SUMMARY

Purpose

To analyze and evaluate a sample of Soviet produced thiokol fuel tank sealant.

Factual Data

The sample was received as an inclosure with report number ATIC 61102. The information included in that report was as follows:

1. A specimen of the sealing material used in the fuselage integral fuel tank of the Soviet Type 150 experimental aircraft built by former Junkers personnel was obtained and was forwarded for evaluation.
2. Information from other reports on the Type 150 aircraft indicate that it is a two jet engine swept-wing bomber. A large honeycomb type tank is located above the bomb bay (see Figure 1 appendix I). The interior of the tank is constructed with vertical aluminum tubes (see Figure 2 appendix I). Some difficulty was reported in sealing this tank.

The sample as received was stuck between layers of cloth and separation from the cloth was not deemed advisable. It was suggested that a similar size sample of U. S. Thiokol be stuck between layers of similar cloth and comparison tests for low temperature flex be run on both samples.

Discussion

The sample of Soviet produced rubber designated as "thiokol" was a graygreen material. Its soft and gummy texture indicated that it was uncured. The sample as received was stuck between layers of cloth.

In order to derive as much information as possible from this very small sample, the following test procedure was used:

1. Determine the type of polymer and composition by chemical and infra-red spectrographic analysis.
2. Determine the swell characteristics of the elastomer in 100 octane gasoline.
3. Compare qualitatively the low temperature flexibility of the Soviet elastomer with a typical U. S. thiokol.

These tests showed that the polymer had an ether linkage similar to U. S. thiokol B or thiokol D and that an ester type of plasticizer was used. The sample showed a swell of 5.6 per cent after seven days in 100 octane gasoline. Further, the sample was stiff at -40°F and brittle at -65°F . The samples of U. S. thiokol showed approximately the same percent of swell in 100 octane gasoline for seven days. The U. S. samples were flexible at -40°F and -65°F .

Conclusions

The Soviet thiokol had inferior low temperature flexibility when compared with

SECRET

SECTION I

The low temperature flexibility of the Soviet thioelastomer was compared with that of three U. S. -produced thioelastomeric products: Thiokol LF-2 (Thiokol Corporation) and sealants EC-501 and EC-712 (Minnesota Mining and Manufacturing Company). LF-2 is the raw Thiokol polymer used in making the sealants. The results (see Table I) showed that the Soviet material was very stiff at -40°F and brittle at -65°F . The three U. S. products were flexible at both temperatures.

The Soviet material was found to have good resistance to swell. The results in Table I indicate a value of 5.6 per cent when the material was aged in 100 octane gasoline for a period of seven days at 75°F . This value compares satisfactorily with that reported for U. S. -produced thiokols.

Infra-red analysis made from the acetone extract showed that the Soviet thioelastomer had an ether linkage similar to that of Thiokol D ($-\text{CH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{SS}-$) which is made from thiokol B by treatment with sodium hydroxide.* It is possible that the Soviet material is a mixture of these two thiokols. In addition to an ether linkage, there is evidence of carbonyl absorption (possibly an ester). There is no evidence of hydroxyl, nitrile, or carbon-to-chlorine linkages.

Thioelastomers are prepared by condensation of alkali polysulfides such as sodium polysulfide and various dihalides typified by (1) ethylene dichloride, (2) dichlorodiethyl ethers, and (3) dichlorodiethyl formal. The infra-red data indicate that the Soviet product was probably prepared by condensation of sodium polysulfide or sodium sulfide and dichlorodiethyl ether.

The evidence of carbonyl, possibly an ester grouping, indicates that a plasticizer was probably used in the thio-rubber; however, the size of the sample did not permit positive identification of this material.

Chemical Analysis. Microtechniques were used to determine the total sulfur, carbon, hydrogen, nitrogen, and chlorine percentages in the Soviet thiokol (see Table I). The sulfur determination was also checked using macroanalysis. The oxygen content was obtained by calculation. Since the chemical analysis was determined on the sample as received, it was necessary to correct the values for the filler content. Table II gives the percentages of the various elements present, based on the total sample, i.e., elastomer plus filler; also, Table II shows the values corrected to the basis of the elastomer without filler. Table III shows some U. S. thiokol rubbers and the calculated percentages of the constituent elements. From Tables II and III, it can be seen, on the basis of chemical analysis, that the Soviet sample corresponds closest to the $-\text{C}_2\text{H}_4\text{OC}_2\text{H}_4\text{OC}_2\text{H}_4\text{SS}-$ polymer unit.

TABLE I. SUMMARY OF CHEMICAL ANALYSIS AND PHYSICAL PROPERTIES OF SOVIET-PRODUCED THIOELASTOMER

COMPOSITION⁽¹⁾

Rubber content, per cent	59.8
Sulfur, per cent	34.2
Carbon, per cent	19.9
Oxygen, per cent ⁽²⁾	15.7
Hydrogen, per cent	3.7
Nitrogen, per cent	0.2
Chlorine, per cent	0.1
Ash content, per cent	31.2
Acetone extract, per cent	7.0

PHYSICAL PROPERTIES

Low-temperature flexibility at:	
-40°F	Very stiff
-65°F	Brittle
Swell in 100 octane gasoline after aging 7 days at 75°F per cent	5.6

-
-
- (1) Percentages reported were calculated on the basis of the total sample, as received.
- (2) Per cent oxygen was calculated by subtracting the sum of the percentages of constituent elements from 100 per cent.

SECRET

TABLE II. COMPOSITION DATA FOR SOVIET THIOKOL

Constituent	Amount present ⁽¹⁾ in sample as received, per cent	Amount present ⁽²⁾ in elastomer only, per cent
Carbon	19.9	28.9
Hydrogen	3.7	5.4
Sulfur	34.2	49.7
Oxygen	—	15.7 ⁽³⁾
Nitrogen	0.2	0.3

(1) Elastomer plus filler.

(2) Values calculated by dividing per cent of constituent present (on basis of total sample as received) by the per cent of ash-free material.

(3) Per cent oxygen reported represents the difference found by subtracting the sum of the percentages of constituent elements from 100 per cent.

TABLE IV. SPECTROGRAPHIC ANALYSIS OF ASH SAMPLE
FROM SOVIET-PRODUCED THIOKOL

Ingredients ⁽¹⁾	Amount Present in Ash, ⁽²⁾ Per Cent	
Silicon	40	-60
Magnesium	20	-40
Iron	5	-25
Aluminum	0.5	- 5.0
Calcium	0.3	- 3.0
Zinc	0.2	- 2.0
Nickel	0.05	- 0.5
Manganese	0.05	- 0.5
Chromium	0.05	- 0.5
Lead	0.02	- 0.2
Copper	0.02	- 0.2
Barium	0.005	- 0.05
Strontium	0.005	- 0.05
Titanium	0.002	- 0.02
Molybdenum	0.001	- 0.01
Tin	0.001	- 0.01
Antimony	0.001	- 0.01

(1) Ingredients were determined as oxides by spectrographic analysis, but are not necessarily added to or present, as such, in the rubber.

(2) The figures reported throughout the table are ingredient percentage ranges on the basis of the ash.

T53-813

⁵
SECRET

SECRET

However, infra-red analysis shows that there were some ester groups present. The presence of these groups would reduce the sulfur value and increase the oxygen; the other groupings would change correspondingly. The presence of ester groups would tend to bring the structure closer to that indicated by infra-red analysis, i.e., $-\text{CH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{SS}-$.

SS

Analysis of Filler Material. A sample of the Soviet sealant material was ashed and found to contain 31.2 percent ash. Table IV summarizes the spectrographic analysis obtained on a very small ashed sample of the Soviet thioelastomer. The principal fillers, reported as oxides, were found to be silicon and magnesium, plus iron which may have been present as an impurity in the filler. These results indicate that magnesium silicate or a clay material probably was used as the primary filler.
