystal growth was terminated at the solidification fraction 60%, as for the crystal shown in Fig. 2. For further improvement, optimization of melt composition should be carried out.

Fig. 5 shows a Ce:LiCAF:$\text{NaF}$ laser setup.
We have already demonstrated an output energy of 30 mJ from a UV solid-state Ce:LiCAF laser that operated at 290 nm at a repetition rate of 10 Hz. In order to obtain higher output energy, we increased the pumping energy. Fig. 5 shows a setup for laser experiments. We obtained 60 mJ at 10 Hz, to our knowledge the highest performance so far reported for Ce:LiCAF.

Fig. 6 shows the transmission edge of the LiCAF and LiSAF single crystals grown under Ar and CF₄ atmosphere. The transmission edge of LiCAF was measured to be at 112 nm and that of LiSAF 116 nm, the shortest reported to our knowledge. The absorption of around 125 nm observed from the crystals grown under Ar atmosphere, disappeared when crystals were grown under CF₄ atmosphere. These transmission characteristics show high potential as optical window materials in the UV and VUV wavelength region.

Recently, there has been significant interest in using 157-nm laser sources in projection lithography as successors to 193-nm based systems. One of the most serious problems in realizing a 157-nm based system is the development of suitable optical materials for lenses and other optical components. In particular, for an all-refractive design of 157-nm laser source, a second material other than CaF₂ is strongly required, because CaF₂ is the most promising material to be used. Primary candidates for a second material were LiF and MgF₂; however, they have several disadvantages such as a fragile and hydroscopic nature and large birefringence.

We have identified KMgF₃ (KMF) as a new promising optical material for 157-nm based systems. The reasons to focus on KMF are as follows: (1) It belongs to the cubic crystal system, so theoretically it has no birefringence. (2) As it is composed of K and Mg cations, which have smaller atomic weight than Ca, it can be expected to have a shorter transmission edge than CaF₂. (3) As it melts congruently at a melting temperature of 1070 °C, it can more likely be grown to a large size. BaLiF₃ (BLF) can also be a promising candidate, since it belongs to the cubic crystal system and it can transmit 157-nm.

Crystal growth was performed in the same CZ system as for LiCAF and LiSAF. The starting material was prepared from commercially available high purity powders (>99.99%). The pulling rate was 0.5 to 1.5 mm/h and the rotation rate was 15 rpm.

Fig. 7 shows an as-grown KMF and BLF single crystals 20 mm in diameter and 90 mm in length, pulled at a rate of 1 mm/h. No cracks, bubbles or inclusions were observed. The thermal expansion coefficients of KMF and BLF along <111> was estimated to be 1.98 x 10⁻⁵ K⁻¹, 3.06 x 10⁻⁵ K⁻¹, respectively, over the range 100 - 500 °C. The variations of birefringence among KMF-wafer, BLF-wafer and LiCAF-wafer were of order 10⁻⁷, 10⁻⁵, and 10⁻⁷, respectively. Furthermore, the transmission edge of KMF and BLF single crystals was determined to be 115 nm and 120 nm. Fig. 6 shows the transmission spectrum of KMF and BLF single crystals in VUV wavelength region, compared with LiCAF and LiSAF. These transmission characteristic shows high potential as optical material in the UV and VUV wavelength region.
3. NEW LANGASITE SINGLE CRYSTALS FOR PIEZOELECTRIC APPLICATIONS

The recent progress of electronic technology requires new piezoelectric crystals having properties intermediate between those of quartz and LiTaO$_3$ (LT). Currently, Langasite (La$_3$Ga$_5$Si$_2$O$_{14}$; LGS) crystals have received attention as new candidates for piezoelectric applications$^{13,14}$. The LGS crystal has the Ca$_3$Ga$_2$Ge$_4$O$_{14}$-type structure with the space group P321. There are four kinds of cation sites in this structure, which can be described by the chemical formula, $A_3B_2C_3D_2O_14$. In this formula, $A$ and $B$ represent the decahedral (twisted Thomson cube) site coordinated by 8 oxygens, and the octahedral site coordinated by 6 oxygens, respectively. $C$ and $D$ represent tetrahedral sites coordinated by 4 oxygens. Different isovalent and aliovalent substitutions in a given structure are quite interesting in themselves, and could, perhaps, also result in useful structural and physical properties.

High-quality single crystals of LGS, and its aliovalent analogs La$_3$Nb$_{0.5}$Ga$_{5}$O$_{14}$ (LNG) and La$_3$Ta$_{0.5}$Ga$_{5}$O$_{14}$ (LTG), were grown by the conventional CZ technique$^5$. Fig.8 shows the as-grown LTG single crystals of approximately 2 and 3 inches diameter. Pulling and rotation rates were 1 mm/h and 10 rpm, respectively.

Lattice parameters of the grown crystals were found to be almost constant from shoulder to tail of the boules. Concentrations of each oxide, i.e. La$_2$O$_3$, Ga$_2$O$_3$, SiO$_2$, Nb$_2$O$_5$ and Ta$_2$O$_5$, were almost constant, within the estimated errors, throughout the crystallizing process. The uniformity of lattice parameter and chemical composition suggests that the stoichiometric composition is close to the congruently melting composition of the three compounds.

Synthesis of more than 70 chemical compositions were attempted. The incorporation of different $A$ cations (Na$,^+$, Ba$^{2+}$, Sr$^{2+}$, Bi$^{3+}$, Nd$^{3+}$, etc) and $B$ cations (Li$^+$, Mg$^{2+}$, Ga$^{3+}$, Ti$^{4+}$, Sb$^{5+}$, Mo$^{6+}$, etc) into the $A$ and $B$ sites was studied, respectively. Materials which showed a langasite-type single phase were crystallized in fiber form by the µ-PD method, and subsequently their bulk crystals were also grown by the Cz technique. Bulk single crystals of Sr$_3$Ga$_5$Ge$_4$O$_{14}$, Na$_2$CaGe$_3$O$_{14}$, Pr$_3$Ga$_5$Si$_2$O$_{14}$ and La$_3$Al$_{2}$Ga$_{5}$Si$_2$O$_{14}$ were successfully produced by Cz technique. In Fig.9, La$_{3-x}$Sr$_x$Ta$_{0.5}$Si$_2$O$_{14}$, $x=0.1554$ (LSTG) and Sr$_3$TaGa$_5$Si$_2$O$_{14}$ (STGS) single crystals are shown as examples.

Using LGS single crystals, we made monolithic-type filters (10.4 and 21.4 MHz) as seen in Fig.10. The electrical properties of these filters include low input and output impedance, small size and low attenuation, compared with those made of quartz (see Table I).

A 71MHz-wide passband SMD (Surface Mount Discrete-type) filter for the GSM (Global System for Mobile Communication) base station was also made, which exhibited superior properties. The main features of the electrical characteristics are listed below:

1) Low input and output impedance (940kΩ/0.5pF, versus several kΩ for quartz filter);

(2) Interstage coupling requires only capacitors (For quartz filter, transfer is required);
(3) Electrode gap may be wide (approximately 100mm, vs. several mm for quartz filter).

| Table II Characteristics of LNG, LTG and LGS compared with those of LT and quartz. |
|--------------------------------------------|------------|------------|------------|------------|----------------|
| phase transition | LiTaO₃ | LGS | LNG | LTG | quartz |
| melting point (°C) | 1650 | 1490 | 1470 | 1500 | - |
| Mohs hardness | 5.5 | 6~7 | 6~7 | 6~7 | 7 |
| electromechanical coupling factor k (%) | 43 | 15~25 | ~30 | ~30 | 7 |
| Q-factor | 5000 | 30,000~ | 40,000~ | 40,000~ | 60,000~ |
| equivalent series resistance (Ω) | - | 5~10 | 2~5 | 2~5 | 10~20 |
| thermal stability (ppm) | 200~400 | ~150 | ~150 | ~150 | 10~20 |

In Table II, the characteristics of LNG, LTG and LGS are given, along with those of LT and quartz. Since LNG, LTG and LGS have no phase transitions and have lower melting point and higher hardness, the possibility of growing high-quality crystals allowing easy processing is expected to be likely. Their electromechanical coupling factors k and thermal frequency stability are between those of LT and quartz. The above characteristics indicate that LGS-family crystals are more promising materials for piezoelectric devices than lithium tetraborate (Li₂B₄O₇) and berlinite single crystals, which have similar piezoelectric properties.

Li₂B₄O₇ is easily soluble in all acids and bases, and easily deliquescent in air, while berlinite single crystals are difficult to grow to a large size.

Fig.11 shows the dependence of the electro-mechanical coupling factor, k₁₂, on the lattice parameter a in the langasite-type crystals. As can be seen from the figure, an increase in lattice parameter a leads to an increase of the electro-mechanical coupling factor, k₁₂. The electro-mechanical coupling factor of LTG is the largest of the langasite-type crystals studied. Therefore, we conclude that substitution of the B site is effective for improvement of the piezoelectric properties. This tendency serves as a guide for development of improved compounds of langasite-type structure.

4. FIBER CRYSTALS

Directionally solidified ceramic eutectics are drawing a strong interest because of their high structural stability up to the melting temperature. Recently, promising results were reported for Al₂O₃/Y₃Al₅O₁₂ (YAG) and Al₂O₃/GdAlO₃ systems. However, because of processing difficulties, the experimental data for oxide eutectics are still limited and often uncertain.

We have applied the μ-PD method for the growth of Al₂O₃/YAG
eutectic fibers. The μ-PD method involves downward pulling of a crystalline fiber 0.1-2.0 mm in diameter through a capillary hole arranged in a crucible bottom. The μ-PD features two points important for eutectic growth: (1) a very high axial temperature gradient exists near the growth interface of the order of 3-5×10³ °C/cm²⁰. It permits high pulling rates and assures a planar interface and process stability. Secondly, (ii) composition is always uniform along the fiber length, since melt convection is impossible inside the narrow capillary channel.

A high-temperature version of μ-PD employed an iridium crucible directly coupled to the RF power generator. A sapphire <0001> seed was used for growth of the eutectic fibers. The starting materials were 4N purity Al₂O₃ and Y₂O₃ in the molar ratio of 81.3 mol % Al₂O₃ to 18.7 mol % Y₂O₃³¹. Eutectic fibers 0.25-1.00 mm in diameter and up to 500 mm in length were grown over a range of pulling rate 0.15 - 10.00 mm/min (see Fig.12). Samples of eutectic fibers grown under various pulling rates were examined using scanning electron microscopy (SEM). Several fibers were grown at a step-variable pulling rate starting from 0.15 and up to 10 mm/min. In all these experiments, the 'Chinese script' type structure was found to possess excellent reproducibility, whereas the cellular structure was not found at all. (The microstructure of eutectic sometimes forms the structure, which is resembles to Chinese character. Such microstructure is called 'Chinese-script type' microstructure.) The volume fraction of YAG was 0.45±0.02 for all types of structure including inter-cell areas, which corresponds exactly to the theoretical value for the eutectic composition (0.44). The characteristic script size was found to be very uniform for each cross-section studied. Experimentally, the generally accepted relation \( \lambda \sim v_p^{-1/2} \), where \( \lambda \) is interlamellar spacing of a conventional lamellar structure and \( v_p \) is the solidification rate, also applies to the script structure of the Al₂O₃/YAG system. The constant of proportionality was found to be 10, if \( \lambda \) has dimensions of mm and \( v_p \) mm per second. This value is large enough to allow effective microstructure control by changing solidification rate.

The composite has been shown to have high mechanical strength up to 1800 °C, excellent oxidation resistance, high thermal stability of microstructure and thermal shock stability (Fig.13). Al₂O₃/Tm₃Al₅O₁₂ showed a tensile strength of 620 MPa at 1500 °C in vacuum. This is the highest strength at this temperature to date.

5. B-Ga₂O₃ AS TRANSPARENT CONDUCTIVE OXIDE

B-Ga₂O₃ is transparent with a band gap of 4.8 eV, and belongs to the space group C2/m. It is intrinsically an insulator, but its n-type semiconduction when grown under reducing conditions is well known²². An undesired side effect is the resulting blue coloration, and thus degradation of the transmission, a fundamental property for window applications such as displays, solar cells, etc. Improvement of electrical conductivity through the addition of dopants while preserving the transparency of the pure B-Ga₂O₃ makes of this material a substitutive candidate for transparent conductive oxides (TCOs). Moreover, its shorter absorption edge will allow to extend the application fields of TCOs.

Powders of Ga₂O₃, WO₃ and HfO₂ of nominal 4N purity were mixed, sintered and grown to single crystals using the floating zone (FZ) technique with a double ellipsoid image furnace (ASGAL Co.:SS-10W). The growth was done under previously optimized conditions: growth rate of 5 mm/h, simultaneous rotation of feed and seed rods at 20 rpm in opposite directions, 500 ml/min. gas flow of different N₂/O₂ mixtures. The grown crystals had typical length of 3-4 cm, and diameter varying between 0.5 and 1 cm. For transmission and electrical measurements, crystals were cleaved in the (001) plane to obtain thin platelet-like samples, which exhibited flat, reflective surfaces.

The optical and electrical properties of the as-grown crystals depended on the concentration of the dopants and on the
oxygen partial pressure. Crystal growth from nominally undoped feed rods under 1 atmosphere pressure was impossible due to the appearance and explosion of bubbles, which destabilized the molten zone. The formation of bubbles could be suppressed by the increase of pressure to 2 atmospheres (Fig.14), or by the incorporation of W or Hf as dopants. Fig.15 and Fig.16 show the crystals grown under pure O₂ and 1 atmosphere pressure, with a nominal composition of the feed rod of 6 mol.% WO₃ and 0.2 mol.% HfO₂, respectively. These crystals were visually homogeneous, transparent, colorless and without cracks or inclusions. Improved transmittance and conductivity could be also achieved, indicating the beneficial effects of the substitution of Ga³⁺ by W⁴⁺ of Hf⁴⁺ and the potential optimization of Ga₂O₃ properties for TCO applications.

6. CONCLUSIONS
Various new fluoride and oxide crystals were developed. Ce:LiCAF and Ce:LiSAF single crystals of 18 mm diameter were grown by the CZ technique under CF₄ atmosphere. Under the same growth conditions, Ce:LiCAF single crystals of 50 mm diameter (2 inch) were also grown up to a solidification fraction of 60 %. Laser output energy of 60 mJ was obtained. This demonstrates that Ce:LiCAF is a promising material for high-energy UV pulse generation. KMF and BLF single crystals of 20 mm diameter were also grown. LiCAF, LiSAF, KMF and BLF single crystals showed a transmission edge at 112 nm, 119 nm, 115 nm and 120 nm, respectively. These characteristics indicate the high potential of these crystals as optical materials. A series of new promising langasite-type materials were found. LGS, LNG and LTG single crystals with maximum size of 3 inches in diameter were successfully grown by the Czochralski technique. Prototype models of wide passband filters were prepared using these crystals. LGS, LNG and LTG single crystals showed to have superior piezoelectric properties compared to other compounds with properties intermediate between those of quartz and LT. By applying the high-temperature μ-PD technique, directionally-solidified eutectic Al₂O₃/REAG fibers were grown. Al₂O₃/Tm₃Al₂O₇ showed a tensile strength of 620 MPa at 1500 °C in vacuum. Undoped and doped β-Ga₂O₃ single crystals were grown by the FZ technique. The substitution of Ga³⁺ by W⁴⁺ or Hf⁴⁺ improved transmittance and conductivity, indicating the potential optimization of β-Ga₂O₃ properties for TCO applications.

ACKNOWLEDGMENT
