FOREWORD

In 1961 the Air Force Office of Scientific Research brought out volume one of the Air Force Scientific Research Bibliography, containing abstracts of publications resulting from its support of fundamental research in the sciences from 1950 through 1956 in the Nation's colleges, universities, and research organizations.

For the first time, a Federal agency sponsoring fundamental research undertook to provide comprehensive access to the work it had funded. The value of that effort may be measured first by the demand for the book itself, and secondly by the favorable response from those who create the scientific literature, those who use it, and those whose work it is to ensure its availability.

AFOSR research supported from 1957 through 1958 is covered in this volume, prepared by the Special Bibliographies Section of the Science and Technology Division, Library of Congress.

The sponsorship of high quality research of itself does not ensure the creative transformation of new science into technology on a timely basis. There must also be effective communication among fundamental researchers, and between them and the scientists and engineers with responsibility for the solution of technological problems.

These volumes are part of AFOSR's effort to facilitate that communication. Their publication is the result of the firmly held conviction that a granting organization's responsibility for basic science continues beyond publication by the researcher in the literature.

William J. Price

William J. Price
Executive Director

PREFACE

Prolegomenon

Time's arrow, entropy, is a measure of disorder, of the tendency for hot drinks to cool, of toys to become distributed in an ankle-deep layer of plastic potsherds, of papers to disappear without a trace. The Creation of the universe from chaos (or ylem) was a magnificent act of negative entropy; things have been getting worse, entropy-wise, ever since.

Whenever an experiment is performed in the laboratory, it is paid for by, inter alia, an increase in entropy. Reagents are dissolved, reacted, and thrown down the sink; electrical energy turns to heat. The price paid in increase in entropy is always, inevitably, greater than the amount of information gained. A measure of the experimenter's efficiency is the ratio between the entropy spent to buy information and the negative entropy of the information so bought.

A similar test of efficiency might be applied to organizations sponsoring research. Funds are received, in a state of minimum entropy. They are dispersed, with an increase in entropy, to various institutions and thence to scientists who in turn, with a further increase of entropy, spend them to buy information. This is dispersed through the myriad channels of scholarly publications, to a state of maximum entropy. The needs of science or scientists may well have been served by this process; the full needs of the sponsoring organization are not.

There is, for example, the role of the organization as a negative entropy device itself. It lives in a warm soupy broth of unsolicited proposals (with a few propositions thrown in for good measure). From these it selects those few, within the limits of an always inadequate budget, which it deems most relevant to the purposes for which it was established--the general welfare, the cure of cancer, or in the case of the Air Force Office of Scientific Research, the future needs of the United States Air Force. The sponsoring organization, then, acts as a meta-corporate author towards papers of more probable relevance in a given field of research.

There is the simple cybernetic desirability of providing a feedback loop.

There is the practical problem of having something to show for funds expended; something more than a simple numerical tally or even a listing of titles of papers produced.

Negentropy costs money; in the case of this bibliography, a cent for every four dollars spent in supporting the research. The average AFOSR publication, based on some \$159 million spent in the support of research, costs somewhere between \$18 and \$19 thousand to produce (dividing the cost of the research by the number of publications ensuing). We think that the money spent to produce this bibliography was a sound investment.

Scope

This is the second volume of a continuing bibliographic series. The first volume, issued in 1961, covered the period 1950 through 1956.

This volume of the bibliography includes, within the limitations of the law of diminishing returns, abstracts of all technical notes, technical reports, journal articles, books, symposium proceedings, and monographs produced and published by scientists supported in whole or in part by the Air Force Office of Scientific Research during calendar years 1957 and 1958.

The Air Force Office of Scientific Research supports fundamental research in the five major scientific disciplines: physics, chemistry, engineering sciences (subsuming mechanics and propulsion), life sciences (both biological and behavioral, but not medical), and mathematics (including, during the period of this bibliography, the information sciences). Thus, these abstracts are multi-disciplinary, their common link being their support by AFOSR.

Sources Searched

References, reports, and clues to the existence of reports were found by searching the indexes and report collection of the Air Force Office of Scientific Research Technical Library,

and the collection of the Defense Document Center (formerly ASTIA). Detailed searches were made of each contract file in the several AFOSR Directorates and Divisions.

In addition, cover-to-cover searches were made of over 200 scientific journals, issued mostly in the time period 1957-1962.

Form of Entry and Arrangement

Inherent in the organization of this book is the concept of the reports within a contract as an unanalyzed monographic series. Reports are posted chronologically and/or alphabetically under contracts, these in turn under laboratories, and these under contractors. This does, in fact, provide a rough subject grouping, with the detailed subject index leading into clusters of like reports.

The abstracts are coded for possible future machine searching. A three letter mnemonic code designates the contractor; two digits are reserved for the contract; and three for the report within the contract. While the same codes have been retained in Volume II for those contractors and contracts which appeared in Volume I, the addition of new codes, and of interpolated code numbers, because of new contracts, has made it impossible to maintain the codes strictly in the same alphabetical and chronological order as that of the entries, that is, by contractor and contract number. Hence, the running page headings used in the present volume can serve only as approximate guides to the areas of interest. The searcher is urged to make use of both the Subject Index and the Code Number Index as aids in finding material on a given subject.

The form of entry is, in general, that being used for DDC catalog cards, i. e. : source of the document; title; personal author, if any; date; pagination; report number; contract number; and accession number.

Availability of Reports

The principal accession or control numbers, which indicate the locations of reports in collections are:

- AD **ASTIA Document, or Accessioned Document:** available at DDC (Defense Documentation Center), Cameron Station, Alexandria, Virginia 22314
- TIP **Technical Information Pilot:** available at above address.
- ATI **Air Technical Index:** available at above address.
- PB **Publication Board:** for sale by the Office of Technical Services, Department of Commerce, Washington, D. C. 20235

The fact that a report is abstracted in this book means that a copy of this report existed at the time the abstract was written; it should not be construed to imply that AFOSR necessarily has a copy available for distribution. Those seeking reports should go to the cited agencies, not from AFOSR.

Indices

A detailed subject index, arranged alphabetically, and a special subject classification for mathematics, have been provided. In addition, there are a contract index, an OSR control number index, a personal author index, and the "Code Number Index" already mentioned. The latter is arranged alphabetically by code number, and indicates the page or pages on which the material from the corresponding source (contract) is to be found. Finally, the "Code Guide," relating the three-letter codes to the respective contractors, has been placed at the beginning of the text.

Acknowledgements

Many people have made this book possible. The work has been fostered and encouraged by the previous Commanders and Executive Director of the Air Force Office of Scientific Research:

Brigadier Generals H. F. Gregory and B. G. Holzman, Colonels A. P. Gagge and Jack L. Deets, Dr. Knox Millsaps and the present Executive Director, Dr. William Price. The book would have been impossible to produce without the accurate records maintained to the highest standards of bibliographic accuracy by Eleanor Capps, doyenne of documentation in AFOSR. Perhaps, most important of all, has been the cheerful and willing cooperation of the scientific staff of AFOSR in assisting the bibliographers in locating reports and helping with subject analysis.

The bibliographic team has worked under the leadership of G. Vernon Hooker, with general guidance by Dr. Clement R. Brown, Head of the Special Bibliographies Section, Science and Technology Division, Library of Congress. In addition to Mr. Hooker, the chief workers on this volume have been Aaron S. Dann, Doris C. Yates, and Marion S. Carr. Much preliminary work on this and future volumes was done by Mabel H. Duffner, a former member of the group. Other present and former employees of the Section who gave valuable assistance in the work of abstracting, subject indexing, and cataloging of entries included Thomas C. Goodwin, Bruce Blankenhorn, Jack R. Gibson, Louis Aronica, Frank Lupis and Sandra McInnis. Recognition is also due those who participated in the work of preparing the manuscript for publication, especially Mrs. Carr, Patricia Gravatt, Phyllis Martin and Evelyn Briscoe. Duane D. Starbuck of the Library of Congress drew most of the chapter end-plates.

This bibliographic task has been supported and monitored by the Information Sciences Directorate, AFOSR, as part of a continuing research program to study and devise new and better ways of handling scientific and technical information.

GENERATION OF SUPERSONIC DISSOCIATED AND IONIZED NON-EQUILIBRIUM STREAMS, by D. E. Rosner and H. F. Calcote. Oct. 1958, 33p. incl. illus. diagrs. table, refs. (Rept. no. TM-10) (AFOSR-TN-58-1080) (AF 49(638)300) AD 207590 Unclassified

A small-scale research tool was developed which produces a steady state, supersonic, highly non-equilibrium stream of atoms and ions, with a dc or ac glow discharge as an energy source. Fully expanded streams of air, nitrogen, argon, and helium, at Mach numbers from 2 to 4 were studied. Translational static temperatures in the test section are estimated to be not far from ambient. Preliminary measurements indicated that roughly 50% of the energy input is utilized in dissociating and ionizing the gas while the total efficiency of the device is about 80%. Estimates of the resulting degrees of dissociation and ionization were made on the basis of power balance, pressure, and electrical probe measurements. Non-catalytic surface coatings appeared to exert a strong effect on the convective heat transfer rate. The estimated magnetic field strength necessary to produce easily measurable magnetogasdynamic effects on aerodynamic heat transfer rates is about 10^4 gauss. This field strength is also computed as required for high temperature plasma jets discharging at 1 atm. Since probe observations indicated that the stream carries a net charge, still stronger magnetohydrodynamic interactions are anticipated. (Contractor's abstract)

STEADY-STATE SURFACE TEMPERATURES IN DISSOCIATED HIGH-SPEED GAS FLOWS, by D. E. Rosner. Nov. 1958, 5p. incl. refs. (Rept. no. TP-9) (AFOSR-TN-58-1082) (AF 49(638)300) AD 222523 Unclassified

Also published in Jour. Aero/Space Sciences, v. 26: 384-385, June 1959.

This paper treats the problem of insulated wall temperature assumed by a surface in a partially dissociated supersonic gas stream. Specifically, a simplified theory is developed containing a "catalytic parameter" which, in addition to usual terms, contains a ratio of characteristic diffusion time to characteristic reaction time at the surface. Limiting examples are illustrated with this parameter. (Appl. Mech. Rev. abstract)

GENERATION OF HIGH VELOCITY STREAMS OF ATOMS AND IONS (Abstract), by H. F. Calcote. [1958] [1]p. (AF 49(638)300) Unclassified

Presented at Symposium on Unstable Chemical Species, Los Angeles, Calif., June 23-24, 1958.

A technique has been developed for producing a non-thermal jet of atoms and ions at high velocity. The products of a low temperature electric discharge are expanded through a supersonic nozzle to form a shock free stream. This stream is being employed in aerodynamic studies of non-equilibrium dissociated gas, both in continuum and molecular flow and in measurements of ion and atom recombination rates. Magnetohydrodynamic studies will also be possible with this new tool. The present program is directed toward characterizing the stream in terms of its aerodynamic and physical chemical properties. The measurement of aerodynamic properties and plasma properties, i.e., ion and electron concentrations and electron temperatures is examined, and preliminary results are presented. DEVELOPMENT OF A LOW TEMPERATURE PLASMA JET (Abstract), by H. F. Calcote and D. E. Rosner. [1958] [2]p. (Bound with its AFOSR-TR-58-125) (AF 49(638)300) Unclassified

Presented at Conference on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

The objectives of this program are to (a) design and fabricate a low-temperature, high-velocity plasma jet, (b) determine characteristic gasdynamic and physical-chemical properties, and (c) investigate possible applications of the results. The potential applications include heat transfer measurements in a highly non-equilibrium dissociated gas and magnetogasdynamic studies in a non-equilibrium partially ionized gas. The apparatus consists of a low-temperature electric-discharge which is expanded through a supersonic nozzle into a low-pressure chamber, producing a jet containing large non-equilibrium concentrations of ions and atoms. The discharges include dc glows, 800 cps glows, and 20 megacycle electrodeless discharges, at pressures of from 10 to 800 mm Hg. The jet exhausts into a pressure of 1-20 mm Hg. The first equipment constructed and tested indicated that roughly 50% of the energy went into dissociating the gas (air) and roughly 5% went into ionization. A shock-free stream was obtained. In addition to air the noble gases helium and argon have been used. The first apparatus has been completely rebuilt, increasing

AER.01:009; AER.02:012-014

the pumping capacity and providing for more accurate measurements. The possibility of achieving magnetogasdynamic effects in the jet can be estimated by evaluation of the magnetogasdynamic parameter Q defined by

$Q = \sigma B^2 L / \rho U$ where ρ = density, U = exhaust jet velocity, L = characteristic length, B = magnetic field strength, and σ = electrical conductivity. Easily detectable magnetogasdynamic effects are expected when Q is of order unity.

THE EFFECT OF PHYSICAL ADSORPTION ON THE ABSOLUTE DECOMPOSITION RATES OF CRYSTALLINE AMMONIUM CHLORIDE AND CUPRIC SULFATE TRIHYDRATE, by R. D. Schultz and A. O. Dekker. [1956] [6]p. incl. refs. (AF 18(600)1026; continued by AD 18(603)74) Unclassified

Published in Jour. Phys. Chem., v. 60: 1095-1100, Aug. 1956.

The linear decomposition rates for the decomposition reactions $NH_4Cl \rightarrow NH_3 + HCl$ and $CuSO_4 \cdot 3H_2O \rightarrow CuSO_4 \cdot H_2O$ are interpreted on the basis of a modified Langmuir-Hinshelwood bimolecular surface reaction mechanism. An absolute rate treatment (similar in method to that developed by Laidler, Glasstone and Eyring for heterogeneous processes) accounts for the unusually low reaction probabilities per collision of gaseous product molecules with the reaction interface in terms of interference by a physically adsorbed product layer. SOME EFFECTS OF OXIDIZER CONCENTRATION AND PARTICLE SIZE ON RESONANCE BURNING OF COMPOSITE SOLID PROPELLANTS, by L. Green, Jr. [1957] [24]p. incl. illus. diagrs. tables. [AF 18(600)1048] Unclassified

Presented at Twelfth Annual meeting of the Amer. Rocket Soc., New York, Dec. 2-5, 1957.

Also published in Jet Propulsion, v. 28: 159-164, Mar. 1958.

A comparison of four experimental, composite propellant formulations with nominally constant burning rates, tested at 170°F in internal-burning tubular charges partially supported the widely held belief that the tendency toward irregular reaction increases as the energy content of the propellant is raised. However, the highest-energy formulation showed a smooth reaction, apparently as a result of a burning rate lower than was anticipated on the basis of Crawford bomb measurements. The results suggest that the rate of energy release (the product of burning rate, propellant density, and heat of explosion) affords a better measure of the relative stability behavior of various formulations than does either burning rate or energy content alone. A subsequent brief comparison at 170°F of three other composite propellants with constant energy content, but with varying burning rates (obtained by varying the oxidizer particle-size distribution), indicated that the tendency toward irregular reaction increased as the burning rate increased or as the particle size became finer. Owing to propellant processing difficulties, efforts to study the influence of burning rate alone while controlling both oxidizer concentration and particle-size distribution were not successful. It is recommended that the apparent influence of a coarse oxidizer particle-size distribution in suppressing resonance burning be investigated further. (Contractor's abstract)

SOME EFFECTS OF CHARGE CONFIGURATION IN SOLID PROPELLANT COMBUSTION, by L. Green, Jr. [1958] [3]p. incl. diagrs. table, refs. [AF 18(600)1048] Unclassified

Published in Jet Propulsion, v. 23: 463-465, July 1958.

Static tests were performed employing a high energy, composite solid propellant at 170°F in four different types of charge. As expected, the external-burning rod

AER. 03:004-006; AER. 06:001, 002

grain yielded the most stable reaction. The tubular charge ranked second in reaction stability from both the gross and fine-time-scale viewpoints. Contrary to expectations, the star-perforated charge furnished the most exaggerated examples of resonant burning. The propellant showed significantly different burning characteristics in each configuration. The internal-burning, star perforated, and tubular grains burned more rapidly. The external-burning rod grains appeared to show a higher pressure exponent, and the rod-in-shell charges showed an intermediate value.

HIGH-FREQUENCY COMBUSTION INSTABILITY, by H. B. Ellis and R. S. Pickford. Sept. 1956 [49]p. incl. illus. diags. (Rept. no. TN-17) (AFOSR-TN-56-547) (AF 18(600)1155) AD 110366 Declassified

High-frequency combustion instability is an important problem in thrust-chamber development. Of the various high-frequency combustion-chamber modes, the tangential mode is frequently the most destructive. When encountered, the tangential mode may impose serious delays in thrust-chamber design and development. Investigation of this problem at Aerojet has resulted in the construction of a model of tangential-mode combustion instabilities. The model is discussed from the aspects of the expected behavior of a tangential-front system and the experimental data obtained. The experimental data appear to substantiate the hypothesis presented. (Contractor's abstract)

BASIC RESEARCH ON COMBUSTION IN LIQUID ROCKET THRUST CHAMBERS, by R. S. Pickford, H. C. Kreig, Jr., and H. B. Ellis. Final technical rept. Jan. 1957, 1v. incl. illus. tables, refs. (Rept. no. 1193) (AFOSR-TR-56-61) (AF 18(600)1155) AD 115015 Declassified

The tangential combustion instability in liquid-propellant rocket motors has been investigated. A physical-process mechanism for fully developed instabilities has been proposed and a system established for the various front modes. The axial and radial distribution of the front occurring in the experimental chamber is discussed. Luminosity, instantaneous pressure, and front motion have been correlated, and an estimate has been made of the movement of chamber gas during unstable combustion. The relative characteristics of three basic injection elements have been investigated by determining the rate of heat transfer from a non-reactive gaseous atmosphere to the injected liquid spray. The effects of gas temperature and pressure, injection orifice diameter,

impingement angle, and relative velocity between the test liquid and the gas are discussed. The investigation was conducted using three test liquids with varying physical properties. (Contractor's abstract)

AN IMPROVED INSTRUMENT FOR THE MEASUREMENT OF LINEAR PYROLYSIS RATES OF SOLIDS, by M. K. Barsh, W. H. Andersen and others. July 15, 1957 [19]p. incl. illus. diags. (Rept. no. TN-20) (AFOSR-TN-57-513) (AF 18(600)74; continuation of AF 18(600)-1026) AD 136499 Unclassified

Also published in Rev. Scient. Instruments, v. 29: 392-395, May 1958.

An improved instrument has been designed and constructed for the measurement of the linear decomposition and sublimation rates of solid substances. This instrument, which is provided with automatic recording devices, eliminates many of the shortcomings of the earlier prototypes and makes possible the determination of linear rates with a precision of 1%. Important new features include (1) an integral heating element and thermocouple assembly; (2) stainless-steel and Plexiglas construction throughout; (3) heavy solid-copper electrical conductor supports for the heating element; and (4) a precision position-sensing potentiometer. The use of cut strands of Plexiglas 55 is recommended for periodic standardization and calibration of the instrument. (Contractor's abstract)

CHEMICAL FRAGMENTS AS ULTRA-ENERGY PROPELLANTS, by W. H. Andersen and G. Moe. July 1957, 32p. incl. refs. (Abstracts Bull. no. 1; rept. no. 1284) (AFOSR-TN-57-408) (AF 18(603)110; continuation of AF 18(600)1216) AD 132486 **Unclassified**

Unclassified literature regarding the research and investigation of highly reactive molecular fragments were abstracted and compiled. The general approach to this literature survey was to abstract pertinent literature and to include abstracts of the most important papers listed only by reference in E. W. R. Steacies (Atomic and Free Radical Reactions, ACS monograph no. 125, 1954). Abstracts of the following journals are presented for the period of 1953 through 1956: (1) Jour. Chem. Phys., 1953 through 1956; (2) Jour. Phys. Chem., 1953 through 1956; (3) Jour. Amer. Chem. Soc., 1956; (4) Jour. Appl. Chem., 1956; (5) Trans. Faraday Soc., 1955 and 1956; (6) Proc. Roy. Soc., 1954 through 1956; (7) Phys. Rev., 1956; (8) Chem. Rev., 1956; and (9) Jour. Inorg. and Nuclear Chem., 1956. The abstracts are grouped within the following categories: (1) production, (2) identification, (3) stabilization, and (4) properties. Within each category, the abstracts are arranged chronologically by year and are numbered consecutively.

AER.08:002

CHEMICAL FRAGMENTS AS ULTRA-ENERGY PROPELLANTS, by W. H. Andersen, J. H. Abraham and others. Oct. 1957, 54p. incl. refs. (Abstracts Bull. no. 2; rept. no. TN-22) (AFOSR-TN-57-699) (AF 18(603)-110) AD 136692 **Unclassified**

The Aerojet-General Corp. is investigating, under sponsorship of the Directorate of Advanced Studies of the Air Force Office of Scientific Research, Air Research and Development Command, certain ultra-energy substances as potential propellants for rocket propulsion. These investigations have necessitated an extensive review of the literature concerned with chemical fragments, embracing the related subjects of production, identification, stabilization, and determination of properties. The ultra-energy substances include charged (ions) and uncharged (free radicals) molecular fragments. This area of research has aroused considerable interest in recent months. Workers in a number of laboratories, both in this country and abroad, are now actively engaged in free-radicals research. As was mentioned in the previous bulletin of this series, it was felt that the information accumulated in the Aerojet-General file of reference abstracts would be interesting and beneficial to other workers in the field. This information should be particularly valuable to those who are only now entering the field. It is the purpose of this bulletin to help make the

AER. 08:003-005; AER. 09:001

information generally available. (Contractor's abstract)

This report is the third in a series of abstract bulletins reviewing the unclassified literature covering research on highly reactive molecular fragments. It embraces the related subjects of production, identification, stabilization, and determination of properties. It is a comprehensive but not exhaustive bibliography covering work reported in journals from 1954 to 1956.

RESEARCH ON FREE RADICALS AS ROCKET FUELS
(Abstract), by G. Moe. [1957] [2]p. [AF 18(603)110]
Unclassified

AER.08:005

Aerojet-General Corp., Azusa, Calif.

Published in Program for Symposium on The Formation and Stabilization of Free Radicals, Nat'l. Bur. Standards, Washington, D. C. (Sept. 18-20, 1957), Washington, Nat'l. Bur. Standards, 1957, p. C1-C2.

A CALORIMETRIC TECHNIQUE FOR THE STUDY OF FREE RADICAL REACTIONS AT LOW TEMPERATURES (Abstract), by J. M. Flournoy. [1958] [1]p. (AF 18(603)-110)
Unclassified

An analysis has been made of the relationship between the thrust derivable from a rocket and the energy content of the propellant. This analysis indicates that significant increases in the performance of rocket propellants are possible if certain types of free radicals and atoms could be utilized. The atoms and radicals might be introduced into a suitable working fluid, such as hydrogen. The heat of reaction of the radicals would raise the temperature of the working fluid to the desired operating temperature. In this way specific impulse values considerably greater than those obtained from conventional chemical fuels have been calculated. Recent developments in experimental techniques for the production, stabilization, and identification of free radicals and atoms are discussed including a 1000-curie Cobalt-60 gamma ray source which has been designed for irradiation of solids at liquid helium and liquid nitrogen temperatures, and a special low-temperature calorimeter designed to operate in a gamma radiation field, which is capable of measuring heat changes of a few small calories at 77°K. Measurements have been made of the heat generated by radical reactions during the warming of ice samples that have been exposed to

Presented at Symposium on Unstable Chemical Species, Los Angeles, Calif., June 23-24, 1958.

A simple calorimetric technique is described for the determination of the amount of energy stored in ice samples after exposure to γ -radiation. Samples of ice weighing about 4 grams are irradiated for periods up to 200 hours in a 1000-curie cobalt-60 source. The maximum dosage rate is about 1.3×10^5 rep/hr, which corresponds to an energy input of about 0.25 calories per hour per gram of sample. The data from four preliminary experiments indicates that somewhat less than 1% of this energy is stored in the ice at 77°K and is released slowly when the temperature of the sample reaches about 100°K. Assuming that the energy release comes from recombination of H and OH radicals, produced by the radiation, the efficiency of radical formation is approximately 10^{11} radical pairs per gram of water per rep, for dosages up to 2×10^6 rep and decreases to about 2×10^{10} r.p./gm-rep after 1.5×10^7 rep. Experiments are in progress to determine more accurately the variation in energy storage with total dosage, the rate of recombination as a function of temperature, and if possible the upper limit of radical concentration attainable with this γ -irradiation technique. An endothermic reaction occurs when the samples are warmed to 120°K, and amounts to about five times as large a heat change as that caused by the exothermic recombination reaction. The possible nature of this process is discussed. (Contractor's abstract)

INTERACTION OF BURNING LIQUID DROPLETS AND SHOCK WAVES, by K. Sato. Final rept. Mar. 1, 1957-Mar. 31, 1958. Aug. 27, 1958, 1v. incl. illus. diagrs. table. (AFOSR-TR-58-119) (AF 49(638)82) AD 202909 Unclassified

Experiments were performed to determine the interaction of shock waves on liquid droplets and were recorded by means of high-speed photography. Photographic evidence obtained has shown clearly that the viscous drag of the gas flow behind the shock, and not the shock front itself, is responsible for droplet breakup. The results obtained have indicated that the range of shock strengths used in this program (Mach 1.08 to 2.55) has resulted in the shear mode of droplet disintegration. Also, the degree of dispersion of liquid droplets in the burning cases was considerably greater than that in the non-burning, apparently because of deviations from spherical shapes resulting in higher drag forces. When the injected fluid forms non-spherical droplets, useful comparison of breakup with shock strengths cannot be made, because a parameter which describes deviation of droplets from spheres is needed before correlations can be made. In order to establish this parameter, secondary atomization should be considered as a mode for droplet breakup of the injected propellants. This could result in droplets which are much smaller than those obtained without secondary atomization, and could be the controlling factor in the combustion process. Therefore, it would be necessary to evaluate breakup at these droplet sizes in order to permit correlation of experiments conducted in a shock tube with the phenomena occurring in a rocket combustion chamber. The evaluation of the critical flow velocity, which will result in droplet breakup, will be a function of droplet configuration (that is, deviation from spherical shape) as well as other physical properties of the droplet. Therefore, further studies will be required on the behavior of propellant droplets under conditions simulating as closely as possible those existing in rocket chambers before a definite atomization criteria can be achieved.

A THEORETICAL STUDY OF THE RECOMBINATION KINETICS OF ATOMIC OXYGEN, by S. T. Demetriades and M. Farber. Nov. 8, 1957, 1v. incl. diagrs. tables, refs. (Rept. no. TN-21) (AFOSR-TN-58-18) (AF 49(638)111) AD 148057; PB 136998 Unclassified

Presented at 133rd meeting of the Amer. Chem. Soc., San Francisco, Calif., Apr. 13-18, 1958.

Also published in ARS Jour., v. 29: 528-530, July 1959.

Favorable conditions are determined for the study of the recombination kinetics of atomic oxygen. A rate constant for the oxygen-recombination mechanism, $O + O + M \rightarrow O_2 + M$, of the order of 10^{15} to 10^{16} $\text{cc}^2/\text{mol}^2\text{-sec}$, depending on the temperature, has been derived theoretically. For a recombination rate of this magnitude, static experiments can be performed in the range of temperatures from 1500 to 2000°K and pressures

of the order of 10^{-3} atm, provided that the wall recombination is not faster than predicted by the rate of collisions of colliding oxygen atoms with the wall. The present estimate of the rate of oxygen recombination is compared with previous estimates and with the rate of oxygen-molecule production due to wall recombination and to the ozone-recombination mechanism, $O_3 + O \rightarrow 2O_2$.

If the recombination-rate constant for the three-body homogeneous process is below 2×10^{15} $\text{cc}^2/\text{mol}^2\text{-sec}$ or the wall recombination is a first-order process, dynamic experiments would be required to eliminate wall effects. (Contractor's abstract)

THE USE OF PLANETARY ATMOSPHERES FOR PROPULSION, by S. T. Demetriades and C. B. Kretschmer. Apr. 1958 [18]p. incl. tables. (Rept. no. TN-24) (AFOSR-TN-58-229) (AF 49(638)111) AD 154132 Unclassified

Also published in Fourth annual meeting of the Amer. Astronaut. Soc., New York (Jan. 29-31, 1958), N. Y., Amer. Astronaut. Soc., 1958, p. 46-1 - 46-14.

Reaction kinetics of atomic oxygen in the earth's upper atmosphere is presented, and a preliminary analysis is made of an atomic-oxygen propulsion unit. Estimates of the mechanism and magnitude of the recombination rates for atomic oxygen are presented in the homogeneous phase as well as in the heterogeneous phase (i.e., on a catalytic surface). These estimates are based on the results of collision-rate theory, absolute reaction-rate theory, and the interpretation of experimental data available in the literature on other 3-body recombination reactions and surface-recombination reactions. Assuming 100% efficiency in utilizing the atomic-oxygen

recombination energy, a thrust of 40 dynes per cm^2 of inlet area is obtained at 100 km altitude. This thrust is independent of the flight speed and depends on the altitude only; and it compares favorably with the expected drag at those altitudes at low flight speeds. The ideal thrust-to-minimum-drag ratio is generalized for any recombination power plant in any planetary atmosphere; and it is shown that as a first approximation, this ratio is independent of altitude and absolute concentrations. (Contractor's abstract)

THE UTILIZATION OF ATOMIC OXYGEN RECOMBINATION IN THE EXOSPHERE (SIGNIFICANCE OF FINDINGS), by S. T. Demetriades, C. B. Kretschmer, and M. Farber. Mar. 18, 1958, 5p. (AFOSR-TN-58-262) (AF 49(638)111) Unclassified

The possibility of utilizing the atomic oxygen and atomic nitrogen present in the upper atmosphere for propulsion purposes is discussed. At high altitude 30% by volume or 20% by weight of the available oxygen is dissociated offering an inexhaustible supply of energy for propulsion and other purposes. An experimental program involving the study of atomic oxygen recombination rates is described.

A PRELIMINARY INVESTIGATION OF AN ATOMIC-OXYGEN POWER PLANT, by S. T. Demetriades and C. B. Kretschmer. Mar. 4, 1958, 30p. diagra. tables, refs. (Rept. no. TN-23) (AFOSR-TN-58-325) (AF 49(638)111) AD 154229; PB 137008 Unclassified

Assuming 100% efficiency in utilizing the atomic-O recombination energy, a thrust of 5.7×10^{-4} lbf/sq in. of inlet area was obtained at an altitude of 100 km. Theoretical estimates indicated that the recombination of atomic O can be effected in a continuous-flow (open cycle) power plant by ram-compression alone, without a catalyst. Thrusts of the order of 5.7×10^{-5} lbf/sq in. of inlet area were achieved with power-plant lengths less than 1000 ft, at flight speeds of about 11,000 fps ($M = 10$) and altitudes of about 100 km. These thrusts compared favorably with the minimum frictional drag expected at those altitudes at low flight speeds, but were not sufficient to sustain flight at orbital speeds. At 100 km, the thrust of a ramjet power plant, in which 50% of the atomic O was recombined and 36% of the energy of recombination was lost due to internal losses, is only 13 dynes/sq cm of inlet. At orbital speed at that altitude, the minimum frictional drag was about 13 dynes/sq cm of the outer surfaces. A purely catalytic atomic-O power plant will require an effective length several times greater than the inlet radius and therefore cannot fly at orbital speeds. Flight of an atomic-O ramjet at orbital speeds only becomes feasible if the drag can be reduced by a factor of 10 or more and if the total recombination rate can be increased by a factor of 10 or more.

UTILIZATION OF ATOMIC OXYGEN RECOMBINATION IN THE UPPER ATMOSPHERE (Abstract), by S. T. Demetriades, C. B. Kretschmer, and M. Farber. [1958] [1]p. [AF 49(638)111] Unclassified

Presented at meeting of the Petroleum Div. of the Amer. Chem. Soc., San Francisco, Calif., Apr. 13-18, 1958.

Published in 133rd meeting of the Amer. Chem. Soc. Abstracts of Papers, 1958, p. 5-Q.

In the upper atmosphere at 100 km there is approximately 10^{-6} cal per cc of available energy in the form of atomic oxygen. This offers an inexhaustible supply of energy for propulsion and other purposes. The rational design of an atomic-oxygen power plant requires knowledge of the efficiency of conversion of this available energy. This efficiency depends primarily on the recombination rate of atomic oxygen. This paper presents the reaction kinetics of atomic oxygen in the upper atmosphere and a preliminary analysis of an atomic-oxygen propulsion unit. Estimates are presented of the mechanism and magnitude of the recombination rates for atomic oxygen in the homogeneous phase as well as of the recombination rates in a heterogeneous system - that is, on a catalytic surface. These estimates are based on the results of collision rate theory, absolute reaction rate theory, and the interpretation of experimental data available in the literature on other three-body recombination reactions and surface-recombination reactions. Assuming 100% efficiency in utilizing the atomic-oxygen recombination energy, a thrust of 40 dynes per sq cm of inlet area is obtained. This thrust is independent of the flight speed and depends on the altitude only and it compares favorably with the expected drag at those altitudes at low flight speeds.

ATOMIC OXYGEN RECOMBINATION RATES (Abstract), by C. B. Kretschmer. [1958] [1]p. (AF 49(638)111) Unclassified

Presented at Symposium on Unstable Chemical Species, Los Angeles, Calif., June 23-24, 1958.

The rate constant for recombination of oxygen atoms by the three-body mechanism:

is known from shock tube experiments to lie in the range $10^{15} - 10^{17}$ cm⁶/mole² at temperatures in the neighborhood of 3000°K. No measurements of this rate

AIR FORCE SCIENTIFIC RESEARCH

AER. 12:001, 002; AER. 13:001;
ANS. 01:003, 004

constant at lower temperatures or by other experimental methods have been reported. By an application of Eyring's theoretical treatment, the following estimate has been obtained: $k_1 = 3 \times 10^{16} (300/T)^{1.5}$. Since some of the shock-tube measurements on air have been interpreted as implying rates of recombination greater than the rate of pertinent three-body collisions, it has been conjectured that recombination in air occurs by a chain mechanism involving nitric oxide. The possibility of such a chain mechanism is discussed. Finally, the present outlook for utilization of the atomic oxygen content of the upper atmosphere as a source of energy for propulsion is reviewed.

ION SOURCES (Abstract), by R. J. Sunderland. [1958] [1]p. (AF 49(638)214) Unclassified

Presented at Symposium on Unstable Chemical Species, Los Angeles, Calif., June 23-24, 1958.

Ionically propelled space vehicles will require total ion currents ranging from several hundred to several thousand amperes. The source of these ions must be capable of continuous operation for periods extending to several earth years. Such a source would be composed of a large number of modular units each having high ion current densities, high ion efficiencies, and high ion-to-neutral-particle ratios. Ideally, the unit must be flexible enough to allow the current to be varied over a wide range, and light enough so that the complete source contributes only insignificantly to the total mass of the power plant. Existing ion sources vary in their degree of applicability from poor to favorable, and a number of sources now under study may eventually provide the necessary copious ion beams.

MINNEAPOLIS TEST REPORT "PROJECT FAR SIDE," by C. P. Merrell and P. A. Pankow. July 19, 1957, 7p. illus. diagrs. table. (In cooperation with General Mills, Inc., Minneapolis, Minn.) [AF 49(638)55] Declassified

This is a report on "Project Far Side," a test held at General Mills Flight Center, Minneapolis, Minn. on June 28, 1957 for the purpose of providing information to be used in later operational flights. The flight proved beyond doubt the ruggedness of the balloon, the reliability and strength of all mechanical components, the practicality and feasibility of the balloon and load launching system, the alignment of the load and balloon system, and it also established a new record for balloon volume. The ability of the 212-1-1 balloon to withstand shock and carry heavy loads was undoubtedly proved. The "Far Side" suspension system performed all of the tasks which could be tested with a dummy rocket. No member appeared to be overly stressed or weakened. Three recommendations for improvements are as follows: (1) a cable holdback should be designed for the suspension arm in place of nylon; (2) the instrument bag attachment point should be lowered to the midpoint of the cage; and (3) the support method should be changed in the upper ring (nylon or styrofoam).

On the basis of the limited amount of vehicle performance data that were obtained in six attempted flights, it is possible that Flights 2, 5 and 6 performed properly and reached altitudes of 3,000 - 4,000 miles. Unfortunately, the lack of adequate ground instrumentation and the loss of telemetry signal preclude positive proof of this. It has not been possible to establish positively whether the telemetry fadeout was due to some peculiar propagation phenomenon (for example, the very intense electron densities reported by Van Allen at altitudes of 600 - 1800 miles), reentry, or component failure. However, since the optical tracking data, particularly in Flights 5 and 6, indicate good performance through second stage burning (which unfortunately was the maximum range of the optical system) and the telemetry data during these periods are either missing or somewhat confusing, an interpretation of performance based primarily on the limited telemetry data would seem questionable.

The mission of the Air Force Office of Scientific Research, an agency of the Air Research and Development

AIR FORCE SCIENTIFIC RESEARCH

AIR.01:004 - AIR.01:008

Command, is the encouragement of exploratory effort, the understanding of its results and utilization of its findings for the present and future needs of the Air Force. Their method of operation includes making missions known to research sources, examining their lines of investigation and providing whatever support and guidance they may need. To accomplish this, AFOSR seeks help from its academic and industrial laboratories. AFOSR with its military and civilian personnel are charged with the sole task of recognizing the military implications of this work and supporting with funds, tools, procurement methods and communications, those persons who can supply the essential ingredients for certain given tasks. Some of the work and progress made by AFOSR is presented in this paper.

AEROTHERMOELASTICITY, by M. Rogers. [1958] [11]p. incl. diagrs. table, refs. (AFOSR-TN-58-500) AD 158310 Unclassified

Also published in Aero/Space Engineering, v. 17: 34-44, Oct. 1958.

The present method of handling aerothermoelastic problems is to divide the general problem into two separate problems—the athermal and the aeroelastic—each of which can be handled, to a large degree, by methods already available to the structural engineer. This division rests on assumptions which may not always be valid under high-temperature flight environments. Research is needed to clarify the strength of the interactions between heat input and aeroelastic phenomena, other than the well-known reductions in moduli of elasticity of the structural materials and the introduction of thermal stresses. The general problem of aerothermoelasticity

is too complex to be successfully approached by analytical means alone. New and unique experimental facilities are needed for aerothermoelastic research before significant progress can be made. Model tests are useful in developing optimum theories. Complete simulation in the laboratory of all the elastic, inertial, and unsteady aerodynamics and of heat-transfer properties of a prototype is virtually out of the question, except for geometric scale ratios of nearly one. Thus, "restricted purpose" models must be employed. (ASTIA abstract)

THE ANALYTIC CAUCHY PROBLEM FOR THE ITERATED WAVE EQUATION, by E. P. Miles, Jr. Apr. 1958 [13]p. (Technical note no. BN-133) (AFOSR-TN-58-340) (In cooperation with Maryland U. Inst. for Fluid Dynamics and Applied Mathematics, College Park) (AF 49(638)81) AD 154245 Unclassified

Presented at meeting of the Amer. Math. Soc., New York, Aug 26, 1958.

Also published in Portugal. Math., v. 18: 111-119, 1959.

A basic set of polynomial solutions for the iterated wave equation is developed from which an explicit closed form

solution of the associated Cauchy problem with polynomial data is obtained. The corresponding problem with polyharmonic and analytic data is discussed. This problem has been solved in the case of more general data, but the present method gives simple closed form solutions in many cases where the multiple integrals involved in the other solutions would be difficult to evaluate. An example is given in which a singularity of the data is not propagated into the solution on the characteristic surface leading from the singular point. (Contractor's abstract, modified)

ON CERTAIN REFLECTION PRINCIPLES, by E. P. Miles, Jr. July 1958 [10]p. incl. refs. (Technical note no. BN-146) (AFOSR-TN-58-702) (In cooperation with Maryland U. Inst. for Fluid Dynamics and Applied Mathematics, College Park) (AF 49(638)81) AD 162236 Unclassified

The classical reflection principle for harmonic functions due to Schwarz has been generalized for biharmonic functions by Poritsky and Duffin and for polyharmonic functions by Huber. If a polyharmonic function of order p , which is such, that the function and its first $p-1$ derivatives vanish on the hyperplane of reflection, has an analytic continuation across this hyperplane, then a locally valid expansion for the function is obtained in terms of the Cauchy data on the hyperplane. From this expansion an alternate reflection principle of limited range is obtained which is shown to be reducible to the Schwarz, Duffin, and Huber principles for $p = 1, 2, 3$, respectively, within their common range of validity. A brief description is also presented of a corresponding heuristic approach to the reflection principle for the Helmholtz equation.

For each pair of integers, $n \geq 0$ and $m > 0$, and the associated sets of non-negative integers a_1, a_2, \dots, a_k

ALF.02:001 - ALF.02:004

such that $a_k \geq 2m-1$ and $\sum_{j=1}^k a_j = n$, the set of homogeneous polynomials

$$P_{a_1}^n = \sum_{j=0}^{n-a_k/2} (-1)^j \left[\begin{matrix} j+[a_k/2] \\ [a_k/2] \end{matrix} \right] \nabla^{2j} \left(\prod_{x=1}^{k-1} x^{a_x} \right) \cdot \frac{x_k^{a_k+2j}}{(a_k+2j)!}$$

is shown to form a basic set of k variable polyharmonic polynomials of order m (i.e., solutions of $\nabla^{2m} u = 0$).

Deletion of the factor $(-1)^j$ gives an analogous basic set for the iterated wave equation

$$\left(\sum_{j=1}^{k-1} \frac{\partial^2}{\partial x_j^2} - \frac{\partial^2}{\partial x_k^2} \right)^m u = 0.$$

The paper concludes with the expansion of an arbitrary polynomial in terms of the basic set. (Contractor's abstract)

IONIC CONDUCTIVITY AND DIFFUSION IN ALKALI HALIDES, by E. A. Giess. A Review. Sept. 1957, 62p. incl. diagrs. tables, refs. (AFOSR-TN-57-814) (AF 18(600)1448) AD 136604 Unclassified

A general review is presented of the theory of ionic conduction and diffusion processes in alkali halides, especially as related to the defect solid state. Consideration was given to (1) the theory of densities of vacancies and their heats of formation, (2) the simple diffusion theory, (3) the simple ionic conduction theory, (4) the Nernst-Einstein relation, (5) the correlation effect, (6) the intrinsic ionic conduction, and (7) the extrinsic ionic conduction. The review does not cover the field of dielectric loss measurements which has produced much useful information. The extensive field of color centers and related optical phenomena were also omitted. Although the theory is considered to be in an advanced stage, there are still several aspects of the subject which have not been satisfactorily explained. The role played by the crystal substructure and surface in these processes, the exact cause of the polarization phenomena, and the explanation for the observed deformation and cold-working effects are some of the unsolved problems. (ASTIA abstract)

SYMPOSIUM ON THE DEFECT SOLID STATE - DIFFUSION IN IONIC SOLIDS, by T. J. Gray, B. D. James, and E. A. Giess. Second annual rept. Sept. 1957, 105p. incl. diagrs. tables, refs. (AFOSR-TN-57-

615) (AF 18(600)1448) AD 154871 Unclassified

A quantitative theory has been given for contribution to ionic conductivity of frozen-in vacancies and, using experimental data, it has been estimated that such an effect could be observed in very pure sodium chloride crystals. Furthermore, a rough theoretical approach to vacancy-formation kinetics has been suggested and some experimental evidence for its validity has been cited. (Contractor's abstract)

DIFFUSION AND CONDUCTION IN IONIC SOLIDS, by E. A. Giess. June 1958, 1v. incl. diagrs. tables, refs. (AFOSR-TN-58-910) (AF 18(600)1448) AD 202408 Unclassified

The extrinsic (low-temperature) conductivity of NaCl was studied, with particular attention being given to the differences in conductivity between solution-grown and melt-grown crystals. The principal effect which was observed was an increase in the extrinsic conductivity of the solution-grown crystals after they had been heated to high temperatures in the intrinsic range; this effect was not observed in melt-grown crystals. A review of literature and general theory is presented on the theory of vacancies and their heats of formation, simple diffusion theory, simple ionic conduction theory, Nernst-Einstein relation, the correlation effect to explain the low-temperature failure of the Nernst-Einstein relation, and intrinsic and extrinsic ionic conduction.

CERTAIN ASPECTS OF DIFFUSION AND CONDUCTION IN ALKALI HALIDES, by E. A. Giess and T. J. Gray. [1958] 7p. incl. refs. (AFOSR-TN-58-911) (AF 18(600)-1448) AD 204589 Unclassified

Also published in Conf. on the Kinetics of High-Temperature Processes, Massachusetts Inst. of Tech., Cambridge (June 23-27, 1958), Cambridge, Technology Press, 1958, p. 11-13.

A dc pulse technique has been used to measure the ionic conductivity of NaCl crystals of low level Pb and Mg impurity content which have been grown from solution. The low temperature conductivity has been found to be irreversibly connected to the extrinsic conductivity and is explained by a tendency of the crystal vacancies to congregate at dislocations and other mosaic surfaces. A PbCl₂ coordination complex is believed to exist in the Pb impurity samples after annealing in the intrinsic region.

THE ELECTRICAL RESISTIVITY OF SINGLE-CRYSTAL ALUMINA OVER THE TEMPERATURE RANGE 1000°-1500°C, by L. E. Sobon. May 12, 1957, 11p. incl. diagrs. refs. (AF 49(638)87) Unclassified

The electrical resistances of two samples of single-crystal sapphires was measured over a temperature range of 1000° to 1500°C. A furnace and sample holders were designed, and a unique method for measuring resistivity was used. This method does not require an external power supply in the measuring circuit. The geometry of the circuit is such that current leakage between sample holder has no effect on the measurements.

SOME OBSERVATIONS OF THE DIELECTRIC PROPERTIES OF Al_2O_3 , by H. C. Graham. July 1957, 41p. incl. diagrs. tables, refs. (AF 49(638)87) Unclassified

The purposes of this investigation were to (1) determine some of the fundamental dielectric values, i.e., capacitance and dielectric loss of alumina as a function of temperature and frequency, and (2) to develop a measuring apparatus capable of obtaining reproducible results over the temperature and frequency range of -200 to 500°C and 10^2 to 10^5 c/s, respectively. The values of capacitance reported are relative as no attempt was made to obtain absolute values. The samples measured were single crystal corundum and polycrystalline pressed alumina. In both cases they were made from Linde gamma alumina "high purity" powder (Linde Air Products Company). The values of capacitance and dielectric loss are given for all points; the dielectric constant is calculated at room temperature and 10^3 c/s for the single crystal measured both perpendicular to and parallel to the optic axis; the effective dc resistance for the single crystal is compared with previous work on resistivity of Al_2O_3 ; an activation energy is calculated for one of the peaks observed on the single crystal measured perpendicular to the optic axis; and a brief analysis of all the peaks observed is presented.

SOME OBSERVATIONS OF THE DIELECTRIC LOSS IN ALUMINA (Abstract), by H. C. Graham, N. M. Tallan, and D. P. Detwiler. [1958] [1]p. (AF 49(638)87) Unclassified

Presented at meeting of the Amer. Ceramic Soc., Washington, D. C., Apr. 26-May 1, 1958.

Published in Bull. Amer. Ceramic Soc., v. 37: 31, Apr. 1958.

The dielectric loss and dielectric constant of single crystal and polycrystalline alumina were measured between temperatures of -200 and +500°C and between frequencies of 10^2 and 10^5 cps. Single crystals of alpha alumina prepared by the Verneuil process, containing traces of several impurities, were measured both perpendicular to and parallel to the optic axis and $\tan \delta$ values are presented. Several indications of Debye-type loss maxima were observed and an activation energy of approximately 10 ev is calculated for one of these. The effective dc resistance of the single crystal found by extrapolation of the loss curve to higher temperatures is compared with values of the resistance previously found in these laboratories by direct measurement at elevated temperatures. Polycrystalline samples pressed from the gamma alumina powder used as raw material for the flame-fusion crystal preparation were sintered at temperatures between 955°C and 1400°C. Measurements of the dielectric loss for these samples revealed the disappearance of loss maxima after the polymorphic inversion from gamma alumina to alpha alumina and the presence of significant conduction loss in polycrystalline samples at temperatures lower than those found for single crystal samples. The activation energy associated with the loss maxima found in gamma alumina was calculated to be approximately 1 ev.

THE HEATING OF SLABS WITH ARBITRARY HEAT INPUTS, by T. R. Goodman. May 28, 1958, 17p. (AFOSR-TN-58-524) (AF 49(638)347) AD 158337; PB 135560 Unclassified

Also published in Jour. Astro/Space Sciences, v. 26: 187-188, Mar. 1959.

The method of heat balance integral [T. R. Goodman, Trans. Amer. Soc. Mech. Engrs., v. 80: 335, 1958] with a cubic profile has been applied to predict the surface temperatures of slabs when the heat flux at the surface is an arbitrary function of temperature and time. The method has been extended to the case of thermally dependent transport properties. The technique always reduces the problem to the solution of a first order ordinary differential equation which can frequently be solved by quadratures. In all cases, however, the resulting ordinary differential equation is far simpler to solve than the partial differential equation of heat conduction. The method will be particularly useful when the data is given empirically, as, for example, in the case of a missile trajectory when the external conditions

THE ABLATION OF MELTING BODIES WITH HEAT PENETRATION INTO THE SOLID, by T. R. Goodman. Aug. 1, 1958, 20p. incl. diags. (AFOSR-TN-58-789) (AF 49(638)347) AD 202115; PB 136753 Unclassified

The equation describing the ablation of melting bodies was described by the author previously (Aerodynamic Ablation of Melting Bodies. Third U. S. Congress of Appl. Mech., Brown U., June 1958). For this equation, assumptions were made that once the melting of the surface started, all the heat flux was used in producing molten material, and none of the heat penetrated beyond the melt line into the solid. Distribution of the heat flux along the surface was assumed to be uniform. Now, both restrictions are removed, and heat is allowed to diffuse into the solid as well as to produce melt. The heat flux is distributed according to the laminar boundary-layer theory. The results are worked out in detail for a flat plate. As a consequence of allowing heat diffusion into the solid, there are now 2 concurrent phenomena, for each of which there is an associated rate: (1) the rate of heat diffusion into the solid, and (2) the rate at which a quasi-steady-state ablation process is established. For purposes of computing the rate at which molten material is ablated from a body, the simple quasi-steady theory is adequate except at very early time. (Contractor's abstract)

THE MELTING OF FINITE SLABS, by T. R. Goodman and J. J. Shea. Aug. 15, 1958, 40p. incl. diags. (AFOSR-TN-58-824) (AF 49(638)347) AD 202908; PB 138064 Unclassified

Presented at West Coast conf. of the Amer. Soc. Mech. Engineers, Stanford, Calif., Sept. 9-11, 1959.

Also published in Jour. Appl. Mech., v. 27: 16-24, Mar. 1960.

An approximate method, known as the heat balance integral, is used to determine the melting rate of a finite slab which is initially at a uniform temperature below the melting point. The slab is acted upon by a constant heat input at one face and has its other face either insulated or kept at its initial temperature. The first three terms of series solutions in an intrinsically small parameter are obtained for the time histories of melting and the temperature distribution in the slab. (Contractor's abstract)

PHYSICS OF FLUIDS, ed. by F. N. Frenkiel. 1958-1960. (AF 49(638)275) Unclassified

This publication is devoted to original contributions to the physics of fluids covering kinetic theory, statistical mechanics, structure and general physics of gases, liquids, and other fluids, as well as certain basic aspects of the physics of fluids bordering geophysics, astrophysics, biophysics, and other fields of science. The scope of these fields of physics includes: magneto-fluid dynamics, ionized fluid and plasma physics, shock and detonation wave phenomena, hypersonic physics, rarefied gases and upper atmosphere phenomena, physical aeronomy, transport phenomena, hydrodynamics, dynamics of compressible fluids, boundary layer and turbulence phenomena, liquid state physics, and superfluidity. Beginning as a bimonthly publication on January 1958, this journal will become a monthly as soon as it appears desirable.

MATHEMATICS ADVISORY AND EVALUATION SERVICES. Sept. 30, 1957-May 31, 1959. (AF 49(838)-204; continuation of AF 18(800)994) Unclassified

This contract provides for a reviewing panel of outstanding mathematicians in select and specialized areas of mathematics, who evaluate proposals and the research accomplished under contract, upon request. The evaluations are performed on an individual basis, usually by correspondence, for proposals or technical results of a rather complex nature, concerning which the expert advice of mathematicians practicing in that area is desired. Such evaluations form part of the basis on which the overall research being performed under contract is critically analyzed and evaluated. The contract also provides for a permanent panel of six of the world's leading mathematicians to provide a continuing overall appraisal of the Air Force research program in mathematics, to insure that the common interests of the Air Force and the mathematical community are effectively advanced in accord with the best interests of the country.

MATHEMATICAL REVIEWS, ed. by J. V. Wehausen and S. H. Gould. 1949-1958. (AF 49(838)239; continuation of AF 18(600)132) Unclassified

Unavailability of the German comprehensive reviewing and abstracting service for mathematics during World War II caused the American Mathematical Society to start its own abstracting service. This effort was supported in part by the Office of Naval Research (1946-1949) and then by the Air Force Research and Development Command (1949-1958) under what eventually became the Mathematical Sciences Directorate of Air Force Office of Scientific Research. A yearly rate of over 5,000 abstracts has been maintained, amounting to 11 volumes each year. *Mathematical Reviews* is the only comprehensive English language mathematical abstracting service. It covers all fields of mathematics from topology and advanced algebra to mathematical physics and mechanics. It obtains and abstracts all the major and most of the minor mathematical publications in the world and deliberately stresses papers written in Russian and less accessible languages by providing more comprehensive reviews of these papers. *Mathematical Reviews* at the present time uses over 750 reviewers who are the recognized authorities in their respective

CONCURRENT FAT LOSS AND FAT GAIN, by S. M. Garn and R. W. Young. [1956] [8]p. incl. diagrs. table, refs. (AFOSR-TN-57-46) [AF 18(600)1566] AD 115084 Unclassified

Also published in Amer. Jour. Phys. Anthropology, v. 14 (new series): 497-504, Sept. 1956.

The thickness of the subcutaneous fat-plus-skin shadow was measured on standardized teleoroentgenograms of 338 white subjects aged 12.5 to 65 years. As expected, trochanteric fat increased in both sexes with the larger absolute increase observed in the females. Anterior leg fat diminished in both sexes, and to the same degree, reaching a near-minimum in the fourth decade. This phenomenon (fat loss during fat gain) was statistically significant by the F and χ^2 tests and indicated an adult rearrangement of fat. In discussing the subject, attention was called to trend reversals in infancy, at adolescence, and in specific fat depot sites in the adult. No evidence as to the underlying mechanism for this adult rearrangement was found. (Contr ctor's abstract)

ROENTGENOGRAMMETRIC DETERMINATIONS OF BODY COMPOSITION, by S. M. Garn. Dec. 1957 [17]p. incl. diagrs. tables, refs. [AFOSR-TN-57-403] (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1566 and National Institute of Mental Health) AD 132481 Unclassified

Also published in Human Biology, v. 29: 337-353, Dec. 1957.

The weight of fat and the fat-free weight were estimated

on an individual basis for each of 251 adult males and females, using the thickness of iliac crest fat for females and trochanteric fat for males. The study was based upon standardized soft-tissue x-rays of the subjects. The roentgenogrammetric method has the particular advantage of being capable of providing information not only on fat (and therefore the fat-free mass), but also of providing estimates of muscle mass and skeletal weight as well.

ANT.02:006

Antioch Coll. Fels Research Inst., Yellow Springs, Ohio.

AN IMPROVED METHOD OF ESTIMATING BODY FAT CONTENT BY THE USE OF TELEOROENTGENOGRAMS, by S. M. Garn. Final rept. Jan. 9, 1957 [24]p. incl. diagrs. tables, refs. (AFOSR-TR-57-7) (AF 18(600)1566) AD 115085 Unclassified

Soft-tissue teleoroentgenograms were taken on 138 young adult males in order to further improve techniques for the estimation of body fat. A total of 12 fat sites were measured including the lateral and medial arm; deltoid "insertion"; lower thoracic, iliac crest and spine; upper and mid trochanteric; and medial, lateral, anterior, and posterior leg. In general, "central fat" showed the highest correlations with weight and the greatest degree of communality with other fat sites. The results indicate that while multiple sites yield somewhat better estimates of total body fat, the use of one or two sites, highly correlated with weight and showing maximum communality with other fat sites, often may be substituted. Further, one particular site (lower thoracic), while not the best single predictor of body fat, may be of considerable practical importance since this site is easily measured on conventional chest-plates such as are taken in mass radiographic studies.

Antioch Coll. Fels Research Inst., Yellow Springs, Ohio.

SELECTION OF BODY SITES FOR FAT MEASUREMENT, by S. M. Garn. [1957] [2]p. incl. diagr. table. (AF 18(600)1566) Unclassified

Published in Science, v. 125: 550-551, Mar. 22, 1957.

Fat measurements were made on a representative group of young adult American males. From a series of six regions x-rayed, measurements were made at 12 sites. These included the medial and lateral arm, the "pocket" formed by the triceps and deltoid muscles, the lower thoracic site, the iliac crest and spine, the upper and middle trochanteric sites, and the 4 quadrants of the lower leg. All fat thicknesses were positively inter-correlated, with values of r ranging from 0.32 to 0.96. In general, deltoid, thoracic, iliac, and trochanteric fat (areas of "central" fat) showed considerably higher group

intercorrelations than "peripheral" or extremity fat. Correlations with weight were also higher than those for the central fat sites. The iliac spine, mid-trochanteric, and lower thoracic exhibited the greatest degree of communality and the highest correlations with weight. While pelvic fat appears to be the best single predictor of fat in general, as is also true of the older adult male, the lower thoracic site may prove to be of considerable practical use.

ANT.02:008

Antioch Coll. Fels Research Inst., Yellow Springs, Ohio.

FAT WEIGHT AND FAT PLACEMENT IN THE FEMALE, by S. M. Garn. [1957] [2]p. incl. table. [AF 18(600)1566] Unclassified

Published in Science, v. 125: 1091-1092, May 31, 1957.

Standardized soft tissue x-rays were taken on 107 healthy adult American-born women with a mean age of 39 and on 81 healthy adult males with a mean age of 40 years. Fat-shadow measurements were made at the following sites: lateral arm, medial arm, deltoid "pocket", iliac crest, mid-trochanteric, lateral leg, medial leg, anterior leg, and posterior leg. The women exceeded the men in 7 out of 9 fat-plus-skin measurements, with female/male ratios for subcutaneous fat up to a median value of 1.89. From the intercorrelation matrices, trochanteric fat emerged as the best single predictor of total fat for adult males; iliac crest fat had the greatest communality with other fat sites for the female. Prediction estimates on an individual basis indicated a median weight of fat for females of 13.7 kg, not markedly greater than the median of 12.6 kg for the males. Estimates based on other central fat sites were very similar. Relative to the total weight, the sex difference was marked. The % of fat was estimated as 23.7 for the females and 16.8 for the males. Since female subcutaneous fat thicknesses were generally greater, but total fat was not notably different, it follows that the sex difference in the proportion of outer and inner fat is considerable. Women carry more fat on and less in their smaller frames.

STUDIES OF THE DETERMINATION OF GERMANIUM BY THE HETEROPOLY BLUE METHOD, by E. R. Shaw and J. F. Corwin. Apr. 15, 1957 [16]p. incl. diagrs. table, refs. (Technical note no. 1) (AFOSR-TN-57-195) (Also bound as Appendix 1 with its AFOSR-TN-57-428; AD 136417) (AF 18(600)1490) AD 126490; AD 136417a Unclassified

Also published in Anal. Chem., v. 30: 1314-1316, Aug. 1958. (Title varies)

The cause of the up to 100% variation in absorbancies found when identical samples were analyzed for GeO_2 by the heteropoly-blue molybdate complex method was traced to the differences in individual interpretation of the literature-recommended time interval between the addition of the molybdate and the reductant. By a time study, the optimum interval was selected, and the best acid and molybdate concentrations were determined with the result that different operators can obtain results which agree within 5%. THE PHYSICAL CHEMISTRY OF WATER SOLUTIONS AT HIGH TEMPERATURES AND PRESSURES. Technical rept. [1957] 1v. incl. illus. tables, refs. [Technical note no. 2] (AFOSR-TN-57-428) (AF 18(600)1490) AD 136417 Unclassified

Research was conducted on 3 aspects of H_2O solutions.

(1) The GeO_2 - H_2O system: The possibility of producing new crystalline forms of GeO_2 was investigated by the hydrothermal process. The reactions of H_2O with GeO_2 resulted in formation of soluble or insoluble forms of GeO_2 . The reactions of basic solutions (NaOH) produced 2 uncharacterized forms, $\text{Na}_2\text{Ge}_4\text{O}_9$ and $\text{Na}_3\text{HGe}_7\text{O}_{16} \cdot 4\text{H}_2\text{O}$. The 2 forms were described from a crystallographic viewpoint and a mechanism was proposed for their formation. (2) Conductivity of H_2O solutions: A number of autoclave modifications were tested for hydrothermal measurements at and above the critical temperatures. Only one modification (i.e. autoclave with spark plug) was successful, and measurements indicated either a 2-phase system or a density gradient above the critical point. As the solution charge increased the system became more homogeneous. (3) Reactions of SiO_2 and H_2O solutions: Reactions of $\text{Ca}(\text{OH})_2$ and SiO_2 were investigated under controlled conditions. The reaction involved a slow devitrification of silica glass which added a regulated amount of SiO_2 to the solution. The mechanism consisted of the formation of xonotlite, $5\text{CaO} \cdot 8\text{SiO}_2 \cdot \text{H}_2\text{O}$, then amorphous SiO_2 which transformed to β -cristobalite and finally to α -cristobalite. The reactions of $8\text{r}(\text{OH})_2$ with SiO_2 were investigated. The reactions and mechanism were approximately the same as those for $\text{Ca}(\text{OH})_2$. The α -quartz-cristobalite transformation was sensitive to the pH of the solution and to the presence of certain ions which on hydrolysis form sufficient OH to cause silica glass to be transformed either into cristobalite or α -quartz. FACTORS GOVERNING THE HYDROTHERMAL FORMATION OF CRISTOBALITE AND QUARTZ, by R. G. Yalman. [1957] [15]p. incl. diagrs. tables. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)1490] and Signal Corps under [DA 36-039-sc-64605])
Unclassified

Published in Proc. Eleventh annual Symposium on Frequency Control, Asbury Park, N. J. (May 7-9, 1957), Ft. Monmouth, N. J., Army Signal Engineering Labs., 1957, p. 142-156.

In studying the hydrothermal growth of quartz under isothermal conditions good results were obtained at 400° in a bomb 50% filled with 40M solutions of various compounds. Nutrient solutions used were Ca(OH)₂, NaF, Na₂SO₄, CaSO₄, H₂SO₄, HCl, pure H₂O, and NaOH. The following conclusions were established: (1) devitrification takes place in weakly alkaline solutions with the formation of cristobalite and in stronger alkaline solutions with the formation of quartz; (2) the specific mineralizing properties of individual ions are due to the hydrolysis of these ions with the subsequent formation of hydroxide ion; and (3) the formation of insoluble oxides or silicates decreases the hydroxide ion concentration of the nutrient solutions at 400° causing a corresponding decrease in devitrification of silica glass and in the formation of cristobalite and quartz. The hydrothermal reactions between dilute water solutions of earth metal oxides and silica glass were studied under carefully controlled experimental conditions at temperatures and pressures well above those associated with the critical conditions for water and water solutions. Under these conditions calcium and strontium oxides reacted rather rapidly with the silica and the reaction products, calcium and strontium silicates, were sufficiently soluble in water so that the silica glass continued to devitrify. The oxides of barium and magnesium reacted much less rapidly and

beryllium oxide almost not at all. Barium and magnesium oxides form coatings on the silica surface that inhibit further reaction. The beryllium oxide does not react with silica under these conditions. (Contractor's abstract)

The hydrothermal reactions of silica glass have been studied under isothermal conditions at 400°C and 5000 psi. The results indicate that no reaction occurs with sulfuric, phosphoric, and hydrofluoric acids, in potassium hydrogen sulfate solutions or in pure water. In weak sodium hydroxide solutions silica glass devitrifies to form cristobalite, and in stronger sodium hydroxide solutions quartz is formed. The mechanisms of these

ANT.03:007 - ANT.03:010

reactions involve the trihydrogen and dihydrogen silicate ions. Similar results are obtained with increasing pH in buffered phosphate, sulfate, and fluoride solutions. The formation of quartz and cristobalite in these solutions is due to the hydrolysis of the anions present. There is no evidence that hydrothermal reactions of silica glass at 400°C in fluoride containing solutions are due to the formation of the fluosilicate ion. (Contractor's abstract)

Studies were made of the effect of F^- on the crystallization of cristobalite and quartz under isothermal conditions at 400° and 350 atm and of the stability of SiF_6^{2-} at room temperature. Studies indicated that the mineralizing action of F^- is due to the hydrolysis of F^- and not to the formation of SiF_6^{2-} . The concentration of the OH^- formed during hydrolysis determines the kind of crystalline SiO_2 produced. In essentially neutral or acid

solutions, including HF, neither cristobalite nor quartz is formed. Cristobalite is the main product when the amount of OH^- formed is 0.005 M or less. At higher concentrations quartz is the primary product. (ASTIA abstract)

HYDROTHERMAL REACTIONS UNDER SUPER-CRITICAL CONDITIONS. V. REACTIONS BETWEEN SILICA AND ALKALINE EARTH METAL SALTS, by J. F. Corwin. [1958] [3]p. incl. tablee. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1490 and Signal Corps under DA 38-039-sc-64605) Unclassified

Published in Jour. Phys. Chem., v. 62: 1086-1088, Sept. 1958.

The reaction of dilute solutions of the salts of the alkali earth metals with silica has been investigated by using the devitrification of clear fused quartz as a measure of the rate of reaction, and x-ray, optical and chemical analysis as a measure of the structure of the crystallized material. By carrying out these reactions under controlled conditions using compounds of the alkaline earth metals it has been found that the crystalline structures resulting from the reactions of these solutions vary in a systematic way from α -cristobalite and several other modifications of the silica structure to silicate minerals. The rate of reaction and the formation of crystalline structures are correlated with the initial pH of the solution and the relative dimensions of the ions involved. On the basis of these correlations, the natural occurrence of α -quartz and talc is inferred since the concentration of these dilute solutions is quite similar to that of ground water. The current status of fundamental and technological researches on flame stabilization is reviewed. From the technological viewpoint, the dependence of stability limits on combustible temperature, pressure, velocity, mixture ratio, and flameholder size can be described in terms of scaling parameters; no systematic correlations are available for the description of the variation of stability limits with burner/flameholder geometry, inlet turbulence, or other inlet inhomogeneities. From the fundamental viewpoint, the gross features of the aerodynamic, thermal and chemical structure of the stabilizer wake have been identified. While the fundamental researches have led to a reasonably clear understanding of the flame stabilization mechanism, technical flame holder design and development have benefited only indirectly from the results of the fundamental investigations.

Also published in Combustion and Flame, v. 1: 438-451, Dec. 1957.

An energy balance equation for the flame front relates the actual flame temperature T_f to the adiabatic temperature T_f^a and a heat loss parameter λ . From this equation real values of T_f are possible only for limited ranges of T_f^a and λ , depending on the character of the heat loss mechanism. Flame propagation limit criteria are deduced for the special cases of (1) convective heat loss applicable to flame quenching in a circular tube, and (2) radiative heat loss applicable to free flames near the composition limit. Illustrative numerical applications are made to hydrocarbon/air data. The theoretical results for both quenching and composition limits are in satisfactory agreement with the observed data.

Presented at meeting of the Phys. and Inorg. Chem. Div. of the Amer. Chem. Soc., Miami, Fla., Apr. 7-12, 1957.

Abstract published in 131st meeting of the Amer. Chem. Soc. Abstracts of Papers, 1957, p. 36R.

Also published in Jour. Phys. Chem., v. 62: 385-390, Apr. 22, 1958.

In Part II of this series the cell $Ag/AgCl, KCl/Cl_2$ was shown to behave reversibly from pure $AgCl$ to a mole fraction of about 0.05. It was shown that the free energy of dilution of $AgCl$ by KCl is linear with concentration down to the lower value and then drops sharply toward

minus infinity, i.e., thermodynamic functions cannot be obtained for systems which behave irreversibly. In agreement with the results obtained by other authors for the $AgBr-KBr$ system, the AF of dilution in the $AgCl-KCl$ system also deviates negatively from ideality. For the $AgBr-NaBr$ system these authors had already found a positive deviation. It therefore seemed of interest to carry a system showing such deviation to lower concentrations to see if an abrupt reversal of slope would occur at some critical concentration. In the previous paper, some preliminary results were reported that showed silver to react with KCl , the reaction being driven by the distillation of the alkali metal. The fact that the solutions were not stirred constantly prevented us from obtaining accurate rate data. In the present work the kinetics of the reactions $Ag + NaCl \rightarrow AgCl + Na$ are reported in some detail. This type of oxidation-reduction reaction has been used extensively for preparative purposes. For example, metallic sodium has been prepared from its fused halides by reduction with less active metals, the distilled sodium being condensed in cooler portions of the system. A STUDY OF THE SYSTEM $KCl-NiCl_2$, by R. F. Kruh and A. P. Lockhart. [1956] [3]p. incl. diagr. (Bound with its AFOSR-TR-57-5; AD 115070 as Appendix VII) (AF 18(600)960)

Unclassified

A thermal analysis of the system $KCl-NiCl_2$ was undertaken to provide a possible explanation of the color change that results from heating mixtures of nickel chloride and potassium chloride. The change is a striking one from yellow to blue as the temperature rises, and it is reversible. It was felt that this change might have its origin in a crystal transition of a possible compound formed by KCl and $NiCl_2$. Although a compound $KNiCl_3$ appears to be formed it was concluded that (1) there was no thermal indication of a crystal transition for $KNiCl_3$ either above or below the eutectic temperature, viz. $504^\circ C$; and (2) the high vapor pressure of $NiCl_2$ made it impossible to complete the phase diagram in the apparatus used. HIGH-TEMPERATURE CHEMISTRY OF FUSED SUBSTANCES, by R. F. Kruh. Final rept. Mar. 1, 1957, iv. incl. diagrs. tables, refs. (AFOSR-TR-57-5) (AF 18(600)960) AD 115070 Unclassified

Work under the contract consisted of 4 general areas: (1) high-temperature electrochemistry, (2) the thermodynamics of ion-pair formation, (3) the stereochemistry of complex ions, and (4) molten-state reactions. Studies were made on fused-salt solutions by measurements with galvanic cells and on their reactions with metals. These reactions, mainly between Ag and NaCl, were classified in table form. Experiments were performed on electrolyte-solvent interactions in solvents with low dielectric constants and the thermodynamic functions calculated. Ion orientation in high-temperature modifications of alkali-metal bifluorides was found to involve randomization rather than free or hindered rotation. Appendices are included containing technical reports and reprints of published articles.

ISOTOPE SHIFTS IN THE MoI SPECTRUM (Abstract), by R. H. Hughes. [1957] [1]p. [AF 18(603)26] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 200, Apr. 25, 1957.

The isotope shift in MoI $4d^4 5s^2 \ ^3D_4 - 4d^5 5p \ ^3P_3^0$ transition at $\sigma = 16\ 577$ kayzers ($\lambda = 6031\text{\AA}$) has been studied in the hollow cathode spectrum from enriched even isotopes with a Fabry-Perot interferometer. The 94 - 92, 96 - 94, 98 - 96, 100 - 98, and 100 - 92 shifts in millikayzers are -25.8, -18.5, -12.0, -26.0, and -83.9, respectively. The minus sign indicates a shift in the field effect direction. The estimated limit error of the measurements is ± 1.5 mK. The direction of the variation in the shifts was predicted by the position of the first excited states and the electric quadrupole transition probabilities as measured by Coulomb excitation when these quantities are related to the isotope shift through the intrinsic deformation of these even-even nuclei. The

magnitude of these variations is smaller, however, than would be expected in terms of the deformation parameters as calculated by Heydenburg and Temmer.

THE EFFECT OF THE SELF-MAGNETIC FIELD UPON THE CHARACTERISTICS OF A POSITIVE COLUMN IN THE GENERAL CASE, by M. Hoyaux and P. Gans. [1954] 14p. incl. diagrs. (Rept. no. EOARDC-TN-54-2) [AFOSR-TN-57-271] (AF 61(514)630-C) AD 126573 Unclassified

The motion of the charge carriers in the positive column of an electrical discharge in a gas is investigated, taking into account the forces due to the self-magnetic field of the arc and considering the general case in which no particular symmetry is assumed for the system. An expression for the mean drift velocity of the charge carriers is established, taking into account the principle of ambipolar diffusion. This also enables the component of the electric field in the direction of the ionization density gradient to be found. In a previous investigation (ATE.01:001) of a discharge in which the self-magnetic field is assumed to be negligible, it was found that the component of the electric field perpendicular to the ionization density gradient derived from a potential which was called the primitive potential. In this paper, the condition that a primitive should exist in the general case is examined. The resulting condition seems to have no immediate physical interpretation and needs to be examined in detail for each particular geometry considered. Finally, the fundamental equations for the energy balance of the electrons and the conservation of charge are established together with the equation of continuity. These results are generalizations of those previously obtained for the case in which the self-magnetic field is neglected. (Contractor's abstract)

PRELIMINARY EXPERIMENTS WITH AN IMPROVED TYPE OF PLASMOGRAPH, by M. Hoyaux and P. Gans. [1955] iv. incl. diagrs. (Rept. no. EOARDC-TN-55-1) [AFOSR-TN-57-272] (AF 61(514)630-C) AD 66706 Unclassified

An improved type of plasmograph having an extremely low resolving time of the order of 2 μsec is described. This instrument permits the measurement of Langmuir

ATE.01:012 - ATE.01:014

probe characteristics for a discharge excited by an alternating electric field. It functions by selecting one point on the probe characteristic during each cycle of operation. The probe potential is varied between cycles so that a different point on the characteristic is recorded on each successive cycle. It is, of course, necessary that the point observed on each cycle should correspond exactly to the same instant in phase. In this way, the characteristic corresponding to that instant in phase is obtained. By varying the phase at which the points are observed, the probe characteristics, and hence, the plasma parameters can be obtained for the whole cycle of operations. Preliminary experiments have been carried out in order to evaluate the performance of the plasmograph. The results are extremely interesting although the experiments are not sufficiently extensive to permit definitive conclusions to be drawn. It appears, however, that during the striking of the arc, a series of waves of ionization travels along the tube with a velocity of the order of some 100's of m/sec.

negligible. The effect was in the direction of a decrease in the arc drop as was the case for the effect of the self-magnetic field alone. The cause for the observed increase in arc drop for heavy current was undetermined. (ASTIA abstract)

THE INFLUENCE OF THE GVOSDOVER EFFECT UPON THE CHARACTERISTICS OF A POSITIVE COLUMN WITH AXIAL SYMMETRY IN THE DOMAIN IN WHICH THE SELF-MAGNETIC FIELD IS IMPORTANT, by M. Hoyaux and P. Gans. [1955] [49]p. incl. diagrs. tables, refs. (Rept. EOARDC-TN-55-4) [AFOSR-TN-57-274] (AF 61(514)630-C) AD 80099

Unclassified

A theoretical study has been conducted on the influence of the scattering of the electrons in the discharge by the coulomb microfield of the positive ions (Gvosdover Effect). This effect opposes the autostrictive effect of the self-magnetic field, and it is found that the radial distribution of the charge carriers tends more closely to that observed at low current densities (a zero order Bessel function) than if the self-field is considered to act alone. The integrodifferential equations for the case of a positive column with axial symmetry have been set up and solved numerically by means of punched-card machines. On the basis of these results, a graphical method has been developed for the determination of the arc drop in practical cases. The values of the axial electric field are found to increase with increasing current, the increases being in order of magnitude agreement with those observed experimentally upon mercury-arc rectifiers. THE EFFECT OF THE IONIZATION DUE TO ATOMS IN A METASTABLE EXCITED STATE UPON THE CHARACTERISTICS OF A POSITIVE COLUMN WITH AXIAL SYMMETRY, by M. Hoyaux and P. Gans. [1955] [47]p. incl. diagrs. tables. (Rept. no. EOARDC-TN-55-3) (AFOSR-TN-57-273) (AF 61(514)630-C) AD 80098

Unclassified

Previous investigation of the effect of the self-magnetic field upon the characteristics of a Hg-vapor arc is extended to the case in which the ionization due to the presence of Hg atoms in metastable excited states in the plasma is not negligible. Hg has a metastable excited state whose energy is more than half the ionization potential. The following types of processes involving these atoms were considered to lead to the creation of ion-pairs: (1) collisions of the second kind between 2 atoms in metastable states, and (2) direct ionization of an atom in a metastable state by collision with a free electron. The contribution of these 2 processes to the resultant ionization density was considered and an integro-differential equation was set up which takes into account both this effect and that of the self-magnetic field. This equation involves a parameter (A) which measures the influence of the self-field, and another (B) which measures the contribution due to the metastable atoms. The equation was solved numerically by means of punched card machines for a range of values of the 2 parameters. A set of nomographs were plotted, based on these solutions, which enable A and B and the electron temperature to be determined for given values of the discharge parameters. The graphs indicate that in the range of pressures, etc. normally used in practical Hg arc rectifiers, the influence of the metastable atoms upon the value of the arc drop is

A stroboscopic method has been employed to study the propagation of luminous fronts in fluorescent tubes both on striking and at extinction. The method is essentially that described previously by Ledrus. Measurements have been carried out on tubes with walls of "conducting" glass and of normal glass. There was no difference in the results with the limits of experimental error. On striking the tube, it was found that the luminous front, if it exists, is propagated with a velocity much greater than the maximum detectable by this method. This maxi-

ATH. 01:001; ATL. 01:002;
ATL. 02:001

imum velocity is of the order of 50 km/sec. On extinction, luminous fronts leave the anode and cathode simultaneously with velocities of the order of 3 km/sec. They accelerate as they move towards the center and their velocities become unmeasurable. The dependence of the velocity on the wall temperature was investigated. The velocity was found to increase with increasing wall temperature. A theoretical interpretation of the behavior of the "extinction" fronts is suggested based on the decay of the residual ionization in the reverse half cycle. (Contractor's abstract)

Experiments were conducted to determine the characteristic temperature (θ) of various elements. The method consists in scattering a pencil of x-rays on the material under consideration and measuring the intensity of the diffracted rays. The integrated intensity of diffraction lines (111) and (422) of Ag was measured at 6 different temperatures between 81° and 774°K. The temperature of each measurement was determined from the angular shift of the diffraction line (422). By applying the formula of the usual Debye theory to each neighboring pair of temperatures a value of θ was obtained. Each value of θ corresponds to a temperature which lies at the middle of the temperature interval. The temperatures and the corresponding values for θ were as follows: (1) 136°K and 202; (2) 243°K and 233; (3) 405°K and 200; (4) 592°K and 178; and (5) 726°K and 121. For temperatures below 200°K, specific heat measurements can be used; they give values of θ around 215. Above 200°K, the specific heat measurements do not give accurate results. At higher temperatures, θ can be determined only from x-ray experiments. Measurements by Andriessen (Physica, v. 2: 417, 1935) gave a constant value of θ - 218 up to 670°K. An apparatus similar to that used for the Ag measurements was used on W at above room temperatures. The surface oxidized rapidly and all intensities gradually diminished. The difficulty was overcome by heating in a stream of hot CO₂. (Contractor's abstract, modified)

Thermocouples have been fabricated of wire as small as 7.6 μ diameter and embedded in composite and double-base solid propellants. The propellants were ignited at high pressures and as the burning surface passed the thermocouple junction emf-vs-time curves were obtained simultaneously with high-speed motion pictures of the burning. It has been hoped that burning-surface temperatures could be obtained by refinement of such techniques, but the experimental difficulties, primarily thermocouple breakage and optical problems, showed that it is not practical to embed and observe sufficiently small thermocouples for the degree of space resolution which is required, at least for composite propellants oxidized with ammonium perchlorate. Also published in ARS Jour., v. 29: 275-283, Apr. 1959.

A two-dimensional open burner has been developed for studying turbulent flames. Stoichiometric natural gas-air flames with inlet flow velocities of 15, 20, 30 and 40 ft per sec were investigated. Densitometer traverses of time exposures were used to locate the position of the mean flame front and its root-mean square displacement. Flash tube exposures of the flame with one micron magnesium oxide particles in the flow were taken to determine the flow lines into and through the flame front. The large reduction of brightness that occurred when the flow passed through the flame front, due to the reduction of particle concentration, shows clearly the outline of the instantaneously wrinkled flame front and the islands of unburned gas often present in the burned gas. From the intercepts of the flow lines and the mean flame front, the local turbulent flame velocity along the flame front was calculated. The turbulent flame velocity increased rapidly with distance above the burner rim. The flame velocity increase can be entirely accounted for by flame wrinkling. Both this result and the appearance of the flash tube photographs, showing the instantaneous flame front, support the wrinkled flame concept of turbulent flame propagation. (Contractor's abstract)

ON HYPERSONIC BLUNT-BODY FLOW WITH A MAGNETIC FIELD, by N. H. Kemp. Feb. 1958, 11p. incl. diags. (Research rept. no. 19) (AFOSR-TN-58-437) (AF 49(638)61) AD 205520 Unclassified

Also published in Jour. Aeronaut. Sciences, v. 25: 405-407, June 1958. (Title varies)

The purpose of this note is to present the effect of a magnetic field on the inviscid flow near the stagnation point of a blunt axisymmetric body in the practical case of small magnetic Reynolds number. It is stated that the main effect of the magnetic field is to change the inviscid rather than the viscous flow. This will make possible a prediction of the change in heat transfer and pressure drag caused by the field. The method used to analyze the flow is that introduced by Lighthill. In such case a spherical shock shape and incompressible flow are assumed.

TWO-DIMENSIONAL INCOMPRESSIBLE MAGNETO-HYDRODYNAMIC FLOW ACROSS AN ELLIPTICAL SOLENOID, by N. H. Kemp and H. E. Petschek. Apr. 1958, 66p. incl. diags. (Research rept. no. 26) (AFOSR-TN-58-438) (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)61 and Air Force Ballistic Missiles Div. under AF 04(645)18) AD 159613 Unclassified

Also published in Jour. Fluid Mech., v. 4: 553-564, Nov. 1958.

An analysis has been made of the two-dimensional flow of an incompressible, constant-conductivity fluid through an elliptically-shaped solenoid containing a constant magnetic field directed normal to the flow plane. The effect of both Hall current and ion slip has been included in the Ohm's Law used for the fluid. The analysis was performed by means of a perturbation procedure in two parameters, one being the magnetic Reynolds number R_m and the other the ratio of magnetic force per unit area to dynamic pressure, S . Calculations were carried through the first order in each parameter, and closed-form analytic expressions were obtained for the force and moment on the solenoid, the current density, stream function, magnetic field and other pertinent physical quantities. It was found that for the zero order, there is a force but no moment on the solenoid. For the first order in S , where the flow field changes but the magnetic field does not, there is a moment and a force, the latter being antiparallel to

the zero order force. For the first order in R_m , where the magnetic field changes but the flow field does not, there is a moment, but no force. Thus, through the first order the lift to drag ratio is the same as the zero order. (Contractor's abstract, modified)

THE PRODUCTION OF HIGH TEMPERATURE GAS BY MAGNETIC ACCELERATION, by G. S. Janes and R. M. Patrick. Mar. 1958, 13p. incl. illus. diags. (Research rept. no. 27) [AFOSR-TN-58-439] (AF 49(638)61) AD 205519 Unclassified

This preliminary study in the field of gaseous magneto-hydrodynamics is focused on the electrical conductivity of high-temperature gases which allows the application of forces by means of rapidly changing magnetic fields. With this effect in mind, two experiments for studying the dynamic interactions of high-temperature gases with magnetic fields are described. The first experiment entails the use of an electrodeless gas accelerator. In conjunction with this, an inductive energy source is employed. The second introduces electrodes. It is concluded that the latter experiment, utilizing the above device, is more desirable than the former since: (1) the Phillips ionization gauge effect allows efficient preionization at low pressures; (2) the plasma and current-carrying gas are confined by the axial magnetic field, thus eliminating contamination from the walls; (3) the magnetic field follows the gas slug down the tube in an efficient manner, thus minimizing power requirements; and (4) more adequate time and space are available for experimental observations. Preliminary results indicate that a plasma sample has been obtained where the ion armor radius is less than the mean free path which in turn is comparable with the annular separation distance.

Also published in Vistas in Astronautics, v. 2: 118-126, 1958.

A propulsion motor for space ships is described which

AVC.01:005 - AVC.01:007

produces thrust by using a magnetic field to expel a plasma. It is pointed out that the main difference between this magnetic accelerator and the ion rocket is that the magnetic device produces an electrically neutral plasma as the accelerated mass, while the ion rocket accelerates a charged mass. Experiments have been carried out using a model of this device. The results of these experiments as well as application of these results to an actual propulsion motor are discussed. A comparison between this magnetic accelerator and other means of acceleration, in particular ion rockets, is made. Furthermore, it is pointed out that the mass of the capacitors which furnish the accelerating current for the magnetic device accounts for the major portion of its total mass. REDUCTION OF FLIGHT TIME AND PROPELLANT REQUIREMENTS OF SATELLITES WITH ELECTRIC PROPULSION BY THE USE OF STORED ELECTRICAL ENERGY, by M. Camac. Oct. 1958, 26p. Incl. diags. (Research rept. no. 36) (AFOSR-TN-58-1013) (AF 49-638)61 AD 206156; PB 138439 Unclassified

Presented at Thirteenth annual meeting of the Amer. Rocket Soc., New York, Nov. 17-21, 1958.

Flight plans are analyzed for satellites having a lower thrust than the local gravitational forces. Electrical propulsion near the earth is a good example of such a system. Several missions in the gravitational field of the earth were considered and the payload mass ratio was compared as a function of the flight time when electrical propulsion is used. Two types of missions were analyzed in detail: (1) A trip from a small to a larger circular orbit and subsequent return to the earth, and (2) navigation between orbits at low altitudes. For trips starting from a low circular orbit to a larger circular orbit and subsequent return to the earth, the incorporation of electrical energy storage was shown to reduce the flight time while increasing the payload mass ratio. For making a rendezvous or similar trips at essentially the same altitude, the advantage of the electrical storage shows up quickly. The flight plans for most of these missions require that impulses be applied at only definite regions of the orbit and free flight the rest of the way. This includes missions requiring a change in the orbit plane. A transfer from a circle to an ellipse or from one ellipse to another requires that impulses be applied at limited portions of the orbit. The storage of energy permits the utilization of all the available energy thereby substantially reducing the time for a given maneuver.

ELECTRIC ARC GAS HEATERS FOR RE-ENTRY SIMULATION AND SPACE PROPULSION, by T. R. Brogan. Sept. 1958, 29p. Incl. illus. diags. (Research rept. no. 35) (AFOSR-TN-58-1081) (Sponsored jointly by Air Force Office of Scientific Research under AF 49-638)61 and Air Force Ballistic Missile Div. under AF 04(645)18 AD 205516 Unclassified

Presented at Thirteenth annual meeting of the Amer. Rocket Soc., New York, Nov. 17-21, 1958.

Because the available test time is limited, questions involving the exposure of materials to the high energy re-entry environment cannot be answered in contemporary quasi-steady sources of high temperature air. This paper describes the development and calibration of an arc powered wind tunnel designed to provide steady flow simulation of the conditions encountered during re-entry. Flight velocities between 16,800 and 21,800 ft/sec can be simulated with this device. The flow properties in the tunnel test section can be determined to a degree of accuracy sufficient for quantitative experiment. Use of the arc as the gas heater for an electrically propelled space vehicle is discussed. The results of a preliminary study of helium as an arc-heated propellant are presented. A METHOD OF ACCELERATING A GAS TO HIGH VELOCITIES WITH A MAGNETIC FIELD (Abstract), by R. M. Patrick. [1958] [1]p. [AF 49(638)61] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 39, Jan. 29, 1958.

A coaxial cylindrical geometry has been used to accelerate a gas between two conducting cylinders. The acceleration mechanism works as follows. A low-frequency (1 kc) discharge through a solenoid placed around the coaxial cylinders produces a uniform magnetic field in the axial direction inside the cylinders. At the time of maximum axial field strength a discharge between the two cylinders is initiated from a condenser bank with a ringing frequency of over 200 kc. The body force due to the radial current between the two cylinders and the azimuthal magnetic field produced by the current flowing in the cylinders results in an acceleration away from the point of initial breakdown in the axial direction.

Conditions have been produced where the mean free path for ions and electrons is longer than their gyro radius in a magnetic field, and with the mean free path small compared to the radial distance between the cylinders. Measurements have been made of the light emitted by the accelerated gas, the local magnetic field strength, the radial gas current, and the velocity of the gas.

APPLICATION OF MAGNETOHYDRODYNAMICS TO FLIGHT (Abstract), by T. [R.] Brogan, A. Kantrowitz and others. [1958] [1]p. [AF 49(638)61] Unclassified

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 288, June 19, 1958.

The interest in magnetohydrodynamics (MHD) has been spurred primarily by astrophysical problems and by problems associated with the fusion reactor. More recently it has been suggested that MHD may be applicable to high-speed flight problems. The fundamental advantage offered by MHD is that it becomes possible to exert forces on a fluid without the use of solid surfaces and hence, for example, avoid the high heat transfer encountered in hypersonic flight. The primary factor limiting the range of applicability of MHD is the magnitude of the electrical conductivity that it is possible to induce in the air stream. If one assumes conductivities corresponding to those produced by bow shock waves on an object, one can outline flight regions in which MHD devices should be superior to conventional aerodynamic shapes. These regions are of rapidly increasing importance since they include, among other things, the critical parts of satellite re-entry trajectories. The results of some preliminary calculations and experiments on MHD flow properties are also presented.

MAGNETOHYDRODYNAMICS (Abstract), by H. E. Petschek. [1958] 2p. (Bound with its AFOSR-TR-58-125; AD 162274) (AF 49(638)61) Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

A summary is presented of the research performed by the contractor on the fundamental properties as well as the practical applications of magnetohydrodynamics (MHD). MHD forces have been studied in argon using a conventional high temperature shock tube. Experiments on 1 and 2 dimensional flow of a gas through a magnetic field have demonstrated that lift as well as drag forces can be obtained. Preliminary investigation of arc jets and MHD generators has indicated their practical incorporation in space propulsion systems. A minimum of 50% efficiency was obtained in operating arc jets in He up to specific impulses of 1100 sec. Theoretically the MHD generator would consist essentially of a flow of hot gas with a magnetic field perpendicular to the flow. Thermal energy in the generated currents would be converted directly into electric power by electrodes. Such a generator (1) would achieve considerable increase in specific power output (for levels exceeding several megawatts), (2) could be operated at higher temperatures than a turbine generator, and thus (3) would require a smaller radiator. Theories and initial results are also presented of experiments on gas properties and MHD forces at temperatures up to 10^6 K.

TORSIONAL MAGNETO-HYDRODYNAMIC WAVES IN THE PRESENCE OF FINITE VISCOSITY, by E. Blue. Jan. 15, 1957, 95p. incl. diagrs. tables, refs. (Technical note no. 1 (Type 2)) (AFOSR-TN-57-57) (AF 18-(600)1041) AD 115096
Unclassified

The purpose of the present investigation was to carry out the solution of an idealized boundary value problem corresponding to an experiment involving the generation of a system of torsional magneto-hydrodynamic waves in liquid sodium in the presence of finite viscosity. In addition, the analysis of the solution of the problem led to the formulation and design of "ideal" experiments which would provide suitable tests of the linearized theory. The original experiment was performed in Sweden by Lehnert who obtained theoretical results based on zero viscosity. These results exhibited an apparent systematic discrepancy with experiment. In order to account for this discrepancy the theory of viscous torsional magneto-hydrodynamic waves is developed. The introduction of viscosity gives rise to a higher order differential equation and hence an additional set of modes which do not appear in Lehnert's formulation. The numerical computations are carried out on the U. C. L. A. high speed digital computer (SWAC). With the aid of SWAC, the effect of including finite viscosity as well as the effect of changing various physical and geometric parameters is studied. It is found that including viscosity in the formulation has a negligible effect. The theoretical formulation obtained in the limiting case of zero viscosity agrees with Lehnert's nonviscous formulation. However, the numerical results using Lehnert's parameters are somewhat improved by the more accurate machine computations and part of the discrepancy between theory and experiment is removed. The remaining discrepancy between the theoretical results obtained and Lehnert's experimental points is attributed to "geometric" approximations, made in formulating the idealized boundary value problem. Since the idealized boundary value problem corresponding to the proposed experiments will involve no "geometric" approximations, it is concluded that these experiments will constitute valid tests of the linearized theory. Theoretical results for these proposed experiments are obtained. (Contractor's abstract)

The theoretical investigation of the soluble unbounded media and boundary value problems involved in these phenomena is restricted (1) to a purely macroscopic approach to serve as a guide in the solution of the more complicated problems of plasma dynamics and (2) to a class of soluble linearized wave propagation problems. The macroscopic medium (homogeneous and isotropic) is characterized by the constant parameters μ , ϵ , and σ , where $\mu\epsilon = c^{-2}$ and σ is the (ohmic) conductivity. The modes of propagation are examined for 5 cases: (1) an ideal incompressible fluid, (2) an ideal compressible fluid subject to adiabatic processes, (3) an ideal elastic solid, (4) an incompressible fluid with finite viscosity, and (5) a compressible fluid with finite viscosity and heat conductivity. A study of the energy and momentum balance in a magneto-hydrodynamic field resulted in the derivation of a heat diffusion equation in a compressible fluid with finite viscosity and heat conductivity.

A method was developed for measurement of the Hall effect and mobility at 80°K on InSb ingots. The method made use of 4 probes arranged in a diamond array. Two probes parallel to the ingot axis measure the resistivity voltage in the direction of current flow, and the 2 probes perpendicular to the ingot axis measure the Hall voltage. The element purification and zone-refining techniques resulted in a n-type carrier concentration in the 10^{13} /cu cm range. Total ionized impurity contents of about 1×10^{14} /cu cm (electron mobilities of 500,000 at 77°K) were obtained by a fractional reprocessing technique. Initial attempts to obtain large single crystals revealed difficulties caused by nitrides or oxides floating on the surface of the melt. An effective method was devised for eliminating the oxide from the seed by lowering the seed into molten InSb. Studies of a new thermomagnetic effect indicated that galvanometric and thermomagnetic measurements made with the specialized boundary conditions of zero transverse electric fields and thermal gradients are useful in determining (1) the mobility and concentration of the electrons and holes and (2) the position of the Fermi level with respect to the conduction and the valence band, and (3) the energy band separation in intrinsic InSb. The measurements showed promise of being a sensitive method of determining the amount of impurity or electron-hole scattering. A study was made of the magnetic field dependence of the Hall coefficient in InSb.

the weak field plateau of the Hall coefficient is determined experimentally. It has previously been pointed out that the weak field Hall coefficient as a function of the amount of ionized impurity scattering has a minimum at approximately $\beta = 0.87$, where $\beta = 6\mu_L/\mu_1$. Calculations show that inclusion of the second band increases the value of β at which this minimum occurs, and also augments its depth. These predictions are compared with the experimental data.

EFFECTS OF IONIZED IMPURITY SCATTERING ON THE MAGNETORESISTANCE IN GERMANIUM (Abstract), by R. K. Willardson and A. C. Beer. [1957] [1]p. [AF 18(603)39] Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 142, Mar. 21, 1957.

The transverse magnetoresistance effect is analyzed in the region where the scattering mechanism involves both lattice vibrations and ionized impurities. The doubly degenerate valence band model is used, with neglect of the warping of the heavy mass band. Effects of anisotropy are investigated by using an ellipsoid model representative of the conduction band. Results are given in terms of impurity scattering parameters, $\beta = \nu_L/\mu_1$ representative of each band. The factor 6 often used in impurity scattering formulas and obtained by maximizing the non-logarithmic factor in the integrand of the conductivity transport integral in the limit of impurity scattering only is replaced by ν . This parameter is then determined separately for each value ν_L/μ_1 as well as for the Hall and the conductivity transport integrals. Results are compared with data for specimens with acceptor concentrations ranging from 10^{13} to 10^{18} /cm³ and at temperatures between 50 and 300°K. Experimental mobility values were obtained using the strong-magnetic-field limits of the Hall coefficients and the zero-field conductivities.

EFFECTS OF IONIZED IMPURITY SCATTERING ON THE HALL COEFFICIENT IN p-TYPE GERMANIUM (Abstract), by G. L. Kendall, A. C. Beer, and R. K. Willardson. [1957] [1]p. [AF 18(603)39] Unclassified

Presented at meeting of the Amer. Phys. Soc., Oklahoma U., Norman, Mar. 1-2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 97, Mar. 1, 1957.

Experimental studies of the Hall coefficient in single crystals of p-type germanium were carried out in this region of mixed scattering, i.e., where the contribution of both lattice vibrations and ionized impurities must be considered. The magnitude of the impurity scattering was varied both by controlling the temperature and by using specimens of different impurity contents. In particular, data are presented for specimens with acceptor concentrations ranging from 10^{13} to 10^{18} /cm³ and at temperatures between 50 and 500°K. The data are analyzed using the two-band model as applied to hole conduction. In order to simplify calculations,

BAT. 02:004, 005; BAT. 03:001

St. Louis, Mo., Nov. 29-30, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 347, Nov. 29, 1957.

The Hall coefficient was measured as a function of magnetic field from 20 to 20 000 gauss at fixed temperatures in the region between 50°K and 300°K. The n-type InSb had carrier concentrations of about $1 \times 10^{14} \text{ cm}^{-3}$ mobilities of about $5 \times 10^5 \text{ cm}^2/\text{v-sec}$ at 50°K. The corresponding values for the p-type sample were $1 \times 10^{15} \text{ cm}^{-3}$ and $1 \times 10^4 \text{ cm}^2/\text{v-sec}$, respectively. In the extrinsic region, the variation of the Hall coefficient with magnetic field ranged between 5% and 20% for n-type samples, and between 20% and 40% for the p-type. In all samples a broad minimum occurred between 1000 and 10 000 gauss. In the intrinsic range, the variation in the Hall coefficient for the n-type specimens was about 15%. For all specimens at all temperatures used, the absolute value of the Hall coefficient was largest at low fields. Implications of the data are discussed with regard to scattering processes, quantization effects of large magnetic fields, and band structural considerations, including anisotropy and warping of the energy surfaces, and valence band degeneracy.

HALL AND TRANSVERSE MAGNETORESISTANCE EFFECTS FOR WARPED BANDS AND MIXED SCATTERING, by A. C. Beer and R. K. Willardson. Dec. 30, 1957 [30]p. incl. diags. tables, refs. (Technical note no. 1) (AFOSR-TN-58-98) (AF 18(603)39) AD 148147; PB 136193 Unclassified

Also published in Phys. Rev., v. 110: 1286-1294, June 15, 1958.

Evaluation of the transport integrals for warped electron energy bands by a method developed by McClure has been carried out for relaxation times determined by mixed scattering from acoustic phonons and ionized impurities. The analysis involves third and fifth harmonics and coefficients whose values depend on the shape of the energy surface. The Hall and transverse magnetoresistance coefficients are calculated for parameters characteristic of the degenerated valence bands in Ge and Si, as obtained from cyclotron resonance data. For Ge, results are consistent with observation in regard to a density-of-states ratio for fast and slow holes of about 4% and in the occurrence of fine structure, especially a minimum in the Hall coefficient between 1000 and 2000 gauss at 80°K, depending on the impurity content. With parameters representative of Si, substantially different behavior is predicted in line with the experiment. The Hall characteristics indicate smaller effects due to the warping than are found in Ge.

Orientation effects are not examined. The field dependence of the Hall coefficient at 196°K and 300°K could not be interpreted in terms of the model.

INVESTIGATION OF THE EFFECTS OF THE VALENCE BAND DEGENERACY ON THE CONDUCTION PROCESSES IN GERMANIUM, by A. C. Beer, F. J. Reid and others. Final rept. Dec. 31, 1957, 18p. incl. diags. tables. (AFOSR-TR-58-9) (AF 18(603)39) AD 148077; PB 133476 Unclassified

The effects of ionized impurity scattering on the Hall coefficient in p-type Ge were studied. The experimental studies were carried out in the region of mixed scattering where the contribution of both lattice vibrations and ionized impurities are considered. The single p-type Ge crystals were 2 x 2 mm in cross section and about 1 cm long. The Hall coefficient was plotted as a function of magnetic field for a crystal with resistivities of 1 and 14 Ω -cm. The effects of increased impurity scattering lowered the value of a weak-field Hall coefficient. In the comparison of experiments with theory the consistency was good to within approximately 1% in the region preceding the minimum with the choice of parameters indicated. The transverse magnetoresistance effects in p-type Ge were studied. The value of the magnetoresistance decreased with increasing impurity content at all temperatures. The transport integrals were evaluated for warped bands using the method for relaxation times determined by mixed scattering from acoustic phonons and ionized impurities. (Contractor's abstract)

TRANSVERSE MAGNETORESISTANCE AND HALL EFFECT IN N-TYPE InSb, by R. T. Bate, R. K. Willardson, and A. C. Beer. July 15, 1958 [24]p. incl. diags. table, refs. (Technical note no. 1) (AFOSR-TN-58-641) (AF 49(638)222) AD 162173; PB 136148 Unclassified

Also published in Jour. Phys. Chem. Solids, v. 9: 119-128, Feb. 1959.

Data on transverse magnetoresistance and Hall effect are given for fixed temperatures between 50°K and 200°K covering the range from the weak magnetic field region to the strongfield quantum limit in InSb samples of high mobility and sufficient purity that classical statistics are applicable. At weak fields, results are in semiquantitative agreement with predictions of theory based on a simple mixed scattering mechanism and a spherical conduction band. At the highest fields, the transverse magnetoresistance data approach the H^2/T behavior expected on the

BAT.03:002-004; BAY.01:001

basis of the quantum treatment of Argyres and Adams [Phys. Rev., v. 104: 900, 1956], and the result in the quantum limit for the purest specimen shows good agreement with the theory for reasonable values of the electron effective mass. (Contractor's abstract)

sponding values for the p-type sample were $1 \times 10^{15} \text{ cm}^{-3}$ and $1 \times 10^4 \text{ cm}^2/\text{v-sec}$. In all cases, $\Delta\rho/\rho$ varied as H^2 at low fields. At low temperatures and high fields, the resistivity of the n-type samples was proportional to H/T , the parameter occurring in expressions for longitudinal magnetoresistance in the quantum limit. In no case did the resistivity saturate at high fields. The field dependence of resistivity in n-type material was less complex than that reported by others in less pure material, presumably because effects of degeneracy and magnetic field dependence of Fermi level were small. Results are correlated with data on the magnetic field variation of Hall coefficient, and are discussed with regard to scattering processes, large field quantization effects, and band structural considerations.

HALL COEFFICIENT AND MAGNETORESISTANCE IN SEMICONDUCTING DIAMOND, by R. T. Bate and R. K. Willardson. Mar. 1, 1959, 12p. incl. diagrs. refs. (Technical note no. 2) (AFOSR-TN-58-916) (AF 49(638)222) AD 204565; PB 139918 Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Nov. 28-29, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 376, Nov. 28, 1958.

Also published in Proc. Phys. Soc. (London), v. 74: 362-367, 1959.

The Hall coefficient and transverse magnetoresistance of a pair of natural p-type semiconducting diamonds which have R_0 values of 1000 at room temperature have been measured as a function of applied magnetic field and sample temperature. A 10% monotonic increase in the Hall coefficient has been observed as the applied field increased from 500 to 20,000 gauss. This behavior is similar to that of p-type silicon and suggests a warped valence band as does the larger than expected value of the transverse magnetoresistance which has been found to vary as H^2 for applied fields below 4000 gauss. PREPARATION AND SOME CHARACTERISTICS OF SINGLE-CRYSTAL INDIUM PHOSPHIDE, by T. C. Harman, J. I. Genco and others. [1958] [5]p. incl. illus. diagrs. [AF 49(638)222] Unclassified

Published in Jour. Electrochem. Soc., v. 105: 731-735, Dec. 1958.

A technique for purifying phosphorus, reacting elemental indium and phosphorus, purifying the compound, indium phosphide, by a directional recrystallization, and growing large crystals all in one glass tube is described. A crystal puller for decomposable solids is described in detail and results for indium phosphide discussed. The electron mobility as a function of temperature is given for two single-crystal specimens. An electron mobility of 4000 $\text{cm}^2/\text{v-sec}$ at 300°K for a specimen containing a carrier concentration of $1 \times 10^{17}/\text{cm}^3$ was achieved. Lifetime measurements by the photoconductivity-decay method are discussed. The optical-transmission characteristics of specimens containing electron concentrations of $10^{10}/\text{cm}^3$ and $10^{15}/\text{cm}^3$ are presented.

The estimation of one second was studied in four men before and after administration of LSD. A schizophrenia-like increase in overestimation of short durations was not found, but the coefficient of variation of three subjects increased, suggesting that temporal frames of reference tended to become vague or "lost". A double-blind study of one subject with low doses of LSD and a distilled-water placebo gave similar results: no shift in temporal concept after LSD but an increase in variability of judgment with doses as small as 4 γ . Some implications of the difference between the measures obtained with schizophrenics and with normals given LSD are discussed. Further applications of the method are suggested. THE TIME SENSE: ANCHOR EFFECTS AND APPARENT DURATION, by S. Goldstone, W. K. Boardman, and W. T. Lhamon. [1957] [9]p. incl. tables. (AFOSR-TN-57-202) (AF 18(603)79) AD 126499 Unclassified

Also published in *Jour. Psychol.*, v. 44: 145-153, May 1957.

Anchor effects on temporal judgments of a standard physical unit, 1 sec, were studied in 121 normal subjects divided into 3 groups: short anchor (0.1 sec), long anchor (2.0 sec), and neutral anchor (1.0 sec). Judgments under all anchor conditions were influenced in the expected direction. The short anchor pulled judgments down, while the long anchor pulled judgments up. An anchor reversed condition demonstrated an interaction between past and present anchors.

THE TIME SENSE: DIFFERENTIAL EFFECT OF SECOBARBITAL, DEXTRO-AMPHETAMINE SULFATE AND PLACEBO UPON TIME ESTIMATION MEASUREMENTS IN NORMAL SUBJECTS, by S. Goldstone, W. K. Boardman, and W. T. Lhamon. [1957] [13]p. incl. table, refs. (AFOSR-TN-57-277) (Sponsored jointly by Air Force Office of Scientific Research under AF 18-(603)79 and U.S. Public Health Service) AD 126579 Unclassified

Also published in *Brit. Jour. Psychol.*, v. 49: 324-328, Nov. 1958 (Title varies).

[Secobarbital], dextro-amphetamine and placebo were compared with respect to changes produced in perceived duration in ninety normal subjects. A method was employed which permitted quantitative derivation of a subject's concept of 1 sec, pre-drug, 30 min post-drug and 60 min post-drug. The following findings were obtained:

(1) a significant decrease in the clock-measured value of the apparent second with the ingestion of dextro-amphetamine; (2) a significant increase in the clock-measured value of the apparent second with the ingestion of quinal barbitone; and (3) a trend toward increase in the apparent second with placebo. These findings were discussed in terms of earlier reports and a theoretical framework was offered. (Contractor's abstract)

PSYCHOPATHOLOGY AND PSYCHOPHYSIOLOGY OF MINIMAL LSD-25 DOSAGE, by T. Greiner, N. R. Burch, and R. Edelberg. [1958] [3]p. incl. diag. (AFOSR-TN-57-377) (AF 18(603)79) AD 132451 Unclassified

Also published in *A.M.A. Arch. Neurol. and Psychiatry*, v. 79: 208-210, Feb. 1958.

Physiological and psychiatric changes in man from doses of lysergic acid diethylamide (LSD-25) below the normal range are presented. Seven micrograms activated the nonspecific galvanic skin response and induced cycles of rapid and profound shifts in effect. Between 7 μ g and 40 μ g the dosage response of LSD is consistent with the spectrum of psychopathology associated with the ill-defined group of "borderline" schizophrenic processes.

DRUGS AND HUMAN FATIGUE: GSR PARAMETERS, by N. R. Burch and T. Greiner. [1958] [8]p. incl. diagr. (AFOSR-TN-57-530) (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)79] and WADC Aero Medical Lab.) AD 136516 Unclassified

Presented at Norway meeting of the NATO-AGARD, May 1956.

Published in *Jour. Psychol.*, v. 45: 3-10, Jan. 1958.

Experiments have been performed measuring fatigue by use of the GSR and illustrating shifts in GSR response patterns under prolonged wakefulness and drug-simulated fatigue. Two definite types of fatigue patterns resulted: depression and hyper-excitability. Depression often precedes or alternates with excitability, the latter being paralleled by behavioral excitability such as excessive laughter. It is also shown that prolonged stress produces both behavioral and neurophysiological manifestations of fatigue.

ROLE OF A SELECTIVE MEMBRANE IN THE GALVANIC SKIN REFLEX (Abstract), by R. Edelberg, T. Greiner, and N. R. Burch. [1957] [1]p. (AF 18-(603)79) Unclassified

Presented at Seventy-eighth meeting of the Amer. Physiol. Soc., Chicago, Ill., Apr. 15-19, 1957.

Published in Fed. Proc., v. 16: 33, Mar. 1957.

Although the vascular and the sweat gland theories of the galvanic skin reflex have both found strong support during an unsettled 65-year controversy, the preponderance of evidence can be interpreted in favor of a membrane hypothesis. This paper offers additional evidence in support of an active membrane in the sweat gland and/or in the epidermal epithelium as the site of the changes in apparent skin resistance following both emotional and physiological stimuli. It has been shown by a system of separate but simultaneous recordings from 2 homologous sites that the GSR is profoundly influenced by the nature and concentration of the electrolyte in contact with the skin. Both resistance changes and potential changes are greatly reduced by exposure to electrode paste or low concentrations of NaCl and are greatly potentiated by exposure to CaCl₂. In contact with appropriate electrolytes, the membrane shows considerable rectifier properties and the GSR is strongly influenced by the polarity of the current. It has further been demonstrated that any resistance change produced by artificial vascular engorgement is an artefact resulting from the pressure of the engorged segment on the electrode. It is concluded that the GSR depends upon changes in the selective permeability of a negatively charged membrane whose behavior resembles that of nerve membrane.

THRESHOLD DOSES OF LSD IN HUMAN SUBJECTS (Abstract), by T. Greiner, N. R. Burch, and R. Edelberg. [1957] [1]p. (AF 18(603)79) Unclassified

Presented at Seventy-eighth meeting of the Amer. Physiol. Soc., Chicago, Ill., Apr. 15-19, 1957.

Published in Fed. Proc., v. 16: 303, Mar. 1957.

In doses above 40 µg LSD produces behavioral alterations and florid perceptual distortions that have been well documented in human subjects. Performance of complex tasks is impossible and the model psychosis is obvious even to inexperienced eyes. Doses below 20 µg are of practical concern if gross performance is spared, but sporadic affect disorders yield ideational

and motivational impairment; on the other hand, theoretic interest is centered about the possible similarity of the threshold "model" psychosis to incipient schizophrenia. The subjects were young, nonpsychotic males, well aware of the action of LSD. A series of doses at intervals of a week ranged from 4-20 µg, along with placebo. All data were interpreted in a double-blind state. In addition to frequent psychiatric interviews, subjects made extensive notes of their attitudes and thoughts both during and after the drug effects. An adjective check list was prepared from the earlier experiences. Bioelectric recordings included frequent samples of EEG and GSR. Pupillary-iris ratios were measured from serial photographs. Severe mood swings were outstanding with an early euphoric phase followed by depressive features. Double-blind judgment about the dosage was only fair with many inversions in the ranking. Placebo was not always distinguished although ranked as the minimum effect. Alerting patterns in EEG and GSR were noted in the dose range above 10 µg. The dosage response relationships for specific disturbances of affect and thought will be described.

RIGHT-LEFT GRADIENTS IN BODY IMAGE, BODY REACTIVITY, AND PERCEPTION, by S. Fisher. [1958] [32]p. incl. refs. (AFOGR-TN-58-1029) (Sponsored jointly by Air Force Office of Scientific Research under (AF 18(603)79) and [U. S. Public Health Service]) AD 162296 Unclassified

Also published in Genetic Psychol. Monographs, v. 61: 197-228, May 1960.

A study was made of 36 men and 42 women with a battery which embraced a wide variety of body image, body reactivity, perceptual and personality measures. Right-handed subjects who clearly experience the right side of the body as larger than the left more often manifest a GSR reactivity pattern involving greater reactivity on the left side as compared to the right side than do subjects who do not experience such a distinction. There is a significant relationship between the sex attributes assigned to the left body side and right-left GSR directionality. The greater the degree to which subjects can clearly differentiate the 2 sex roles and yet simultaneously integrate the values of both within themselves, the more likely they are to differentiate the 2 sides in the body image scheme and to manifest a left directional GSR pattern. Subjects who have mature body images are more often left GSR directional than subjects characterized by an immature body image. There are also individual right-left directionalities in perception which generalize beyond single perceptual situations. (Contractor's abstract)

PREDICTION OF BODY EXTERIOR VS. BODY INTERIOR REACTIVITY FROM A BODY IMAGE SCHEMA, by S. Fisher. [1958] [7]p. incl. table. (AFOSR-TN-58-1030) (AF 18(603)79) AD 162297 Unclassified

Also published in Jour. Personality, v. 27: 56-62, Mar. 1959.

Experiments have been run to determine whether individuals with definite body image boundaries are characterized by relatively high reactivity in the outer body layers and relatively low reactivity in the body interior. A group of girls 9 to 15 years of age were tested. The Rorschach test was used to evaluate boundary definiteness. GSR and heart rate were chosen to represent body exterior and body interior reactivity, respectively. Results show that the Barrier score is positively correlated with no. of GSR responses ($r = +.31$, $p < .10$) and negatively correlated with heart rate ($r = -.19$).

A DEVELOPMENTAL ANALYSIS OF SOME BODY IMAGE AND BODY REACTIVITY DIMENSIONS, by S. Fisher and R. L. Fisher. [1958] [14]p. incl. table, refs. (AFOSR-TN-58-1031) (AF 18(603)79) AD 162298 Unclassified

Also published in Child Development, v. 30: 389-402, 1959.

The study concerns the relationship between body image concepts of the right and left body sides and the relative Galvanic skin response (GSR) reactivity of the two sides. 119 right-handed subjects from 5 to 17 years were tested. Anisokonic lenses, puppets, Rorschach responses and the Thematic Apperception Test were employed. Results indicate (1) left directional reactivity is rare in right-handed persons until adolescence; (2) only chance relationships exist between body image measures and right-left reactivity patterns before adolescence; (3) effective differentiation in the right-left body image axis depends somewhat on parental models exemplifying well defined sex roles; and (4) a more complex system for disposition of excitation arises at adolescence.

EXTENSIONS OF THEORY CONCERNING BODY IMAGE AND BODY REACTIVITY, by S. Fisher. [1958] [8]p. incl. refs. (AFOSR-TN-58-1032) (AF 18(603)79) Unclassified

Also published in Psychosomatic Med., v. 21: 142-149, Mar.-Apr. 1959.

Previous research findings have indicated that important socialization experiences may become translated into body image attitudes and these in turn into body reactivity gradients or landmarks. On this basis a theory is offered that proposes that many of the crucial roles learned by the individual need to be transposed into body attitudes before they can become an integral part of his identity. A further formulation is offered that views many psychosomatic symptoms as representing distorted attempts by individuals under stress to maintain fading body excitation landmarks whose existence have considerable reassurance value. POSSIBLE SENSITIZING OF TACTILE RECEPTORS BY THE GALVANIC SKIN REFLEX (Abstract), by R. Edelberg and N. R. Burch. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under (AF 18(603)79) and National Institute of Mental Health) Unclassified

Presented at Eightieth meeting of the Amer. Physiol. Soc., Philadelphia, Pa., Apr. 14-18, 1958.

Published in Fed. Proc., v. 17: 39, Mar. 1958.

The electrical changes of the GSR may be in part a by-product of the sensitizing of tactile receptors by sympathetic discharge. Tactile sensitivity in humans was measured with a vibratory stimulus of 250 cps, GSR with a constant current system. After a delay of 5-20 sec following the onset of a GSR attending emotional or sensory stimulation, there is a conspicuous increase in tactile sensitivity which then gradually decays unless further GSRs occur. The amount of change in threshold is proportional to the amplitude of the GSR but tactile sensitivity is not correlated with basal resistance per se. This change is observable either in the dry state or under water and therefore cannot be due to the skin-softening action of sweat as proposed by Darrow. Survey of the hand and forearm shows a high topical correlation between tactile sensitivity and GSR activity in regions having similar innervation. The temporal and spatial relations are consistent with the hypothesis that both the galvanic changes and the threshold changes are common effects of the release of a chemical mediator which takes longer to diffuse to the tactile receptors than to the membrane responsible for the skin's resistance. A delayed adrenal effect may be involved as well.

Research performed during the report period consists of two phases. Phase B is a study of the liquid phase reaction between rocket propellants. Results of FNA/hydrocarbon mixing studies indicate that IWFNA can be used in place of WFNA but that red and white acids cannot be used interchangeably. Spectrophotometric methods and qualitative organic analyses were used to identify FNA/hydrocarbon reaction products, to deduce the reaction sequence and to estimate the extent of the reaction. Phase D is the observation of burning propellants in rocket engines. Details considered are (1) a windowed motor, (2) the development of a new high-speed flashing unit, (3) a single-sweep mirror camera, and (4) illuminating optics and filters.

A HIGH SPEED STRIP CAMERA FOR ROCKET CHAMBER RESEARCH, by K. R. Stehling, J. L. Freeland, and R. Schmidt. [1958] [11]p. incl. illus. diagsr. (AF 18(600)1156)
Unclassified

A camera, developed at the Bell Aircraft Corporation for the photography and measurement of events occurring within a rocket thrust chamber, is described. It is a continuous "strip" device having no provision for separation of the images. The optical train consists of an f/2.5, 178 mm f.l. Aero Ektar photographic lens which focusses the light on a 2-in. by 2-in. front-surface aluminized mirror. The mirror-actuating mechanism, details of which are presented, allows the mirror to sweep through a 40° arc at a rate of 20°/msec, giving a writing speed of approximately 1000 ft./sec. A Packard G iris shutter is placed in front of the lens to prevent light from entering the lens aperture before and after an exposure is made. It is pointed out that the opening and closing of the shutter can be synchronized with the beginning and end of the mirror's travel, and the mirror in turn can trigger photoelectrically the external flashing light source. Tests using this camera have shown that it can resolve and photograph small droplets traveling at high velocities. The mirror mechanism is rugged and dependable, and the mirror's speed is reasonably linear. The useful depth of field at 4x magnification is approximately 0.1 in., and the maximum resolving power is calculated to be 425 lines/mm.

THE MIGRATION OF GRAIN BOUNDARIES IN METALS UNDER THE INFLUENCE OF A TEMPERATURE GRADIENT, by R. W. Cahn and R. W. Lucas. Technical summary rept. Oct. 1956 - Oct. 1958, 1v. incl. illus. diagsr. refs. (AFOSR-TN-58-1056) (AF 61(514)1020) AD 206941; PB 146844
Unclassified

An exploratory investigation of temperature gradient induced grain boundary migration was made to further the knowledge of the structure of high angle boundaries, the structure of grain boundaries at high temperature, and modification of these structures by the presence of solute atoms. An apparatus with a constant temperature bath, capable of producing a range of temperature gradients, was constructed. Large grained polycrystalline specimens of Zn were used for the experiments on grain boundary migration. Results on Zn specimens indicate that it is necessary to have a certain concentration of impurities at the boundary, and the boundary must be at a temperature within a few degrees of the melting point. These deductions are compatible with previous observations on Al. In the case of very high temperatures and low impurity concentrations, impurities not only increase the rate of grain boundary migration but appear to be an essential cause of it. (ASTIA abstract)

STUDY OF CROSS LINKAGES IN GELATIN, by H. L. Gottleb and J. Bjorksten. Final research rept. Mar. 1957, 75p. incl. tables. (AFOSR-TR-57-26) (AF 18(600)-1010) AD 126444
Unclassified

A study is being made of the effect of cross linking agents on the susceptibility of gelatin to enzymatic hydrolysis. It is definitely shown that the enzymatic hydrolysis is interfered with by cross linking agents. The work covers chromium, formaldehyde and p-benzoquinone as cross linking agents. Amino acids in the hydrolysate were determined by chromatography. The possible error is quite large, and it was therefore necessary to accumulate an amount of data sufficient for statistical analysis. While certain amino acids seem to be blocked more than others, in a large number of tests, it is believed that a separate pinpointed study will be necessary to determine the specific linkages involved. The present broad study may prove useful in aiding to select promising areas for pinpointing. Data were obtained on the effect of preceding ionizing radiation on the hydrolysis of gelatin. While a few of the series seem to indicate a possibility of some effects, the fluctuations and variability in results preclude conclusions, except possibly after further statistical

A COMMON MOLECULAR BASIS FOR THE AGING SYNDROME, by J. Bjorksten. [1958] 18p. incl. diagrs. refs. (AF 18(600)1010) Unclassified

Also published in Jour. Amer. Geriatrics Soc., v. 6: 740-748, Oct. 1958.

While the manifestations of aging are many, there are certain underlying phenomena which they all have in common. The clinical symptoms of degenerative diseases have been observed and by the use of histological technique definite microscopic changes were found. The chemical processes underlying these changes have not been properly elucidated. With advancing age, there is a slowing in metabolism, a loss of elasticity of the tissues, an increasing brittleness in bone and cartilage, a loss of water binding capacity, and above all, a reduced resistance to disease and to trauma of all kinds. A curve, which is based on the mortality rate from the total US population, shows the reduced resistance.

QUARTZ FIBERS IN HIGH TEMPERATURE RESISTANT MATERIALS, by W. S. Fiedler, B. A. Cash and others. Final rept. May 1, 1956-May 31, 1958, 71p. incl. illus. diagrs. tables, refs. (AFOSR-TR-56-91) (AF 18(603)42) AD 162132 Unclassified

The continuous production of vitreous silica fiber by cane drawing and drawing from a bushing was studied. Drawing from cane gave the most rapid development of a method for producing single vitreous silica fibers. Fibers were drawn to a fineness of 8μ . Fibers 20μ in diameter were successfully coated with metallic Al and Ag. Hot-pressed laminates were made from the Al-coated samples. A method of heating the cane for drawing was developed to utilize a carbon resistor surrounding the tip of the cane which allowed for close temperature control. The life of the carbon resistor, although limited, was sufficient to allow the drawing of one length of cane at a time. The development of bushing spinning resolved itself into a problem of protecting the high melting metals (Mo, Nb, Ta, and W) from the effects of high temperature oxidation. Progress was made toward the development of an inert gas shield for these bushings. Special measuring techniques indicated that tensile strengths of the fibers produced from cane in the $20\text{-}\mu$ range were in the range of 75,000 to 400,000 psi. The

coating technique of drawing the fibers through molten Al did not degrade the tensile strength of these fibers. Dense, well-appearing laminates could be produced from these Al fibers. (ASTIA abstract)

NEUTRONS FROM THE HE^3 BOMBARDMENT OF B^{10} , by F. Ajzenberg-Selove, M. L. Bullock, and E. Almqvist. [1957] [24]p. incl. diagrs. table, refs. (AFOSR-TN-57-445) (Sponsored jointly by Air Force Office of Scientific Research under [AF 10(600)997], Atomic Energy Commission and Atomic Energy of Canada, Ltd.) AD 136435 Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 28, Jan. 30, 1957.

Also published in Phys. Rev., v. 108: 1284-1288, Dec. 1, 1957.

The neutron spectrum from the $\text{B}^{10}(\text{He}^3, n)\text{N}^{12}$ reaction has been studied at bombarding energies of 2.54 and 3.60 mev by the method of proton recoils in nuclear emulsions. The Q value of the reaction has been measured to be 1.46 ± 0.06 mev. The mass of N^{12} is found to be 12.02255 ± 0.00007 amu. The data also indicate excited states of N^{12} at 1.06 ± 0.08 , 1.56 ± 0.08 , (1.97 ± 0.010) , 2.35 ± 0.08 , 3.18 ± 0.015 , and 3.46 ± 0.15 mev, in good agreement with the known levels of the mirror nucleus, B^{12} . At the bombarding energy of 2.54 mev, the center of mass angular distribution of the ground

state neutrons is isotropic, while at 3.60 mev, the angular distribution is peaked forward so that the ratio $I(0)/I(140) = 2.9 \pm 0.7$. (Contractor's abstract, modified)

ANGULAR DISTRIBUTIONS OF NEUTRONS FROM $Al^{27}(d,n)Si^{28}$, by A. G. Rubin. [1957] 22p. diagrs. refs. (AFOSR-TN-57-446) [AF 18(600)997] AD 136436
Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 233-234, Apr. 25, 1957.

Also published in Phys. Rev., v. 108: 62-68, Oct. 1, 1957.

By using the method of proton recoils in nuclear emulsions, angular distribution of neutrons emitted to low-lying states of Si^{28} in the reaction $Al^{27}(d,n)Si^{28}$ have been obtained at deuteron energies of 2.16 and 6.00 mev. As might be expected, the angular distributions obtained at $E_d = 2.16$ mev show considerable deviations from the predictions of the simple Butler stripping theory. The angular distributions obtained at $E_d = 6.00$ mev have been analyzed by means of the Butler theory to obtain parities and limits on the spins of Si^{28} states. These results are, for the ground state, $J^\pi = 0^+, 1^+, 4^+$, or 5^+ ; 1.78-mev state, $J^\pi = 2^+$ or 3^+ ; 4.82-mev state, $J^\pi = 1^-$ to 4^- ; 8.24-mev state, $J^\pi = 2^+$ or 3^+ ; 6.88-mev state, $J^\pi = (1^- \text{ to } 4^-)$; 7.90-mev state, $J^\pi = 2^+$ or 3^+ ; 8.57-mev state, $J^\pi = 2^+$ or 3^+ ; 9.39-mev state, $J^\pi = 2^+$ or 3^+ . It is pointed out that the odd parity of the 4.82-mev state of Si^{28} is consistent with the possible shell-model states of a spheroidal nucleus. (Contractor's abstract)

The neutron spectrum and angular distributions of neutron groups from the reaction $Al^{27}(d,n)Si^{28}$ were obtained by the method of proton recoils in nuclear emulsions. A thin Al target was bombarded with 2.16-mev deuterons from the M.I.T. Rockefeller

Van de Graaff generator. Neutrons were detected by means of 400- μ Ilford C-2 emulsions placed at 9 angles to the incident beam. The plates were scanned with a Leitz binocular microscope equipped with a moving stage, at 1000 magnification. Neutron spectra were obtained at 8 angles from 0° to 120° . A total of 12,500 tracks was scanned. Excited states of Si^{28} were obtained from these measurements from 1.78 ± 0.10 to 10.25 ± 0.06 mev. The cross-section for formation of the 9.37 state of 0° is 10.1 millibarns per steradian, within a factor of 2. A second bombardment for the same reaction was made with a bombarding energy of 6.00 mev to obtain valid stripping angular distributions; emulsions were placed at 9 angles to the incident beam, at 15° intervals, from 0° to 135° . The angular distributions which were obtained were compared with the Butler stripping theory to obtain the parities and limits on the spins of the states in Si^{28} which were reached in the reaction. A thin target of isotopic B was bombarded with 7.03 mev protons. The

neutrons from the $B^{11}(p,n)C^{11}$ reaction indicated an excited state of C^{11} at 2.01 ± 0.08 mev. The reaction $P^{31}(p,n)S^{31}$ was studied at $E_p \pm 17.2$ mev. The energy spectrum of the neutrons was determined by means of proton-recoil measurements in nuclear emulsions. The mass excess ($M - A$) of S^{31} was calculated to be -10.04 ± 0.20 mev. Excited states of S^{31} were located at 1.15 ± 0.15 , 2.28 ± 0.20 , 3.35 ± 0.20 , 4.51 ± 0.15 , 5.94 ± 0.30 , and 6.41 ± 0.20 mev.

THE LANGEVIN EQUATION AND THE H THEOREM (Abstract), by A. Siegler. [1957] [1]p. (AF 18(603)29)
Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 23, Jan. 30, 1957.

BOS.03:005, 006; BRU.01:001

The Langevin equation, $\dot{\alpha} + \gamma\alpha = a(t)$, where γ is a constant and $a(t)$ is the derivative of the Wiener random function, gives probability distributions for $\alpha(t)$ that are symmetrical in time. Nonetheless, the sample functions show an exponential decay if the initial value of α is fixed. The set of curves $\alpha(t)$ is ergodic; this follows from the ergodicity of the Wiener function. Physically this means that its probability distributions could be duplicated by a set consisting only of a single suitably constructed infinite curve and all those curves obtainable from it by time displacement (all values of time displacement being equally weighted). From the time symmetry of the distributions one can infer that there is no difference between the essential structure of this curve and that obtained from it by reversing the time. Almost all of the curves of the set are H curves, reconciling time reversibility with the overwhelming tendency of systems to approach equilibrium. These remarks lend themselves readily to graphical demonstration.

QUANTUM EFFECTS IN BROWNIAN MOTION, by H. Goldring and A. Siegel. June 26, 1957, 19p. Incl. diagrs. tables, refs. (AFOSR-TN-58-345) (AF 18(603)29) AD 158616
Unclassified

The equations of motion of particles in a random process are given by the Langevin equation $\ddot{x} + c\dot{x} = F(t)$, where $F(t)$ is the random force acting on the particle. This random force is prescribed by means of a spectral distribution function which in the classical case is proportional to kT and in the quantum mechanical case is proportional to $\hbar\omega/e^{\hbar\omega/kT} - 1$, where $a = \hbar\omega/kT$. The correlation functions of the particle velocity in the random process are calculated for the classical and quantum mechanical cases in order to investigate the possible manifestations of quantum effects and their magnitude. A method for calculating the correlation function for the particle displacement is also indicated. It is shown that the force spectrum is independent of the statistics of the colliding particles if the process is regarded as an additive one, i.e., if the time of collision is neglected.

STOCHASTIC BASIS OF THE EULERIAN VARIATIONAL PRINCIPLE IN LINEAR DISSIPATIVE PROCESSES, by A. Siegel [1957] [7]p. [AFOSR-TN-58-345a] [AF 18-(603)29]
Unclassified

Also published in Phys. Rev., v. 106: 609-615, May 15, 1957.

The application of the Eulerian variational method to the Onsager Lagrangian of a linear dissipative process implies that variables undergoing strong spontaneous fluctuations (i.e., following curves other than the characteristic exponential decay from a given initial value) obey, on a macroscopic time scale a simple differential equation which also describes the more usual exponential decay curve. To justify this from the stochastic model of such processes in which the variable obeys the Langevin equation, requires that two things be proved: (1) as a necessary condition, that the stochastic curves under the given conditions do indeed cluster strongly about the solution of the differential equation; (2) as a sufficient condition, that the approximate time integral (actually obtained as a finite sum) of the Onsager Lagrangian be close to its relative minimum, for a time subdivision that is fine in the macroscopic sense. (1) is proved by deriving the conditional probability density of the Langevin variable at a time intermediate between two other times from the values of the variables at these times. The proof of (2), which utilizes this distribution function, follows lines similar to the more special case previously treated by the author. (Contractor's abstract)

LINEARIZED BOUNDARY PROBLEMS IN KINETIC THEORY (Abstract), by S. Ziering and E. P. Gross. [1957] [1]p. [AF 49(638)27]
Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 203 Apr. 25, 1957.

The steady flow of a gas between two parallel plates is investigated by solving the linearized Boltzmann equation with the distribution function subject to simple microscopic boundary conditions. Examination of the low-pressure limit shows the essentially discontinuous nature of the distribution in velocity. To satisfy boundary conditions, one should distinguish between velocities directed towards and away from a solid. Accordingly, Yvon's method in radiative transfer theory is followed, and expansion is undertaken of each section of the distribution in polynomials orthogonal over the respective half of the velocity range. The space dependent coefficients satisfy a set of linear differential equations. This technique is applied to the problems of shear flow and heat conduction to obtain solutions valid for arbitrary ratios of mean free path to plate separation. Linearization restricts the validity to low speeds and small temperature differences. Numerical results are obtained for inverse fifth and hard sphere molecules. Rapid convergence over the entire pressure region is a direct consequence of strict embodiment of the discontinuous feature. The lowest approximation agrees with high

approximations of the slowly convergent full range methods of Chang and Uhlenbeck and Mott-Smith.

THEORY OF THE POLARON (Abstract), by E. P. Gross and C. Willis. [1957] [1]p. [AF 49(638)27] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 186-187, Apr. 25, 1957.

A study is made of the energy spectrum and eigenfunctions of the polaron Hamiltonian, for which the interaction of electron and lattice vibrations is linear in the creation operator α_k^+ and the annihilation operator α_k of the lattice quanta. The unitary transformation $u = e^s$ is introduced, where $s = \sum_k \{ \alpha_k \varphi_k^+(q) - \alpha_k^+ \varphi_k(q) \}$ for which the $\varphi_k(q)$ depend on the electron coordinate q and also contain parameters representing averages over the electron state. The new lattice coordinates are measured with respect to a weighted function of instantaneous and average electron coordinates which depends on the coupling strength. The transformed Hamiltonian is found to be a quadratic form in α_k and α_k^+ . The trial functions $\psi(q) \cdot \phi(\alpha_k^+ \alpha_k)$ are used in order to obtain the lowest energy state. If ϕ represents the vacuum state, and ψ is a plane wave, and $\varphi_k(q)$ depend only on the instantaneous electron coordinate, then the procedure leads to the intermediate coupling theory. If ϕ is localized and $\varphi_k(q)$ depends only on average electron state then the strong limit is obtained. With more general φ_k , ψ , ϕ the physical effects of the small oscillation theory are obtained and an accurate description of the transition region is derived. The results are readily generalized to the case of many electrons.

CLASSICAL THEORY OF BOSON WAVE FIELDS, by E. P. Gross. [1958] 21p. (Technical note no. 2) (AFOSR-TN-58-510) (AF 49(638)27) AD 158321 Unclassified

Also published in Ann. Phys., v. 4: 57-74, May 1958.

The subject of discussion is the Hamiltonian for a system of bosons interacting by two body forces, as expressed in the formalism of second quantization. In this paper, we examine properties of the classical wave field governed by the Hamiltonian. For a general potential there is always an exact solution representing a uniform density. Exact solutions are exhibited, which represent disturbances of a definite velocity and of arbitrary amplitude. For small amplitudes the disturbances obey Bogolyubov's dispersion relation. Corresponding exact solutions are found for disturbances when the system moves as a whole. For suitably attractive potentials we find a class of exact solutions, degenerate in energy, with spatially periodic density. These solutions have a lower energy than the uniform type. Small amplitude excitations are investigated for the periodic case. They are phonons for long wave lengths, but show a band character at shorter wave lengths. A theory of the motion of foreign atoms in the boson fluid is formulated. (Contractor's abstract)

KINETIC THEORY OF LINEAR SHEAR FLOW, by E. P. Gross and S. Ziering. [1958] [10]p. incl. diagrs. (Technical note no. 3) (AFOSR-TN-58-511) (AF 49(638)27) AD 158322 Unclassified

Also published in Phys. Fluids, v. 1: 215-224, May-June 1958.

The flow of a monatomic gas between two parallel plates kept at the same temperature and moving in opposite directions is studied. The relative velocity of the plates is much smaller than the speed of sound. The deviation from the equilibrium distribution, $\phi(c, x)$, satisfies the linearized Boltzmann equation. The customary boundary conditions are adopted in which a fraction of the molecules is specularly reflected and the rest emitted with a Maxwellian distribution characteristic of the plate. The

BRU.01:006 - BRU.01:008

method consists of setting $\phi = \phi^+$ for $c_x > 0$ and $\phi = \phi^-$ for $c_x < 0$ so that positive and negative velocities are distinguished. We take $\phi^\pm = a_0^\pm(x)c_z + a_1^\pm(x)c_z c_x$. The space functions are determined by taking half-range velocity moments of the Boltzmann equation. Explicit results for the distribution function, flow velocity and stress are given for a general law of force. Numerical results are worked out for hard sphere molecules. The method treats both microscopic boundary conditions and conservation laws exactly. Precise results are obtained both for the low-pressure region and for the high-pressure coefficient of viscosity. The region of slip flow is analyzed. Maxwell's slip condition is remarkably close to the condition obtained here from the kinetic theory. In this region of pressures, the deviations from the velocity profile of the hydrodynamic slip flow theory are everywhere very small, and are completely negligible at distances greater than $1/8$ of a mean free path from a plate. RAYLEIGH'S PROBLEM AND KINETIC THEORY OF GASES (Abstract), by E. A. Jackson and E. P. Gross. [1958] [1]p. [AF 49(638)27] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 65, Jan. 29, 1958.

The problem of an infinite plate in a gas set impulsively into uniform motion along its plane is studied. We seek solutions of the linearized Boltzmann equation appropriate to the case when the speed of the plate is less than the sound speed. The accurate description of the gas depends on distinguishing between the molecules which are impinging on, or leaving, the plate. In order to do this we use Yvon's method of half-range distribution functions previously used to study the Couette flow problem for all values of density. This method enables us to satisfy the boundary conditions and thereby obtain exact results for both long and short times. With the problem formulated in terms of half-range distribution functions, it is necessary to use only a few velocity polynomials to obtain excellent results. Comparing the results with those based on the Navier-Stokes theory and by Grad's thirteen moment method, it is found that they become inaccurate for times less than the collision period.

THEORY OF NONLINEAR BOSON FIELDS (Abstract),

by E. P. Gross. [1958] [1]p. [AF 49(638)27]

Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 54, Jan. 29, 1958.

The Hamiltonian is studied for nonrelativistic interacting bosons (such as helium atoms) written in the formalism of second quantization. The approach is based on an analysis of exact solutions of the associated classical equations of motion. There is always a solution in which the wave field is spatially uniform; for a purely repulsive potential this is the lowest energy solution. Solutions are found which represent large amplitude disturbances which for small amplitudes satisfy the Bogolyubov relation between frequency and wave vector. For a potential with a sufficiently strong attractive part, there is a spatially periodic solution. This is shown to be the appropriate solution for liquid helium. The associated disturbances have phonon character for long wavelength but the spectrum has a band character at short wavelengths. A procedure is given for finding corresponding quantum wave functions. A variety of problems, such as the behavior of the boson fluid in a rotating cylinder, flowing through a pipe, propagating disturbances on a carrier background, is solved by investigating the solutions of the classical fluid with appropriate boundary conditions.

KINETIC THEORY OF THE IMPULSIVE MOTION OF AN INFINITE PLANE, by E. P. Gross and E. A. Jackson. [1958] [11]p. incl. refs. [AF 49(638)27] Unclassified

Published in Phys. Fluids, v. 1: 318-328, July-Aug. 1958.

The half-range method of solution of the Boltzmann equation is used to give a kinetic theory treatment of the Rayleigh problem. In contrast to the Navier-Stokes or Grad theories, the method yields exact results for the initial stress and slip velocity at the boundary. It also indicates corrections to the classical Rayleigh results, even at long times compared to the collision periods of the gas molecules. The corrections are shown to be related to the usual slip boundary conditions of hydrodynamics plus an additional part arising from boundary layer effects. The half-range method predicts corrections to the standard methods of between 10%-25% for all values of the time. (Contractor's abstract)

Literature on the effects of ultrasonic waves on corrosion was surveyed. Equipment and techniques were developed to make corrosion tests on metals in (1) stagnant solutions, (2) solutions with ultrasonic waves, (3) solutions with mechanical agitation, and (4) solutions with mechanical agitation and ultrasonic waves. The ultrasonic waves were imparted by a quartz transducer to the solution in which the corrosion specimens were immersed. The corrosion was measured by the potential of the sample under test against a saturated calomel electrode and by the determination of the total Fe dissolved in the attacking solution in the course of the test. Ni-Cr 18-8 stainless steel and Armco Fe were submitted to corrosion tests with the use of N HCl and N/100 HCl, respectively, in the different conditions of the solutions. Corrosion tests were also made, in the same conditions and on the same materials, but with the solutions saturated with pure N or with pure O instead of air. The influence of the ultrasonic waves on the corrosion of the stainless steel and Armco Fe was studied. The presence of ultrasonic waves in the electrolyte increases the rate of corrosion on both steels. The tests with gas saturated solutions showed that this action of the ultrasonic waves is connected with the presence of O in the attacking solution. A magnetostrictive ultrasonic wave generator was built for work on corrosion with the use of ultrasonic waves of different energy and frequency and different electrolytes.

Studies were made of the catalytic properties of Re and some of its compounds in hydrogenation reactions, and the effect of rhenium trichloride on the course of Grignard reactions. Rhenium heptasulfide was established as the best hydrogenation catalyst among sulfide

BCU.02:002 - BCU.02:005

catalysts. Rhenium disulfide was comparable but not as effective. Studies on the oxides of rhenium, Re_2O_7 , ReO_3 , ReO_2 , $\text{ReO}_2 \cdot 2.5 \text{H}_2\text{O}$, Re_2O_3 , and $\text{ReO} \cdot 2 \text{H}_2\text{O}$ demonstrated that the activity of a substance of a given composition depended on the precise technique used in preparation. New procedures were developed for the preparation of $\text{ReO}_2 \cdot 2.5 \text{H}_2\text{O}$, Re_2O_3 , and $\text{ReO} \cdot 2 \text{H}_2\text{O}$. Rhenium oxides were not as effective as the standard Pt and Ni catalysts in the hydrogenation of the C-C multiple bond, the ketonic carbonyl group, or the nitro group. The rhenium oxides, particularly rhenium heptoxide in situ, were demonstrated to be the most effective catalysts known in the hydrogenation of carboxylic acids to the corresponding alcohols. Grignard reactions were profoundly altered by the presence of small amounts of transition metal salts. Rhenium trichloride was not significantly effective in this type of reaction in the small amounts used.

MAXIMUM AND MINIMUM VALUES FOR THE ELEMENTARY SYMMETRIC FUNCTIONS OF HERMITIAN FORMS, by M. Marcus and B. N. Moysl. [1957] [3]p. (AF 18(603)83) Unclassified

Published in Jour. London Math. Soc., v. 32: 375-377, July 1957.

Let A be a Hermitian matrix of order n . For each k between 1 and n , let x_1, x_2, \dots, x_k vary over all sets of k orthonormal vectors in the unitary n -space. If A is nonsingular, it is proved that the linear subspace spanned by a minimizing or maximizing set x_1, \dots, x_k for the function $\Pi = i^k (Ax_1, x_1)$ is invariant under A . If A is positive semi-definite and if $0 \leq \sigma \leq 1$, $1 \leq r \leq k$, then the maximum of the r th elementary symmetric function of $(Ax_1, x_1)^\sigma$ ($1 \leq i \leq k$) is shown to be

$$\binom{k}{r} k^{-\sigma r} \left(\sum_{i=1}^k \lambda_i \right)^{\sigma r},$$

where $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$ are the eigenvalues of A . (Math. Rev. abstract)

SOME EXTREME VALUE RESULTS FOR INDEFINITE HERMITIAN MATRICES, by M. Marcus, B. N. Moys, and R. Westwick. [1957] [9]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18-(603)83 and National Research Council of Canada) Unclassified

Published in Illinois Jour. Math., v. 1: 449-457, Sept. 1957.

Let A be a square, complex indefinite Hermitian matrix of order n which has a set of positive and negative eigenvalues λ_j which can be ordered $\lambda_j \geq \lambda_{j+1}$, and let x_i ($i = 1, \dots, k$) be an orthonormal set of unit vectors in the unitary space V_n . Consider two functions F_1 and F_2 such that F_1 is the product of k of the a_i and F_2 is the second elementary symmetric function of the a_i , where a_i denotes the inner product of Ax_i and x_i . The invariant and extremum properties of the two functions are investigated and it is found that: (1) the set of vectors for which the value of either of the functions assumes a minimum value is such that the set spans a k-dimensional invariant subspace of A. In addition for F_1 the set of vectors which yields a maximum value for F_1 also spans a k-dimensional invariant subspace of A; (2) the extreme values of F_1 are given as a product of sums of the λ_j ; and (3) the minimum value of F_2 is given as the second elementary symmetric function in the λ 's up to λ_k and the maximum value as a function of the maximum of numbers (a,b) where a and b are given as sums of the λ 's.

INEQUALITIES FOR SYMMETRIC FUNCTIONS AND HERMITIAN MATRICES, by M. Marcus and L. Lopes. [1957] 8p. (AF 18(603)83) Unclassified

Published in Canad. Jour. Math., v. 9: 305-312, 1957.

For $a_i \geq 0, b_i \geq 0$ ($i \leq 1 \leq n$) and $1 \leq r \leq n$, the inequality $E_r^{1/r}(a_1 + b_1, \dots, a_n + b_n) \geq E_r^{1/r}(a_1, \dots, a_n) + E_r^{1/r}(b_1, \dots, b_n)$ is proved, where E_r denotes the rth elementary symmetric function. If $E_{r-1}(a_1, \dots, a_n) > 0, E_{r-1}(b_1, \dots, b_n) > 0$, then

$$E_r^{1/r}(a_1 + b_1, \dots, a_n + b_n) \geq E_r^{1/r}(a_1, \dots, a_n) +$$

$$E_r^{1/r}(b_1, \dots, b_n), \text{ where}$$

$$E_r^{1/r}(a_1, \dots, a_n) = \frac{E_r(a_1, \dots, a_n)}{E_{r-1}(a_1, \dots, a_n)}, E_0(a_1, \dots, a_n) = 1.$$

According to the authors, H. Sameison has observed that the first inequality is a consequence of a concavity result of W. Fenchel (C. R. Acad. Sci. Paris, v. 203: 764-766, 1936) on mixed volumes of convex bodies. However, Fenchel's result is not used in the authors' inductive proof. The paper concludes with applications to eigenvalues of the sum of two positive semi-definite Hermitian matrices. In particular, if A, B are two such matrices of order n and if $\{\alpha_i\}, \{\beta_i\}, \{\lambda_i\}$ are the eigenvalues of A, B, A+B respectively, each arranged in increasing order, then

$$E_r^{1/r}(\lambda_1, \lambda_2, \dots, \lambda_k) \geq E_r^{1/r}(\alpha_1, \alpha_2, \dots, \alpha_k) +$$

$$E_r^{1/r}(\beta_1, \dots, \beta_k) \text{ holds for } 1 \leq r \leq k \leq n. \text{ (Math. Rev. abstract)}$$

Let M_n denote the algebras of n -square matrices over the complex numbers and let U_n be the unimodular group, H_n the set of Hermitian matrices, and R_k the set of matrices of rank k in M_n . Let $ev(A)$ be the set of n -eigen-values of A , counting multiplicities. The structures are determined for any linear transformation T of M_n into M_n having one or more of the following properties: (1) $T(R_k) \subseteq R_k$ for $k = 1, \dots, n$; (2) $T(U_n) \subseteq U_n$; (3) $\det T(A) = \det A$ for all $A \in H_n$; and (4) $ev(T(A)) = ev(A)$ for all $A \in H_n$. T is not assumed to be a multiplicative homomorphism, but T satisfies $T(\alpha A + \beta B) = \alpha T(A) + \beta T(B)$ for all $A, B \in M_n$ and for all complex numbers α, β . It is shown that if T satisfies property (1) then there exist non-singular matrices U and V such that either $T(A) = UAV$ or $T(A) = UA'V$ for all $A \in M_n$, where A' indicates the transpose of A . If T satisfies properties (2), (3), or (4), then it must in turn satisfy (1). Additional restrictions on U and V are determined in each case.

EXTREMAL PROPERTIES OF HERMITIAN MATRICES II, by M. Marcus, B. N. Moysl, and R. Westwick. Aug. 1958, 8p. (AFOSR-TN-58-668) (Bound with its AFOSR-TN-58-667; AD 162119) (AF 18(603)83) AD 162200
Unclassified

Also published in Canad. Jour. Math., v. 11: 379-382, 1959.

An extension of the results on the extremal properties of Hermitian matrices of M. Marcus and J. L. McGregor (Canad. Jour. Math., v. 8: 524, 1956) is presented for arbitrary Hermitian matrices. The principal result yields the extreme values of a function which is a sum for all w of the inner product of X_w , which is Grassman exterior product of r unit orthogonal vectors x_i , and $C_r(A)X_w$, which is the exterior product of r terms Ax_i , where A is the matrix in question. The extreme values are given as the r th elementary symmetric function of the eigenvalues of the matrix A , with indices running from 1 to s and $n-k+s+1$ to n , subject to the condition that $0 \leq s \leq k$, where n is the order of the square matrix.

HERMITIAN MANIFOLDS WITH ZERO CURVATURE, by W. M. Boothby. [1958] 5p. [AF 18(603)83]

Unclassified

Published in Mich. Math. Jour., v. 5: 229-233, 1958.

The problem is considered of determining those complex-analytic manifolds with a Hermitian metric whose curvature vanishes everywhere. It is easy to see that the identical vanishing of the curvature implies that there exists in a neighborhood of each point a field of n independent (in fact, orthonormal) parallel analytic vectors, where n is the dimension of the manifold. If the manifold is simply connected, such a field may then be defined over the entire manifold, and the manifold is therefore parallelisable (a complex-analytic manifold of complex dimension n is said to be parallelisable if there exist n analytic vector fields defined over it which are independent at each point). On the other hand, if a complex-analytic manifold is parallelisable, then it has a Hermitian metric with curvature zero. Hence, for a complex-analytic manifold, the existence of such a metric is a somewhat weaker property than parallelisability. H. C. Wang has shown that a compact, complex-analytic, parallelisable manifold has a complex Lie group as its universal covering space. Here this is generalized to the corresponding theorem for the case of vanishing curvature. (Contractor's abstract)

DIAGONALS OF DOUBLY STOCHASTIC MATRICES, by M. Marcus and R. Ree. Apr. 1958, 11p. (AFOSR-TN-58-377) (AF 49(638)152) AD 154284
Unclassified

Also published in Quart. Jour. Math., v. 10: 296-302, 1959.

A real n -square matrix $S = (S_{ij})$ which is called doubly stochastic if $a_{ij} \geq 0$, $\sum_{k=1}^n s_{ik} = \sum_{k=1}^n s_{kj} = 1$ for all i and j , is studied for the conjecture that the minimum value of the permanent of S as S varies over all doubly stochastic matrices can be uniquely assumed for the matrix all of whose entries are $1/n$. The permanent of S is defined by

$$p(S) = \sum_{\sigma} \prod_{i=1}^n s_{i\sigma(i)}$$
 where σ varies over all $n!$ permutations of the integers $1, \dots, n$. The statement (b) there exists a permutation σ such that $\sum_{i=1}^n s_{i\sigma(i)} \geq 1$ and $s_{i\sigma(i)} > 0$ for $i = 1, \dots, n$, follows as a consequence of the conjecture and is proved together with some corollaries. Best possible uniform lower bounds are obtained on the elements of some diagonals of a doubly stochastic matrix.

Also published in Proc. Amer. Math. Soc., v. 9: 886-892, Dec. 1958.

Let V be an additively written elementary p -group of order p^n , where $n > 1$, and let $\varphi(u,v), \psi(u,v)$ be two biadditive functions defined on V and with values in a field K of characteristic p . Let k be a fixed nonzero element in V , and assume that the following two conditions are satisfied: (1) If α, β are nonzero elements in K then $\alpha\varphi(u,v) + \beta\psi(u,v) = 0$ for all v implies $u = 0$; (2) $\varphi(k,v) = 0$ for all v . If φ is identically zero, these two conditions are equivalent to saying that ψ is nondegenerate. Define an algebra L over K with basis $\{e_u \mid u \in V, u \neq 0, u \neq k\}$ by the multiplication table: $e_u e_v = \varphi(u,v) e_{u+v} + \psi(u,v) e_{u+v+k}$ where $e_0 = e_k = 0$. The purpose of this paper is to show that the algebra L is simple if $p > 2$.

LIE ELEMENTS AND AN ALGEBRA ASSOCIATED WITH SHUFFLES, by R. Ree. [1958] [11]p. incl. refs. [AF 49(638)152] Unclassified

Published in Ann. Math., v. 68: 210-220, Sept. 1958.

Let R be any associative commutative ring with 1 and \mathcal{U} the free R -module on the basis elements $a(I)$, where $I = (i_1, \dots, i_r)$ runs over all r -tuples ($r \geq 0$) of numbers from 1 to m . The author defines a commutative associative multiplication on \mathcal{U} by using the notion of a shuffle: If I and $J = (j_1, \dots, j_s)$ are two sequences of integers from 1 to m , then any arrangement of $i_1, \dots, i_r, j_1, \dots, j_s$ in a single sequence $K = (k_1, \dots, k_{r+s})$ such that the order of the i 's and of the j 's is preserved is called a shuffle. In this way I and J give rise to $\binom{r+s}{r}$ shuffles, not necessarily distinct. Now the product in \mathcal{U} is defined by $a(I)a(J) = \sum a(K)$, the sum being taken over all shuffles K of I and J . Next let \mathcal{B} be the algebra of all power series in the noncommuting indeterminates X_1, \dots, X_m over R . Each element $F = \sum a(I)X_I$ of \mathcal{B} defines a linear mapping $\varphi: \mathcal{U} \rightarrow R$ by $\varphi(a(I)) = a(I)$. Assume that R admits division by any positive integer. Then the author shows (Theorem 2) that F is a Lie element if and only if $\varphi(a(I)a(J)) = 0$ for all $I, J \neq \emptyset$. From this result Friedrichs' criterion for Lie elements and the Dynkin-Specht-Wever formula are deduced. With F and φ as before, $\log F$ may be defined as a power series, provided that $\varphi(F) = 1$. In that case (Theorem 5) $\log F$ is a Lie element if and only if φ is a homomorphism from \mathcal{U} to R . The resulting relations on φ , viz. $\varphi(I)\varphi(J) = \sum \varphi(K)$ (where K runs over all shuffles of I and J) are called the shuffle relations. Theorem 5 is shown

ON GENERALIZED CONJUGATE CLASSES IN A FINITE GROUP, by R. Ree. Apr. 1958, 9p. (AFOSR-TN-58-378) (AF 49(638)152) AD 154285

Unclassified

Also published in Illinois Jour. Math., v. 3: 440-444, Sept. 1959.

A proof is given that the number of σ -classes equals the number of σ -invariant classes of conjugate elements in a finite group where G and σ represent a fixed homomorphism of G into itself. A subset S of G is called σ -invariant if $x \in S$ implies $x^\sigma \in S$. The above theorem is an immediate consequence of the following theorem: (1) the number of σ -classes in G is equal to the number of σ -invariant irreducible ordinary characters of G , and (2) the number of σ -invariant irreducible modular characters (with respect to p where p is an arbitrary prime number) is equal to the number of σ -invariant p -regular classes of conjugate elements in G . In particular, the number of σ -invariant ordinary characters is equal to the number of σ -invariant classes of conjugate elements in G .

ALGEBRAIC STRUCTURE AND CONFORMAL MAPPING, by M. Heins. May 1957, 17p. (AFOSR-TN-57-192) (In cooperation with Inst. for Advanced Study, Princeton, N. J.) (AF 18(603)70) AD 126487 Unclassified

Also published in Trans. Amer. Math. Soc., v. 89: 267-276, Sep., 1958.

Beginning with the theorem of Bers (Bull. Amer. Math. Soc., v. 54: 311-315, 1948) and the theorem (unpublished) of Chevalley and Kakutani, considerable attention has been given to problems of determining conformal properties of non-compact Riemann surfaces (including plane domains) in terms of algebraic properties of rings or fields of meromorphic functions on them. The present article stems from this circle of ideas and is primarily concerned with the determination of conformal properties of a Riemann surface F in terms of the field $M(F)$ of all meromorphic functions on F . Some of the results in this direction are contained in the following theorems of the author. Theorem A: Let ϕ denote an isomorphism of $M(G)$ into $M(F)$ which preserves the complex constants; then

$$\phi = \{(p, q) \mid (p, q) \in F \times G; \phi(g)(p) = g(q), g \in M(G)\}$$

is either empty or else a conformal (not necessarily one-to-one) map of F into G . Theorem B: If G is compact, or if ϕ is continuous, then ϕ is not empty and

hence is a conformal map of F into G . A subfield K of $M(F)$ is said to be separating if, for each pair of points on F , there is a function in K taking different values at these points. Theorem C: If K_1 is an arbitrary subfield of $M(F)$ containing the complex constants as well as non-constant functions, then there exists a conformal map ψ of F onto a Riemann surface G such that $g \circ \psi$ maps a separating subfield of $M(G)$ onto K_1 .

This representation is unique up to conformal equivalence. Unlike much of the recent work in this area, the present article considers some of the implications of continuity on the algebraic transformations. In particular, it is shown that every continuous "homomorphism" of $M(F)$ into the complex field plus ∞ is obtained by evaluating the functions of $M(F)$ at some point of F . This is the principal tool used in the proof of Theorem B. (Math. Rev. abstract)

ON CERTAIN MEROMORPHIC FUNCTIONS OF BOUNDED VALENCE, by M. Heins. Nov. 1957, 9p. (AFOSR-TN-57-502) (In cooperation with Inst. of Advanced Study, Princeton, N. J.) (AF 18(603)70) AD 136492 Unclassified

Also published in Rev. Math. Pures Appl., v. 2: 263-267, 1957.

If E is a closed set in the plane with the property that there are no non-constant bounded analytic functions in the complement of E , then for each open set $O \supset E$ every bounded analytic function in $O - E$ can be extended to be an analytic function in all of O . Thus the AB-null sets in the plane are removable so far as the bounded analytic functions are concerned. If one has a Riemann surface of infinite genus, it is natural to ask in what sense is its boundary "removable"? Heins (Ann. Math., v. 55: 296-317, 1952) established the following theorem, which seems to the reviewer to be the prototype of the sort of thing one should expect of "removability": Let F be an open Riemann surface with a compact relative boundary I' and an ideal boundary consisting of just one end and that of harmonic measure zero. Then there is a mapping ψ of F into a finite Riemann surface G such that every bounded analytic function f on F is the composition $g \circ \psi$ of ψ with a bounded analytic function on G . (It follows from recent results of Wermer's on function algebras that the hypothesis of this theorem can be weakened to approximately the requirement that each bounded analytic function on F assumes its maximum on I' .) In the present paper Heins gives another criterion or a boundary to be removable in the above sense: Given a Riemann surface F , and suppose that there exists a non-constant meromorphic function f_0 of bounded (finite) valence such that $\{w \mid v_{f_0}(w) = \max v_{f_0}\} \in O_{AB}$, where $v_{f_0}(w)$ denotes the

BRO.01:005; BRO.02:002-004

number of times f_0 assumes the value w on F . Then there is a conformal mapping ϕ of F into a compact Riemann surface G , such that every function f on F of bounded valence is the composition $g \circ \phi$ of ϕ with a rational function g on G . Further, for each function f of bounded valence on F ($w | v_f(w) = \max v_f \in O_{AB}$) is used. The methods of Heins rely heavily on the theory of interior transformations and on the theory of algebraic structure. They will probably play a fruitful role in the further study of the "removability" of the ideal boundary of Riemann surfaces. (Math. Rev. abstract)

ACOUSTIC STREAMING NEAR A BOUNDARY, by W. L. Nyborg. [1958] [11]p. incl. diagrs. refs. (AFOSR-TN-57-792) (Sponsored jointly by National Institutes of Health and Air Force Office of Scientific Research under AF 18(603)54) AD 148024 Unclassified

Also published in Jour. Acoust. Soc. Amer., v. 30: 329-339, Apr. 1958.

An approximate solution is developed for steady flow induced near a fluid-solid interface by a sound disturbance. The result is valid, subject to stated conditions, for the flow near any portion of a surface in the vicinity of which the irrotational oscillatory velocity distribution u_a is known. The validity is limited to the case that the ratio of the kinematic viscosity coefficient of the fluid to the angular frequency of the wave disturbance is small compared to the square of the scale of u_a . Applications of the general result are made to special situations including that of a small source near a rigid plane. It is found that small

compressible bodies, especially resonant gas bubbles, resting on boundaries are likely sites of pronounced microstreaming in a sound field.

PHYSICAL MECHANISMS FOR IRRADIATION EFFECTS OF SOUND AND ULTRASOUND (Abstract), by W. L. Nyborg, F. S. Brumshaw and others. [1957] [1]p. (Sponsored jointly by National Institutes of Health and Air Force Office of Scientific Research under AF 18-(603)54) Unclassified

Presented at meeting of the Acoust. Soc. Amer., New York, May 23-25, 1957.

Published in Jour. Acoust. Soc. Amer., v. 29: 768, June 1957.

Of the many known ways in which high-amplitude sound can produce changes in material processes and systems, there are only a few for which the basic physics is understood. In this paper a report will be made on research directed toward some aspects of the general problem. Since typical sonic irradiation conditions seem forbiddingly complex, an attempt has been made to define "elementary" situations for study, which are nevertheless close enough to practical ones to permit carryover of results. Particular attention is being given to fields in liquids in the neighborhood of (1) a single vibrating bubble resting on a wall and (2) a vibrating tip brought near a wall. In the former case there is interest in the heat produced by the bubble; also in heat transfer through the wall, as affected by bubble-associated acoustic streaming. In the second case, acoustic streaming motions are seen near the vibrating tip which, e.g., exert steady viscous forces on the neighboring wall, capable of removing surface films. Observations are also made of steady circulation and related events induced in plant cells when a leaf is contacted with a vibrating tip. The present frequency range is mainly from 10 to 100 kc. Important features of the acoustic streaming patterns can be explained on the basis of an approximate theory for boundary layer.

Further measurements have been made of the attenuation of ultrasonic waves in pure metals in the helium temperature range where absorption by conduction electrons predominates. The pulse method was used whereby an ultrasonic pulse is generated by a quartz crystal sealed to one of two carefully paralleled faces of the specimen, and the attenuation is measured by the rate of decay of the echoes received by the same crystal. Accurate changes of attenuation with either temperature or applied magnetic field were made by comparing relative changes of a given pulse. The sample was suspended in a helium bath, the temperature of which could be reduced to 1.05°K by pumping. A solenoidal magnetic field capable of 11,000 gauss was used for measuring the effect of magnetic field. Measurements for indium, aluminum, zinc, copper, and polycrystalline indium are given.

MICROSCOPIC EDDYING NEAR A VIBRATING ULTRASONIC TOOL TIP, by F. J. Jackson and W. L. Nyborg. [1958] [2]p. incl. diagrs. (AFOSR-TN-58-991) (AF 18-603)54
Unclassified

Also published in Jour. Appl. Phys., v. 30: 949-950, June 1959.

An experiment has been performed to determine whether sonic effects in liquids result from a unique stirring action associated with microscopic eddies produced near boundaries by sound. The article discusses the apparatus involved. A tapered cone of circular cross section oscillates longitudinally in near-contact with a rigid boundary. Peak-to-peak vibration amplitudes are of the order of 10^{-5} cm. Two distinct pairs of vortices (A, A' near the cone and B, B' near the boundary) appear in the liquid. A, A' appears whenever the cone oscillates and depends on vibration amplitude for shape and speed. B, B' appears only when the distance h between the boundary and the cone tip is small (in this instance, ~400μ). The speed of B, B' decreases rapidly when h increases.

A technique is discussed for studying localized boundary layer heating and microstreaming. A small thermistor is imbedded in a container, its upper face continuous with the surrounding plastic surface. Sound is generated in a liquid of interest by a 10-kc magnetostrictive oscillator. A gas bubble of desired size is placed near or above the imbedded thermistor. The resistance of the thermistor, measured by a dc Wheatstone bridge, is a sensitive indicator of its temperature. Low current operation is suitable for temperature determination in highly localized fields. Operating at higher currents, the thermistor probes localized near-surface flow fields, especially in respect to effectiveness of different parts of these fields in aiding heat transfer from surface points.

SELF-MAINTAINED TRANSVERSE OSCILLATIONS OF A JET (Abstract), by W. L. Nyborg. [1958] [1]p. (AF 18(603)54)
Unclassified

Presented at meeting of the Acoust. Soc. Amer., Washington, D. C., May 7-10, 1958.

Published in Jour. Acoust. Soc. Amer., v. 30: 676, July 1958.

A thin flat (subsonic) jet, temporarily divided by an edge, tends to set itself into transverse oscillation; the accompanying sounds have been called "edge tones." Any of a number of modes or "stages" may be excited, depending on parameters of the system and on its history. When a resonator is present (as in an organ pipe), further complications appear. Although acoustical and hydrodynamical characteristics of the apparently simple jet-edge system have been studied for over a century, a complete theory still does not exist. An adequate theory should account for the frequency characteristics, jet oscillation configurations, and self-maintenance conditions for the different modes, as well as for the generated vortex arrays. In this paper available information on characteristics of jet-edge and jet-edge-resonator systems will be reviewed, and the more recent theoretical approaches discussed.

EFFECTS OF ACOUSTIC STREAMING ON THE PHOTOGRAPHIC PROCESSES (Abstract), by F. J. Jackson and W. L. Nyborg. [1958] [1]p. (Sponsored jointly by National Institutes of Health and Air Force Office of Scientific Research under AF 18(603)54)
Unclassified

Presented at meeting of the Acoust. Soc. Amer.,
Washington, D. C., May 7-10, 1958.

Published in Jour. Acoust. Soc. Amer., v. 30: 678,
July 1958.

It has been known for some time that ultrasonic irradiation of a photographic plate immersed in a liquid causes differential darkening of the emulsion. It was observed by some investigators that suppression of cavitation either entirely eliminated or greatly reduced the darkening action. Because of the complex and erratic nature of typical cavitation, it is difficult to determine which of its many aspects may be responsible for the observed darkening. In experiments to be reported here, it is found that small scale acoustic streaming in the vicinity of the emulsion will cause a darkening effect whether cavitation is present or not. Special experimental arrangements are utilized; by use of moderate sonic amplitudes, cavitation is either entirely suppressed or else carefully controlled. Controlled "cavitation" is effected by allowing a single bubble of appropriate size to be present at the emulsion-liquid interface. Photographs of emulsions irradiated under various conditions (frequencies 10-50 kc) will be shown; density distributions will be compared with those which might be expected on the basis of known characteristics of the acoustic streaming.

THE SUPERCONDUCTING ENERGY GAP FROM
ULTRASONIC ATTENUATION MEASUREMENTS, by
R. W. Morse and H. V. Bohm. [1957] [10]p. incl. diagra.
[AF 49(638)6] Unclassified

Also published in Phys. Rev., v. 108: 1094-1096,
Nov. 15, 1957.

The ratio σ_g/σ_n of superconducting to normal attenuation was measured as a function of temperature T for several specimens of S_n and I_n , at frequencies (28-56 mc/sec) such that the ultrasonic wavelength was small compared with the electronic mean free path. The variation of σ_g/σ_n with T followed quite closely a form predicted by Bardeen on the basis of the Bardeen-Cooper-Schrieffer theory. It is suggested that such measurements offer a means of finding the variation of energy gap with temperature.

MAGNETIC DEPENDENCE OF ULTRASONIC
ATTENUATION IN METALS AT LOW TEMPERATURES
(Abstract), by R. W. Morse, H. V. Bohm, and [J.] D.

Gavenda. [1958] [1]p. [AF 49(638)6] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York,
Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3:
44-45, Jan. 29, 1958.

At low temperatures the dominant mechanism of ultrasonic attenuation in pure metals is interaction with conduction electrons. This attenuation is strongly affected by a magnetic field. Helium temperature measurements are reported at frequencies from 8 to 100 mc for fields up to 10 000 gauss in both polycrystal and single crystal samples of indium, tin, copper, aluminum, and zinc. The measurements include longitudinal and shear waves for various orientations of H. The effect depends on the parameter kl , where k is the propagation constant of the wave and l is the electron mean-free-path. When $kl < 1$, the attenuation falls monotonically with applied field, varying as H^{-1} when the radius of the electron orbit $r < l$. When $kl > 1$, the attenuation generally goes through a series of maxima and minima before decreasing monotonically. The resonances are found in both poly- and single crystal samples. The observations in copper and indium are consistent qualitatively with resonances occurring for coincidences of the electron orbit diameter and the ultrasonic wavelength. The results in tin are more complicated suggesting the superposition of another effect which, in contrast to the first, causes a large increase in attenuation with increasing magnetic field. This is strongly frequency-dependent and at 50 mc results in an attenuation for large fields twice that at zero field.

LOW-TEMPERATURE LATTICE CONDUCTIVITY IN
METALS (Abstract), by R. W. Morse. [1958] [1]p.
[AF 49(638)6] Unclassified

BRO. 09:005; BRO. 10:001, 002

Presented at meeting of the Amer. Phys. Soc.,
Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3:
203, May 1, 1958.

The lattice thermal conductivity in metals can be comparable with the electronic conductivity with impure metals or alloys, and with superconductors well below the transition temperature. Phonon-electron scattering generally is the mechanism determining the lattice conductivity. Theory has not been too successful in accounting for the observed conductivity because of uncertainty concerning the shear wave interaction with electrons, and because of the unknown effect of superconductivity on the phonon-electron interaction. Here empirical values of the phonon-electron interaction as deduced from measurements of ultrasonic attenuation will be used to calculate the lattice conductivity of tin, indium, and copper. These apply to both longitudinal and shear waves, and in the case of tin and indium, to both the normal and superconducting states. It is shown that one would expect shear waves to contribute significantly. Calculated lattice conductivities agree reasonably well with values reported in the literature for these metals. The comparison with the temperature dependence of the lattice conductivity in the superconducting states is also fairly good.

ULTRASONIC ATTENUATION IN SUPERCONDUCTORS:
DEPENDENCE ON ELECTRON FREE PATH (Abstract),
by H. V. Bohm and R. W. Morse. [1958] [1]p. [AF 49-
(638)6] Unclassified

Presented at meeting of the Amer. Phys. Soc.,
Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3:
225-226, May 1, 1958.

When the electron mean free path (l) is long compared to the ultrasonic wavelength (λ), i.e., $kl = 2\pi l/\lambda > 1$, then the attenuation of longitudinal waves by electrons in superconductors can be related simply to the superconducting energy-gap of the theory of Bardeen, Cooper, and Schrieffer. We report here measurements in superconducting indium which cover the range of both $kl > 1$ and $kl < 1$. Besides the expected kl dependence on the magnitude of the attenuation, the superconducting attenuation seems to decrease more rapidly below the transition temperature (T_c) the smaller the value of kl when $kl < 1$. The frequency dependence, which is square-law for the normal state when $kl < 1$, is not radically altered throughout the superconducting range (it actually becomes slightly stronger than square-law). A comparison will also be made with shear waves when $kl > 1$.

Here the attenuation shows a considerably more rapid decrease with temperature below T_c than for longitudinal waves of either comparable kl or frequency.

AN APPROXIMATE BOUNDARY-LAYER THEORY FOR SEMI-INFINITE CYLINDERS OF ARBITRARY CROSS-SECTION, by E. Varley. Jan. 1958 [27]p. incl. diagr. table. (AFOSR-TN-58-53) (AF 49(638)232) AD 148095 Unclassified

Also published in Jour. Fluid Mech., v. 3: 601-614,
Mar. 1958.

An estimate is given of the distribution of skin frictional force per unit length, and of displacement area, on the outside of a semi-infinite cylinder, of arbitrary cross section, moving steadily in a direction parallel to its generators. A Pohlhausen method is employed with a velocity distribution chosen to yield zero viscous retarding force on the boundary layer approximations. (The smallness of the fluid acceleration far from the leading edge has been shown by Batchelor.) Like the Rayleigh methods, this method is expected to yield reasonable results at large distances from the leading edge. However, for a large class of cross sections, which includes all convex cross sections and locally concave cross sections with re-entrant angles greater than $1/2\pi$, the method yields the expected square root growth of the boundary layer at the leading-edge, with a fairly close approximation to the coefficient, from which it is not unreasonable to suppose that the skin frictional force and displacement area are given with

reasonable accuracy along the whole length of the cylinder. Results for the elliptic cylinder and the finite flat plate are given in closed form, valid for the whole length of the cylinder, and are expected to be in error by at most 20%. In addition, some estimate is given of the effect of corners on skin frictional force and displacement area. (Contractor's abstract)

AN EXPERIMENT ON COMPRESSIBLE FLOW PERTURBATIONS, by T. A. d'Ews Thompson and R. E. Meyer. June 1958, 23p. incl. diags. (AFOSR-TN-58-447) (AF 49(638)232) AD 158253 Unclassified

Presented at annual meeting of the Amer. Soc. Mech. Engineers, New York, Nov. 30-Dec. 5, 1958.

Also published in Jour. Appl. Mech., v. 26: 114-119, Mar. 1959.

The effect which a slight tilting of liners of a supersonic wind-tunnel nozzle has on the Mach number distribution in the test-rhombus is determined on the basis of the linear perturbation theory (Aeronaut. Quart., v. 7: 71-84, Feb. 1956). Experiments are reported which (1) confirm that the first-order subsonic and transonic perturbations of the flow may be neglected compared with the supersonic perturbations, and (2) indicate that appreciable effects not accounted for by the first-order theory occur when the flow possesses high local pressure gradients.

AERODYNAMIC FORCES ON A CYLINDRICAL SHELL IN PANEL FLUTTER, by M. Hoyt. Dec. 1958, 12p. incl. diags. (AFOSR-TN-58-974) (AF 49(638)232) AD 205598 Unclassified

Presented at Mechanics Div. AFOSR Contractors meeting, Kansas City, Mo., Oct. 23-24, 1958.

The aerodynamic forces resulting from the unsteady distortion of a circular cylinder of finite length, in a uniform supersonic stream, are determined. The problem is very similar to that of finding the steady flow past a quasi cylindrical duct. The forces on the finite cylinder are compared with corresponding forces on an infinite cylinder, which have been used previously in cylindrical panel flutter analysis. In the case of infinite length, circumferential distortion introduces a constant factor into the expression for the surface pressure. On a cylinder of finite length, circumferential distortion causes the surface pressure to be damped in the axial direction. The effect of finite length of cylinder

should therefore be to improve panel flutter characteristics. (Contractor's abstract)

AN INVESTIGATION OF THE UNSTEADY FLOW PATTERN IN THE WAKE OF CYLINDERS AND SPHERES USING A HOT-WIRE PROBE, by C. Cometta. Oct. 1957, 31p. incl. illus. diags. refs. (Technical rept. no. WT-21) (AFOSR-TN-57-760) (AF 18(600)664) AD 136749 Unclassified

Results obtained by hot wire anemometer surveys of wakes behind circular cylinders at subsonic speeds and high Reynolds numbers are presented. The investigation was concerned in particular with the behavior of the Strouhal number at and near the critical Reynolds number. The irregular range above a Reynolds number of 300, in which turbulent velocity fluctuations accompany the periodic formation of vortices, and which was believed not to extend beyond $Re = 10,000$, is shown to exist up to $Re = 1,000,000$. Above a Reynolds number of $Re = 200,000$ and a cylinder diameter to channel width ratio of 0.23 there appeared two simultaneous vortex streets. On the outside of the ordinary vortex street there were observed two layers containing oscillations of lower frequency. The dependence of the Strouhal number on Reynolds number behind three-dimensional bodies, such as spheres, was determined. Periodic formation of vortices could not be observed above a Reynolds number of 40,000. For spheres of diameter greater than about 2 cm there appeared to be a critical Reynolds number of 7400 at which the Strouhal number changed rapidly from one value to a very much different

BRO.04:015 - BRO.04:018

value. This phenomenon could not be satisfactorily explained. It is believed that there exists only one type of vortex formation for spheres, namely a relatively stable arrangement of vortex loops. (Contractor's abstract)

REVERSE FLOW AND SUPERSONIC INTERFERENCE, by J. H. Clarke. July 1958 [42]p. incl. diagrs. refs. (AFOSR-TN-58-625) (AF 18(600)664) AD 162155
Unclassified

Also published in Jour. Fluid Mech., v. 6: 272-288, Aug. 1959.

A general analytic proof is presented of the invariance of the drag of an arbitrary spatial distribution of horseshoe vortices and sources under reversal of the undisturbed flow from a volumetric formulation of the momentum theorem of linearized theory. A reverse-flow relation for steady subsonic or supersonic flow was obtained by consideration of the interference drag of 2 such singularity distributions. The relation, a generalization of the Ursell-Ward theorem, may be applied to configurations with bodies whose surfaces are not quasi-cylindrical and whose surface pressures are quadratically related to the perturbation velocity. The relation is used to discuss several interfering 2-body arrangements in supersonic flow. In certain cases, it was shown that the drag and lift may be determined without knowledge of the interference flow field associated with the arbitrarily prescribed body geometry. The simplicity of the results permits the formulation of optimum problems. The invariance of the drag under flow reversal with unchanged geometry is also established. The role of edge forces in the results is discussed.

ON TRANSONIC FLOW ABOUT SLENDER THREE-DIMENSIONAL BODIES, by H. U. Thommen. Sept 1958 [135]p. incl. illus. diagrs. refs. (Technical rept. no. WT-27) (AFOSR-TN-58-714) (AF 17(600)664) AD 162249; PB 142189
Unclassified

The nonlinear differential equation for the perturbation potential of transonic flow about slender three-dimensional bodies is transformed into a nonlinear integral equation by means of multiple Fourier transforms. Two parameters are introduced, and an attempt is made to choose these parameters locally, such that the nonlinear integral equation can be approximated by a linear one. Two different methods of choosing the parameters are investigated, varying one or both parameters. Pressure distributions were measured on a family of three half bodies of revolution with parabolic nose section. The tests were carried out for Mach numbers from 0.50 to 0.90 in steps of one tenth and from 0.95 to 1.05 in steps of 0.025. Additional tests for a Mach number of 1.10 are incomplete due to the power limitations of the auxiliary suction equipment. All tests were performed using two different wall configurations for the top and bottom walls: (a) longitudinally slotted walls, 18.75% open; and (b) perforated walls, 22% open. The agreement of the measurements for the different walls is in general good. Comparison of the experimental results with the theoretical predictions indicates that the method is suited in its present form only for supersonic free stream (two variable parameters) and for Mach numbers below the critical (one variable parameter). For supercritical but subsonic free stream both methods fail in the region, where in the physical space the flow is locally supersonic. (Contractor's abstract)

TRANSONIC FLOWS THROUGH A STRAIGHT CASCADE OF SLENDER AIRFOILS, by A. D. Wood. Aug. 1958, 163p. incl. diagrs. refs. (Technical rept. no. WT-28) (AFOSR-TN-58-732) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)664 and Office of Naval Research under Nonr-56209) AD 162267; PB 142095
Unclassified

The steady, transonic flow of an isentropic, isenergetic fluid through an arbitrary two-dimensional cascade of slender airfoils is investigated. By application of a double exponential Fourier transform the nonlinear partial differential equation for the perturbation potential is transformed to a nonlinear integral equation which may, if desired, be solved by an iterative procedure. Two methods are investigated with the object of finding a relatively simple first approximation to the solution in which the nonlinear effects are included. The general

transonic result so obtained contains the customary linear subsonic and supersonic solutions as special cases. (Contractor's abstract)

THE OSCILLATING-DISK VISCOMETER, A COMPARISON BETWEEN THEORY AND EXPERIMENT, by F. C.-Y. Liu. June 1958, 91p. incl. diags. tables, refs. (AFOSR-TN-58-409) (AF 18(600)891) Unclassified

A disk oscillating between two fixed plates has been in use for more than one and one half centuries as an instrument for the measurement of viscosity. A review is given here of the existing theories regarding this kind of instrument, including the theories advanced by Kestin and Person, the scheme originated by Newell and the formula given by Aspetta and Newell. The basic assumptions underlying these schemes are emphasized. All three schemes are subjected to experimental verification by means of the measurements performed by Pilarczyk, and by Kestin and Leidenfrost. Results of the experimental investigation are discussed, and the limits of validity of the different formulas are investigated. The accuracy of each scheme for the evaluation of viscosity is also given. The scheme originated by Kestin and Person gives an uncertainty of no more than 0.1% for relative determinations of viscosity on condition that calibration is performed in the way indicated by Kestin and Wang, and is valid over the whole range of pressures investigated experimentally. The scheme due to Newell has an uncertainty of 0.5% in the absolute determination of viscosity but the error is reduced to less than 0.05% for relative measurements. However, the scheme in question is valid for gases at comparatively low pressures only. The scheme proposed by Aspetta and Newell leads to an uncertainty of 1.5% in

AN ABSOLUTE DETERMINATION OF THE VISCOSITY OF TWELVE GASES OVER A RANGE OF PRESSURES, by J. Kestin and W. Leidenfrost. [1958] [53]p. incl. diags. tables, refs. (AFOSR-TN-58-620) (AF 18(600)-891) AD 162149 Unclassified

Also published in Physica, v. 25: 1033-1062, Nov. 1959.

The measurements were based on a new theory of the oscillating-disk viscometer which includes the effect of the finite radius as well as that of its cylindrical circumference. The theory is first compared with very precise measurements obtained in an instrument whose brief description is also given. The experiments verify the theory to within 0.15% when no correction for the paddle effect of the mirror is applied. The latter has been determined empirically with respect to measurements on air and with it, it is permissible to assume that the theory holds exactly when the boundary layer thickness is large enough, as assumed in Newell's theory. The precise lower bound of the boundary layer thickness for which

BRO. 05:014-017; BRO. 06:002

Newell's theory is applicable has been determined experimentally with reference to measurements on nitrogen. The final measurements performed at 20°C for air, argon, carbon dioxide, deuterium, helium, hydrogen, krypton, neon, nitrogen, oxygen, and water vapor, and, in addition, at 20°C for air, argon, nitrogen, oxygen, and xenon are believed to be accurate, on an absolute basis, to 0.05% and precise to 0.01 - 0.07% depending on the gas. A thorough statistical analysis of the present measurements and those due to Michels and Gibson on nitrogen is given. This shows that apart from being subject to a much larger standard deviation, the latter results are statistically identical with the present measurements over the same range of pressures. It is, consequently, believed that the reliability of both sets of data is very high because they have been obtained by entirely different methods. Extensive numerical results and interpolation formulas are given. (Contractor's abstract)

AN EXPERIMENTAL INVESTIGATION OF THE INTERNAL FRICTION OF THIN PLATINUM ALLOY WIRES AT LOW FREQUENCIES, by J. Kestin and J. R. Moszynski. July 1958, 30p. incl. diags. tables. (Technical rept. no. 11; rept. no. AF-891/11) (AFOSR-TN-58-752) (AF 18(600)891) AD 201516; PB 137431
Unclassified

The measurement of viscosity of gases and vapors by the method of small oscillations requires the knowledge of the internal friction of the suspension wire, and of its variation with temperature. Since these data are not available and in order to choose suitable wires for the steam viscosity measurements, an instrument was built for the measurement of internal friction of thin wires at low frequencies and at elevated temperatures. The instrument is described and results are presented of an investigation of a series of wires made available by Sigmund Cohn and Company. It was found that wires made of No. 479 Platinum Alloy (8% Tungsten, 92% Pt), stress relieved and in sizes of 0.002 in. diam or over are most suitable, and their damping characteristics and elastic constants at any temperature in the range up to 400°C can be predicted quite accurately. ON THE CORRELATION OF EXPERIMENTAL VISCOSITY DATA, by J. Kestin and H. E. Wang. [1958] [5]p. incl. diags. tables. [AF 18(600)891] Unclassified

Published in Physica, v. 24: 604-608, July 1958.

The paper gives empirical correlations for low-density viscosity with temperature and viscosity excess with density, for carbon dioxide (measured by Michels, Botzen and Schuurman) and nitrogen (measured by Lazarre and Vodar). It is shown that in carbon dioxide, the correlation breaks down around the critical point, but otherwise includes the whole range of states from liquid to gaseous. In the case of nitrogen, the correlation seems to break down at the higher densities for lower temperatures. Smoothed values for the viscosity of carbon dioxide are given. (Contractor's abstract)

160-174, 1959.

A theory is presented of a disk oscillating between 2 fixed plates considered as an instrument for absolute measurements of viscosity. The existing theories relating the viscosity to the decrement of oscillation are improved by calculating the effects of the edge. The separation between the plates is assumed to be small compared with both the radius of the disk and the boundary layer thickness. As compared with the infinite fluid case, the only new feature is the additional boundary condition that the fluid velocity must vanish on the plates instead of at infinity. A comparison is made with the experimental data of Kestin and Pilarczyk (Trans. Amer. Soc. Mech. Engineers, v. 76: 987, 1954) for which the theory discussed is estimated to be correct to 0.1%.

The viscous drag exerted by a fluid on an oscillating disk is determined by methods similar to those used previously (A. G. Azpeitia and G. F. Newell, Theory of Oscillation Type Viscometers III, A Thin Disk, ZAMP). The problem is to find the viscous drag $D(s)$ by evaluating the integral $D(s)$

$$= \frac{\rho \delta^5 s}{I} \int_A \int \xi^2 \frac{\partial w}{\partial \eta} d\sigma, \text{ in which } w \text{ is a solution of the}$$

$$\text{equation } \frac{\partial^2 w}{\partial \xi^2} + \frac{3}{\xi} \frac{\partial w}{\partial \xi} + \frac{\partial^2 w}{\partial \eta^2} = -sw \text{ with the boundary}$$

conditions $w = 1$ on the surface A of the disk; x, η are coordinates which measure positions relative to one edge of the disk whereas ξ, η are the cylindrical coordinates measured from the center of the bottom surface of the disk; the radius of the disk is ξ_0 , the thickness is $2\eta_0$, and the boundary layer thickness is δ . The boundary layer thickness is assumed to be small compared with both the thickness and the radius of the disk. An extrapolation of the formulas derived agrees sufficiently well with those for the thin disk which makes it possible to interpolate between the 2 to evaluate the drag for arbitrary-shaped disks provided the boundary layer thickness is small compared with the radius. The method of solution for the fluid flow near the right angle turn can be applied to the solution of other problems such as heat transfer near a right angle turn. (ASTIA abstract)

The most important methods are given for the experimental investigation of the viscosity of gases at high pressures and temperatures. The paucity of experimental data at combined high pressures and temperatures is stressed and the need for a considerable effort in this direction is brought into relief. A general criteria is

BRO.06:007; BRO. 11:001;
BRO.08:004, 005

established for a successful viscometer for gases at high pressures and temperatures and it is shown that the capillary viscometer offers the best choice at the present time. The three possible alternatives (the oscillating-body, the rotating-cylinder, and the falling-body viscometers) require an intensive period of development before their potential could be accurately assessed. The main difficulties encountered in their use are connected with the complexities of the flow field which they create. In the first, secondary motion causes the scattering of data and inferior reproducibility. In the last, vortex shedding and pressure drag contribute unaccountable terms to the skin friction force. Some consideration is given to the problem of empirical correlation of experimental data. In particular, it is shown that the well-known correlation between density and the residual viscosity $\mu - u_0$, i.e., the difference between its value at a given temperature and pressure, and the corresponding value at zero pressure shows signs of breaking down at high densities.

HEAT TRANSFER FROM SURFACES OF NON-UNIFORM TEMPERATURE DISTRIBUTION. PART I. LAMINAR TRANSFER FROM ISOTHERMAL HEAT POLES ON A FLAT PLATE, by H. H. Sogin. Sept. 1958, 1v. incl. diags. tables, refs. (AFOSR-TN-58-930) (AF 49(638)-46) AD 205095; PB 139919

Unclassified

A purely hydrodynamic boundary layer grows from the leading edge of a flat plate at zero incidence. Downstream is a heated, isothermal surface of finite length-an isothermal heat pole. It is followed by a second isothermal heat pole, the surface between the two being adiabatic. The Rubesin-Klein-Tribus method is used to

calculate rates of heat transfer by forced convection from the two poles. The general results are applicable to poles of any length in either laminar or turbulent flow. Predictions of laminar transfer are based on Eckert's step function. In experimentation, naphthalene cast in trays is used to simulate the isothermal heat poles while the inert material between them simulates the adiabatic wall. The velocities range from about 40 to 90 FPS, and the air temperatures from 72 to 88°F. The boundary layer is shown to be laminar. The theoretical and experimental results are found to be in good agreement, confirming the calculation method and Eckert's step function. The experimentation is extended to an array of several equally spaced poles in tandem. Effects of roughness and spanwise diffusion are noted. (Contractor's abstract)

The recrystallization behavior of aluminum with additions of less than 0.1% of Cu, Mg, Si, Mn, Ag, Ni and Zn was studied after tensile deformations of 15%. It was found that the effect of impurities upon the recrystallization of aluminum is much smaller after low deformations than after high deformations, although the calculated activation energies are similar in magnitude ($51 - 61 \times 10^3$ cal/mol). It was noted that for some of the alloy additions the recrystallization temperature, after an initial increase, decreases again with increasing amounts of impurities. This behavior could not be related to the properties of the alloy elements or to any existing theory of recrystallization. (Contractor's abstract)

The influence of small additions (less than 0.14%) of Cu, Mg, Si, Mn, Ag, Ni, Zn and Fe upon the recrystallization of high purity Al (99.998%) was investigated by x-ray diffraction methods. Deformation of 40% and 90% by rolling: The recrystallization was appreciably delayed by the impurities. Fe additions of the order of 1/100 of a percent increased the recrystallization temperature

by 210°C and decreased the rate of recrystallization by a factor up to 10^{11} . Cu, Si, and Mg produced corresponding effects of 150°C and 10^7 . The effect of Ag was much smaller. The increase in recrystallization temperature was caused by atoms in solution and was not due to a second phase. Although generally the recrystallization temperature increased with increasing impurity concentrations, the effect due to the first 0.01% was, in most cases, larger than the increase caused by all the further additions. Deformation of 15% in tension: The effect of impurities upon the recrystallization of Al was much smaller after this low deformation than after the high deformation previously discussed. The recrystallization rate was increased by a factor of only 7 at most, although the calculated activation energies remained similar in magnitude (51 to 61×10^3 cal/mol). With Cu, Ni and Mg, the recrystallization temperature initially increased and then decreased with larger amounts of alloying additions. This unexpected behavior was not caused by difference of grain size or of chemical analysis.

A SURVEY OF THE RECOVERY OF DAMPING AND MODULUS CHANGES FOLLOWING PLASTIC DEFORMATION, by A. Hikata and A. Granato. Jan. 15, 1957 [24]p. incl. diagrs. table, refs. (Rept. no. AF-136/1) (AFOSR-TN-57-54) (AF 18(603)136) AD 115093 Unclassified

Also published in *Acta Metallurgica*, v. 6: 470-480, July 1958. (Title varies)

Measurements of the changes in attenuation and elastic constants with time following plastic deformation are compared with the results of a theory which assumes these changes are a result of dislocation pinning by deformation-induced point defects. It is found that the measured time law is that predicted by the theory for specimens which have been deformed between about 0.4 and 4%. For smaller and larger deformations, deviations from this time law are obtained. Although measurements so far available permit only a qualitative check of the predictions of the theory with regard to the dependence of the recovery rate on purity and deformation, a check of the temperature dependence is afforded by recovery measurements of Young's modulus for copper. From these an activation energy for the migration of vacancies in copper is determined to be 1.0 ev. A number of experiments needed for checking the theory further are proposed.

Presented at Second Pacific Area Nat'l. Meeting of the Amer. Soc. for Testing Materials, Los Angeles, Calif., Sept. 17-18, 1956.

Published in Symposium on Nondestructive Testing, Los Angeles, Calif. (Sept. 17-18, 1956), Philadelphia, Amer. Soc. for Testing Materials, 1957, p. 63-70.

A brief survey of the effects observed in the propagation and recovery behavior of ultrasonic waves in materials during stress or fatigue cycling is presented. In all cases studied, the results show that the ultrasonic attenuation increases as a function of the number of cycles of loading and unloading. The loading in the experiments was done in tension and in tension and compression. The form of the attenuation-cycles curve depends among other things on the magnitude of the load and the speed of cycling.

THEORY OF THE THERMAL BREAKAWAY OF A PINNED DISLOCATION LINE WITH APPLICATION TO DAMPING PHENOMENA, by L. J. Teutonico, A. Granato, and K. Lücke. May 1, 1958 [136]p. incl. diagrs. tables. (AFOSR-TN-58-512) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)136, Office of Ordnance Research under DA 19-020-ord-3650, and Atomic Energy Commission under AT(30-1)1772) AD 158323 Unclassified

An investigation is made of the model of a pinned dislocation line under stress. The model used is that originally given by Koehler and later employed by Granato and Lücke in their theory of mechanical damping due to dislocations. By taking into account thermal fluctuations the probability of the thermal breakaway of such a dislocation line is calculated. The effect of this breakaway on the decrement and apparent modulus change felt by a stress wave traveling through a solid is also considered. The decrement is found to be both hysteretic, since the dislocation is irreversibly broken away from the pinning agents, and relaxational, since the dislocation passes with a temperature-dependent mean frequency from one configuration of minimum energy through a saddle point configuration to another minimum configuration. A comparison is made of this theory with the Granato-Lücke (G.L.) theory and reveals that the present theory

BRO. 12:004-006; BRO. 13:001, 002

includes: (1) temperature effects which reduce to the G.L. theory as the temperature approaches absolute zero, (2) a dependence on the wave frequency, and (3) a decrement dependence on stress which is different from the G.L. theory but which fits the available data as well as the G. L. theory of mechanical damping.

The objective of the work undertaken under this contract has been that of studying fatigue effects in metals. Initially the work in this area was concerned with determining how ultrasonic "attenuation-time" or attenuation and velocity recovery with time after deformation depends on deformation and stress cycling. As more was learned about the interaction of dislocations with point defects and how this affected ultrasonic attenuation and velocity, it became apparent that considerably more work had to be done to understand dislocation behavior and recovery to follow fatigue or stress cycling changes in solid materials. A list of publications is presented concerning the work done on the interaction of point defects with dislocations and the resulting influence on attenuation and velocity.

EVIDENCE FOR DISLOCATION BREAKAWAY IN PURE ALUMINUM, by R. Truell and R. G. Bayer. [1958] [2]p. incl. diagr. (AF 18(603)136; continued by AF 49(638)450)
Unclassified

Published in Phys. Rev., v. 110: 1206-1207, June 1, 1958.

Attention is called to the very rapid increase in acoustic attenuation at low strains (especially below 0.02%), and it is pointed out that this effect has been observed only in the high-purity almost single-crystal aluminum sample; it is not observed for example in much less pure commercial aluminum (about 99.8%). It is proposed that this attenuation increase at very low strain is an example of "dislocation breakaway" and that the effect is caused by an increase in dislocation loop length arising when the dislocations free themselves from relatively weak pinning at low strains.

Artificially nucleated crystals were grown in strained aluminum single crystals by cutting them at one end with pliers and then subjecting them to recrystallization heating. Recrystallization always started at the cut end with many fine grains. After further heating most of these fine grains disappeared and only a few large crystals were left. They grew further into the deformed matrix, and one of them finally occupied the full diameter of the wire. Laue and Debye Scherrer X-ray photographs showed that in the early stage of recrystallization the orientation of the many fine grains were distributed at random. The crystal finally obtained usually had an orientation characterized by a $40^\circ [1\bar{1}1]$ rotation relative to the deformed matrix. This indicates that the preferred orientation of the final crystals originates by growth selection. (Contractor's abstract)

Grain orientations and growth rates were investigated in strained Al single crystals. The crystals were grown from Al wire, cut, and subjected to recrystallization heating. After additional heating, most of the fine grains disappeared, and only one crystal finally occupied the full diameter of the wire. A large majority of the final crystals showed an orientation which was characterized by a 40° rotation around the [111] axis of the deformed matrix. The results indicated that the preferred orientation of the final crystals originates in growth selection. No preferred orientations were obtained when the single crystal wires, containing 0.09% Fe, 0.09% Si, 0.03% Zn, and 99.79% Al, were annealed for 1 hr or longer between 600° and 640°C prior to deformation. Reheating below 500°C produced typical age-hardening effects. When the reannealing time was increased, the yield point of the crystals increased, reached a maximum, and finally decreased. Recrystallization again produced preferred orientations in samples which had been reheated until the maximum yield point was reached or exceeded.

INFLUENCE OF THERMAL HISTORY ON PREFERRED ORIENTATIONS IN THE RECRYSTALLIZATION OF TECHNICALLY PURE ALUMINUM, by R. E. Green, Jr., B. G. Liebmann, and H. Yoshida. Nov. 15, 1958 [9]p. incl. diagrs. refs. (AFOSR-TN-58-1014) (AF 49(638)-479; continuation of AF 49(638)75) AD 162279; PB 13793; Unclassified

The influence of the state of impurities (dissolved or precipitated) on the generation of preferred orientations in recrystallization of strained aluminum single crystals has been investigated. The crystals contained 99.79% Al, 0.09% Fe, 0.09% Si and 0.03% Zn, only the iron not being well within its solid solubility limit. No preferred orientations were obtained when the crystals were annealed for several hours at 620°C prior to deformation. On reheating at temperatures below 500°C the yield point of the crystals increased, reached a maximum and finally decreased, a typical behavior correlated to the precipitation of a second phase (iron).

Recrystallization produced preferred orientations in samples which were reheated until the maximum yield point was reached or exceeded. This would indicate that iron in supersaturated solid solution prevents the generation of preferred orientations while it has no effect of this kind when precipitated. This effect of the state of impurities explains contradictory results previously obtained by different groups (Graham-Cahn [Jour. Metals 1956, p. 504, 517] and Liebmann-Lücke-Masing [Zeitschr. Metallk., v. 47: 57, 1956]) investigating growth rates and preferred orientations in the recrystallization of aluminum single crystals. A possible mechanism for the prevention of preferred orientations by dissolved iron is discussed (based on growth selection and interaction between grain boundaries and foreign atoms).

ON THE QUANTUM-STATISTICAL THEORY OF TRANSPORT PROCESSES. I. CORRELATION FUNCTION OF FLUXES, by H. Mori. Oct. 1, 1957, 30p. incl. refs. (AFOSR-TN-57-565) (AF 18(603)87) AD 136581; PB 136171
Unclassified

A time-dependent kinetic equation governing the correlation function of the flux $\Psi_{ff}(t)$ is established for dilute gases and is integrated to give the correlation time in terms of the transport cross section. The spectrum of the binary collision operator Λ_{ij} is determined for intermolecular interactions which have spherically symmetric short range forces. For the hard-core molecule assumption Λ_{ij} consists of two discrete values in the classical limit. If F_p satisfies the equation $\Lambda F_p = \lambda_v F_p$, then $\Psi_{ff}(t) \sim \exp(-t\lambda_v)$, where Λ is the master collision operator. Approximate eigenvalues of Λ are obtained corresponding to the viscosity and heat fluxes. A simple relation between the macroscopic transport coefficient and the corresponding relaxation time in momentum space is derived from the fluctuation-dissipation theorem. This relation leads to a new approach to the transport properties of dilute gases, which is different from Enskog-Chapman's method, but yields the same results in the classical limit. An expansion formula for the canonical transformation describing the motion of a dilute gas is obtained and is employed to clarify the postulate of random a priori phases in the momentum representation for spatially uniform gases. This is done by formulating exactly and quantum-mechanically Brout's idea in the classical derivation of the master equation.

CORRELATION TIMES OF FLUXES IN THE QUANTUM

BRO. 15:003, 004; BRO. 16:001

THEORY OF TRANSPORT PROCESSES (Abstract), by H. Mori. [1957] [1]p. [AF 18(603)87] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 203, Apr. 25, 1957.

The various kinetic coefficients can be expressed in terms of the correlation function of the corresponding flux F , $\Psi(t) = \langle FF(t) + F(t)F \rangle$. We mainly consider the viscosity coefficient of the quantum gases η , where

$$F = \sum_{i=1}^N p_{ix} p_{iy}$$

The change with time of the Heisenberg

operator $F(t)$ can be described by an operator $T(t, t_0) = \exp[(t - t_0)L]$, where $LF = [F, H]/\hbar$. In order to separate the effects due to the molecular interaction from the free motion, define $K(t, t_0) = \exp(-tL_0)T(t, t_0)X \exp(t_0L_0)$, where L_0 is the L operator of the kinetic energy H_0 .

Then, the binary collision approximation leads, in the limit of $N \rightarrow \infty$, to $K(t, 0) = \exp[\int_0^t \sum_{ij} w_{ij}(t)]$, where w_{ij} is related to the scattering matrix for the collision between molecules i and j to give $\langle p|w_{ij}|p \rangle = t\Omega_{ij}p|F|p$.

Ω_{ij} is the collision integral operator familiar in the kinetic theory of dilute gases and contains the complete quantum-mechanical scattering cross section.

$\psi_{ij} = p_x p_y$, ($p = p_j - p_i$), is an eigenfunction of Ω_{ij} with the eigenvalue $w_{ij} = -3|p|Q(p)/mv$, where $Q(p)$ is the transport cross section. Thus, if, on the average, the deviation of the w_{ij} is small from their average value as for the classical Maxwell molecule, then the correlation function decays exponentially with time to give $\eta = 4\langle F^2 \rangle / 3nkT \langle 2|p| X Q/m \rangle$. The behavior of η is discussed for some potential functions.

TIME-CORRELATION FUNCTIONS IN THE STATISTICAL MECHANICS OF TRANSPORT PROCESSES, by H. Mori. Aug. 1, 1958 [13]p. incl. refs. (AFOSR-TN-58-1015) (AF 18(603)87) AD 208226 Unclassified

Also published in Phys. Rev., v. 111: 694-706, Aug. 1, 1958.

A kinetic equation governing the time dependence of the correlation function of flux is established for dilute gases and is integrated to yield a relation between the correlation time and the transport cross section. The spectrum of the binary collision operator is determined for spherically symmetric forces between molecules, which, for

the hard-core model, consists of two discrete values in the classical limit. Hence it is shown that the question of validity of approximating the correlation function by an exponential decay depends upon the type of intermolecular force and the temperature of the system. Approximate eigenvalues of the master collision operator are obtained corresponding to the fluxes of viscosity and thermal conduction, and their relations to the macroscopic transport coefficients are derived. These relations lead to a new approach to the transport properties of dilute gases, which is different from Enskog-Chapman's method but yields the same results in the classical limit. An expansion formula for the canonical transformation describing the motion of dilute gases is obtained and is employed to clarify the assumption of random a priori phases in the momentum representation for spatially uniform gases. This is done by formulating the quantum-mechanical equivalent of Brout's idea in the classical derivation of the master equation. (Contractor's abstract)

TRANSPORT EQUATION IN QUANTUM GASES, by H. Mori and J. Ross. [1958] [6]p. incl. refs. (AFOSR-TN-58-1064) (AF 18(603)87) AD 222511 Unclassified

Also published in Phys. Rev., v. 109: 1877-1882, Mar. 15, 1958.

A derivation of the quantum-mechanical analog of the Maxwell-Boltzmann equation of transport for gases at low density is presented. The analysis requires: the definition of a time differential which is necessary for the selection of only secular variations in the time dependence of the distribution functions (coarse-graining in time); a binary collision approximation; the connection between the phase-space transformation function, relating the Wigner distribution function at different times, and the transition matrix in the theory of scattering of two particles; and a coarse-graining in configuration space leading to a kinetic equation for spatially nonuniform systems. A consequence of the binary collision approximation is the exclusion of the effects of symmetrization (Bose-Einstein or Fermi-Dirac statistics) resulting in density-dependent terms. BRO. 16:002-005; BRO. 17:001

Dielectric constant and loss measurements of solid hydrogen chloride, and hydrogen and deuterium bromide and iodide, are summarized and discussed in relation to order-disorder phase transitions. Electrostatic calculations indicate the importance of dipole interactions for the structures and rates of molecular orientation in the low temperature phases, but specific effects show the significance of other factors as well. In the less ordered temperature phases, the dispersion behavior is characteristically different, but more complete dielectric measurements and structural evidence will be needed for a proper understanding. THE VISCOSITIES OF SOME UNDERCOOLED LIQUID ALKYL HALIDES, by D. J. Denney. [1958] [12]p. incl. table, refs. (AFOSR-TN-58-664) (AF 49(638)31) AD 162195 Unclassified

Also published in Jour. Chem. Phys., v. 30: 159-162, Jan. 1959.

The viscosities of i-butyl bromide, i-amyl bromide, and i-butyl chloride were measured over a temperature range in which η changed from 10^2 poise to about 10^8 poise. The temperature dependence of η is very close to that of the dielectric relaxation time indicating the similarity of the molecular processes involved. This similarity thus appears to apply to 'non-associated' polar liquids as well as to hydrogen bonded liquids. (Contractor's abstract, modified)

A COAXIAL DISPLACEMENT DIELECTRIC CELL FOR LIQUIDS USABLE TO 250 Mc/s, by S. E. Lovell and R. H. Cole. [1958] 5p. (AFOSR-TN-58-662) (AF 49(638)31) AD 162193 Unclassified

Also published in Rev. Scient. Instruments, v. 30: 361-362, May 1959.

A cell has been developed for bridge measurements of capacitance and dielectric or conduction loss in liquids at frequencies up to 250 mc/s. The apparatus consists basically of a short length of coaxial line, filled with liquid, with a dielectric plunger which can be moved axially to replace variable amounts of liquid in the annular space between the conductors. The measured changes in capacitance and conductance with plunger displacement can then be used to calculate the dielectric properties of the displaced liquid. Corrections for imperfect plunger fit, lead capacitance, and inductance are small, and procedures for making them are given. Dielectric constants from 3 to 300 and high losses can be measured from -70 to 100°C with 3cc or less of sample.

SOME RECENT DEVELOPMENTS IN ELECTRO-ENCEPHALOGRAPHY, by H. W. Shipton. [1957] [5]p. incl. illus. diags. [AF 61(514)1178] Unclassified

Published in *Brit. Commun. and Electronics*, v. 4: 222-226, Apr. 1957.

Electroencephalography techniques are surveyed from the laboratory, rather than in the clinic, viewpoint. The automatic LF wave analyser is described with recent improvements. Transistor amplifiers, incorporated in machines with more channels than the usual 6 or 8, have been developed and their disadvantages, e.g. liability to drift, sensitivity to temperature change, and high noise level, have been fairly easily overcome. The evolution of the "toposcopic" display system, developed at Burden Neurological Institute for measurement of signal frequency and spatial location rather than amplitude, is reported and includes a description of the most recent innovation, the circular sweep toposcope.

Experiments and their results are reported for the investigation of how brain mechanisms operate during

the course of learning and forgetting in humans. An assumption has been made that the mechanics of brain function are based on processes of statistical selection and reflexion. The particular aspect of these processes discussed is "timing", or coordination in time, of the preservation and classification of a sequence of events. Time and space relations of electrical events in the brain have been measured by a toposcopic method employing a cluster of 22 cathode ray tubes. In this method rhythmic variations in voltage are transformed into changes of brilliance and then projected upon a spiral scanning time-base, the speed of which can be very accurately controlled and adjusted. Since the scale is coiled helically on the tubes, the length of photographic exposure can be prolonged achieving "line-to-line correlation." The extreme regularity and stability of the alpha processes in the subjects studied, and the subtle variations during thinking, strongly suggest that there is available a mechanism for preserving and comparing the sequence of events in time.

A system has been devised in which spiral scan is used. The diameter of the scan is increased smoothly during the camera exposure so that repetitive signals lie on the same angular bearing but with changing radius. Thus trace-to-trace correlation is substituted for the summation process of earlier systems. It has been shown that this leads to an improvement in signal noise ratio, and alleviates ambiguities which otherwise would arise.

[THE PRESENTATION AND IDENTIFICATION OF THE COMPONENTS OF THE ALPHA RHYTHMS] La présentation et l'identification des composantes des rythmes alpha, by W. G. Walter and J. Sipton. [1957] [8]p. (AF 61(514)1178) Unclassified

Published in EEG Clin. Neurophysiol., Suppl. 6: 177-184, 1957.

"Alpha rhythms show variations of topology, amplitude, frequency and phase with respect to one another and ... to time, so that methods for studying them should envisage a 7-dimensional continuum. No methods yet described approach this ideal, nor is it easy to relate more than a few of these parameters to estimates of mentality or personality." A combination of frequency analysis and toposcopy contains a good proportion of the basic information, but data presented in these coordinates have to be further processed to relate them to changes during an experiment. It has been demonstrated that alpha rhythms are essentially plural and that their differential components are distinguishable by their frequency, phase relations in various regions, domains, and relations to mental changes.

MELTING-POINT PURITY DETERMINATIONS: LIMITATIONS AS EVIDENCED BY CALORIMETRIC STUDIES IN THE MELTING REGION, by J. P.

McCullough and G. Waddington. Jan. 15, 1957 [41]p. incl. diags. tables, refs. (Contribution no. 65) (AFOSR-TN-57-1) (Sponsored jointly by Air Force Office of Scientific Research under [CSO-680-57-4] and American Petroleum Inst.) AD 115031 Unclassified

Presented at Internat'l. Symposium on Purity Control by the Thermal Analysis, Amsterdam (Holland), Apr. 24-26, 1957.

Also published in Anal. Chem. Acta, v. 17: 80-96, July 1957.

Typical melting curves, chosen from the results of more than 125 melting-point studies, are presented to illustrate both the reliability and the inherent limitations of the calorimetric method of purity determination. It is shown that this method usually is one of the best means of accurately determining small concentrations of impurity. However, analysis of anomalous melting curves leads to the conclusion that pseudo-equilibrium curves are often obtained as a result of inhomogeneous distribution of purity in the liquid phase or of non-equilibrium distribution of impurity between the solid and liquid phases. Evidence is given to support the contention that solid solutions were formed in as many as half of the samples studied and that, for this reason, impurity values calculated for perhaps 1/3 of the samples are in error by 200% or more. Although these large uncertainties in impurity values usually correspond to less than 0.1% uncertainty in purity values, modified procedures are proposed to minimize such errors. Expressions are derived for the constitutive dielectric parameters of a cubical lattice whose elements consist of a triad of mutually perpendicular polarizable elements. The analysis gives the fundamental relations for the simulation by suitably disposed dipoles, of three-dimensionally isotropic dielectrics with dielectric constants greater than, equal to, and less than unity. Three different approaches have been used. One of these is a complete and rigorous solution which gives the dielectric tensor for the general case of unrestricted spacing to wavelength ratio. This rigorous analysis shows that the Clausius-Mosotti relation often used in predicting the properties of such lattices is a satisfactory approximation only if the spacing is very small with respect to wavelength. Using the general principles developed in this paper, conditions are derived for the realizability of reflectionless media. (Contractor's abstract)

Presented at I.R.E. National Convention, New York, Mar. 18-21, 1957.

Also published in I.R.E. National Convention Record, Pt. 2: 120-133, 1957.

A small-signal equivalent circuit for a junction transistor is presented which is applicable to alloy or grown types of p-n-p or n-p-n transistors, and which is valid from dc up to twice the cutoff frequency. The equivalent circuit is in the form of four short-circuit admittances, each of which can be represented by a simple network of lumped elements constant with frequency. The derivation is based on physical principles and takes into account base widening and collector barrier capacitance. Equations for the equivalent circuit element values are given either in terms of physical parameters or in terms of six practical measurements. The four-admittance representation is given both for common-emitter and common-base connections, and a relation between the common-emitter and the common-base cutoff frequencies is derived and experimentally verified. Measurements of the real and imaginary parts of the four admittances as functions of frequency for several transistors show excellent agreement with the values predicted by the equivalent circuit. Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

A column of ionized mercury vapor is placed in a parallel plate transmission line and the resulting reflection coefficient observed. From the measurement of reflection coefficient as a function of discharge current, plasma resonance is demonstrated. In accordance with the theory applied, but in contrast to the results of other investigators, resonance is found at only one value of discharge current. The discharge current required to produce resonance is measured as a function of frequency. The functional dependence observed is as predicted by theory, but the current is higher than the theoretical value. The discharge current required to produce resonance is measured as a function of gas pressure. The dependence that is found follows that predicted theoretically at high gas pressure, but deviates sharply from the theoretical form at lower gas pressures. (Contractor's abstract)

Presented at Congrès International des Circuits et Antennes Hyperfréquences, Conservatoire National des Arts et Métiers, Paris (France), Oct. 25, 1957.

The strong limitations on the applicability of exact methods of analysis to electromagnetic boundary-value problems encouraged the development of approximation techniques. Among the most practical of the techniques was Schwinger's variational method which eliminated the special difficulties in solving the integral, integro-differential or matrix equations associated with linear antennas. Two complementary forms of the principle were used: one was a function of the surface electric fields and the other was a functional of surface magnetic fields. The complementary forms were applied to the calculation of the input impedance of a circular diffraction antenna consisting of a coaxial waveguide fitted with a limitless flange and open to free space. The difference between the two forms was taken as a measure of the quality of the approximation. The starting point of the principle was the integral equation formulation of the boundary-value problem of waveguide discontinuities. (ASTIA abstract)

The conventional formulas for the attenuation of waves due to the wall losses in uniform waveguides are based on the two assumptions that the wall currents are the same as the loss-free currents and that the surface resistance of the highly conductive walls is isotropic. In the limit of high frequencies the former assumption remains valid whereas the latter assumption breaks down. As the frequency is increased the surface resistance becomes anisotropic in the sense that it assumes different values depending on whether the wall current is longitudinal or transverse. New attenuation formulas are derived, which take into account the high-frequency anisotropy of the surface resistance and hence yield accurate results for all frequencies. (Contractor's abstract)

Also published in Jour. Appl. Phys., v. 29: 1052-1063, July 1958.

An order of anisotropy related to the granularity of a lattice at high frequencies is described and investigated. Three different approaches were used to evaluate the expression for the dielectric parameters of a cubical lattice with isotropic elements: (1) a molecular analogy with a consideration of static dipole interaction; (2) an

CIT.02:014, 015; CIT.13:001-003

analysis based on the summation of scattered time-varying fields in which it is demonstrated that the use of the trapezoidal summation approximation completely removes retardation effects; and (3) an exact solution valid for all values of spacing to wavelength ratio. The exact solution brings to light the type of anisotropy existing in artificial structures which is usually ignored. This is an anisotropic effect which exists even in arrays composed of isotropic elements arranged in structurally isotropic patterns. The isotropy is caused by the granularity of the artificial structure. At higher frequencies, when the interelement spacing becomes appreciable in terms of wavelength, this granularity becomes important. This effect is calculated in terms of the high-frequency anisotropy tensor. This study also has direct application in the design of isotropic materials for the control and direction of microwave energy.

The radiation fields were calculated for a half-wave horizontal, linear antenna located at the surface of a plane earth of finite conductivity. Results indicated that a horizontally polarized field is radiated in the mid-plane perpendicular to the antenna and that this field is zero in the plane of the earth. A vertically polarized ground wave is radiated which is maximum in the direction of the axis of the antenna and zero at right angles to the antenna. Ground resistivity measurements were made at a number of locations in central and southern California. A correlation between these measured values and the geology of the terrain indicated that for the high values of ground resistivity, which are necessary for optimum antenna efficiencies, the rock formations must be relatively unfractured and that the amount of annual rainfall and other climatic conditions are of little significance.

THE BASAL SLIP IN ZINC UNDER STATIC AND DYNAMIC LOADING, by T. Vreeland, Jr., D. S. Wood, and D. S. Clark. May 1957 [40]p. incl. illus. diagrs. table, refs. (AFOSR-TN-57-316) (AF 18(600)490) AD 132387 Unclassified

Also published in Jour. Mech. and Phys. of Solids,
v. 6: 111-126, 1958.

This paper presents the results of an investigation of static and dynamic shear behavior of two purities of zinc single crystals. All the crystals tested were in the form of cylindrical rods with the [0001] crystallographic direction parallel to the rod axis. The static tests were performed by applying simple transverse shear loading in one of the slip directions to one end of the crystals with the other end of the crystals rigidly clamped. The static shear stress vs stress strain relations are obtained from these tests. The dynamic tests were conducted by suddenly stopping

(within a period of about 25×10^{-6} sec) one end of the crystals which were moving in the slip direction with various velocities. The resulting waves of plastic shear deformation which propagate from the stopped ends of the crystals toward the free ends are analyzed. The analysis is based upon the assumption that elastic strains may be neglected in comparison with the plastic strains. The use of the results of this analysis in conjunction with measurements of the permanent lateral deflections of the crystals resulting from the dynamic tests leads to the determination of dynamic shear stress vs shear strain relations. The results of this study show that the stress required to produce a given permanent basal shear strain in single crystals of zinc is considerably greater under the dynamic conditions employed than under static conditions. This stress decreases with increasing temperature.

PARTIALLY PINNED TILT BOUNDARIES, by T. Vreeland, Jr., D. S. Wood, and D. S. Clark. Sept. 1957, 22p. incl. diagrs. (Technical note no. 3) (AFOSR-TN-57-624) (AF 18(600)490) AD 136612 Unclassified

Also published in Acta Metallurgica, v. 7: 240-245,
Apr. 1959.

Results are presented of a theoretical study of the conditions under which small angle tilt boundaries in a crystal can be moved when subjected to a stress which does not produce general slip. The dislocations in the boundary are assumed to be partially pinned by Cottrell atmospheres, intersecting substructure, or precipitates along the dislocation lines. The results show that partially pinned dislocation boundaries may move at lower stresses than similarly pinned isolated dislocations if the density of pinned segments is sufficiently low. Stress concentrations at pinned segments on a small angle boundary are discussed. A "yield condition" for motion of certain partially pinned boundaries is described in which pinned dislocations are left behind when the boundary is moved. (Contractor's abstract)

TILT BOUNDARY MOTION PRODUCED BY STATIC AND DYNAMIC SHEAR STRESS IN ZINC CRYSTALS, by T. Vreeland, Jr. Nov. 1958, 45p. incl. illus. diags. refs. (Technical note no. 5) (AFOSR-TN-58-1065) (AF 18(600)490) AD 207225 Unclassified

Also published in Acta Metallurgica, v. 9: 112-116, Feb. 1961.

Results of an experimental study of the motion of small angle tilt boundaries in crystals of zinc are presented. Crystals grown from 99.999+ per cent purity zinc, and zone refined zinc, were subjected to static and dynamic shear loading. The dynamic loading system employs a gas shock tube to achieve shear stress in the test specimen containing a small angle boundary. The time for the application of a shear stress in the dynamic test is of one μ sec. Boundaries in crystals of zone refined zinc move at static stresses of approximately 3 lb/in.², while stresses of approximately 20 lb/in.² do not move boundaries in 99.999+ per cent purity zinc. The stress required to initiate boundary motion in a dynamic test is one to two orders of magnitude greater than the stress required in the static test. The boundary velocity increases with increasing dynamic stress. The drag stress on the boundary is proportional to the boundary velocity. These observations are discussed in terms of the forces which act on dislocations constituting the small angle tilt boundary. (Contractor's abstract)

THE INFLUENCE OF ULTRASONIC WAVES ON SOME CHEMICAL CONVERSIONS OF ORGANIC COMPOUNDS, by D. L. Currell. Final rept. July 31, 1957, 14p. incl. tables, refs. (AFOSR-TR-57-51) (AF 18(600)385) AD 136437 Unclassified

Investigations were made to determine whether or not ultrasonic ring cleavage could be realized and the evolution of acetylene gas detected in the absence of AgNO₃. Benzene, PhBr, PhOH, pyridine, pyrrole, and pyrazine were suspended in pure H₂O. During ultrasonic treatment, the volatile products were swept by an inert gas, either N or Ar, into a trap containing ammoniacal cuprous solution. Reddish-purple cuprous acetylide was collected and titrated for acetylene. When the compound contained heterocyclic N, a parallel experiment was conducted in which a KOH solution was substituted for the cuprous reagent. The alkaline solution which trapped the HCN was treated as the ammoniacal extracts of Ag-containing precipitates. After conversion into prussian blue, the cyano group was estimated colorimetrically. The results indicated that the ultrasonic conversion took place in the absence of Ag. The compounds treated yielded more acetylene when AgNO₃ was present. The cyanide yields were, in general, higher in the absence of AgNO₃.

SOME EXPERIMENTS WITH ULTRASONIC WAVES, by L. Zechmeister and E. F. Magoon. [1957] 6p. incl. refs. (AF 18(600)385) Unclassified

Also published in Festschrift Arthur Stoll, Birkhäuser, Basel (Switzerland), 1957, p. 59-63.

It has been found that certain halogen derivatives yield silver halide precipitates when subjected to ultrasonic waves in the presence of silver nitrate. Aromatically bound halogens have been considered to be passive preventing precipitation by silver ions. The action of the ultrasonic waves seems to lead to a collapse of the aromatic ring with the formation of acetylene. Acetylene has been formed from benzene by the use of ultrasonic waves. The direct cleavage of pyridine to form acetylene and hydrogen cyanide has been possible with a 5% yield.

EXPANSION PROCEDURES AND SIMILARITY LAWS FOR TRANSONIC FLOW, by A. F. Messiter, Jr. Sept. 1957, 104p. incl. refs. (AFOSR-TN-57-626) (AF 18(600)383) AD 136613; PB 139955 Unclassified

The transonic flow past slender bodies and thin wings is investigated with the use of a general theory of expansion procedures. It is assumed that the solutions for the velocity components possess asymptotic expansions of a very general form, and the differential equations and boundary conditions for the first and higher approximations are obtained by applying appropriate limiting procedures to the full equations. The following cases are treated: (1) bodies of revolution at zero incidence; (2) bodies of nearly circular cross-section, at zero incidence; (3) bodies of revolution at an angle of attack; and (4) thin wings at zero incidence. Certain first-order similarity laws are derived for these prob-

lems, and the order of magnitude of the error is stated in each case.

A TWO-DIMENSIONAL AIR INTAKE IN A SONIC STREAM, by L. E. Fraenkel. Mar. 1958, 39p. incl. diagrs. refs. (AFOSR-TN-58-113) (AF 18(600)3) AD 152021 Unclassified

Also published in Jour. Fluid Mech., v. 4: 629-643, Nov. 1958.

Transonic small-disturbance theory is applied to a simplified model of the flow near the front of a ducted body. The body is assumed to consist simply of two parallel flat plates which extend from the inlet station to infinity downstream. The velocity far upstream is sonic, and the velocity far downstream in the duct, which is assumed to be known, is slightly subsonic. Air is therefore "spilled" around the intake edges. An analytic solution is found for the resulting flow field up to the "limiting Mach wave", and asymptotic solutions are found for the supersonic flow and for the shock wave far from, and near, the intake edges. The pressure distribution along the outside walls is then known at both ends, and its computation is completed by an empirical procedure. Distributions of pressure along the center-line and along the inside and outside walls are shown. These results may be used to compute the drag of sharp-edged intakes with a very small frontal area. FLUTTER OF CURVED PLATES WITH EDGE COMPRESSION IN SUPERSONIC FLOW, by Y. C. Fung. Mar. 1957 [32]p. incl. diagrs. table, refs. (Rept. no. 5; Galcit rept. no. 86) (AFOSR-TN-57-187) (AF 18(600)1142) AD 126482 Unclassified

Presented at Fifth Midwest Conference on Fluid Mechanics, Ann Arbor, Mich., Apr. 1-2, 1957.

In order to explain a significant quantitative discrepancy between previous theory and experiments on the large amplitude flutter of buckled plates in a supersonic flow, the effects of the initial curvature and of a static pressure differential across the plate are calculated. It is found that the order of magnitude of the initial deviation from flatness required to account for the discrepancy is quite reasonable, so that the explanation may very well lie in that direction. The critical flutter condition of a buckled plate is sensitive to the mean compressive load

(the so-called "membrane" stress) in the plate. If the plate is not perfectly flat, lateral deflection will occur under edge compression, and for any specific amplitude of deflection the compressive load is less than the critical buckling load of a perfectly flat plate. This reduction of the compressive load is beneficial to the prevention of panel flutter. Hence it is found that, within certain limits, an increase in the initial deviation from flatness raises the critical value of the parameter Q , which is proportional to the dynamic pressure of flow, or the square of the "reduced velocity" at flutter. The static pressure differential across the plate, p , has very little effect on the critical reduced velocity when p is small, but becomes very effective in preventing flutter when p is sufficiently large. The trend of theoretical dependence of the critical reduced velocity on the amplitude of the buckle agrees with that of the experiments in the "large amplitude" flutter range. However, the "small amplitude" flutter that occurred in the experiments when the amplitude of the buckle was very small remains unexplained. Although it cannot be claimed that the analysis brings the theory and experiment into agreement, since the initial warping of the test specimens was unknown and the numerical calculations are severely simplified; the importance of the initial warping is well borne out by such a comparison. (Contractor's abstract)

can be quoted for the flutter of unbuckled panels that is supposedly linear in character, however a large theoretical literature exists. One center of interest is concerned with a controversy on the applicability of Galerkin's method to panel flutter. To study this problem the flutter condition was formulated as an integral equation and solved by numerical methods, thus avoiding the constraint of assumed modes. For a plate (with finite bending rigidity) the results confirm those given by Galerkin's method. In order to assess the importance of panel flutter in supersonic aircraft design, the limiting amplitude of flutter is calculated. (Contractor's abstract)

PLANE COUETTE FLOW AT LOW MACH NUMBER ACCORDING TO THE KINETIC THEORY OF GASES, by H.-T. Yang and L. Lees. Feb. 1, 1957, 37p. incl. illus. tables. (Memorandum no. 36) [Sponsored jointly by Air Force Office of Scientific Research and Army Ordnance under DA-04-495-ord-19] AD 126308 Unclassified

The 13-moment approximation developed by H. Grad for solving the Maxwell-Boltzmann equation is applied to the problem of the relative shearing motion between 2 infinite, parallel flat plates (plane Couette flow). In order to bring out the molecular effects as directly as possible, the problem is linearized by requiring that the Mach number is small compared with unity, and that the temperature difference between the 2 plates is small compared with the ambient temperature. According to the linearized Grad equations the shear stress in this case is given by the usual Navier-Stokes relation for all values of the parameter Re/M [where Re = Reynolds number and M = Mach number], in agreement with R. A. Millikan's postulate. Also, the linearized boundary conditions for this problem are identical with the Maxwell slip relations utilized by Millikan, so that the same expressions for slip velocity and drag coefficient are obtained. An examination of the drag obtained by Kuhlthian, Chiang, and Bowyer and Taibot in their rotating cylinder experiments at low densities shows that the variation of $1/C_D M$ [where C_D = drag coefficient] with Re/M is predicted reasonably well by this theory over a range of Mach numbers of 0.15 to 1.40, in spite of the fact that the theory is supposed to hold only for low Mach numbers. Presented at National summer meeting of the Inst. of Aeronaut. Sciences, Los Angeles, Cal., June 17-20, 1957.

Also published in Jour. Aeronaut. Sciences, v. 25: 145-160, Mar. 1958.

Theory and experiments of the "large amplitude" flutter of a buckled plate are discussed. It is shown that an increase in the initial deviation from flatness raises the critical value of the "reduced velocity". The static pressure differential across the plate, p , has very little effect on the critical reduced velocity if p is small, but becomes very effective in preventing flutter when p is sufficiently large. Exploratory experiments show that the panel flutter in a transonic and low supersonic flow is essentially a single-degree-of-freedom one, (i.e., points on the plate oscillate practically in phase). For a plate of given thickness in a flow of given stagnation pressure, flutter first occurs at a critical Mach number, and then may disappear at a higher Mach number; the region of Mach number in which flutter occurs decreases with increasing plate thickness. No detailed experiments

NOZZLE, by R. E. Oliver and B. E. Cummings. [1957] [2]p. incl. diagr. (Sponsored jointly by Office of Ordnance Research and [Air Force Office of Scientific Research] under DA-04-495-ord-19) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 466-467, June 1957.

An experimental investigation was conducted in the Gaicit 2½ x 3 in. supersonic wind tunnel to determine the effect of a known distortion of the throat section of a hypersonic nozzle on the flow in the region downstream from the throat. The flow in a nozzle with a rectangular throat section was compared with the flow in the same nozzle with the throat region distorted to produce a throat height which varied linearly across the throat section. The flow was investigated by means of pitot pressure surveys in the horizontal plane of symmetry of the undistorted nozzle. The magnitude of the effect produced by this throat distortion was observed to be approximately that predicted by one-dimensional isentropic flow relations. However, the sign of the effect was reversed in about the distance required for a curved Mach line starting at the throat to cross the channel. Mach numbers were determined from isentropic flow relations. The resulting constant Mach number contours in the horizontal plane of symmetry of the undistorted nozzle are shown. Also shown are the approximate characteristics in this plane. The one-dimensional Δ 's presented are the distortions of the constant Mach number contours as predicted by one-dimensional isentropic flow relations. There was no apparent decay of the distortion effect within the region of this investigation.

NORMAL-FORCE CHARACTERISTICS OF DELTA WINGS AT SUPERSONIC SPEEDS, by S. Lampert. [1957] [9]p. incl. illus. diagrs. (Sponsored jointly by [Air Force Office of Scientific Research] and Army Ordnance under DA-04-495-ord-19) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 667-674, 682, Sept. 1957.

Some of the more important results of a series of wind-tunnel investigations conducted at the Jet Propulsion Lab. to determine the aerodynamic-force characteristics of delta wings are presented. A family of five delta wings was designed to cover the range of slope ratios, leading-edge slope to Mach wave slope, from 0.15 to 4.1. Lift or normal-force characteristics for these wings were systematically studied as a function of Reynolds number and Mach number. The results of these investigations are presented as normal-force coefficients per radian for the Mach number range 1.33 to 4.55. These measurements are compared with the linear theory both

as a function of Mach number and slope ratio. It was found that the experimental measurements were in good agreement with and exhibited the trend of the theory in the range of slope ratios 0.15 to 0.70; whereas notable departures from the theory were observed for slope ratios greater than 0.70. For a given wing the systematic variation of the wing profile indicated that there existed a much greater dependence of the lift on profile or edge configuration than on Reynolds number for slope ratios greater than 0.70. THE EFFECTS OF BLUNT LEADING EDGES ON DELTA WINGS AT MACH 5.8, by K. F. Nicholson. June 10, 1958, 34p. illus. diagrs. refs. (Memorandum no. 45) (Sponsored jointly by [Air Force Office of Scientific Research] and Army Ordnance under DA-04-495-ord-19) Unclassified

Also published in Jour. Aero/Space Sciences, v. 25: 786-787, Dec. 1958.

Pressure distributions were measured on a series of four delta wings with subsonic and supersonic leading edges, both sharp and blunt. The blunt leading edge radius was about 0.5 per cent of root chord. Schlieren studies were also made to determine top and side view shock locations. The tests were conducted at a nominal Mach number of 5.8, and at Reynolds numbers between 0.335×10^6 and 0.901×10^6 based on root chord. Angular settings covered a range $-0.2^\circ \leq \alpha \leq 0.5^\circ$ in pitch at zero yaw (about $-11.5^\circ \leq \alpha \leq +30^\circ$), and a range of $\alpha/V = \pm 0.125$ (about $\pm 7.2^\circ$) at a fixed angle of pitch of 11.5° . The effects of bluntness were found to be small. Also, the pressures produced by shock wave interactions with the boundary layer, and the inviscid pressures generated by the blunt leading edges, were found to be small compared with the inviscid pressures producing lift on the basic wing. Spanwise pressure distributions show no similarity to those obtained by linearized theory. Centerline lower surface pressure in pitch at zero yaw is bracketed between the Newtonian value $\Delta P/q = 2(w/V)^2$ and the two-dimensional exact value. (Contractor's abstract)

AN EXPERIMENTAL INVESTIGATION OF THE STABILITY OF THE HYPERSONIC LAMINAR BOUNDARY LAYER, by A. Demetriades. [1958] [2]p. incl. illus. diagrs. (Sponsored jointly by Office of Ordnance Research and [Air Force Office of Scientific Research] under DA -04-495-ord-19) Unclassified

Published in Jour. Aero/Space Sciences, v. 25: 599-600, Sept. 1958.

The shape of the instability region at $M = 5.8$ is generally preserved in comparison with the stability diagram at lower Mach numbers, although the area it encloses seems to be much smaller. Both neutral branches are displaced to considerably lower frequencies (larger wavelengths) than the Schubauer-Skramstad neutral branches, and to higher Reynolds numbers than the corresponding Laufer-Vrebalovich data at $M = 2.16$. The amplification rates observed were generally small; for example, the total amplification across the instability region is of the order of 1.4 at a nondimensional frequency of 5×10^{-5} .

UNSTEADY FLOWS IN AXIAL TURBOMACHINES, by W. D. Rannie and F. E. Marble. [1957] 21p. incl. diagrs. tables. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)178 and Office of Naval Research under Nonr-22023) Unclassified

Of the various unsteady flows that occur in axial turbomachines certain asymmetric disturbances, of wave length large in comparison with blade spacing, have become understood to a certain extent. These disturbances divide themselves into two categories: self-induced oscillations and forced disturbances. A special type of propagating stall appears as a self-induced disturbance; an asymmetric velocity profile introduced at the compressor inlet constitutes a forced disturbance. Both phenomena have been treated from a unified theoretical point of view in which the asymmetric disturbances are linearized and the blade characteristics are assumed quasi-steady. Experimental results are in essential agreement with this theory wherever the limitations of the theory are satisfied. For the self-induced disturbances and the more interesting examples of the forced disturbances, the dominant blade characteristic is the dependence of total pressure loss, rather than the turning angle, upon the local blade inlet angle. (Contractor's abstract)

PERFORMANCE OF AXIAL COMPRESSORS WITH ASYMMETRIC INLET FLOWS, by R. Katz. Final rept. June 1958, 150p. incl. illus. diagrs. tables, refs. (AFOSR-TR-58-39) (AF 18(600)178) AD 162112; FB 144039 Unclassified

Over-all performance measurements and circumferen-

tial surveys of total pressures, velocities, and flow angles were obtained in an axial compressor in which inlet disturbances covered about 25% of the inlet annulus area. Three configurations were tested to find the principal effects in a single rotor, a complete stage, and a multi-stage machine. A total pressure disturbance at the inlet of a compressor stage was considerably reduced in magnitude and distorted from its original form downstream of the stage; the circumferential extent of the total pressure disturbance was decreased downstream of the stage. The angle perturbations were a maximum at the plane of a blade row and decreased exponentially upstream and downstream. Large perturbed flow angles downstream of a rotor blade row could cause stalling and flow separation in the following stator blade row when the axial spacing was small. In a multi-stage compressor an inlet disturbance was rapidly reduced through the stages. Ideally, the average total pressure was unaffected by an inlet disturbance; losses which occurred in the rotor and stator blade rows caused the average total pressure to be reduced. At the lower flow rates, the losses were the greatest. A linearized theory was developed which correctly describes the flow process. The additional blade forces were largest when the losses and the leaving angle deviations were neglected. A safe estimate of blade forces may be made with only a knowledge of the disturbance and the mean flow characteristics of the compressor.

EMISSIVITY ESTIMATES FOR HEATED NO, by A. Thomson. Nov. 1957, 1v. incl. diagrs. tables. (Technical rept. no. 6) (AFOSR-TN-57-782) (AF 18(603)2) AD 148388 Unclassified

The emissivity of the β and γ systems of NO has been calculated between 4000°K and 6000°K for a range of optical densities. Both the positions and intensities of the bands were assumed to be distributed statistically. An approximately uniform average value for the square of the vibrational matrix elements was assigned to all contributing transitions. The emissivity was calculated at low pressure (pure Doppler broadening) and at high pressure (no rotational fine structure). It is found that, for the specified temperature range, the error induced by neglecting the rotational fine structure is less than 40%. The results obtained do not differ by more than about 50% from those described by Kivel, Mayer and Bethe although the present analytical procedure is quite different. (Contractor's abstract)

THE DETERMINATION OF ABSOLUTE INTENSITIES

CIT.09:009, 010; CIT.14:001, 002

AND f-NUMBERS FROM SHOCK TUBE STUDIES, by S. S. Penner. Dec. 1957, 42p. incl. refs. (Technical rept. no. 5) (AFOSR-TN-58-11) (AF 18(603)2) AD 142722 Unclassified

Also published in NATO AGARDographs, no. 41: 161-182, 1961.

A discussion is presented of the experimental and computational procedures in determining radiant energy transfer. The basic physical laws are outlined which refer to equilibrium radiation from heated gases. A critical evaluation is made of experimental procedures for absolute intensity measurements which apply also to shock-tube investigations. Published experimental shock-tube studies on emissivity measurements of air are summarized. These studies include qualitative spectroscopic research behind shock fronts for selected atomic and molecular systems. A quantitative interpretation is presented of 2-path data for the determination of temperature, concentration, and absolute intensities.

SHOCK TUBE STUDIES OF ACETYLENE DECOMPOSITION, by W. J. Hooker. Apr. 1958, 10p. incl. illus. diags. (Technical rept. no. 7) (AFOSR-TN-58-293) (AF 18(603)2) AD 154202 Unclassified

Also published in Seventh Symposium (International) on Combustion, Oxford U., London (Gt. Brit.) (Aug. 28-Sept. 3, 1958), London, Butterworths Scientific Publications, 1959, p. 949-952.

Extensive experimental studies were conducted on the rate of decomposition of Ar-acetylene mixtures by means of shock waves. Spectrally integrated radiation measurements in the visible region of the spectrum were made of the simultaneous emission and absorption of the transmitted radiant energy by the heated gases and solid particles behind the incident shock front. Emission from the acetylene $\Sigma_u^+ - \Sigma_g^+$ parallel band at 3287 cm^{-1} was recorded concurrently. Activation energies of 26 and 33 kcal/mol respectively, were found for the first and second-order, decomposition reactions of acetylene. Measurements were made of the induction time for incipient formation from Ar-acetylene mixtures. Tests were conducted to determine if impurity or inert gas radiation contributed to the measured emission. No radiation was detected in the visible or IR regions of the spectrum. There was no measurable scattering at right angles to the chopped transmitted radiation in the visible region.

ELASTIC CONSTANTS OF ZINC SINGLE CRYSTALS (Abstract), by M. Croutzeilles and E. A. Stern. [1957] [1]p. [AF 18(600)1561] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bul. Amer. Phys. Soc., Series II, v. 2: 213-214, Apr. 25, 1957.

The five elastic constants of zinc single crystals have been measured from liquid nitrogen to room temperature. An ultrasonic resonance technique with electrostatic drive, similar to that of Pursey and Pyatt, is utilized. The electrostatic drive does not require mechanical contact between exciter and specimen, and thus is particularly suitable for measurements as a function of temperature since there is no stress produced by differential thermal expansion between the specimen and exciter. The problem of the propagation of elastic waves along an infinite cylinder composed of an anisotropic hexagonal crystal whose c axis is also the axis of the cylinder was solved exactly. Using this solution, it is possible in principle to measure all five elastic constants of a hexagonal crystal by measuring the variation of velocity of longitudinal waves as a function of frequency. In practice three constants were obtained this way, while the other two were obtained by measurements on two other differently oriented crystals.

TEMPERATURE VARIATION OF ELASTIC CONSTANTS

(Abstract), by E. A. Stern. [1957] [1]p. [AF 18(600)-1561] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 214, Apr. 25, 1957.

By considering the quantum mechanical behavior of a particle acted upon by an anharmonic potential well, a method is developed which permits the calculation of the temperature variation of the adiabatic elastic constants. This method is applicable to any solid, since it does not require central forces between atoms. It is in contrast to the method of Born and his collaborators which assumed a special central force between atoms. Using the calculation of Fuchs on the elastic constants of Na and Li, the temperature variations of the adiabatic elastic constants of Na and Li are calculated from 0°K to room temperature, neglecting their respective allotropic transformations at 32°K and 78°K. The calculation for Na is compared with experiment in the temperature range of the measurements.

THEORY OF THE ANHARMONIC PROPERTIES OF SOLIDS, by E. A. Stern. June 1958 [47]p. incl. diags. tables, refs. (Technical rept. no. 1) (AFOSR-TN-58-563) (AF 18(600)1561) AD 158381 Unclassified

Also published in Phys. Rev., v. 111: 786-797, Aug. 1, 1958.

A theory is presented which includes the anharmonic terms in the expansion of the lattice vibrations. This theory can be used to calculate the anharmonic properties of solids such as the thermal expansion coefficient, the temperature dependence of elastic constants, the dependence of elastic constants under stresses, and the deviation of the specific heat from the Dulong-Petit law at high temperatures. The theory is applied to sodium under the assumption of a special force interaction between nearest neighbors only. Three parameters are obtained from experimental measurements of the elastic constants near 0°K, the temperature dependence of the compressibility, and the thermal expansion. From this the variation of the volume with pressure, and the deviation of the specific heat from the Dulong-Petit law at high temperatures are calculated and are found to be in satisfactory agreement with experiments. The temperature derivative of the compressibility is calculated to be proportional to the specific heat and is found to be in satisfactory agreement with the experimental measurements for sodium.

EXACT SOLUTION OF LONGITUDINAL ACOUSTIC WAVES PROPAGATING ALONG AN ANISOTROPIC CYLINDER, by E. A. Stern. Jan. 1959, 14p. incl. diags. (Technical rept. no. 2) (AFOSR-TN-58-1053) (AF 18-(600)1561) AD 206981 Unclassified

Exact solutions are obtained for the problem of axially symmetric longitudinal elastic waves propagating along a cylinder composed of a hexagonal crystal whose c-axis is along the cylinder axis. It is shown that the solutions for this particular anisotropic case have qualitatively the same type of modes of propagation as in the isotropic case of the Pochhammer-Chree solutions. Good agreement between theory and experiment is obtained for the velocity as a function of wavelength. (Contractor's abstract)

THE ATMOSPHERE OF THE WHITE DWARF VAN MAANEN 2, by V. Weidemann. [1960] [26]p. incl. diags. tables, refs. (AFOSR-TN-58-728) (In cooperation with Mount Wilson Observatory, Pasadena, Calif.) (AF 49(638)21) AD 249555
Unclassified

Also published in Astrophys. Jour., v. 131: 638-663, May, 1960.

The spectrum of the white dwarf van Maanen 2, which contains only strongly broadened and blended ultraviolet iron lines and the H and K lines of Ca II, has been analyzed. Model-atmosphere calculations have been carried through for three different effective temperatures with corresponding values for the gravity ($\theta_e = 0.76, 0.87, \text{ and } 1.0$; $\log g = 8.4, 8.0, \text{ and } 7.5$). If the dependence on depth of the line-formation process is taken into account, the ultraviolet spectrum can be successfully understood. The symmetry of the individual profiles indicates that impact-pressure broadening due to van der Waals forces is the main damping mechanism. The gas pressure derived from the observed damping constants is found to be approximately 2000 atm, which is more than a hundred times the value expected for a model with the assumed surface gravity and with normal (main-sequence) abundances. An investigation of the dependence of pressure on both hydrogen and metal abundances and an evaluation of the central intensities of the lines show that, in order to account for the pressure excess the hydrogen abundance (ϵ_H) must be reduced to $\log \epsilon_H = -1.75$ and the metal content (ϵ_M) must be diminished by $\Delta \log \epsilon_M = -3.9$ as compared with that of the sun. If molecule formation is taken into consideration, the figures are changed to $\log \epsilon_H = -1.65, -1.16, \text{ or } -0.43$, and $\Delta \log \epsilon_M = -3.6, -3.9, \text{ or } -4.2$ for $\theta_e = 0.76, 0.87, \text{ or } 1.0$. The color and excitation favor $T_e = 5800^{\circ}$ ($\theta_e = 0.87$) as the most probable value of the effective temperature. (Contractor's abstract)

CIT. 15:007-009; CAL. 07:001

Also published in *Astrophys. Jour.*, v. 129: 347-355, Mar. 1959.

A curve-of-growth analysis has been used to compare abundances in two G dwarfs of the Hyades with those of the sun. The abundances of Na, Mg, Si, Ca, Sc, Ti, Cr, Mn, Fe, and Ni are found to be the same as in the sun within 25 per cent. Ba is overabundant by a factor of 2. The results can be interpreted in either of two ways. If the overabundance of Ba is spurious, then it seems most likely that the enrichment of the interstellar medium between presolar times and the time of formation of the Hyades stars has been negligible. On the other hand, if Ba is indeed overabundant, then the material that has enriched the interstellar medium must have had the solar abundance of the other ten elements studied. By considering the processes discussed by Burbidge et al (*Rev. Modern Phys.*, v. 29: 547, 1957) it can be shown that Ba and other very heavy elements can be overabundant if the material had been subjected to a temperature of 10^8 degrees but no greater. SHARP LINES IN THE SPECTRUM OF NOVA RS OPHIUCHI, by G. Wallerstein. Oct. 24, 1957, 10p. incl. table. (AFOSR-TN-58-821) (In cooperation with Mount Wilson Observatory, Pasadena, Calif.) (AF 49(838)21) AD 202905 Unclassified

Also published in *Astron. Soc. of the Pacific*, v. 70: 537-543, Dec. 1958.

The spectral history of the nova from 14 July 1958 up to 30 July 1958 as obtained by the author at the Mount Wilson Observatory is presented. The spectral data includes absorption lines obtained by use of the 60 inch telescope at Mount Wilson as well as the 100 and 200 inch telescopes at Palomar, as well as the calculated radial velocity of the emitting gases. The spectral absorption data is used to investigate the presence of a pre-existing stationary circumstellar gas envelope surrounding the nova star. The data seem to be unexplainable in terms of a model in which the radial velocity and density of the gases are a function of the radial position alone.

VELOCITY CHANGES OF CHARGED PARTICLES IN A PLASMA, by F. D. Kahn. [1959] [7]p. incl. table. (AFOSR-TN-58-929) (In cooperation with Inst. for Advanced Study, Princeton, N. J. and Mount Wilson Observatory, Pasadena, Calif.) (AF 49(838)21) AD 204735 Unclassified

Also published in *Astrophys. Jour.*, v. 129: 468-474, Mar. 1959.

A comparison is made of the different ways in which an ionized gas may change the velocities of fast-moving protons. It is found that a beam with a very well-defined velocity may lose its kinetic energy through the excitation of unstable oscillations, but it seems most unlikely that the stringent conditions necessary for this process will ever occur in any astrophysical application. Bohm and Pines have shown (*Phys. Rev.*, v. 85: 338, 1952) that, single protons lose energy by leaving a wake in the plasma. If sufficiently intense plasma oscillations are excited, the protons may also gain energy through acceleration in random electric fields. Fast electrons can be accelerated even more efficiently in this way. (Contractor's abstract)

INFRARED ABSORPTION BY THE N_3 RADICAL, by D. E. Milligan, H. W. Brown, and G. C. Pimentel. [1956] [1]p. [AF 49(638)1] Unclassified

Published in *Jour. Chem. Phys.*, v. 25: 1080, Nov. 1956.

Aside from the intrinsic interest in the infrared spectrum of a free radical, the results given in this paper may have

CAL.07:002 - CAL.07:004

important bearing on the results of Broida et al. The apparent stability of N_3 radical in the condensed solid makes it less likely that nitrogen atoms are trapped in the solid nitrogen. It is not expected that there would be sufficient activation energy retarding the reaction $N + N_2 = N_3$ to permit both N and N_3 to be present in solid nitrogen. Furthermore, the reactions of formation and loss of N_3 radicals may play a role in the glow phenomena.

Pt. I also published in Jour. Chem. Phys., v. 27: 486-490, Aug. 1957. Pt. II also published in Jour. Amer. Chem. Soc., v. 80: 62-64, Jan. 5, 1958.

Part I. The stretching and bending vibrational modes of the hydrogen bonded polymers of water have been studied by the matrix isolation technique using solid nitrogen at 20°K as a matrix. Absorptions are assigned to water monomers (3725, 3633 and 1600 cm^{-1}), to dimers (3691, 3546 and 1620 cm^{-1}) and to higher polymers (3510, 3365, 3318, 3222 and 1633 cm^{-1}). The frequencies suggest that the dimers have cyclic rather than open (or bifurcated) structures. The absorption coefficients of the bending modes decrease slightly in the higher polymers while those of the stretching mode increase by a factor of about twelve. This intensity behavior cannot be explained solely on the basis of enhanced ionic character of the O-H group in the hydrogen bond. Part II. The use of the matrix isolation technique for the study of reaction rates of chemical reactions with heats of activation as low as one or two kcal is described. Reactions which might be studied include isomerization, bond rupture, bond formation reactions and the process of diffusion in the solid matrix. A crude estimate of the rate of diffusion of ammonia in solid argon is presented. The heat of activation of the isomerization of cis- HNO_2 to trans- HNO_2 was measured at 20°K in solid nitrogen and found to be much lower than current estimates.

MATRIX ISOLATION STUDIES: INFRARED SPECTRA OF INTERMEDIATE SPECIES IN THE PHOTOLYSIS OF HYDRAZOIC ACID, by E. D. Becker, G. C. Pimentel, and M. Van Thiel. [1957] [6]p. (AF 49(638)1)

Unclassified

Published in Jour. Chem. Phys., v. 26: 145-150, Jan. 1957.

The matrix isolation method has been used to investigate the photolysis of hydrazoic acid (HN_3) suspended in xenon, argon, and nitrogen matrices at 20°K. Infrared spectra of the photolyzed material in argon and nitrogen matrices show absorption bands of NH_3 and a number of other prominent spectral features that are probably due to unstable molecules, including intermediates in the formation of NH_3 . In a xenon matrix no new bands are observed on photolysis of HN_3 at 20°K, but the presence of the imine radical (NH), or of nitrogen and hydrogen atoms, is inferred from the formation of NH_4N_3 when the material is warmed to 70°K. The mechanism of photolytic production of radicals in a matrix is examined, and the probably importance of the heat of fusion of the matrix is discussed. The utility of the matrix isolation technique in the infrared study of unstable reaction intermediates is demonstrated. (Contractor's abstract)

INFRARED STUDIES OF HYDROGEN BONDING OF METHANOL BY THE MATRIX ISOLATION TECHNIQUE, by M. Van Thiel, E. D. Becker and G. C. Pimentel. [1957] [5]p. (AF 49(638)1) Unclassified

Published in Jour. Chem. Phys., v. 27: 95-99, July 1957.

The O-H stretching mode of hydrogen bonded methanol has been studied by the matrix isolation technique using solid nitrogen at 20°K as a matrix. The bands are narrow and permit assignment of absorptions at 3660, 3490, 3445, 3290, and 3250 cm^{-1} to the species, respectively, monomer, dimer, trimer, tetramer, and higher polymers. The results correlate with the room temperature concentration dependence of the H bonded O-H stretching mode of methanol in solution. The dependence of frequency upon polymer size suggests that methanol dimers and trimers have cyclic structures and higher polymers have open (chain) structures. In the cyclic structures, the strain associated with the bent H bond is assumed to account for the low-frequency shift of dimers and trimers compared to higher polymers. (Contractor's abstract)

MATRIX ISOLATION METHOD: SOME STUDIES BY ELECTRONIC SPECTROSCOPY (Abstract), by S. Leach. [1957] [1]p. (AF 49(638)1) Unclassified

Published in Program for Symposium on The Formation and Stabilization of Free Radicals, Nat'l. Bur. Standards, Washington, D. C. (Sept. 18-20, 1957), Washington, Nat'l. Bur. Standards, 1957, p. R1.

A low temperature cell for the study of the UV and visible absorption spectra of free radicals is described. In the experiments the radicals are produced by UV photolysis or by an electric discharge and they are isolated by means of the matrix method. During a single experiment, spectra may be taken over the ranges 1850A to 13 μ , 2100A to 15 μ , or 2300A to 25 μ by suitable modifications of the apparatus. The experimental problems involved and the advantages of the quasi-simultaneous study by electronic and IR spectroscopic techniques are discussed. The possibilities and usefulness of an extension of the method to photolysis by far UV radiation are considered.

MATRIX ISOLATION STUDIES. 1. THE PHOTOLYSIS OF NITROMETHANE AND OF METHYL NITRITE IN AN ARGON MATRIX; INFRARED DETECTION OF HNO, by H. W. Brown and G. C. Pimentel. May 10, 1958, 19p. incl. tables, refs. (AFOSR-TN-58-429) (AF 49(638)1) AD 158232 Unclassified

Also published in Jour. Chem. Phys., v. 29: 883-888, Oct. 1958.

The photolysis of nitromethane in solid argon at 20°K gives methyl nitrite. All other products can be explained in terms of the secondary photolysis of methyl nitrite. This work provides a definitive basis for segregating the vibrational frequencies of the *cis*- and *trans*- isomers of methyl nitrite. The primary products of photolysis of methyl nitrite under these conditions are formaldehyde and nitroxyl, HNO. The identification of HNO, detected by its infrared spectrum for the first time, is confirmed by the band shifts occurring upon deuteration. The vibrational frequencies of HNO (1570 and 1110 cm^{-1}) and DNO (1560 and 822 cm^{-1}) correspond to a bent molecule with a double bond between the nitrogen and oxygen atoms, thus supporting the structure HNO over the possible arrangement HON. The bending force constant, $0.67 \cdot 10^{-11}$ dyne-cm, suggests that the HNO angle is near 110°, larger than the earlier estimate of 102° based on electronic spectra. (Contractor's abstract)

MATRIX ISOLATION STUDIES: POSSIBLE INFRARED SPECTRA OF ISOMERIC FORMS OF DIAZOMETHANE AND OF METHYLENE. CH_2 , by D. E. Milligan and G.

C. Pimentel. Sept. 10, 1958, 19p. incl. tables, refs. (AFOSR-TN-58-818) (AF 49(638)1) AD 202643 Unclassified

Also published in Jour. Chem. Phys., v. 29: 1405-1412, Dec. 1958.

The photolysis of diazomethane has been studied by the matrix isolation method. Argon and nitrogen matrices were used at 20°K. There is distinct infrared spectral evidence that unstable species have been detected spectroscopically: the production of stable products is inhibited until diffusion is permitted and a red glow accompanies diffusion. Among the identified products produced during diffusion are ethylene, propylene, methane, and polyethylene. The data suggest that methylene is present as well as a tautomeric structure of diazomethane. One of the absorptions observed at 1362 and 1114 cm^{-1} could be the bending mode of CH_2 . THE PROMISE AND PROBLEMS OF THE MATRIX ISOLATION METHOD FOR SPECTROSCOPIC STUDIES, by G. C. Pimentel. [1958] [3]p. [AF 49(638)1] Unclassified

Published in Spectrochimica Acta, v. 12: 94-96, Mar.-Apr. 1958.

A variety of types of study were made possible by the matrix technique. These studies include: (1) Band narrowing; (2) Free radicals; (3) Primary act of photolysis; and (4) Kinetics. Examples are also given for each of these studies. In attempting to exploit the possible applications of the matrix technique, a variety of practical and interpretive difficulties have been discovered. Two of these problems are discussed. The matrix isolation method has wide and interesting applications, particularly with infrared spectral techniques.

APPROXIMATE SOLUTIONS OF PARABOLIC AND HYPERBOLIC PARTIAL DIFFERENTIAL EQUATIONS, by M. Lee. Oct. 1957, 83p. refs. (Technical rept. no. 7) (AFOSR-TN-57-777) (AF 18(600)1117) AD 146093
Unclassified

An investigation is made of the approximate solutions of certain mixed initial-boundary value problems for nonlinear parabolic and hyperbolic partial differential equations. Two methods of implicit approximation are discussed. The first method replaces the first boundary-value problem for the partial differential equation by an initial value problem for a nonlinear system of ordinary differential equations. The second method leads to boundary-value problems for nonlinear partial difference equations over a rectangular lattice. In both cases, the properties for the approximate solutions are established which are analogous to properties of exact solutions. On the basis of these derived estimates, theorems concerning the relationship between the approximate and exact solutions are derived.

LOWER BOUNDS FOR THE FIRST EIGENVALUE OF ELLIPTIC EQUATIONS AND RELATED TOPICS, by M. H. Protter. June 1958, 25p. (Technical rept. no. 8) (AFOSR-TN-58-434) (AF 18(600)1117; continued by AF 49(638)398) AD 158238
Unclassified

A general method is described which yields a lower bound for the first eigenvalue, for any second order elliptic equation with any bounded domain. The results of the method for the membrane equation are applied to the case of the rhombus and triangle, and a comparison is made of their lower bounds by the method of symmetrization. A natural extension is given of the method of arbitrary functions to the case of three functions. The discussion is limited to the membrane equation

and a simple example is given. The general comparison theorems of Bocher for ordinary differential equations are extended to partial differential equations. The method of symmetrization is extended to the general linear elliptic second order equation to yield lower bounds for the first eigenvalue in the most general case.

THE SUSPENSION OF THE GENERALIZED PONTRJAGIN COHOMOLOGY OPERATIONS, by E. Thoma. Oct. 1957, 25p. (Technical rept. no. 1) (AFOSR-TN-57-858) (AF 49(638)79) AD 135650
Unclassified

Also published in *Pacific Jour. Math.*, v. 9: 897-911, Fall 1959.

Let $A = \sum_k A_k$ be a graded ring with divided powers such that each A_k is a cyclic group of infinite or prime power order (p -cyclic ring). The Pontrjagin operators are functions β_t such that

$$H^{2n}(X; A_{2k}) = H^{2n}(X; A_{2k}) \text{ for all } k, n > 0 \text{ and}$$

$t = 0, 1, \dots$, where $H^q(X, Y; G)$ denotes the functor which

assigns to each pair of spaces (X, Y) its q^{th} cohomology group with coefficients in the group G . Let $S(A)$ be the suspension operator for the cohomology operator A . Let β be the Postnikov square cohomology operator such that

$$\beta : H^q(X, Y; A_{2k}) \rightarrow H^{2q+1}(X, Y; A_{4k}), \text{ where}$$

A_{2k} is an even summand of a p -cycle ring with divided

powers. The following theorem is the main result of this paper: for any cohomology operator β and $S(\beta)$ the suspension operator, then $S(\beta_t) = \beta$ and $S(\beta_t) = 0$

for $t > 2$, where 0 denotes the zero cohomology operator.

Two new properties for the operator β are given:

(1) $\beta(\beta(u)) = 0$, and (2) if the order of $A_{2k} = 2^l$ with

$(l > 1)$ and $2u = 0$ then $\beta(u) = 0$ provided that $u \in H^q(X; A_{2k})$.

THE FUNCTIONAL PONTRJAGIN COHOMOLOGY OPERATIONS, by E. Thomas. Oct. 1957 [11]p. (Technical rept. no. 3) (AFOSR-TN-57-893) (Bound with its AFOSR-TN-57-895; Technical rept. no. 2; AD 135717) (AF 49(638)79) AD 136686
Unclassified

Also published in *Bol. Soc. Matem. Mexicana, Serie II*, v. 3: 19-24, Apr. 1958.

An example is given of a non-trivial functional operator associated with the general Pontrjagin cohomology operator. It is a mapping of the sphere S^{2p-1} onto the

complex projection space M_{p-1} . The operator associated with β_p of the generator of $H^2(M_{p-1}; \mathbb{Z})$ generates the cohomology group of the sphere. The cohomology group can also be obtained by the functional cup-product. If a 3-cell is attached to S^2 in M_{p-1} , then it is found that map of S^{2p-1} into the $(2p-2)$ -space is essential. The above can be obtained by means of the operator associated with β_p but the functional cup-product does not provide a solution.

A NOTE ON NON-STABLE COHOMOLOGY OPERATIONS, by F. Peterson and E. Thomas. Oct. 1957, 12p. (Technical rept. no. 2) (AFOSR-TN-57-695) (Bound with its AFOSR-TN-57-693; Technical rept. no. 3; AD 136686) (AF 49(638)79) AD 136717 Unclassified

Also published in Bol. Soc. Matem. Mexicana, Series II, v. 3: 13-18, Apr. 1958

Let θ be a primary cohomology operator of the type $(\pi, n; G, p)$ and f a continuous map of the space X into the space Y . Let θ_f be a functional cohomology operator such that $\theta_f(u)$ is a subset of $H^{q-1}(Y; G)$. If θ is an additive cohomology operator (homomorphism), then $\theta_f(u)$ is a coset of the subgroup of $L(\theta, f) = f^*(H^{q-1}(X; G)) + {}^1\theta(H^{n-1}(Y; \pi))$ where ${}^1\theta$ is an operator of the type $(\pi, n-1; G, q-1)$ and is called the suspension of θ . When θ is additive, θ_f maps on cosets of $H^q(Y; G)$ modulo a subgroup $L(\theta, f)$. It is shown that for all operators θ , the subset $\theta_f(u)$ is in fact a coset of the subgroup $L(\theta, f)$ and in all cases $\theta_f(u)$ is to be regarded as an element of the quotient group $H^{q-1}(Y; G)/L(\theta, f)$. This result is shown to be true in the two following cases: (1) even if the additive property holds only for elements of the form $\theta(v + \delta w) = \theta(v) + \theta(\delta w)$, where δ is the coboundary operator such that if $x \in H^{q-1}(Y; G)$, then $\delta(x) = \theta(v)$; and (2) using the Peterson definition of the functional cohomology operations.

THE GENERALIZED PONTRJAGIN COHOMOLOGY OPERATIONS AND RINGS WITH DIVIDED POWERS, by E. Thomas. [1957] 82p. incl. diagrs. refs. (AFOSR-TN-57-770) (AF 49(638)79) AD 149742 Unclassified

Also published in Mem. Amer. Math. Soc., No. 27, 1957, 82p.

The theory of Pontrjagin square cohomology operations is given, which generalizes the "Pontrjagin square." $\Gamma(R)$ is taken as the category of graduated rings A with divided powers. There are applications γ_r ($r = 0, 1, 2, \dots$) which, for all integral $k \geq 1$, put A_{2k} into A_{2rk} , with conditions: $\gamma_0(x) = 1$, $\gamma_1(x) = x$, $\gamma_r(x)\gamma_s(x) = (r, s)\gamma_{r+s}(x)$, $\gamma_r(x+y) = \sum_{s+t=r} \gamma_s(x)\gamma_t(y)$, $\gamma_s(\gamma_r(x)) = \epsilon_{s,r} \gamma_{sr}(x)$ for $s > 0$, $r > 0$, $\gamma_r(xy) = r!$; $\gamma_r(x)\gamma_r(y)$ for x and y of equal degrees ≥ 2 , $\gamma_r(xy) = 0$ for x, y of unequal degrees and $r \geq 2$; $(r, s) = (r+s)!/r!s!$, and

$\epsilon_{s,r} = \prod_{1 \leq i \leq s-1} (ir, r-1)$. The morphisms of the category $\Gamma(R)$ are defined in an evident manner. A given whole prime p is considered which is bounded on the sub-category $\Gamma_p(R)$ formed from A such that, for all $n \geq 1$, A_n is an infinite cyclic group or of order equal to a power of p . The cohomology of the space (or simplicial set) X with coefficients in an $A \in \Gamma_p(R)$ is considered. Various definitions, terminology, and alternative methods are studied and described.

ON HOLONOMY AND HOMOGENEOUS SPACES, by B. Kostant. [1957] [24]p. [AF 49(638)79] Unclassified

Published in Nagoya Jour. Math., v. 12: 31-54, Dec. 1957.

Let G be a compact connected Lie group and K a closed subgroup. The purpose of this paper is mainly to consider questions of holonomy when G/K is provided with an arbitrary invariant metric, not necessarily a natural one, and to see how reducibility properties change when we change from one metric to another. In section 2 of this paper the author proves: Let G/K be given any homogeneous Riemannian metric. Let g and k be respectively Lie algebras of G and K , and let p be any complement to k such that p admits a strictly invariant bilinear form (X, Y) . Let (X, Y) be the bilinear form on p given by the metric tensor. Let $S: p \rightarrow p$ be defined by $(SX, Y) = (X, Y)$. Extend S to g by defining $S = 0$ on k . Now for any $Z \in g$ let D_Z be the operator on p defined by $D_Z Y = [Z, Y]_p$ for all $Y \in p$. Then the linear holonomy algebra is the Lie algebra generated by all operators on p of the form $D_Z + S^{-1}D_Z S - S^{-1}D_{SZ}$, where $Z \in g$. At the beginning of section 3, the author gives an example of a case where g or G is simple yet G/K is reducible, which is a counter-example to the conjecture of Nomiau. In the later part

CAL.09:006 - CAL.09:007

of section 3 he proves the following two theorems and determines the linear holonomy group and the linear holonomy algebra for an arbitrary invariant metric. (1) Let C be an arbitrary permissible metric (that is, a positive definite bilinear form on p which is invariant under $\text{ad}_p K$). Let $s_0(C)$ be the corresponding holonomy algebra, so that $\exp s_0(C) = \tau_0(C)$ is the restricted linear holonomy group. Let $\psi_0(C)$ be the full linear holonomy group. Then $\text{ad}_p K \subseteq \psi_0(C)$ and in fact $\psi_0(C) = \text{ad}_p(K) \cdot \tau_0(C)$. (2) A subspace $p_1 \subseteq p$ is invariant under $\tau_0(C)$ if and only if it is invariant under $\psi_0(C)$. Furthermore the elements of p_1 are fixed under the action of $\tau_0(C)$ if and only if they are fixed under the action of $\psi_0(C)$. Let B be a strictly invariant bilinear form on p , that is, a positive definite bilinear form on p for which D_X is skew-symmetric for all $X \in g$, and let C be any permissible metric. Let $p = \sum_{i=0}^m p_i(C)$ be the direct sum, where $p_0(C)$ is the set of all vectors in p which are fixed by $\psi_0(C)$, and $p_i(C)$, $i = 1, 2, \dots, m(C)$, are irreducibly invariant subspaces under the action of $\psi_0(C)$. In section 4, the author proves: (1) $C < B$ if and only if S leaves the subspaces $p_i(B)$ invariant, $i = 0, 1, \dots, m(B)$. (2) $B < C$ whenever S leaves the subspaces $p_i(C)$ invariant. Conversely, if $B < C$ we may find a permissible strictly invariant metric B' on p which is strongly equivalent to B and which is such that S' leaves the spaces $p_i(C)$ invariant. (3) If we assume $p \cap c = 0$, where c is the center of g , then $B < C$ if and only if S leaves the subspaces $p_i(C)$ invariant. (4) Assume $\text{ad}_p K$ has inequivalent representations. Then any two permissible metrics C_1 and C_2 are weakly equivalent. That is, the decomposition $p = \sum_{i=1}^m p_i(C)$ is independent of the metric C . Sections 5 and 6 are devoted to the applications of these results. To quote one: Assume $\chi(G/K) \neq 0$ and that g acts effectively on G/K . Then with respect to any invariant metric, G/K is irreducible if and only if g is simple. (Math. Rev. abstract)

A FORMULA FOR THE MULTIPLICITY OF A WEIGHT, by B. Kostant. Apr. 1958, 42p. (Technical rept. no. 4) (AFOSR-TN-58-315) (AF 49(638)79) AD 154219
Unclassified

Also published in Trans. Amer. Math. Soc., v. 93: 53-73, Oct. 1959.

A proof is given for the following theorem: Let G be a semi-simple Lie algebra with Cartan subalgebra h . Let $l \subseteq h$ be the discrete group of integral linear forms on h . Let P be the partition function on l which assigns to every $\mu \in l$ the number of ways μ can be partitioned into a sum of positive roots (multiplicities are permitted and order is discounted). Let Δ^+ be the set of positive roots and let $g = \sum_{\alpha \in \Delta^+} \alpha$. Let W be the Weyl group and let $s(\sigma) = g - \sigma(g)$ for any $\sigma \in W$. Then $s(\sigma)$ lies in the cone generated by the positive roots and for $\mu \in l$, $\mu \neq 0$, $P(\mu)$ satisfies the recursive relation $P(\mu) = -\sum_{\sigma \in W} s(\sigma) P(\mu - s(\sigma))$.

Let π be an irreducible representation of G . Write $\pi = \pi_\lambda$ where $\lambda \in l_D$ is the highest weight of π . Let $\nu \in l$ be arbitrary. Let $m_\lambda(\nu) = 0$ in case ν is not a weight of π_λ let $m_\lambda(\nu)$ be the multiplicity of the weight ν . The number $m_\lambda(\nu)$ is given by the formula

$$m_\lambda(\nu) = \sum_{\sigma \in W} s(\sigma) P(\sigma(g + \lambda) - (g + \nu)).$$

California U. Dept. of Mathematics, Berkeley.

A THEOREM OF FROBENIUS, A THEOREM OF AMITSUR-LEVITSKI AND COHOMOLOGY THEORY, by B. Kostant. July 1958, 52p. (Technical rept. no. 5) (AFOSR-TN-58-585) (AF 49(638)79) AD 162105
Unclassified

Also published in Jour. Math. and Mech., v. 7: 237-264, Mar. 1958.

The paper is mainly concerned with the following three theorems: (1) the algebra g of all $n \times n$ (complex) matrices satisfies the standard identity of degree $2n$, i.e.

$$[A_1 \dots A_{2n}] = \sum s(\sigma) A_{\sigma(1)} \dots A_{\sigma(2n)} = 0$$

for any $A_i \in g$, where the sum ranges over all permutations σ of $1, \dots, 2n$, and $s(\sigma) = 1$ or -1 according as σ is even or odd; (2) let l be the group algebra of the symmetric group S_{2n+1} and let α be the cycle

$(1, \dots, 2n+1)$. Then the element $\sum s(\rho) \rho \alpha \rho^{-1}$, where ρ runs over S_{2n+1} , belongs to the 2-sided ideal of l

generated by the element $(\sum \sigma)(\sum s(\tau) \tau)$, where σ runs over all permutations leaving $n+2, \dots, 2n+1$ invariant, while τ runs over all permutations leaving $2, \dots, n+1$ invariant; (3) for the Lie algebra g and an odd integer r , the unique invariant cocycle b_r in the primitive class $P^r(g)$ is given by $\langle b_r, A_1 \wedge \dots \wedge A_r \rangle = \text{tr}[A_1 \dots A_r]$,

where $A_i \in g$. The theorem (1) is due to Amitsur and

Levitki, theorem (2) is a reformation of a special case of a theorem of Frobenius on the characters of alternating groups, and theorem (3) is due to Dynkin. Theorems (1) and (3) as well as a theorem of Kozul-Samelson on the behavior of primitive cohomology classes of Lie algebras under homomorphisms are derived. It is also shown that the algebra of $n \times n$ skew-symmetric matrices satisfies the standard identity of degree $2n-2$ when n is even. Theorems (1) and (2) are shown to be equivalent by an elementary argument. A new proof of theorem (3) which is independent of theorems (1) and (2) is presented. The proof is based on the onto isomorphisms:

$$\Psi_r: H_r(g) \rightarrow B(H), \quad \Psi^r: B(H) \rightarrow H^r(g),$$

where H is the subspace of all elements of the group algebra l of S_r of the form $\sum sg(\rho)\rho\omega^{-1}$ (the sum runs over all $\rho \in S_r$, and $f \in l$), and where B designates the representation of S_r on the space rU of r -tensors over U (the space on which g operates) given by

$$B(\sigma) x_1 \otimes \dots \otimes x_r - x_{\sigma^{-1}(1)} \otimes \dots \otimes x_{\sigma^{-1}(r)}.$$

The above isomorphisms Ψ_r and Ψ^r are obtained by considering the linear mapping η_r defined by

$$\eta_r(A_1 \wedge \dots \wedge A_r) = \frac{1}{r!} \sum A_{\sigma^{-1}(1)} \otimes \dots \otimes A_{\sigma^{-1}(r)},$$

where $A_i \in g$ and the sum ranges over all $\sigma \in S_r$, and by using a theorem of Weyl to the effect that $B(l)$ is the set of all operators on rU which commute with all $A \otimes \dots \otimes A$, where A runs over all nonsingular operators on U .

ON THE COHOMOLOGY OF THE REAL GRASSMAN MANIFOLDS AND THE CHARACTERISTIC CLASSES OF n -PLANE BUNDLES, by E. Thomas. July 1958, 66p. (Technical rept. no. 6) (AFOSR-TN-58-600) (AF 49(638)79) AD 162125; PB 138973 Unclassified

Also published in Trans. Amer. Math. Soc., v. 96: 67-89, July 1960.

The Pontrjagin squares of the Stiefel-Whitney classes have been determined by W. T. Wu (Trans. Amer. Math. Soc., v. 11: 155-172, 1959). Using this computation, Wu proved that the Pontrjagin classes reduced mod 4 of a differentiable manifold are invariants of the homotopy type of the manifold. In the proof of his formulas, Wu used explicit cellular decompositions of the real Grassman manifolds, and as a result, his proofs are extremely complicated and difficult to follow. In the present paper the author gives a new proof of Wu's above-mentioned results, without the use of any cellular decompositions of the Grassman varieties. He uses only

standard, well known facts regarding the cohomology of the classifying spaces for the orthogonal groups and unitary groups together with the fundamental properties of the Pontrjagin squares in his proof. (Math. Rev. abstract)

ON TENSOR PRODUCTS OF n -PLANE BUNDLES, by E. Thomas. Nov. 1958, 52p. (Technical rept. no. 8) (AFOSR-TN-58-1022) (AF 49(638)79) AD 206362; PB 140154 Unclassified

Also published in Arch. der Math., v. 10: 174-179, 1959.

Let η and ζ be respectively r -plane and s -plane bundles over X . Then one may define an rs -plane bundle $\eta \otimes \zeta$ over X , and its Stiefel-Whitney classes are given by a certain polynomial $\Phi_{r,s}$ in the Stiefel-Whitney classes of η and ζ [Borel and Hirzebruch, Amer. Jour. Math., v. 80: 458-538, 1958]. The author gives an elementary proof of this fact. To begin with, the universal example shows that the required classes are given by some such polynomials, say $\Psi_{r,s}$. Next, one can handle the case in which

$r - s = 1$ and η, ζ are the standard bundles over $K(Z_2, 1)$.

One can then handle suitable bundles over the product $(K(Z_2, 1))^{r+s}$, and so determine the polynomials $\Psi_{r,s}$. (Math. Rev. abstract)

It is impossible to do justice in a brief review to this

CAL.10:001 - CAL.10:002

paper which contains a wealth of results dealing with the root structure of Lie groups, the Coxeter-Killing transformation, the reduction of the restriction of the adjoint representation to a 3-dimensional subgroup (3-d.s.) and many related topics. From a well-known theorem of H. Hopf [Ann. of Math., v. 42: 22-52, 1941] it follows that the homology ring of a single Lie group G of rank n is generated by n minimal elements of odd dimension $2m_j + 1$. The integers m_j have been called the exponents of the group. They determine the degrees, $m_j + 1$, of the minimal symmetric invariants of the group, and they also determine, and are determined by, the eigenvalues of γ , the product of n simple reflections which generate the Killing (or Weyl) group. The author proposes, with reason, to call γ the Coxeter-Killing transformation. If, following Steinberg, we define the height of a positive root to be the sum of its coefficients with respect to a basis consisting of simple roots, we may formulate the following theorem: Let the number of positive roots of height 1, 2, ..., h - 1 be p_1, p_2, \dots, p_{h-1} , respectively; then $p_1 \geq p_2 \geq \dots \geq p_{h-1}$, and the partition conjugate to that determined by the p 's consists of the exponents m_j . This result was stated by Robert Steinberg [Trans. Amer. Math. Soc., v. 91: 493-503, 1959], who proved it by verification. It was noticed, independently, by Arnold Shapiro who communicated it privately to the author. The main purpose of the present paper is to prove the above theorem, which is remarkable because of the ease with which it permits the homology ring to be obtained from the root diagram. The proof is effected by establishing a relation (theorem 8.4) between the Steinberg-Shapiro procedure and the eigenvalues of γ and then by appealing to a theorem of the reviewer [Canad. Jour. Math., v. 10: 349-356, 1958], the proof of which is improved in an important respect. In the proof of his central theorem, the author makes much use of the idea of a principal 3-d.s. (due independently to Dynkin and Siebenthal). He shows that the latter is characterized by the following property: the number of irreducible representations obtained when the adjoint representation of G is restricted to a 3-d.s., A, is $\geq n$, with equality if and only if A is principal. Another important result characterizes the Coxeter-Killing transformations: the order of any regular element g of G is \geq the order, h, of γ , with equality if and only if g generates a Coxeter-Killing transformation. Further, the set of all regular elements of G of order h forms a conjugate class. Other results pertain to nilpotent elements and Cartan subgroups. (Math. Rev. abstract)

A COMPARISON THEOREM FOR ELLIPTIC EQUATIONS, by M. H. Protter. Sept. 1958, 6p. (Technical rept. no. 1) (AFOSR-TN-58-842) (AF 49(638)398;

continuation of AF 18(600)1117) AD 203332; PB 138166
Unclassified

Also published in Proc. Amer. Math. Soc., v. 10: 296-299, Apr. 1959.

Hartman and Wintner (Proc. Amer. Math. Soc., v. 6: 862, 1955) obtained a Sturmian comparison theorem for self-adjoint second order linear elliptic equations of the form

$$\sum_{i,j=1}^n \frac{\partial}{\partial x_i} (a_{ij} \frac{\partial u}{\partial x_j}) + fu = 0 \quad a_{ij} = a_{ji}$$

in a bounded domain D with boundary Γ . It is the purpose of this note to extend their result to general second order linear elliptic equations.

The real linear system of first order hyperbolic differential equations:

$$\sum_{j=1}^N p_{ij}(x,y) V_x^j(x,y) + q_{ij}(x,y) V_y^j(x,y) = \sum_{j=1}^N t_{ij}(x,y) V^j(x,y) + r_i(x,y) \quad i=1, \dots, N$$

emanating from a point (0,0). A resultant system of the form:

$$\sum_{j=1}^N a_{ij}(x) V^j(x, \hat{y}_i(x)) = t_i(x), \quad i=1, \dots, N \text{ along } \bar{N} \geq N \text{ arcs}$$

emanating from a point (0,0). A resultant system of the form:

$$U_x^i(x,y) + A^i(x,y) U_y^i(x,y) = \sum_{k=1}^N E^{ik}(x,y) U^k(x,y) + G^i(x,y), \quad i=1, \dots, N$$

with the generalized initial conditions

$$\sum_{j=1}^N \hat{a}^{ij}(x) U^j(x, \hat{y}_i(x)) = \hat{H}^i(x), \quad i=1, \dots, \bar{N}, \quad \bar{N} - N = N_0 - 1.$$

Inequalities are investigated which involve the slopes of the data arcs (from $y = y_1(x)$ or $y = \hat{y}_1(x)$) and the functions A^i (the slopes of the characteristic curves). The consistency of (S_0) at (0,0) is discussed. The existence and

CAL.03:009 - CAL.03:012

uniqueness of a solution is proved to (S_0) in the class of first order continuously differentiable functions on a set of sufficiently small diameter, and the existence and uniqueness in the large is established.

CYCLOTRON AND PLASMA RESONANCE IN SOLIDS, by A. F. Kip. [1956] 5p. (AF 18(603)46)

Unclassified

Presented at Conference on Physics of Magnetic Phenomena, Moscow (USSR), May 1956.

The basically different conditions in which cyclotron resonance and plasma resonance occur in semi-conductors are outlined in this review paper. An attempt to short out the plasma effect and the possibility of observing the cyclotron resonance of a minority carrier in the presence of a low mobility, high concentration carrier are discussed. The presence of eddy current losses in a sample in which the carrier density is large enough to render the sample thickness larger than the skin depth seems to eliminate the possibility of observing cyclotron resonance even though plasma resonance is also impossible.

Also published in Jour. Chem. Phys., v. 26: 1504-1507, June 1957.

The Opechowski calculation of the apparent Curie point, T_C , is extended to the case of magnetically dilute fcc crystals. To first order in temperature the result is equivalent to a molecular field treatment. The calculation is carried to fourth order in temperature and a plot is made of T_C vs p , the fractional concentration of magnetic atoms. The theoretical result is compared to some existing experimental data and values of the exchange interaction, J , are estimated. The above calculation is found to be useful only for $0.8 \leq p \leq 1.0$. For low concentrations a crude calculation is made based on clusters of magnetic atoms. To first order in temperature, a linear relationship is found between apparent Curie point and concentration. (Contractor's abstract)

QUADRUPOLE INTERACTION OF NUCLEI WITH CONDUCTION ELECTRONS, by A. H. Mitchell. 1957, 4p. (Technical rept. no. 75) (AFOSR-TN-57-718) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, and Signal Corps) AD 144247

Unclassified

Also published in Jour. Chem. Phys., v. 26: 1714-1717, June 1957.

The nuclear spin-lattice relaxation time in metals is calculated taking into account the following three interactions between the nuclei and the conduction electrons: (1) the usual contact part of the hyperfine interaction, which is the dominant mechanism; (2) the noncontact part of the hyperfine interaction; and (3) the quadrupole interaction for nuclei of spin $I \geq 1$. It is found that the latter two interactions are of the same order of magnitude. If the electronic wave function at the Fermi surface has a p-wave component comparable with its s-wave component, these two mechanisms may appreciably shorten the relaxation time as calculated using only the contact part of the hyperfine interaction. The Hamiltonian for the exchange interaction between the ferromagnetic d electrons and the conduction s is derived. The ferromagnetic relaxation time caused by the s-d exchange interaction is calculated in a spin wave approximation. When a screened value of the exchange integral (J atomic/30) is used, the calculated relaxation time for nickel at room temperature is 5×10^{-9} sec as compared to the time 2.5×10^{-10} sec needed to account for the experimental line width. The exchange relaxation may be dominant in materials such as alloys which have narrower lines than nickel. (Contractor's abstract)

ABSORPTION COEFFICIENTS FOR EXCITON ABSORPTION LINES, by G. Dresselhaus. Nov. 26, 1956, 3p. (Technical rept. no. 83) (AFOSR-TN-57-720) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, and Signal Corps) AD 144431

Unclassified

Also published in Phys. Rev., v. 106: 76-78, Apr. 1, 1957.

The absorption coefficient for excitons is calculated in the effective-mass approximation. The coefficient is shown to be decreased over what would be expected for a collection of free atoms by the factor $\epsilon^{-1}(a_0/a_B)^3$, where ϵ is the dielectric constant and a_0/a_B is the ratio of the lattice constant to the exciton radius. This result seems not inconsistent with the identification of the observed absorption lines in Cu_2O , CdS , HgI_2 , PbI_2 , and CdI_2 as exciton lines. (Contractor's abstract)

NUCLEAR RELAXATION BY THE HYPERFINE INTERACTION WITH THE ION CORE SPINS IN FERROMAGNETIC AND ANTIFERROMAGNETIC CRYSTALS, by A. H. Mitchell. [1957] 9p. (Technical rept. no. 84) (AFOSR-TN-57-721) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, and Signal Corps) AD 144432

Unclassified

Also published in Jour. Chem. Phys., v. 27: 17-19, July 1957.

The hyperfine interaction of the nucleus with the ion core spins in magnetic crystals provides a relaxation mechanism for the nuclear spins since energy conservation can be obtained by a change in the spin wave energy. In nonconducting magnetic crystals this mechanism may be dominant in the relaxation of the nuclei of the magnetic ions. The relaxation time is calculated for such a nucleus in an antiferromagnetic crystal. (Contractor's abstract)

ELECTRON-SPIN RESONANCE AND MAGNETIC SUSCEPTIBILITY MEASUREMENTS ON DILUTE ALLOYS OF Mn IN Cu, Ag, AND Mg, by J. Owen, M. E. Browne and others. [1957] [15]p. incl. diagrs. tables. (Technical rept. no. 87) (AFOSR-TN-57-723) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, and Signal Corps) AD 144434

Unclassified

Also published in Jour. Phys. Chem. Solids, v. 2: 85-99, Apr. 1957.

An account is given of some magnetic measurements made on alloys of Cu containing from 0.03 to 11 atomic per cent Mn in the temperature range 2° to 400°K. Less detailed work on Ag Mn and Mg Mn is also described. All of these alloys are found to obey a Curie-Weiss susceptibility law, and show an electron spin resonance line with free spin g-value. For most alloys the measured Curie constant suggests that there are between 4 and 5 unpaired electron spins per Mn atom. At low temperatures, alloys with more than about 1 atomic percent Mn appear to be antiferromagnetic, and show what can be interpreted as an unusual form of antiferromagnetic resonance absorption. Broadly speaking, the magnetic behavior is rather like that expected of Mn^{2+} ions coupled by strong short range interactions such as direct and superexchange. The expected long-range indirect exchange via conduction electrons appears to be extremely small, as has been previously pointed out by Owen, Browne, Knight and Kittel. (Contractor's abstract)

MAGNETIC PROPERTIES OF Cu-Mn ALLOYS, by K. Yosida. [1957] [6]p. incl. refs. (Technical rept. no. 88) (AFOSR-TN-57-724) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, and Signal Corps) AD 144435 Unclassified

Also published in *Phys. Rev.*, v. 106: 893-898, June 1, 1957.

The polarization of conduction electrons due to s-d interaction in CuMn alloys is investigated. The uniform polarization due to the first order perturbed energy corresponding to the Fröhlich-Nabarro and Zener mechanism is shown to be completely modified by the first order perturbation of the wave functions and the polarization is concentrated in the neighborhood of the Mn ions. At the same time it is shown that the Fröhlich-Nabarro interaction is included in the Ruderman-Kittel result as one component. This point of view is corroborated by the experimental results on the electronic g-values of the Mn ions and the Knight shift of the Cu-nuclei which can be qualitatively accounted for by the Ruderman-Kittel mechanism. THEORY OF CYCLOTRON RESONANCE IN METALS, by V. Heine. [1957] [24]p. incl. diagrs. refs. (Technical rept. no. 89) (AFOSR-TN-57-725) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, and Signal Corps) AD 144436 Unclassified

Also published in *Phys. Rev.*, v. 107: 431-437, July 15, 1957.

Azbel' and Kaner have shown that a cyclotron resonance phenomenon is possible in a metal under extreme anomalous skin-effect conditions when the magnetic field is parallel to the metal surface. In this paper the correct form of the surface impedance is deduced in a more simple way by using the "ineffectiveness concept" of Pippard. An approximate criterion is also established for how nearly parallel to the surface the magnetic field must be. When the oscillating electric field is not parallel to the constant magnetic field, it produces a polarization of the charge distribution in the metal, and it is shown that this effect does not destroy the resonance in contrast to the situation in semiconductors. ANOMALOUS ELECTRICAL RESISTIVITY AND MAGNETORESISTANCE DUE TO AN s-d INTERACTION IN Cu-Mn ALLOYS, by K. Yosida. [1957] 23p. incl. tables, refs. (Technical rept. no. 90) (AFOSR-TN-57-726) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, and Signal Corps) AD 144437 Unclassified

Also published in *Phys. Rev.*, v. 107: 396-403, July 15, 1957.

The effect of the s-d exchange interaction between the conduction electrons and the Mn ions on the electrical behavior of Cu-Mn alloys is investigated from the molecular-field point of view. The magnitude of the anomalous resistivity calculated with the value of the exchange integral for a free Mn²⁺ ion agrees with the experimental value within a factor of three. Also the temperature dependence of the resistivity obtained by the molecular-field approximation for the antiferromagnetic spin ordering is shown to be quite similar to the behavior exhibited by the alloys with more than 1 atomic percent Mn. For samples with lower concentration of Mn ions, however, the theoretical result shows only a monotonic decrease of the resistance below the Néel temperature. It shows neither the resistance minimum nor maximum which has been found experimentally for the very dilute alloys. The anomalous magnetoresistance calculated on the same basis is approximately proportional to the square of the magnetization and its magnitude is in good agreement with the experimental results, especially above the Néel temperature. The magnetoresistance of ferromagnetic metals is also discussed. (Contractor's abstract)

EXCITON DOUBLET SPLITTING IN IONIC CRYSTALS, by R. Petersen. [1957] 3p. (Technical rept. no. 80) (AFOSR-TN-57-727) (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr 22201], and Signal Corps) AD 144248 Unclassified

Also published in *Jour. Phys. Chem. Solids*, v. 1: 284, Jan. 1957.

The origin of the exciton lines in alkali halide crystals has been previously attributed to an L-S coupling scheme. A mechanism involving the transfer of the excited electron from the anion to the nearest neighbor cations has been proposed. The similarity between rare gas atoms and halogens ions has led to an estimate of the relative intensity of the two lines.

EXPERIMENTAL EVIDENCE FOR ENERGY GAPS IN SUPERCONDUCTORS, by M. Tinkham. [1957] [6]p. diagra. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr-22201], Signal Corps, and National Security Agency) Unclassified

Published in Proc. Fifth Internat'l. Conf. on Low Temperature Phys. and Chem., Madison, Wis. (Aug. 26-31, 1957), Univ. of Wisconsin Press, Madison, 1958, p. 261-265.

A direct spectroscopic experiment is conducted to give evidence for energy gaps in superconductors. The power absorbed in creating excitations is measured as a function of photon energy. Therefore, the presence of an energy gap appears as an absence of absorption below a certain frequency. The data obtained together with specific heat data and recent data supporting a non-local theory appear to establish rather convincingly the existence of an energy gap in the electronic excitation spectrum of superconductors.

EFFECTS OF THE PLASMA IN CYCLOTRON RESONANCE IN METALS AND SEMICONDUCTORS, by C. Kittel. [1957] [14]p. incl. diagr. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, Signal Corps, and National Security Agency) Unclassified

Also published in Proc. Conf. on Radio and Microwave Spectroscopy, Duke U., Durham, N. C. (Nov. 4-6, 1957), Washington, Office of Naval Research [1957] p. 81-85.

The question of the influence of plasma resonance on the cyclotron resonance in metals is discussed. A two-carrier model is introduced to investigate the possibility of observing the cyclotron resonance of one or both carriers, substantially unmodified by plasma effects due to the shorting out of plasma effects by means of the other carrier. The above has been shown to be possible as well as the cyclotron resonance in metals in which a portion of the carriers are non-resonant and act as effective second carriers. The derivation of the charge density decay relaxation time in metals is generalized to remove the discrepancy between the observed and calculated values.

NUCLEAR SPECIFIC HEAT OF COBALT METAL (Abstract), by V. Arp, N. Kurti, and R. Petersen. [1957] [1]p. (AF 18(603)46) Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 388, Dec. 19, 1957.

The specific heat of a sample of cobalt metal has been measured in the temperature range 0.3 to 1.0°K and the contribution from nuclear polarization has been evaluated. An 8-gm polycrystalline sample was cooled in a conventional demagnetization cryostat. Measured amounts of heat were introduced via a manganin resistance wire wrapped around the sample, and temperature was measured by means of a calibrated carbon resistor. The results can be expressed

$$\frac{C}{R} \times 10^4 = \frac{6.2}{T} + 5.6 T$$

where the first term is the nuclear polarization contribution arising from h.f.a. coupling with the spin system, and the second is the usual conduction electron specific heat. The nuclear contribution appears to be in good agreement with a value deduced (by Grace et al, Bull. Amer. Phys. Soc., Series II, v. 2: 136, Dec. 1957) from anisotropy of γ -radiation emitted by polarized Co^{60} nuclei in a single crystal sample.

HYPERFINE STRUCTURE OF PARAMAGNETIC IONS, by V. Zeina. [1957] [2]p. (Technical rept. no. 92) (AFOSR-TN-58-307) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, Signal Corps, and National Security Agency) AD 215158

Unclassified

Also published in *Phys. Rev.*, v. 107: 1002-1003, Aug. 15, 1957.

The hyperfine structure of several paramagnetic ions and atoms such as Mn^{++} is known to contain an unexpected and large contribution due to some admixture of unpaired s electrons in the wave function. An explanation of this is proposed in terms of the effect of exchange with the 3d electrons on the 2s and 3s electrons. Since the spins of the 3d electrons are at least partially lined up, exchange affects 2s, 3s electrons with parallel and antiparallel spin differently, so that the $2s^2 3s^2$ electrons are not exactly paired. A rough preliminary calculation gives sufficiently good agreement to suggest that the proposed mechanism is an important factor, if not the complete explanation. Some detailed differences between various ions remains puzzling. (Contractor's abstract)

Also published in *Phys. Rev.*, v. 108: 243-256, Oct. 15, 1957.

From transmission measurements for thin films of tin and lead, the frequency dependence ω of the complex conductivity $\sigma^*(\omega)$ has been determined for ω between $0.3\omega_c$ and $40\omega_c$, where $\omega_c = kT_c/\hbar$. The reduced frequency dependence $\sigma^*(\omega)/\sigma_{normal}$ expressed in terms of the reduced frequency ω/ω_c appears to be approximately universal and to be independent of the resistance, thickness, and degree of anneal of the films. At $T = 0$ the real part of σ^* appears to be zero for photon frequencies below $3\omega_c$ and it rises rapidly so that it reaches the limiting value σ_{normal} at about $20\omega_c$. Such behavior

suggests an energy gap of width about $3\hbar\omega_c$ in the electron excitation spectrum of the superconducting state. At $T = 0$ and $\omega < \omega_c$ the imaginary part σ_2 of σ^* is about $3.7\omega/\omega_c$. This $1/\omega$ dependence is in accord with the London theory but the London coefficient is about 100 times too large. Pippard's nonlocal modification of the London equations predicts a value of 6.7. For ω between $3\omega_c$ and $5\omega_c$, the value of σ_2 goes to zero as required by a term from the Kramers-Kronig relations. A temperature dependence has been obtained which is not in agreement with present theories.

Also published in *Phys. Rev.*, v. 108: 1212-1218, Dec. 1, 1957.

Measurements of the magnetoresistance coefficients at $4.2^\circ K$ and at $20.4^\circ K$ in single crystals of copper, silver, and gold in the low magnetic field range, and in single crystals of silver for high magnetic field are reported. The low-field results were analyzed under the assumptions that a relaxation time exists and is a function of the energy alone, and that the Fermi surface is a single closed surface within the first Brillouin zone and not touching its boundary. It is found that for copper the magnetoresistance cannot be fitted very well on this model. It is assumed that at low temperature the hypothesis that a relaxation time exists is a good approximation, and suggested that in copper the Fermi surface touches the boundary of the first Brillouin zone. The magnetoresistance of silver in high magnetic fields shows marked anisotropy and no sign of saturation. (Contractor's abstract)

DORFMAN'S PROPOSAL REGARDING CYCLOTRON RESONANCE IN FERROMAGNETIC SUBSTANCES, by C. Kittel. [1957] [1]p. (Technical rept. no. 97) (AFOSR-TN-58-311) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)46, Office of Naval Research under Nonr-22201, Signal Corps, and National Security Agency) AD 215160 Unclassified

Also published in Phys. Rev., v. 108: 1097-1098, Nov. 15, 1957.

The suggestion of Dorfman regarding the possibility of observing cyclotron resonance in ferromagnetic substances in the absence of an applied external magnetic field may be incorrect since the spin-orbit interaction in these substances is invariant under the translation group of the crystal. Other sources show that replacing the spin-orbit interaction by an effective magnetic field in the Hamiltonian will not describe the galvanometric and magneto-optical effects.

The calculations reported in a paper by V. Heine (Proc. Roy. Soc., v. A240: 361, 1957) have been found to contain a systematic numerical error. The new results for the potential of a proton lattice are such as to raise the energy levels by 0.1 rydberg but to shift them relative to each other by only 0.03 rydberg. While this correction is quantitatively quite important, it does not change qualitatively the previous results.

Also published in Jour. Phys. Chem. Solids, v. 6: 99, July 1958.

X-ray measurements on the atomic scattering factors of Cu, Ni, Co, Fe and Cr have been carried out by Weiss and De Marco (Internat'l. Conf. on Problems in Crystal Phys., Massachusetts Inst. of Tech., July 1-5, 1957) to determine the outer electron configuration in the metallic state. They quote the number of d-electrons in bcc iron to be 2.3 ± 0.3 electrons per atom. Microwave resonance and magneto-mechanical experiments yield values of the spectroscopic splitting factor $g > 2$ and magneto-mechanical ratio $g \approx 2$. These results can be reconciled if there exist conduction states which are connected to the magnetic 3d wave-function states by means of spin-orbit perturbation.

Also published in Phys. Rev., v. 110: 836-841, May 15, 1958.

A field-theoretical treatment is given of the magneto-elastic coupling of magnons and phonons in a ferromagnetic crystal. The effects of the coupling are large when the wavelengths and frequencies of the two fields are equal. If the two transverse phonon states of a given wave vector are degenerate, then the rotatory dispersion of the phonons will be large. The possibility exists of creating nonreciprocal acoustic elements, such as acoustic gyrators. At simultaneous resonance the phonon attenuation is expected to be large. The possibility of magnetostrictive transducers at microwave frequencies is discussed. A calculation is given of the damping by eddy currents of spin waves in a metal. (Contractor's abstract)

Also published in Phys. Rev., v. 110: 26-26, Apr. 1, 1958.

The superconducting penetration depth λ is increased when the mean free path ℓ of the electrons in the sample is reduced by lattice disorder, impurities, or diffuse scattering at the sample boundary. This experimental evidence along with a simplification of Pippard's non-local theory is used to interpret the results of the experiments on small particles of superconducting substances. The formal results of London's theory can be taken over if London's λ_0 is modified to $\lambda_0(1 + \xi_0/\ell_{\text{eff}})^{\frac{1}{2}}$, where ξ_0 is Pippard's coherence length and ℓ_{eff} includes both surface and body scattering. This method gives a good fit to Whitehead's susceptibility data on colloidal superconducting mercury, but predicts a narrower nuclear resonance line than is observed by Reif in a similar colloid.

Also published in Phys. Rev., v. 110: 1295-1297, June 15, 1958.

It is possible to excite exchange and magnetostatic spin waves in a ferromagnet by a uniform rf field, provided that spins on the surface of the specimen experience interactions different from those acting on spins in the interior. Modes with an odd number of half-wavelengths should be excited in a flat plate. The definition of what is meant by a different anisotropy interaction is worked out and is a rather lenient condition. Experiments which would determine the exchange energy constant should be possible using sufficiently thin platelets of single crystals having parallel faces. It is perhaps not unlikely that the theory may account for the observation by Waring and Jarrett of a large number of resonance peaks in NiMnO_3 . (Contractor's abstract)

Also published in *Phys. Rev. Letters*, v. 1: 5-6, July 1, 1958.

There are a number of suitable transducers that should produce microwave phonons, and it is suggested that these phonons could be detected by the change in saturation of an electron-spin resonance-line that they cause. The detector would be operated near saturation of the line in a paramagnetic salt with the external magnetic field adjusted so that paramagnetic resonance occurs at the phonon frequency. An approximate calculation shows that a sensitivity of $10^{-4} \mu\text{W}/\text{cm}^3$ of phonon energy flux is possible.

Published in *Physica, Suppl.*, v. 24: S35-S41, Sept. 1958.

An energy gap of 4-4.5 kT_c has been measured for superconducting lead by means of a multiple reflection technique in a lead cavity. This value is in basic agreement with the extrapolated data on thin films but does not agree with the value 3.5 kT_c predicted by the BCS theory or the expected value from the specific heat data of other metals. This possibly indicates that lead does not satisfy the law of corresponding states or that there exists a selection rule inhibiting transitions to states at the edge of the gap.

MAGNETIC FIELD DEPENDENCE OF ULTRASONIC ATTENUATION IN METALS AT LOW TEMPERATURES, by S. Rodriguez. [1958] 30p. diagrs. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr-22201], Signal Corps, and National Security Agency) Unclassified

Also published in Phys. Rev., v. 112: 80-89, Oct. 1, 1958.

A theory of the effect of a constant magnetic field on the behavior of ultrasonic attenuation in normal metals at low temperatures of the order of liquid helium temperatures is given. The ideas are of the same kind as those suggested by Pippard to account for the attenuation in the absence of an external field. The different geometries are specified by the directions of three vectors, the wave vector q of the acoustic wave, the direction of polarization u_0 , and the external magnetic field

H_0 . The analysis shows that, for a transverse wave polarized in the direction of H_0 (i.e., u_0 are parallel and both are perpendicular to q) the attenuation decreases as $|H_0|^{-2}$ are large fields. When u_0 and H_0 are perpendicular and q is perpendicular to both, the attenuation increases as $|H_0|^{-2}$ for large $|H_0|$. For a wave such that u_0 and q are parallel and H_0 is perpendicular to q , the attenuation increases asymptotically to a constant value as $|H_0|$ increases. The maxima and minima obtained experimentally by Morse and co-workers cannot be explained on this model. An absorption similar to that occurring in cyclotron resonance absorption is obtained in the attenuation of transverse waves (u_0 perpendicular to q) when H_0 is parallel to q . THE LINEAR ANTIFERROMAGNETIC CHAIN WITH ANISOTROPIC COUPLING, by R. Orbach. [1958] 27p. diagrs. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr-22201], Signal Corps, and National Security Agency) Unclassified

Published in Phys. Rev., v. 112: 309-316, Oct. 15, 1958.

The exact solution is given for a linear chain of N atoms of spin $\frac{1}{2}$ coupled together by the anisotropic Hamiltonian

$$H = 2J \sum_{i=1}^N [S_i^x S_{i+1}^x + (1-\alpha)(S_i^x S_{i+1}^y + S_i^y S_{i+1}^y)].$$

The energy of the antiferromagnetic ground state is computed and comparison is made with a variational method. The parameter α is allowed to vary between 0 and 1, regulating the relative amount of using anisotropy. The short-range order, $\sum_{i=1}^N S_i^x S_{i+1}^x$, is calculated exactly from the variation of the ground-state energy with α . It is shown that a kink in the short-range order curve calculated using the variational method is fictitious, and the associated discontinuity in $\partial^2 E / \partial \alpha^2$ is nonexistent. A discussion is given of long-range order and criticisms are presented regarding the predictions of the variational method. (Contractor's abstract)

Presented at Magnetism Conference, Philadelphia, Pa., Nov. 1958.

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 400, Dec. 29, 1958.

Also published in Phys. Rev., v. 115: 1181-1184, Sept. 1, 1959.

The exact eigenstates of the exchange Hamiltonian are found for short chains of 4, 6, 8, and 10 atoms of spin $\frac{1}{2}$. A linear dispersion law for magnons in an antiferromagnet is exhibited by the energy spectrum. Rotation operators are applied to the exact ferromagnetic and antiferromagnetic ground states to give semiclassical states simulating 360° Bloch walls. These states are projected upon the exact eigenvectors of the exchange Hamiltonian. The wall energies are computed, and it is shown that the S = 0 and S = 1 states are most important. The periodic boundary conditions are then removed, and the ends of the chain held fixed, both parallel or antiparallel. The energy of the 180° Bloch wall is computed and compared with the classical result. It is found that the semiclassical ferromagnetic wall is a good approximation to the exact wall. The energy of the semiclassical antiferromagnetic wall is not a very good approxima-

tion to the exact wall energy, but the semiclassical energy appears to have the correct dependence on the wall thickness. (Contractor's abstract)

CONDUCTIVITY IN PbS FILMS FROM dc TO 10 kmc/s (Abstract), by D. P. Snowden, A. M. Portis, and R. F. Brebrick. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr-22201], Signal Corps, and National Security Agency) Unclassified

Presented at meeting of the Amer. Phys. Soc., Calif. U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 410, Dec. 29, 1958.

Measurements of conductivity and photoconductivity as a function of frequency from dc to 10 kmc/sec have been made on chemically deposited lead sulfide films. In addition, the mobility of dark and photocarriers has been determined at dc by measurement of the Hall effect and at 10 kmc/sec by microwave Faraday rotation. The electrode design used for the rf measurements avoids the apparent increase in conductivity which has been analyzed by Lax and Sachs as a self-capacitance effect. The increase in conductivity observed in the present experiments is believed to be characteristic of the electrical structure of the sample. All samples exhibit a con-

ductivity which is relatively insensitive to frequency up to about 100 mc/sec. Within a decade of this frequency the conductivity increases by nearly an order of magnitude and then remains constant again into microwave region. The photoconductivity on the other hand is essentially constant over the entire frequency range with a broad hump in the 100-mc/sec range. These results lend support to a model for PbS films consisting of alternate n-type and p-type regions, provided that the contribution of minority as well as majority carriers in both regions is considered.

Presented at meeting of the Amer. Phys. Soc., Calif. U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 400, Dec. 29, 1958.

The authors have investigated the dynamics of domain wall motion in the superconducting intermediate state for lead and tin samples in the form of either rods, diameter 140μ , or small particles, diameter $1-10\mu$. The susceptibility, χ , of the samples was measured as a function of applied magnetic field, H, by placing the sample in an rf oscillator tank coil and observing the frequency shift vs H. The same arrangement was used to determine $d\chi/dH$, but in the case 0.1 to 1% of the applied magnetic field was modulated at a frequency f between 10 cps and 50 kc in order to produce the derivative. The $d\chi/dH$ vs H curve has a maximum value where χ vs H has maximum slope. However, hysteresis effects are observed in $d\chi/dH$ vs H which are not observed in χ vs H. Moreover, a second maximum in $d\chi/dH$ for lead is observed above the critical field. The amplitude of the maximum in the $d\chi/dH$ vs H curve below the critical field is a function of modulation frequency, f , and is proportional to $1/f^2$ for large f . This later behavior is understandable on the basis of a theory of eddy current damped domain wall motion.

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 416, Dec. 29, 1958.

An Azbel-Kaner type cyclotron resonance has been observed in a sample of natural copper. Fundamental and subharmonic resonance minima of order $q = 1, 2, 3, 4$ were observed superimposed on a monotonically decreasing surface resistance with a form qualitatively like $R(H) = R(0) \tanh^{1/3} A/H$. The resonance was observed only near particular sample orientations, and in the region of observability the cyclotron mass was essentially independent of orientation. The agreement between the experimental resonance curve and a theoretical curve calculated using $\omega\tau = 10$ is satisfactory and gives a cyclotron mass $m^*/m_e = 1.37 \pm 0.05$. This mass is consistent with estimates of extremal cyclotron masses calculated from Moliner's analytical expression for Pippard's Fermi surface. No phase shift between experimental and theoretical curves like that reported by Aubrey and Chambers is present.

OBSERVATION OF MICROWAVE FARADAY ROTATION IN MnF_2 (Abstract), by D. Teaney and A. M. Portis.

[1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr-22201], Signal Corps, and National Security Agency)

Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 416, Dec. 29, 1958.

Microwave Faraday rotation has been observed in MnF_2 between 25°K and 300°K. The most striking characteristic of the data is the increase in the rotation by nearly three orders of magnitude as the temperature of the sample is raised above the Néel point. The measurements were made on a single crystal of MnF_2 cemented to the end wall of a bimodal transmission cavity. The detection of antiferromagnetic Faraday rotation is made possible by the exceptional stability of the bimodal cavity. The sample was oriented so that the c axis of the sample coincided with the symmetry axis of the cavity. The filling factor of the sample in the cavity was determined from rotation measurements in the paramagnetic range. From this information and an analysis of the response of the bimodal cavity values of the off-diagonal elements of the susceptibility tensor are obtained as a function of temperature.

THEORY OF MICROWAVE FARADAY ROTATION IN MnF_2 (Abstract), by A. M. Portis. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr-22201], Signal Corps, and National Security Agency) Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 416, Dec. 29, 1958.

Microwave Faraday rotation in antiferromagnetics was predicted theoretically by Wangness, who obtained an expression for the rotation to be expected at $T = 0^\circ K$. The authors extended this treatment to higher temperatures and compared the results with experiment. An equation of motion was used which below the transition had the form introduced by Kittel. Above the transition the equations assumed the familiar Bloch form. Below the transition in the limit of small fields and at frequencies well below the antiferromagnetic resonance frequency it was found that the off-diagonal element of the susceptibility tensor,

$$\chi_{xy} = 2i\omega\gamma H_0 (\chi_{\perp} - \chi_{\parallel}) / \omega_0^2, \text{ where } \omega_0 \text{ is the zero-field}$$

antiferromagnetic resonance frequency. There was generally good agreement between experiment and the predicted curves except in the immediate vicinity of the transition. In particular, the decrease in rotation by three orders of magnitude, which is expected as the material becomes antiferromagnetic, took place over a 10° range of temperature. It did not appear that the temperature dependence in this range could be understood in terms of a simple resonance equation but requires an investigation of the spectrum of excited states.

MICROWAVE FARADAY ROTATION: DESIGN AND ANALYSIS OF A BIMODAL CAVITY, by A. M. Portis and D. Teaney. [1958] [7]p. incl. diagrs. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr-22201], Signal Corps, and National Security Agency) Unclassified

Published in Jour. Appl. Phys., v. 29: 1692-1698, Dec. 1958.

The design and analysis of a bimodal cavity for the observation of microwave Faraday rotation is presented. An equivalent circuit of lumped elements is developed

and the coupling between degenerate cavity modes is expressed in terms of elements of the susceptibility tensor of the material producing the rotation. The theory is checked against experimental results with a paramagnetic salt and substantial agreement is obtained. A cavity of this type when used in conjunction with superheterodyne detection appears to provide a high sensitivity spectrometer for the observation of magnetic resonance. (Contractor's abstract)

EXCITATION OF SPIN WAVES IN AN ANTIFERROMAGNET BY A UNIFORM rf FIELD, by R. Orbach and P. Pincus. [1958] 10p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)46], Office of Naval Research under [Nonr-22201], Signal Corps, and National Security Agency) Unclassified

Also published in Phys. Rev., v. 113: 1213-1215, Mar. 1, 1959.

It is possible to excite exchange and magnetostatic spin waves in an antiferromagnet by a uniform rf field, provided that spins on the surface of the specimen experience anisotropy interactions different from those acting on the spins in the interior. Modes with an odd number of half-wavelengths should be excited in a flat plate. The condition for different anisotropy interactions is worked out and proves to be a lenient condition. Experiments which would determine the exchange energy constant and the anisotropy field should be possible using sufficiently thin platelets of single crystals having parallel faces. RADIATIVE CAPTURE OF ORBITAL K^- MESONS BY NUCLEI (Abstract), by G. Frye. [1958] [1]p. [AF 49-(638)327] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 402, Dec. 29, 1958.

A discussion is presented of the radiative transition of K^- mesons in atomic orbitals from a state (n, l) to a state $(n', l - 1)$ on the assumption that nuclear capture is much more likely from the latter state. The x-radiation may occur together with the orbital K^- -meson capture as part of a two-step process. Then the energy released by the capture is shared with the proton, giving it a continuous spectrum with typical resonance peaks corresponding to the usual x-ray lines. The theory for radiative capture of K^- electrons is applied in detail to this problem. The photon spectrum and the total transition probabilities for radiative capture from $l = 1, 2, 3 \dots$ states are estimated. In radiative capture from the $2P$ state, for instance, two percent of the photons have an energy greater than twice the $1S$ -state binding energy.

NUCLEAR SPIN, HYPERFINE-STRUCTURE SEPARATION AND MAGNETIC MOMENT OF POTASSIUM-43 (Abstract), by F. R. Petersen, F. J. Ehlers and others. [1958] [1]p. [AF 49(638)339] Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 415, Dec. 29, 1958.

With the atomic beam magnetic resonance technique the nuclear spin of ^{43}K has been measured as $3/2$. The isotope is collected on a sulfur coated surface and beta counted in continuous flow proportional counters. An initial search was conducted on the usual flop-in transition ($F = 2, M_F = -1 \rightarrow -2$) at low magnetic fields.

At higher values of the field the quadratic shift of frequency of this line yields a sufficiently good value of the hyperfine structure constant to permit a search for direct transitions between the $F = 2$ and $F = 1$ levels. Of the 6 observable transitions of the $\Delta F = 1$ type the $M_F = 0 \rightarrow 0, 1 \rightarrow 1$ doublet, and the $-1 \rightarrow 0$ doublet transitions have been observed. A preliminary hyperfine

structure separation of $192.6 \pm .2$ mc/sec for the $^2S_{1/2}$ electronic ground state is obtained. Through use of the Fermi-Segrè formula and K^{39} as a reference isotope the magnetic moment becomes $\mu_I = \pm .163 + .002$ n m.

The radioisotope was prepared by $A^{40}(\alpha, p)K^{43}$ reactions with 20 mev alpha particles from the Berkeley 60" cyclotron. The alpha energy is initially degraded from 47 mev to reduce the production of K^{42} through the α, pn reaction. Stable potassium serves as carrier for the radioisotope and is used to calibrate the homogeneous C-field.

TIME DOMAIN SYNTHESIS OF SAMPLED-DATA CONTROL SYSTEMS, by E. I. Jury and F. W. Semelka. Feb. 1957, 32p. illus. diagrs. (AFOSR-TN-57-58) (AF 18(600)1521) AD 115098 Unclassified

Also published in Trans. Amer. Soc. Mech. Engineers, v. 80: 1827-1839, Nov. 1958.

The application of the modified z-transform to synthesis of sampled-data control systems is discussed. The applicability of the modified z-transform as an analysis tool has been demonstrated in recent publications. At present, this transform method is being developed to reduce the process of synthesis of both sampled-data and continuous systems to systematic, straightforward numerical processes. The synthesis procedure presented is a time domain technique which permits the designer to achieve control of the continuous behavior of the system. The desired characteristics are specified in terms of standard synthesis criteria, and from such specifications the required compensation transfer functions are determined. An example illustrates the procedure and an analog computer study shows the nature of the effects realized by this approximation technique.

Also published in Trans. Amer. Inst. Elec. Engineers, v. 77 (Part II): 20-28, Mar. 1958.

The Laplace transform method has been applied to the analysis of multiple-sampler systems. The method of analysis is based on a contour integral, which is derived from the Laplace transformation, and which mathematically describes the operation of a sampler with finite pulse width. This contour integral referred to as p-transformation in references is employed for the exact analysis of linear multiple-sampler open-loop systems with finite pulse width. It is shown that by a combination of a few fundamental steps it is possible to treat any open-loop system. These steps have been outlined and simple examples given to demonstrate their application. The technique is general, no restriction being imposed on the number or the periodicity of samplers present. It may be applied to systems with delayed samplers, and periodic samplers with different periods and pulse widths, as well as to systems which include nonperiodic samplers both with respect to period and/or pulse width. In each case the solution is exact and in systems with periodic samplers it can always be expressed in a closed form. The limiting cases are also considered. As a consequence of these, a method is obtained for analysis of open-loop sample-data systems with zero pulse width which include two or more samplers. (Contractor's abstract)

GENERAL ANALYSIS AND STABILITY STUDY OF FINITE PULSED FEEDBACK SYSTEMS, by G. Farmanfarma. Nov. 20, 1957, 74p. incl. diags. tables, refs. (Series no. 60; issue no. 196) (AFOSR-TN-57-608) (AF 18(600)1521) AD 136598

Unclassified

Also published in Trans. Amer. Inst. Elec. Engineers, v. 77 (Part II): 148-162, July 1958.

A method is presented for the analysis of finite pulsed feedback systems. The pulse width and the pulse shape are considered in its analytical treatment. The technique is based on the superposition principle, as well as some operational properties of the Laplace transform.

The application of this method to systems with periodic samplers leads to a set of simultaneous first order difference equations with constant coefficients. The stability conditions are independent of the input but are functions of the pole-zero configurations of both the open and closed loop transfer functions, as well as the sampler characteristics. The plotted responses of an error pulsed second order system to a step, ramp, and a sinusoidal input function indicate that, in each case, as the pulse width h approaches the sampler period the output approaches the equivalent continuous system response. It can be shown that as $h \rightarrow 0$ and the gain of the system is increased inversely as h , the output corresponds to the equivalent sampled-data system. (Contractor's abstract)

ADDITIONS TO THE MODIFIED z-TRANSFORM METHOD, by E. I. Jury. [1957] [21]p. incl. diags. tables, refs. [AF 18(600)1521]

Unclassified

Presented at Western Electronic Show and Convention, San Francisco, Calif., Aug. 20-23, 1957.

Published in I.R.E. WESCON Convention Record, Pt. 4: 136-156, 1957.

The theory of the modified z-transform is further developed and extended. It is shown that the modified z-transform is a general method that can be systematically applied for the exact analysis of sampled-data control systems or any system that can be described by mixed linear difference-differential equations. The z-transform method is shown to be a special case which can be obtained from the modified z-transform. Tables of various sampled-data systems configuration have been developed which indicates the transfer function of such configurations. Extensive tables of the modified z-transform are introduced which aid considerably in the analysis and synthesis of sampled-data systems. Theorems relating to inverse modified z-transform, initial and final value theorems, differentiation, translation, limiting value, integration, maxima and minima, mean square value are introduced. Stability considerations and hidden oscillations are discussed and the limitations of the z-transform method are indicated. Properties of the modified z-transform transfer function are enumerated which aid in the design of sampled-data system. The modified z-transform method has been applied to the analysis of sampled-data systems with pure delay. Cases of delays which are integer and non-integer values of the sampling period are considered. It is also shown that the modified z-transform can be applied to obtain the inverse Laplace transform of certain functions in a closed form and a short table is introduced to show the equivalence of an infinite series.

A NOTE ON THE OPERATIONAL SOLUTION OF LINEAR DIFFERENCE EQUATIONS, by F. J. Mullin and E. I. Jury. Mar. 14, 1958 [20]p. incl. diagrs. refs. (Series no. 60, issue no. 199) (AFOSR-TN-58-100) (AF 18(600)1521) AD 148149 Unclassified

Also published in Jour. Franklin Inst., v. 266: 189-205, Sept. 1958.

The z-transform is applied to the solution of linear difference equations with constant coefficients; boundary conditions are considered in the resulting solutions, and certain theorems related to the z-transform are applied to obtain qualitative information about the solution. The z-transform is used to solve simultaneous difference equations with constant coefficients and the modified z-transform is used to solve difference equations whose coefficients are periodic functions. Finally the z-transform is applied to the solution of difference equations with periodic coefficients. The methods of solution are illustrated with various examples which indicate the straightforward procedure for applying the z-transform and the modified z-transform to the solution of difference equations. CONTRIBUTION TO STATISTICAL DESIGNING OF SAMPLED-DATA CONTROL SYSTEM, by T. Nishimura and E. I. Jury. Aug. 5, 1958 [158]p. incl. diagrs. refs. (Series no. 60; issue no. 210) (AFOSR-TN-58-613) (AF 18(600)1521) AD 162141; PB 140677 Unclassified

The derivation of the optimum discrete compensator is presented for the continuous-discrete sampled-data control system by means of the modified z-transform. An expression for the discrete power spectral density is introduced in order to solve the complicated problem of the continuous-discrete systems. The idea of the modified z-transform with a fictitious advance is adopted in order to keep the symmetry with the modified z-transform in the ordinary sense. The meaning of the modified z-transform of the power spectral density is explained. The general optimization procedures are demonstrated for the ordinary feedback system with a discrete compensator in the forward path, the feedback system with a pure delay in it, and the feedback system with a discrete compensator in the feedback path. The power spectral densities in the system with finite pulse width, as well as the multiple, and mixed sampling systems are derived. (Contractor's abstract)

THE ANALYSIS OF SAMPLED-DATA CONTROL SYSTEMS WITH A PERIODICALLY TIME VARYING SAMPLING RATE, by F. J. Mullin and E. I. Jury. June 30, 1958 [24]p. incl. diagrs. refs. (Series no. 60, issue no. 207) (AFOSR-TN-58-665) (AF 18(600)1521) AD 162196 Unclassified

Also published in I.R.E. Trans. of Professional Group on Automatic Control, v. AC-4: 15-21, May 1959.

The z-transform is used to solve sampled-data feedback systems which have a periodically time varying sampling rate. Such systems are described by linear difference equations with periodic coefficients; however the difference equation which describes the system at the sampling instants corresponding to KN , where N is the period of the coefficients and $K = 0, 1, 2, \dots$ is a linear difference equation with constant coefficients. Thus, by forming a series of constant coefficient difference equations which individually describe the system at sampling instants corresponding to $n = KN, KN + 1, KN + 2, \dots, (K+1)N-1$, the time varying features of the system are in essence removed from the analysis. The z-transform can then be used to solve the resulting constant coefficient difference equations. The response between sampling instants can also be obtained from the solution of the difference equations. The method presented is straightforward and can be used to analyze any linear sampled-data system which has a periodic sampling rate. It can also be used in problems of inventory control, production control and in the operation research field. Furthermore it can be used in approximating a continuous control system by a sampled system which contains a periodically time varying sampling rate to obtain a better approximation than is possible with a fixed sampling rate. In this method the only periodicity of the sampling rate is assumed and no relationship between the individual sampling intervals is required. A few examples were introduced for analysis purposes and the features of the response of such a system to sinusoidal inputs is indicated in one of the examples. (Contractor's abstract)

ANALYSIS OF INTEGRAL-SQUARE ERROR IN SAMPLED-DATA CONTROL SYSTEMS, by B. H. Bharucha. June 30, 1958, 48p. incl. diagrs. tables, refs. (Series no. 60; issue no. 206) (AFOSR-TN-58-679) (AF 18(600)1521) AD 162211; PB 137786 Unclassified

Finite moments of the squared error of a linear time-invariant (continuous or sampled-data) control system for a non-random input are developed as integrals in the modified z-transform domain. An explicit solution of the zero moment of the total squared error integral is

CAL. 04:014-016; A CAL. 04:014-016;
CAL. 13:001

given as the ratio of determinants of $2n \times n$ matrices where n is the order of the system characteristic polynomial in z . The elements of the matrices are obtained readily from the coefficients of the rational form in z of the modified z -transform of the error signal. The integral-square (total squared) error is now an explicit function of the free parameters of the system and can be studied to realize an appropriate minimization. A short table of solutions of the total squared error integrals is given. (Contractor's abstract)

Two types of sampled-data nonlinearities are investigated: relay sampled-data systems and sampled-data systems which have a saturating amplifier. In the study of relay sampled-data systems a method for determining the exact, continuous response of these systems using the phase plane is developed. This method of analysis is restricted to second and third order systems, but no restrictions are placed on the form of the input to these systems. The relay may be ideal or it may have a dead zone, and the effect of the width of the dead zone on the response of the system is discussed. As a by-product of this study, the limitations of the describing function as a method of analysis becomes clear. For saturating sampled-data systems the necessary and sufficient condition under which these systems are stable is developed, the stability conditions are investigated, and a method for obtaining an approximate numerical solution for the sampled error signal is presented. Finally, a method of compensating

saturated sampled-data systems is discussed. (Contractor's abstract)

A PHASE-PLANE APPROACH TO RELAY SAMPLED-DATA FEEDBACK SYSTEMS, by F. J. Mullin and E. I. Jury. [1958] [11]p. incl. diags. (AF 18(600)1521)

Unclassified

Presented at Pacific General meeting of the AIEE, Sacramento, Calif. Aug. 19-22, 1958.

Also published in Trans. Amer. Inst. Elec. Engineers, v. 77 (Part II): 517-524, Jan. 1959.

The phase plane is used to solve second-order sampled-data feedback systems which contain a relay and zero order hold circuit. The relay quantizes the signal applied to the linear part of the system and each quantization level gives rise to a corresponding set of trajectories in the phase plane. Between the sampling instants the output moves along one of these trajectories; however, the error signal which is applied to the relay depends only on the output and input at the end of the sampling interval; i.e., at the sampling instants. The output at the sampling instants is determined in the phase plane with the aid of two difference equations which are obtained from the time solution of the linear part of the system. This method of solution is not restricted to the study of such systems for step function inputs but may be used equally well to study the effects of sine wave inputs on the system as is illustrated in the examples of the paper. The differential equations of motion of an electron beam of high space charge moving through an axially symmetric magnetic field are readily solved by an analog computer. The solutions produced by the computer represent the beam radius and slope as a function of axial distance for any desired variation of axially symmetric magnetic field. The equations of motion are derived and normalized so as to be easily translated into the machine variables of the analog computer. Three particular field variations are considered in order to illustrate the method of solution. The behavior of an electron beam in the fringing magnetic field region required by Brillouin flow conditions establishes the radius and slope of the beam as it enters the region of the fringing field. Relationships between the magnitude of a periodic magnetic focusing field and its spatial period are developed for electron beams with "minimum-ripple" boundaries. A particular fringing magnetic field at the entrance to the periodic field is determined by an electrolytic-tank analog. The variation of the fringing field with axial distance coupled with the data from the minimum ripple solutions determine the profile of the beam envelope in the region of the fringing magnetic field. By the theory of the Pierce gun the radius and slope of the beam at the anode aperture can be matched to those obtained at the entrance to both the Brillouin and the periodic-magnetic focusing systems. Noise measurements are described on a backward-wave amplifier with movable gun-circuit spacings in order to study the space-charge waves in their coupling

to the backward-wave circuit. Although noise standing waves were observed, the original gun did not provide a very low noise figure. Tests on a gun with no center electrodes on a sealed-off tube showed better noise figures, but not as good as with the Currie gun, so the latter is to be used next in the variable distance tube. Theory of the effect of a virtual cathode is discussed. Design and construction of a diode for measuring noise effects in the gun region are also described. A solid-state maser using adiabatic fast passage in irradiated magnesium oxide is described. Maser gain was obtained at the end of the contract period. Theories of the effect of radiation damping on the adiabatic fast passage are given. Other planned maser experiments are discussed, including an extensive study of the best materials for the two-level maser. Studies on the entrance conditions into a periodic focusing system for electron beams are described, as is a unified point of view toward all focusing systems. (Contractor's abstract)

LAMINAR FLOW IN MAGNETICALLY FOCUSED CYLINDRICAL ELECTRON BEAMS, by J. L. Palmer. Nov. 20, 1958, 25p. incl. diags. (Series no. 60; issue no. 217) (AFOSR-TN-58-990) (AF 49(638)102) AD 205908
Unclassified

The behavior of a cylindrical electron beam in a magnetic field is discussed in terms of a laminar-flow model. By numerical integration of the equations of motion the maximum and minimum radii of excursion and the wave length of the undulations for each electron are presented in graphical form for various boundary conditions on the electron beam. By the proper selection of the boundary conditions, e.g., magnetic field strength at the cathode, the graphs are utilized to describe Brillouin flow, space-charge-balanced flow, immersed flow, confined flow, and, in fact, any electron flow which satisfies the laminar flow criterion. The perturbations introduced by improper injection conditions for any of the flows mentioned can be read directly from the graphs. A study of the wavelength and the amplitude of such perturbations as a function of radial position in the beam determines if a given type of flow with given injection conditions satisfies the laminar flow criterion. The sensitivity of the various types of electron flow to misadjustments of the boundary conditions is clearly revealed by the graphs, e.g., the amplitude of the undulations in Brillouin flow is very sensitive to the adjustment of the magnetic field strength, whereas, for immersed flow a similar deviation in magnetic field strength has very little effect on the amplitude of the undulations. PLASMA WORK (Abstract), by C. Süsskind and J. R. Whinnery. [1958] [1]p. (Bound with its AFOSR-TR-58-125; AD 162274) [AF 49(638)102] Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

Plasmas have been studied from the point of view of providing a source of electron currents of high density for very high-power tubes. Many metallic arcs and discharges of the type occurring in the Philips Ion Gauge have been investigated with some difficulties occurring in breakdown in the transition region between the plasma and high-vacuum interaction region. The Philips Ion Gauge mechanism appears useful from the point of view of long-pulse applications. The most recent emphasis has been on the use for r-f interaction of electrons obtained from a glow discharge in combination with secondary effects from a cold cathode. The pressure in the devices is maintained by a controlled leak from the atmosphere or a pure gas while the device is continuously pumped. The ions are allowed to stay in the interaction region, causing little interference with the high frequency because of their high inertia. Very high current densities are obtained and the principle appears promising for very high power c-w tubes or pulse tubes of high average power. The first successful r-f structure used to demonstrate the principle was an inside-out magnetron using a water-cooled interdigital structure with the glow discharge and the cold cathode consisting of an 8 in. air-cooled aluminum water pipe on the outside. The tube operated at 157 mc with a power output of 50 kw continuous and 50% efficiency. The best operation was with a gas pressure of 10^{-3} to 10^{-4} mm mercury.

Published in Brit. Jour. I.R.E., v. 18: 696-708, Dec. 1958.

Assumption of a particular magnetic-field variation in the transition region of an axially symmetric beam-type device (e.g., klystron, traveling-wave tube) leads to the solution of the equations of electron motion by means of an analogue computer. To illustrate this novel method of solution, beam envelopes are presented for Brillouin flow, periodic magnetic focusing, and space-charge-balanced flow. By matching the beam envelopes with those obtained from the theory of the Pierce gun, dimensions are obtained for an electron gun that produces the required beam. (Contractor's abstract)

APPARATUS FOR THE MEASUREMENT OF BAND AND TOTAL ABSORPTANCES OF GASES. Final rept. June 30, 1958. 64p. incl. illus. diagrs. tables, refs. (Series no. 118; issue no. 1) (AFOSR-TR-58-102) (AF 18(600)-1570) AD 162225; PB 136769 Unclassified

A description is presented of the apparatus designed and built for the measurement of thermal radiation absorptivities and emissivities of CO, CO₂, and, with modification of the gas supply system, H₂O. The range of gas temperatures is 70° F to about 2400° F, and provision has been made for future modifications which will extend the range to 3000° F. The pressure range is 0.5 to 10 atm. An optical absorption path of 15 in. is defined with an accuracy of about 1%. Instrumentation is provided for the measurement of total as well as band absorptivities from 1 to 23μ in the infrared region of the spectrum. All optical components and all metallic structural parts are protected from the chemical activity and high temperatures of the test gases.

ON THE DEVELOPMENT OF GASEOUS DETONATION. I. APPRAISAL OF THE PROBLEM, by A. K. Oppenheim and R. A. Stern. June 1958, iv. incl. illus. diagrs. tables, refs. (Technical note no. DR-1) (AFOSR-TN-58-383) (AF 49(638)166) AD 154290 Unclassified

The phenomena associated with the transition from deflagration to detonation are treated, and salient problems for future study are outlined. The history of the transition problem is traced from the discovery of the detonative mode of combustion. The study is concerned primarily with interaction phenomenon. An extensive bibliography of the literature is presented. A translation by F. A. Urtiew of selected sections from the text on *The Theory of Detonation* by Ya. B. Zel'dovich and A. S. Kompaneets is included in this report.

ON THE DEVELOPMENT OF GASEOUS DETONATION. II. ANALYSIS OF WAVE INTERACTION PHENOMENA, by A. K. Oppenheim and R. A. Stern. July 1958 [48]p. incl. illus. diagrs. tables, refs. (Technical note no. DR-2) (AFOSR-TN-58-384) (AF 49(638)166) AD 154291 Unclassified

Also published in *Seventh Symposium (International) on Combustion*, Oxford U., London (Gt. Brit.) (Aug. 28-Sept. 3, 1958), London, Butterworth's Scientific Publications, 1959, p. 837-850.

Salient phenomena associated with transition from deflagration to detonation are the interactions between the flame and the shock fronts generated during the process. The scant records available in the literature on shock and flame propagation during the development of detonation are used as basis for the dynamic analysis of wave phenomena occurring during the process. It is demonstrated how, by this means, the observed wave interaction phenomena can be rationalized over the whole space-time domain of the process, and, in particular, how the thermodynamic state and the wave velocity in the regime into which the flame propagates can be

determined with sufficient accuracy to deduce specific information on the reaction kinetics of a combustion front accelerating to detonation. As an example a specific analysis is carried out for a mixture of 8% propane, 50% oxygen and 42% nitrogen. It is found that the resulting energies of activation are of an order of 30 to 60 kcal/mol C_3H_8 which is in good agreement with data reported in the literature for combustion of propane under normal conditions. ON THE DEVELOPMENT OF GASEOUS DETONATION. III. IONIZATION WORLD LINES, by G. J. Hecht, A. J. Laderman and others. Jan. 1959 [58]p. incl. diagrs. refs. (Technical note no. DR-3) (AFOSR-TN-58-1133) (AF 49- (638)166) AD 208082; PB 139920 Unclassified

The design and construction of an ionization detection circuit to measure ionization world lines during the development of detonation is described. The ionization processes occurring in flames, shocks, and detonations are reviewed. A critical survey of existing ionization gages is made. The evaluation of performance criteria for the present purpose is described and the design of the gage and electronic apparatus reported. The operation of the instrument is demonstrated by means of experiments performed with stoichiometric hydrogen-oxygen mixtures. It appears that the apparatus is a reliable and sufficiently accurate instrument for the measurement of ionization world lines during the development of detonation and that it can be adjusted so that within most of the operating range it registers the world lines of the flame front. THE STUDY OF ELECTRON BEAM ATTENUATION IN AIR, by B. V. Markevitch and F. C. Hurlbut. Feb. 9, 1957 [47]p. incl. illus. tables, refs. (Rept. no. HE-150-142; series no. 20; issue no. 112) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-22245) AD 126618 Unclassified

An investigation of the attenuation of an electron beam in air was undertaken to examine the possible utility of such measurements for density determinations in rarefied gas streams. An apparatus is described which was designed to direct an electron beam of several kv energy through a test region into a detector. Pinholes, one at the detector entrance and one just preceding the collector plate, limit the cone of acceptance for electrons to approximately 0.002 radians. Attenuation in air of electron beams of 4 to 16 kv energy was measured at

CAL.05:004 - CAL.05:007

gas pressures of 20 to 300 μ of mercury. The results are well described by the classical logarithmic relation of Lambert. Experimental values for the effective total cross section arc represented to within 2 or 3% by the

relation $Q'(\pi) = \frac{3.6 \times 10^{-13}}{V} \text{ cm}^2$ where V is the neces-

sary accelerating potential. The corresponding mass absorption coefficient may be expressed as

$\mu = \frac{7.4 \times 10^9}{V} \text{ cm}^2/\text{gm}$. These values are approximately

10% smaller than predicted on the basis of elastic scattering alone, where the Thomas-Ferml model of the scattering center potential is assumed. The mean deviation of experimental points from the attenuation curves is of the order of 1 μ of mercury at all test pressures. The influence of multiple scattering on the constancy of the mass absorption coefficient in this geometry is apparently inappreciable. It is concluded on the basis of these considerations that an instrument employing an electron beam and collimated detector might well prove useful for aerodynamic studies in rarefied gas streams. THE STRUCTURE OF A SHOCK WAVE IN A GAS HAVING A LONG RELAXATION TIME, by L. Talbot. Mar. 15, 1957, 23p. illus. refs. (Rept. no. HE-150-145; series no. 20, issue no. 114) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-22245) AD 155323

Unclassified

The shock wave structure in a gas possessing a long relaxation time for one of its internal degrees of freedom was investigated. Both the Navier-Stokes equations and a subsidiary relaxation equation were assumed to apply throughout the entire transition. The behavior of the direction field of the differential equations was examined, and one particular shock profile was completed numerically. Comparisons were made with the predictions afforded by the simpler two-stage shock model, wherein it is assumed that the shock structure consists of two distinct regions; an initial shock wave in which the fast degrees of freedom of the gas molecules undergo change while the slow degrees of freedom remain inert, followed by a long relaxation region in which the adjustment to thermodynamic equilibrium takes place. Agreement between the results of the present theory and those of the two-stage model was very good. It is concluded that for shock waves in gases having long relaxation times, calculations based on the simple two-stage model give adequate approximations for the significant parameters. PRELIMINARY DESIGN AND TESTS OF A PLASMA JET, by W. Lai, D. H. Sloan, and L. Talbot. Technical rept. Nov. 15, 1957 [17]p. incl. illus. diags. tables. (Rept. no. HE-150-153; series no. 20, issue no. 115) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-22245) AD 150581

Unclassified

Preliminary design and test results for a plasma jet developed for the University of California Rarefied Gas Dynamics Lab. are presented. It is an argon plasma jet discharged between a carbon cathode and copper cone cathode with intermediate electrically neutral copper electrodes. The tests show that the hydrodynamic pinch and water cooling are sufficient to protect the intermediate electrodes; carbon consumption is negligible. Potential difference, current, and arc length appear to be interdependent as with a free arc. These three parameters should provide a very stable and symmetrical discharge suitable for wind tunnel research.

SLIP FLOW OVER A SHORT FLAT PLATE, by J. A. Laurmann. Dec. 26, 1957, 35p. incl. diags. (Rept. no. HE-150-152; series no. 20, issue no. 116) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-22245) AD 155324

Unclassified

Solutions of the compressible flow Navier-Stokes equations have been obtained for the problem of slip flow over a short flat plate at zero angle of attack by linearization for small values of the ratio of the plate length to the mean free path of the gas. A closed form solution was found possible in the compressible case; in the compressible case a general discussion has been given in terms of splitting of the solution into transverse and longitudinal waves. It was found that the effect of viscous terms of order higher than boundary layer theory extends over distances at the leading and trailing edges of the order of $\frac{\nu}{U}$

is negligible. (Contractor's abstract)

LIFT AND DRAG ON CONE CYLINDERS, by T. Nark. Dec. 30, 1957, 32p. illus. tables, refs. (Rept. no. HE-150-154; series no. 20, issue no. 117) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-22245) AD 155159

Unclassified

The normal and axial forces were measured on a cone-cylinder body of revolution in a supersonic, rarefied gas flow at a Reynolds number of 4050 and a Mach number of 4.0. The angle of attack was varied to a maximum of 16°. The final results, plotted in coefficient form, were compared to Newtonian hypersonic theory for an inviscid fluid. The test was conducted at such low Reynolds numbers that the Newtonian theory did not adequately represent the axial forces, but when a skin friction correction was applied to the theory, the experimental data are within 15 percent of the predicted values. The normal force coefficient was adequately predicted by the Newtonian theory, with the maximum error above 8° being 10 percent. The results of the experimental program indicate that the axial force characteristics of a body of revolution at supersonic speeds and low Reynolds numbers, where the boundary layer is laminar, can be adequately predicted from the Newtonian hypersonic theory and a suitable skin friction correction. The Newtonian theory itself is sufficient to predict the normal force coefficient under the same flow conditions. (Contractor's abstract)

A FLOATING ELEMENT WIND TUNNEL BALANCE, by W. F. Schick. July 15, 1958 [27]p. incl. illus. diagrs. tables, refs. (Rept. no. HE-150-159; series no. 20; issue no. 121) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-22245) AD 203700; PB 140584 Unclassified

This report describes a single component microbalance designed expressly for measuring localized drag near

the leading edge of a flat plate surface. The balance is to be used in the Low Pressures Project Wind Tunnel Number Four at the Richmond Field Station of California U. Sensitivity of the present balance is 0.1 milligram and the maximum range is greater than one gram. The sensitivity can be increased by increasing the weight of the floating element support. Balance design is based on a null system utilizing two sets of flexure pivots for model support and force measurement. There are no knife edges, rolling or sliding contact surfaces, or other devices with frictional inaccuracies used in the primary balance system. Development of this balance was prompted by the desire to study the possible effects of slip and viscous interaction on skin friction in a low density flow. (Contractor's abstract)

PRESSURE DISTRIBUTIONS ON FLAT PLATES AT MACH 4 AND LOW DENSITY FLOW, by J. Aroesty. July 28, 1958, 55p. refs. (Rept. no. HE-150-157; series no. 20; issue no. 120) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-22245) AD 203699; PB 140585 Unclassified

Induced pressures on sharp leading edge flat plates in a supersonic low density air stream were measured over the range $29.7 < Re_x < 4101$ and $3.7 < M < 4.1$.

The Reynolds number corresponding to the leading edge thickness was less than 85, insuring that blunt leading edge effects were negligible, as shown by an earlier study in the Berkeley low density wind tunnel. The measured pressure distributions agree with the analysis of Kuo to a value of $x = 2.5$, and agree with the modified tangent wedge theory to a value of $x = 3.5$. Beyond a value of x of 4, the pressures are less than those predicted by the theories, and essentially reach a constant value of $p/p_\infty = 3.5$ as the leading edge is approached. This reduction in the pressures from the levels predicted by boundary layer theory indicates a possibility of slip effects near the leading edge. (Contractor's abstract)

DESIGN CONSIDERATIONS AND INITIAL EVALUATION OF MODEL B PLASMA GENERATOR, by W. Lai, J. Gustavson, and L. Talbot. Sept. 5, 1958 [13]p. incl. illus. tables. (Rept. no. HE-150-161; series no. 20; issue no. 123) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-22245) AD 204400 Unclassified

An improved dc arc plasma generator is described. The general operation of the unit is as follows: The dc arc burns between the rear electrode, which is the cathode, and an anode, which can be either the expansion nozzle or the constricting orifice (constrictor). Gas is introduced in the arc chamber, passes through the arc, and expands through the constrictor/nozzle assembly into the test chamber, which is maintained continuously at a low pressure by vacuum pumps. In passing through the electrode gap, the gas maintains the arc and is heated to a high temperature. The resultant flow is a supersonic low density jet, of high total enthalpy. (ASTIA abstract)

RECENT OBSERVATIONS OF SLIP IN RAREFIED GAS FLOWS (Abstract), by F. C. Hurlbut and E. Merlic [1957] [1]p. (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-29503) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 45, Jan. 30, 1957.

Values of the tangential momentum transfer coefficient σ have been determined from measurements of drag in a rotating cylinder apparatus. Laminar flows of various pure gases and of air at pressures in the range 15 to 250 microns Hg were established between concentric cylinders. Values of the momentum transfer coefficient were found to be dependent on the pressure history of the

apparatus. When the cylinder surface was held at 0.01 micron Hg for a period of several days, values of σ of approximately 0.9 were measured for air. When the surface was held at a pressure of 250 microns, Hg values of σ were found to decrease with time reaching approximately 0.6 after a number of days. These results are considered in light of other available evidence including that obtained from measurements of molecular scattering at the surface in a molecular beam apparatus.

STUDIES OF MOLECULAR SCATTERING AT THE SOLID SURFACE, by F. C. Hurlbut. [1957] [7]p. incl. diagrs. [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under N7onr-29503] Unclassified

Published in Jour. Appl. Phys., v. 28: 844-850, Aug. 1957.

Experimental studies of molecular scattering at the gas-surface interface are described in which molecular beams of N_2 were scattered at surfaces of steel, aluminum, and glass. Polar surveys of the issuing molecular flux indicate the scattering to be well represented by a cosine distribution in most cases. A moderate deviation from such a distribution was observed in the case of the glass- N_2 interaction. It is shown how measurements of scattering at the surface may be used to derive values of the momentum transfer coefficient, $f(s)$, in a rarefied gas flow where s is defined as the ratio of the mass speed of the flow to the most probable thermal speed of the molecules. In order to complete the calculation where scattering information alone is available from the energy exchange at the surface. In the case of the present calculation, where a surface interaction model was formed in part from the glass- N_2 scattering data, two extremal assumptions relating to the energy exchange lead to values of $f(s)$ of approximately 0.97 at $s = 0.1$. Jan. 29, 1958.

The application of ionization gauges to the detection of molecular beams is discussed and the performance of an existing detection system for surface scattering studies is described. Beams of argon and of nitrogen have been employed to the present writing. Minimum resolvable pressure increments within the gauge volume due to the beam are of the order of 10^{-11} mm Hg. Limitations of the system are considered in relation to those of other currently available detection systems.

Presented at meeting of the Amer. Ceramic Soc.,
Alfred, N. Y., Sept. 10, 1957.

Also published in Jour. Amer. Ceramic Soc., v. 42:
423-429, Sept. 1959.

Model ceramic systems of crystals and glass fabricated by vacuum hot compaction have been used to study methods of detection of internal stress on the crystalline phase. Effects of the volume fraction of the glass, compaction temperature and time, and crystal particle size in modifying induced internal stress are presented. These effects together with x-ray diffraction and wetting studies indicate that internal stress development is closely connected to wetting of the crystal by the glass and the formation of a second crystalline phase. Limited results regarding internal stress effects on strength of ceramic bodies indicate increasing internal stress on the crystal phase decreases the modulus of rupture when the particle size of the crystal component remains constant. The results indicate that the full potential of ceramic systems may not be realized with the presence of internal stress. (Contractor's abstract)

1958.

The development of a free molecule probe for use as an instrument in the investigation of two dimensional rarefied gas flow fields is described. The probe consists of a cross-stream cylindrical wire of diameter small compared with the mean free path of the gas. Measurement of the probe temperature and heat transfer characteristics yields information that can be related theoretically to the state of the flowing gas. This paper describes the use of such information in the study of the qualitative nature of the supersonic flow about sharp leading edges in regions where rarefaction, slip, and boundary layer-shock wave interaction effects are important. The results showed clearly the effect of increasing density. Thus, at the lowest densities and Mach numbers, a clearly defined shock wave and boundary layer emerged from a region of mixed compressive and viscous action at the leading edge, while at the higher densities and Mach numbers there was a large region of strong boundary layer-shock wave interaction and a considerable delay in the formation of clearly defined shock wave. The ductility of several freshly cleaved solids having cubic crystal symmetry has been measured by static bend-testing. Freshly prepared samples were found to be substantially ductile. Oxygen and nitrogen environments produced surface brittleness. Two materials, LiF and MgO, did not show air embrittlement. Controlled impurity tests on LiF showed that there is a marked decrease in ductility with impurity concentration increase.

CAL. 18:003; CLA. 04:004, 005

The effects of impurities and thermal history on the formation and growth of slide bands in MgO crystals were investigated. Slip-band formation and growth was studied in a gold-coated specimen. When slip occurs, dislocations accumulate in the slip bands, interactions take place, and slip decreases or stops in these regions of a crystal. The slip then transfers to another area. An etch pit technique verified that slip bands act as barriers to slip on other systems. Impact, bending, and tensile data were obtained before and after heating MgO crystals to 2200°C for one-half hour to study the effects of heating on properties. An MgO crystal containing either 30 or 3000 ppm Fe had a much higher flow stress than a crystal with 10 ppm Fe; however, the ductility for the crystal with 30 ppm Fe was much lower. Increasing the Fe content to 3000 ppm caused an additional but proportionately smaller effect. Relatively small amounts of impurity can greatly affect the strength and ductility of MgO. The impurity may move to and from dislocations, i.e., moving away during heating and collecting again during cooling if the rate is slow enough. Heat treatment apparently causes effective pinning of the dislocations in the order slip bands. The more dislocations present in a structure, the greater is the effect on strength and ductility. Published in Jour. Amer. Ceramic Soc., v. 41: 161-164, May 1, 1958.

With the progress on dislocation theories and a better understanding of flow phenomena, it was predicted that a class of materials normally considered to be brittle, namely, ionic solids having cubic crystal structures, would possess a degree of ductility. Experimental results on a number of ionic materials indicate that face-centered cubic and body-centered cubic ionic materials can exhibit a considerable amount of ductility under controlled conditions. It was found that these materials are inherently ductile rather than brittle and that there appear to be two factors, a surface reaction with components of the air and impurity concentration, that exert control over the ductility. The examination of the air embrittlement indicated that oxygen and nitrogen are the cause of decreased ductility in water-soluble salts such as KCl and KBr. The effect on the surface can be inhibited by surface treatment or by immersion in oil. Other materials such as MgO and LiF do not seem to exhibit a surface embrittlement. MgO does, however, show a time-dependent ductility that is attributed to the presence of impurities. (Contractor's abstract)

A MODEL OF HETEROGENEOUS SLIP MECHANISM IN METALS (Abstract), by N. E. Friedman and D. Rosenthal. [1957] [1]p. (AF 18(600)1022)

Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 372, Dec. 19, 1957.

Heterogeneous grain deformation, easy and difficult slip, orientation dependence of lattice strains have led to a revision of Taylor's homogeneous five slip mechanism in plastically-deformed polycrystalline metals as follows. The deformation is assumed to start as a single slip in the grain interior and revert to multislip near the boundary in the fraction mV of the grain volume, V . If deformation bands are disregarded, a linear variation of the rotation vector can be assumed in each grain. The displacement vector mV is then the solution of Laplace's equation with conditions of single slip on the inner boundary and uniaxial tension on the outer boundary. Because of the intractable form of the problem the strains in the interior are estimated from the known values on the boundaries. Following Bishop's analysis a monotonic variation with m is found for σ/t (applied/resolved shear stress ratio) in almost every orientation. Large orientation dependence of lattice strains is thus explainable by variation of m as well as variation of resolved shear stress-strain relationships.

X-RAY EVIDENCE OF HETEROGENEOUS PLASTIC DEFORMATION IN METALS (Abstract), by D. Rosenthal and W. B. Grupen. [1957] [1]p. (AF 18(600)1022)

Unclassified

Presented at meeting of the Amer. Phys. Soc., Stanford U., Calif., Dec. 19-21, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 372, Dec. 19, 1957.

Lattice strains in a polycrystalline aluminum alloy were determined under uniaxial compression from shifts of various x-ray diffraction peaks. In the plastic range the results indicated: (a) easy and difficult slip, (b) less strain hardening in the surface grains than in the bulk of metal, and (c) large variation of strain hardening with x-ray orientation. These and other reported discrepancies with Taylor's homogeneous five slip mechanism of plastic deformation have led to a modified, heterogeneous,

CLA. 04:006; CLA. 05:001-003

model of slip. In this model the variation of strain hardening with position and orientation is shown to be consistent with the behavior of single crystals. Also, resolved shear stress-strain relationships for various grain aggregates can be derived from lattice strain data with the help of the model. These relationships are found to be within the limits of scatter obtained for single crystals. (Contractor's abstract, modified)

Deviations from proportionality in the lattice stress-strain diagrams obtained from x-ray diffraction study of plastically deformed polycrystalline aggregates cannot be reconciled with Taylor's homogeneous five slip mechanism of plastic flow. To account for the observed discrepancies a heterogeneous slip mechanism is postulated. Part I describes the relevant theory and derives a lower bound for the expression of the applied stress causing yielding of a particular crystalline aggregate in uniaxial loading. Good qualitative agreement is obtained in Part II when these expressions are compared with the results of an x-ray diffraction study of polycrystalline Aluminum alloy. Within the scope of this study it is concluded that the proposed theory is particularly suited to the analysis of plastic behavior of surface grain aggregates at the initial stages of plastic deformation. A note appended to this report describes a novel technique enabling the study to be extended to large plastic deformations. (Precision Lattice Parameter Measurement of Imperfect Crystals, by R. Asimow.) (Contractor's abstract)

The method of minimum sums of slips or of maximum work results in a number of combinations of 5 slips available for the given imposed strain on the crystal. These combinations can exist in different proportions, so that there are not only a number of rotations corresponding to the number of combinations of 5 slip systems, but a range of rotations. In a number of cases the range covers rotation vectors in all directions in the stereographic triangle. The method of considering the elastic strain determines more definitely the rotations

of a crystal under a given strain, and this method is applied to the calculation of the texture of aluminum polycrystal subject to axial deformation. The observed texture of 70-30 brass does not agree with the texture calculated by considering elastic strains.

A POLYAXIAL INELASTIC STRESS-STRAIN RELATIONSHIP OF FACE-CENTERED CUBIC METALS, by T. H. Lin. Jan. 1958, 18p. incl. diags. refs. (AFOSR-TN-58-151) (AF 49(638)20) AD 152177
Unclassified

A simplified model is considered in which crystals with a common slip plane are treated as one group. Each group is subject to the aggregate stress and slide together on the common plane independent of other groups. The error in stress-strain relations introduced by this model is decreased by using polycrystal uniaxial test data instead of single crystal tests to find the shear stress vs plastic strain on a plane. For this model there is a yield curve on every plane. Each point on the yield curve gives a tangent plane to the yield surface in the 6-dimensional stress space. It gives a smooth yield curve on each plane but a corner in the yield surface. Because of latent hardening, the displacement of the yield curve on one plane induces the motion of many yield curves on the planes. A number of inelastic loadings are calculated, and the results show that the present theory gives better agreement than previous theories. (Contractor's abstract)

NIM-TYPE GAMES, by E. W. Adams and D. C. Benson. Dec. 1956 [47]p. incl. tables. (Technical rept. no. 13) (AFOSR-TN-57-50) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1138 and Office of Ordnance Research) AD 115089 **Unclassified**

CAR.04:016 - CAR.04:018

A general axiomatic characterization of the class of games similar to Nim is given and the general properties of the equivalence classes of positions are mentioned. The most general Nim-type game is shown to be isomorphic to an "ordinal-Nim game" in which the positions are arbitrary finite sets of finite and denumerable ordinal numbers closed under a "natural sum" operation and in which a move transforms one ordinal number "position" to a lower ordinal number, creating a problem in game analysis in the theory of finite and denumerable ordinal numbers. The general theory is applied to Nim, Kaylee, and some variations of Kaylee. The determination of the equivalence classes for Kaylee and its variations is programmed for a digital computer (I.B.M. 650). The computations with certain general considerations determine the equivalence classes for Kaylee and several variations. In some of the equivalence classes a surprising periodicity is shown to hold for some of the particular variations analyzed.

ON THE OSCILLATION OF SOLUTIONS OF SELF-ADJOINT LINEAR DIFFERENTIAL EQUATIONS OF THE FOURTH ORDER, by W. Leighton and Z. Nehari. Mar. 1957, 86p. (Technical rept. no. 16) (AFOSR-TN-57-102) (AF 18(600)1138) AD 120451 Unclassified

Also published in Trans. Amer. Math. Soc., v. 89: 325-377, Nov. 1958.

A systematic investigation of the oscillation properties of the solutions of certain classes of self adjoint linear differential equations of fourth order is given. The most general equation of this type is of the form $(r(x)y''')' + (q(x)y'')' + P(x)y = 0$, $r(x) > 0$, where, in the interval considered, $r(x)$, $q(x)$ and $P(x)$ are functions of C'' , C' and C , respectively and the prime denotes differentiation with respect to x . The functions are assumed to be defined and to belong to the classes indicated in the interval $(0, \infty)$. Part I is devoted to the study of the solutions of $(r(x)y'')' - p(x)y = 0$, $r(x) > 0$, $p(x) > 0$ and Part II to the study of the solutions of $(r(x)y''')' + p(x)y = 0$, $r(x) > 0$, $p(x) > 0$. A number of transformations of the general equation including transformations into the equations of Parts I and II are also studied.

CONDITIONAL PROBABILITY DISTRIBUTION IN THE WIDE SENSE, by L. E. Dubins. Feb. 1957, 9p. incl. refs. (Technical rept. no. 15) (AFOSR-TN-57-80) (AF 18(600)1138) AD 120426 Unclassified

Also published in Proc. Amer. Math. Soc., v. 8: 1088-1092, Dec. 1957.

Proof is given that the result of Doob (Stochastic Processes, New York, 1953) relative to a conditional distribution in the wide sense holds if X is any locally compact Hausdorff space whose one point compactification is metrizable. The following main theorem is proved: Let $Q = [U, \mathcal{U}, u]$ be a probability space and \mathcal{U}_0 a σ -subfield of \mathcal{U} . Suppose X is a locally compact Hausdorff space whose one point compactification is metrizable, and let y be a measurable transformation of U into X (i.e. $y^{-1}(Y) \in \mathcal{U}$ for each Baire subset Y of X); then there exists a function p of Y and w for which conditions (i), (ii), and (iii) hold. (i) $p(Y, w)$ is, for each fixed w , a probability measure defined on the Baire subsets of X ; (ii) $p(Y, w)$ is, for each Y , a function measurable relative to \mathcal{U}_0 ; and (iii) $\int_A p(Y, w) du(w) = u(A \cap y^{-1}(Y))$ for each $A \in \mathcal{U}_0$ and each Baire subset Y of X , A is a set of variables w . If X is only assumed to be a locally compact Hausdorff space then $C(X)$, the Banach space of all continuous real functions of X which vanish at ∞ , need not be separable and the conditional expectation of f with respect to \mathcal{U}_0 need not be a point function but would be a generalized random variable. With technical modifications in the proof of the main theorem, it can be shown that there exists a σ -algebra homomorphism h defined on the weak star measurable subsets of

ON THE FOUNDATION OF THE MECHANICS OF CONTINUOUS MEDIA, by W. Noll. June 1957, 68p. incl. diags. (Technical rept. no. 17) (AFOSR-TN-57-352) (AF 18(600)1138) AD 132425 Unclassified

An attempt is made to introduce the same level of rigor and clarity into the theory of continuum mechanics as is now customary in pure mathematics. A continuous body is defined as a piece of a differentiable manifold which is also a measure space, and forces are defined in terms of vector measures, with precise definitions given for motions. The reaction principle for contact forces and the stress principle are proved. A number of invariance requirements are postulated for the general theory of material behavior. This is done from a point of view which renders classical mechanics a relativistic theory in that there are no preferred frames of reference. The general theory of material properties is discussed with such properties being characterized by constitutive equations. The most general form of a constitutive equation for stresses is investigated.

THE NUMERICAL SOLUTION OF SINGULAR INTEGRAL EQUATIONS, by R. C. MacCamy. Sept. 1957, 22p. (Technical rept. no. 19) (AFOSR-TN-57-515) (AF 18(600)1138) AD 136500 Unclassified

An investigation is made of the singular behavior of the numerical solutions of integral equations at the ends of the interval of integration. The integral equations are translated into functional relations for multivalued analytic functions of a complex variable. The information obtained about the structure of the analytic function is translated back into facts concerning the solutions of the integral equations. Three types of equations, all for $0 < x < 2$, are studied: (I)

$$\int_0^2 [A(x,t)(x-t)^{-1} + B(x,t)\log|x-t| + C(x,t)] f(t)dt = g(x);$$

$$(II) f(x) + (\pi)^{-1} \int_0^2 [A(x,t)(x-t)^{-1} + B(x,t)\log|x-t| +$$

$$C(x,t)] f(t)dt = g(x); (III) f(x) + (\pi)^{-1} \int_0^2 [A(x,t)(x-t)^{-1} +$$

$$B(x,t)\log|x-t| + C(x,t)] f'(t)dt = g(x). \text{ In each case } g(x)$$

is to be analytic for $0 < |x| < 2$ and A, B, and C are to be analytic for $0 < |x|, |t| < 2$. Two cases are considered: (1) $A(x,z) \neq 0$ for $0 < |z| < 2$, $A(0,0)$ real; and (2) $A(x,z) = 0$, $B(x,z) \neq 0$ for $0 < |z| < 2$, $B(0,0)$ real. The main result is the following: Let \mathcal{F} denote the set of all functions $f(x)$ continuous and satisfying a Hölder condition on $0 < x < 2$ and such that $[x(2-x)]^\alpha f(x)$ is continuous at $x = 0$ and 2 , $\alpha < 1$; then $f \in \mathcal{F}$ is a solution of I and II, and f is a solution of III with $f' \in \mathcal{F}$ with $f(x)$ explicitly given for each case under each type of equation.

ON THE PRINCIPAL FREQUENCY OF A MEMBRANE, by Z. Nehari. Nov. 1957 [12]p. (Technical rept. no. 20) (AFOSR-TN-57-713) (AF 18(600)1138) AD 136706 Unclassified

Also published in Pacific Jour. Math., v. 8: 285-293, 1958.

A study is made of the possible generalizations of Rayleigh's theorem to the case of nonhomogeneous membranes: Rayleigh's theorem states that the homogeneous circular membrane has the lowest principal frequency among all homogeneous membranes of the same mass. Certain restrictions are imposed on the density distribution of the nonhomogeneous membrane because the principal frequency of a membrane of given mass can be made arbitrarily small if enough of the mass is concentrated in a small area interior to the simply connected region in the given plane. Conditions are imposed which prevent the excessive accumulation of mass at interior points of the membrane. Proofs are given for the following theorems. Theorem 1. If λ is the principal frequency of a membrane of given mass whose density distribution $p(x,y)$ is such that $\log p(x,y)$ is subharmonic, then $\lambda > \lambda_0$, where λ_0 is the principal frequency of a homogeneous circular membrane of the same mass. Theorem 2. If λ is the principal frequency of a circular membrane of given mass whose density distribution $p(x,y)$ is superharmonic, then $\lambda > \lambda_0$, where λ_0 is the principal frequency of a homogeneous circular membrane of the same mass. Theorem 3. Let α be an analytic subarc of C which is concave with respect to D. If A denotes the principal frequency of a homogeneous membrane whose boundary is free along α and fixed along $C-\alpha$, then $A > \lambda_0$, where λ_0 is the principal frequency of a homogeneous semi-circular membrane of equal mass whose boundary is free along the diameter and fixed along the semicircle.

Also published in *Acta Metallurgica*, v. 7: 191-198,
Mar. 1959.

The surface oxidation kinetics of metallographically polished nickel-cobalt alloys, 10.5 and 25.1% cobalt, have been studied in the temperature range 400° to 800°C using a vacuum microbalance technique. The alloy of largest cobalt concentration oxidized most rapidly. The oxidation rates have been represented, to a first approximation, by cubic and parabolic time laws. In the temperature range of the second order magnetic transformation below the Curie temperature, the Arrhenius temperature coefficients of the rate constants demonstrate continuous variations. It is proposed, with results for nickel oxidation as datum, that these variations are caused by electronic properties of the metal substrate, which influence the rate determining reaction step of metal ion diffusion through the surface oxide layer. June 1957.

Hafnium oxidation rates at 760-mm oxygen pressure in the temperature range 350°-1200°C have been represented by logarithmic, parabolic, and linear-rate equations. The respective activation energies for the rate constants were 11.4, 36.0, and 28.1 kcal/mole. The value of the parabolic rate constant was independent of oxygen pressure in the range 10-760 mm. Transformation from parabolic to linear oxidation was caused by formation of a duplex scale of inner compact and outer porous oxides. Monoclinic hafnia was identified as the surface oxide by x-ray examinations; marker measurements showed that oxygen diffused inward through this oxide to react with hafnium at the metal/oxide interface. Nuclei formation in supercooled liquid metals and nucleation from a vapor phase by using a thermal beam method are described. A theory is presented for the nucleation from the liquid and from the vapor phases which can adequately explain the experimental results in terms of a contact angle between the developing cap-shaped embryo and the substrate surface. It is found that the chemical factors of the substrate surface are less important than the lattice fit with the developing crystal.

The linear formation rates of wustite films have been determined over the temperature range 590° to 1030°C using a vacuum microbalance technique. These rates are dependent directly on the partial pressure of carbon dioxide. Activation energies for film and scale formation in carbon dioxide and oxygen atm are equivalent to either the dissociation energies of carbon dioxide and oxygen, or the activation energy for the diffusion of cation vacancies in wustite. OXIDATION OF AN ALUMINUM-3 PER CENT

MAGNESIUM ALLOY IN THE TEMPERATURE RANGE 200°-550°C, by W. W. Smeltzer. [1958] [5]p. incl. illus. diags. tables, refs. (AF 18(600)1572) Unclassified

Published in *Jour. Electrochem. Soc.*, v. 105: 67-71, Feb. 1958.

A study of the oxidation and magnesium evaporation kinetics has been carried out on an aluminum-3% magnesium alloy. A metallographic examination of the surface oxide films produced was included. The alloy was oxidation resistant to 200°C. At temperatures greater than 350°C the oxidation rate was initially inversely proportional to the oxide film thickness, transforming to a constant rate for long exposures. Selective oxidation of magnesium caused formation of aluminum inclusions in the surface oxide. These inclusions imparted a black discoloration to the alloy surface. Magnesium evaporated from the alloy in a vacuum at temperatures greater than 350°C after an induction period, the duration of which was dependent on the temperature. A comparison of the magnesium evaporation and alloy oxidation rates demonstrated that the oxide film offered resistance to oxidation of the metal. (Contractor's abstract)

A MOLECULAR ORBITAL STUDY OF Be_4 , by R. D.

Cionev and J. S. Dooling. Sept. 1, 1957, 28p. incl. diags. tables, refs. (Technical note no. 2) (AFOSR-TN-57-507) (AF 18(600)1537) AD 136588 Unclassified

Also published in *Jour. Chem. Phys.*, v. 29: 425-431, Aug. 1958.

An LCAO MO SCF study was made of the square, planar Be_4 complex. A complete SCF calculation was performed at four different internuclear distances. In this series of calculations all one- and two-center integrals were evaluated exactly and the value of each three- and four-center integral was estimated by a method considered most suitable for it. The results showed the complex unstable. The energy value when extrapolated to infinite internuclear distance were in good agreement with experiment. A second series of calculations was made to determine the effect of three- and four-center integral approximations on the energies. Here all the multicenter integrals were evaluated by one type of approximation. This introduced a relatively small change in the integral values, but large changes in the energies. This study emphasizes the need for exact values of three- and four-center integrals before exact calculations can be undertaken. (Contractor's abstract)

ON THE DEFINITION OF ENTROPY IN MAGNETIC
RESONANCE, by P. H. E. Meijer. [1957] [8]p. (AF 18-
(603)120) Unclassified

Also published in Proc. Internat'l. Symposium on
Transport Processes in Statistical Mechanics, Brussels
(Belgium) (Aug. 27-31, 1956), N. Y., Interscience
Publishers, Inc., 1958, p. 319-323.

If a system of magnetic spins is dealt with which is slightly off temperature equilibrium as a result of an oscillating magnetic field some difficulty has arisen as to what the correct definition for the entropy would be. The usual definition does not give the entropy expression introduced by Wangness. On the other hand his definition leads to consistent results. It is pointed out that the application of Casimir's consideration on even and odd variables leads to a restriction that confirms Wangness's choice of the definition of entropy. THE EFFECT OF HEPARIN UPON THE TOTAL OXYGEN CONSUMPTION OF ATHEROSCLEROTIC INDIVIDUALS, by H. Engelberg. Sept. 21, 1957 [18]p. incl. tables, refs. (AFOSR-TN-57-632) (AF 18(600)1703) AD 136617; PB 137462 Unclassified

Total oxygen consumption was measured in atherosclerotic individuals before and after heparin, thus eliminating the need for determinations of blood flow. Total basal oxygen consumption and the respiratory quotient were determined in 46 atherosclerotic patients before and after the injection of heparin. In 20 individuals the average increase in oxygen consumption was 32.7%. In 3, the average decrease was 15.3%. In 23 no change appeared after heparin. No increase in oxygen consumption appeared after saline placebos or oral anticoagulants. The respiration quotient showed no characteristic change although frequently it fell after heparin. Various possible mechanisms were discussed which indicated that the lipemia clearing action of heparin is responsible for the increase in oxygen consumption. (Contractor's abstract)

ELECTRODE POTENTIAL MEASUREMENTS ON
INTERSTITIAL OXYGEN SOLUTIONS IN TITANIUM
AT LOW OXYGEN CONCENTRATIONS. APPLICATION

TO QUALITY CONTROL IN HIGH PURITY TITANIUM, by R. S. Dean and I. Hornstein. Apr. 1957 [21]p. incl. diagrs. tables, refs. (AFOSR-TN-57-179) (AF 18(600)1458) AD 126474 Unclassified

A method was developed for determining the O content in sponge Ti having an O content below 0.06%. EMF measurements of Ti-O alloys in molten salt electrolytes up to 1200°C were made in a circular furnace, 12 in. in diameter and 9 in. high. The outer shell of the furnace is made from welded steel, and the heating element is a heavy Nichrome V helical unit. The measurements are made in an argon atmosphere. The EMF generated between the standard reference electrode and the Ti-O unknown is recorded. The electrodes are kept in vibration while readings are taken to minimize concentration polarization. The standard electrode should be a carefully analyzed Ti rod about 1/4 in. in diameter; about 4 in. of the rod may be welded to an ordinary Ti rod. The unknown electrode may be prepared in the same manner as the standard, or it may be a 15-in.-long iron rod the bottom 2 in. of which has been drilled out and the thin sidewalls perforated with 0.1-in. holes about 1/4 in. apart to form a basket into which particles of the material to be measured are placed. The bottom of the basket is then capped. The standard electrode is kept in the molten electrolyte while the measurements are made. The unknown is allowed to come to thermal equilibrium before any EMF readings are taken. The EMF is measured over a period of several minutes to obtain a steady state value. At O contents approaching 0.001%, the EMF of a Ti electrode vs the standard 0.06% O was -56 mv as established by an extrapolated curve of the logarithmic relationship of EMF as a function of O content. THE DEVELOPMENT OF ELECTROLYTIC TITANIUM PROCESSES, by R. S. Dean. [1957] 8p. incl. refs. [AF 18(600)1458] Unclassified

Presented at meeting of the Electrochem. Soc., Washington, D. C., May 1957.

A description is given for the production of Ti in an electrolytic cell by (1) the deposition of the metal on the cathode by direct or indirect discharge of ions which contain Ti, and (2) deposition by a chemical reaction of a solution of alkaline metal formed at the cathode with Ti salts dissolved in the electrolyte. Two subgroup processes involving Cl and F melts are described for the first process and two subgroup processes of the second method, which are chiefly forwarded by the contractor, are presented and documented by references and patent application references.

ELECTRODE POTENTIAL MEASUREMENTS USING INTERSTITIAL OXYGEN SOLUTIONS IN TITANIUM. SODIUM DISSOLVED IN FUSED SODIUM CHLORIDE CONTAINING TITANIUM CHLORIDE, by I. Hornstein. Jan. 1958 [19]p. incl. diagrs. tables. (Rept. no. 2) (AFOSR-TN-58-89) (AF 18(600)1458) AD 148139; PB 134892 Unclassified

Electrode potential measurements were made at 1000°C in an Ar atmosphere between a standard Ti reference electrode and an inert (iron) electrode suspended in a porous TiO₂ tube. The electrode potential was a linear function of concentration and had a negative slope; the results support the assumption that Na dissolved in NaCl electrolyte has an activity which is a negative exponential function of the Na concentration. The partitioning of Na between molten NaCl and molten Pb was studied by heating the samples in a stainless steel bomb at 1000°C for 1 hr. The Na concentration in an electrolyte of NaCl, TiCl_x as determined by the electrode potential measurements was in good agreement with that obtained by lead extraction. Partition coefficients which were calculated from equilibrium data varied with the free Na concentration in NaCl, indicating that elemental Na associates into colloidal particles. The partitioning technique was applied to a study of the composition changes which occur when equilibrium conditions in an electrolyte containing Ti, Na, and Cl are disturbed by the extraction of free Na with Pb. The data indicated that within a narrow range of free Na concentration, the soluble Ti, as well as the average valence of the soluble Ti, will remain constant. However, when the free Na concentration is sufficiently lowered by extraction into the Pb phase, TiCl₃ apparently forms and free Ti; this reaction lowers the soluble Ti concentration with an increase in the average valence.

RESEARCH ON INTERSTITIAL SOLUTES IN METALS, by R. S. Dean and I. Hornstein. Final rept. Aug. 1958, iv. incl. diagrs. tables, refs. (AFOSR-TR-58-127) (AF 18(600)1458) AD 203382; PB 136737 Unclassified

Raney observed that titanium containing oxygen dissolved

CHI.16:001, 002; CHI.03:009

anodically to form Ti^{2+} and TiO_2 . Since this reaction involved the change of oxygen in solid solution to TiO_2 , its free energy would be a measure of the activity of the oxygen in solid solution. The careful electrochemical measurements reported confirm and quantify this conclusion. The refining processes of the Chicago Development Corp. for zirconium and chromium included anodic refining analogous to the anode refining reaction for titanium. Measurements of electrode potentials of zirconium-oxygen and titanium-oxygen confirmed and quantified the mechanism of these anodic reactions. The known behavior of alloying elements in titanium alloy refining, in the Chicago Development titanium refining process, was rationalized by electrode potential measurements on the more important of such alloys in the refining bath of the Chicago Development process. The basic condition of the Chicago Development refining process for titanium, zirconium, chromium, etc., has been stated to be the presence of dissolved sodium in the electrolyte - a condition which requires an unusual activity for the dissolved sodium. Electrode potential measurements reported herein have been effective in determining sodium concentration in such electrolytes. The relationship of oxygen content to electrode potential has been shown to be useful as a control method for oxygen in titanium alloys, and to determine the diffusion of oxygen into titanium on heat treatment under various conditions. SOME ULTRAVIOLET MICROSPECTROPHOTOMETRIC MEASUREMENTS ON ISOLATED NERVE AXONS, by D. A. Eggen. Mar. 1957, 25p. diags. (AFOSR-TN-57-171) (AF 18(600)1482) AD 126465 Unclassified

Precise measurements of the ultraviolet extinction have been obtained for single axons isolated from lobster, shore crab (*Carcinus*), crayfish, and frog nerve. The shape of the absorption curves obtained for these axons indicates the presence of several chromophores but the individual bands cannot be clearly resolved. In the axons of the marine invertebrates an intense absorption due to homarine masks the absorption due to other components. In the other axons there is an indication of absorption bands due to protein and to the purine and pyrimidine chromophores of nucleic acid and ATP. There is also an indication of other bands at 250 and 290 m μ and it is suggested that these bands are due to the presence of a protein rich in basic amino acids which may play a significant role in the production of the action response. During the deterioration of the invertebrate axons, characteristic changes have been observed in both the absorption and scattering fractions of the measured extinctions. The changes in absorption are probably due to a loss, through the axon membrane, of some of the absorbing constituents. The changes in scattering probably result from changes in the macromolecular

changes in the ultraviolet extinction in isolated axons which might result from stimulation. Although the data are not yet conclusive, there is an indication of a decrease in extinction (which may be wavelength specific) when the non-myelinated axon is subjected to a tetanic stimulus. An increase in the extinction at 265 m μ which has been reported to occur during the action response in frog axons has not been observed here. (Contractor's abstract)

INDIRECT TRANSITIONS AT THE CENTER OF THE BRILLOUIN ZONE WITH APPLICATION TO InSb, AND A POSSIBLE NEW EFFECT, by W. P. Dumke. [1957] [22]p. incl. illus. diags. refs. [AFOSR-TN-57-489] (AF 18(603)9) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 185, Apr. 25, 1957.

Also published in Phys. Rev., v. 108: 1410-1425, Dec. 15, 1957.

The theory of indirect optical transitions is extended to the case where both the valence and the conduction band extrema occur at the center of the Brillouin zone. For this band structure, the dominant electron transition involves a virtual optical transition to a conduction band state, accompanied by scattering to a real state in the conduction band by absorption of a long-wavelength optical mode phonon. An analogous transition may also occur for holes. It is likely that the hole transition will be dominant over the electron transition when the curvature of the conduction band is greater than that of the valence band. It is shown that the absorption edge data on InSb are in agreement with this theory. The experimental evidence on InSb is reviewed and found to be consistent

with degenerate valence bands at the center of the Brillouin zone. The absence of any evidence of indirect transitions involving acoustic modes tends to indicate that the shift of the valence maximum away from $k = 0$ due to spin-orbit energy terms is small. A new effect is predicted involving the modulation of the indirect absorption constant by the selective excitation of the long-wavelength optical modes. A simplified theory of this effect is presented and the experimental possibilities of observing it in InSb are discussed. Its existence would verify the proposed indirect transition process as well as indicate the position of the band extrema. (Contractor's abstract)

DEPENDENCE OF LIFETIME AND MOBILITY ON ACCEPTOR CONCENTRATION IN p-TYPE InSb AT 300°K (Abstract), by A. E. Attard and R. N. Zitter. [1957] 1p. (AF 18(603)9) Unclassified

Presented at meeting of the Amer. Phys. Soc., Notre Dame U., South Bend, Ind., June 20-22, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 266, June 20, 1957.

Measurements of PEM and Hall effects and of magnetoresistances have been made on a number of uncompensated p-type InSb samples at 300°K. The general behavior of the observed effects were in agreement with the relations derived in a previous report, so that consistent values of carrier lifetimes and electron and hole mobilities were obtained. Acceptor concentrations of the samples used range from 10^{15} to 10^{18} cm⁻³ (as determined at 77°K). It is found that μ_n varies as $N_a^{-\alpha}$ and μ_p varies as $N_a^{-\beta}$, with $\alpha \approx 1/5$ and $\beta \approx 1/8$. From theoretical considerations, it is expected that direct radiative recombination lifetimes will not be observed in nondegenerate InSb. The result of the present measurements is that the small values of carrier lifetimes ($< 5 \times 10^{-8}$ sec) and the dependence of lifetimes on acceptor concentration in the range $10^{15} - 10^{17}$ cm⁻³ indicate that recombination takes place by a process other than direct radiative recombination. The effects of compensation will be discussed and comparison with lifetimes measurements recently made elsewhere will be evaluated.

COPPER FOIL TRAP OF IMPROVED FORM, by J. Burns. [1957] 1p. incl. diagr. [AF 18(603)9]

Unclassified

Published in Rev. Scient. Instruments, v. 28: 469, June 1957.

Thin copper sheets have been introduced in liquid nitrogen cold traps of ultrahigh vacuum systems. The copper sheets which were originally conceived as a means to reduce the desorption of gases from the upper regions of the trap have been found to be effective in reducing contamination of the system from back-streaming pump oil. It was found that the pumping speed through one of these traps was about three times greater than through a copper-filled trap of the usual form and size, and that its effectiveness in blocking oil vapor appeared to be about the same. A nickel sheet trap was constructed and produced an 80-fold lower ultimate vacuum than in the case in which no trap was used.

ELECTRON TRAPPING IN p-TYPE InSb, by R. N. Zitter, A. J. Strauss, and A. E. Attard. Dec. 10, 1957 [6]p. incl. diagrs. (AF 18(603)9) Unclassified

Carrier lifetimes as derived from photoconductive (PC) and photoelectromagnetic (PEM) measurements in p-type InSb indicate that the former lifetimes are larger than the latter rather than equal as expected from the direct recombination model. This model has been altered to include trapping in discrete levels in the forbidden band. The experimental differences in the lifetimes and the behavior of the temperature variation of the PC lifetimes have generally been accounted for by the altered model.

PREPARATION AND PROPERTIES OF INDIUM ARSE-NIDE, by R. H. Harada and A. J. Strauss. July 31, 1958, 24p. incl. illus. diagrs. refs. (Rept. no. CML-TN-P108-14) (AFOSR-TN-58-742) (AF 18(603)9) AD 202311; PB 137689 Unclassified

Also published in Jour. Appl. Phys., v. 30: 121, Jan. 1959.

Arsenic prepared by reduction of arsenic trichloride and purified by a thermal gradient sublimation technique has been used to prepare zone-refined n-type InAs as pure as any previously reported, although its free carrier concentration is still somewhat greater than 10^{16} cm^{-3} . A horizontal modification of the Bridgeman technique has been used to grow large single crystals of InAs. The results of electrical measurements on the n-type material are in good agreement with those obtained elsewhere. These results, together with the results of heat treatment experiments performed at the Naval Ordnance Lab., support the view that the free carriers in the InAs are produced by ionization of donor impurities (principally sulfur) which originate in the arsenic used for synthesis. Compensated samples of InAs have been prepared by doping with cadmium. One such sample exhibits anomalous electrical properties similar to those reported in the literature for samples doped with zinc. Another cadmium-doped sample has a resistivity of 80 ohm-cm at 77°K, by far the highest value ever reported for InAs. (Contractor's abstract)

THE CHANNELED, SHAPED-SCREEN IMAGE INTENSIFIER, by J. Burns and M. J. Neumann. July 31, 1958, 17p. incl. illus. diagrs. (Rept. no. CML-TN-P108-16) (AFOSR-TN-58-758) (AF 18(603)9) AD 202312 Unclassified

The present status of the channeled, shaped-screen intensifier may be summarized as follows: the principle offers certain characteristic advantages over other types of intensifiers, the chief ones being resolution independent of the number of stages, low voltage operation with the attendant possibility that background levels will be low, and the possibility, depending on design requirements of the photocathode, that the screens can be made to support the atmospheric pressure on thin face-plates, making the construction of large-area tubes a possibility. Thus far a dynode design has been devised which has yielded gains per stage equal to about 75% of the secondary emission ratio of the dynode surface at a design voltage of 400 volts per stage on a five-stage tube having 25-mesh dynodes. It appears that the prob-

lem of finding a suitable interscreen insulation for finer mesh dynodes can be solved by the use of glass enamel; however, it remains to be seen whether this kind of insulation causes any noise or background difficulties. The problem of making fine mesh screens of the proper shape also appears well on its way toward a successful solution. The production of uniform, stable, high-yield secondary emission surfaces on these screens by evaporation of thin films of Mg followed by oxidation is progressing, but has not reached the desired state of reproducibility at this writing. The design of the photocathode and first dynode is still at an early stage, but two designs have been evolved which seem to merit closer study. The successive reduction in scale of the multiplier has reached the 50 to 65-mesh level. The background level and noise characteristics of the multiplier have not yet been measured, but series of tubes in the 50 to 65-mesh scale presently under construction should provide a good indication as to what may be expected in this respect in still smaller-scale multipliers. SOME FEATURES OF THE ANGULAR DISTRIBUTION OF SECONDARIES FROM METAL SINGLE CRYSTALS (Abstract), by J. Burns. [Feb. 1958] 1p. (AF 18(603)9) Unclassified

Presented at the Colloquium of Secondary Emission, Minnesota U., Minneapolis, Feb. 27-28, 1958.

Measurements of the angular distributions of secondaries in several energy ranges have been made on (100) faces of copper and nickel crystals and on the (112) face of a tungsten crystal. The measurements cover a range of primary energies from 200 to 1000 eV at several angles of incidence. Data were obtained on surfaces cleaned by slow ion bombardment, followed by annealing, and on gas-covered surfaces. The main qualitative

CHL03:018 - CHL03:022

features of these angular distributions are discussed with special reference to fine structure and deviations from a cosine distribution in relation to crystal orientation.

CARRIER RECOMBINATION IN p-TYPE InSb (Abstract), by A. J. Strauss and A. E. Attard. [1958] 1p. (AF 18(603)9) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 120, Mar. 27, 1958.

The photoconductive (PC) and photoelectromagnetic (PEM) effects in p-type InSb have been studied in detail as functions of free hole concentration at 77°K, and for several concentrations photoconductivity has been investigated as a function of temperature between 77° and 300°K. At 77°K, it is found that the PEM lifetime, τ_{PEM} , is approximately 2×10^{-10} sec, independent of hole concentration, while $\tau_{PC} = (3 \times 10^7)/p_0$ sec, where p_0 is expressed in cm^{-3} . The fact that τ_{PC} is greater than τ_{PEM} for sufficiently pure samples indicates that excess electrons are trapped in bound states in the forbidden gap, with the ratio of trapped to free electrons equal to $(5 \times 10^{18})/p_0$. Electron trapping is also indicated by the results of quenching experiments with dc light. The data for temperatures below 200°K will be interpreted in terms of a Shockley-Read recombination mechanism; at higher temperatures, direct interband recombination mechanism (probably of the Auger type) appears to predominate.

SEGREGATION CONSTANTS AND CARRIER MOBILITIES IN InSb (Abstract), by A. J. Strauss. [1958] 1p. (AF 18(603)9) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 119, Mar. 27, 1958.

The following distribution coefficients have been measured for InSb crystals pulled from the melt at an extraction rate of 1.3 cm/hr and rotation rate of 130 rpm:

Cd, 0.26; Zn, 3.38; Se, 0.17; Te, 0.54. The distribution coefficient for zinc has been found to vary with extraction and rotation rates in the manner predicted by the theory of Burton, Prim, and Slichter. Hall mobilities at 77°K have been measured for uncompensated samples containing impurity concentrations between 10^{15} and $10^{19} cm^{-3}$. Mobilities calculated from scattering theory are in moderately good agreement with the experimental values for n-type samples, but the agreement is considerably less satisfactory for p-type samples.

RECOMBINATION OF CARRIERS IN InSb, by R. N. Zitter, A. J. Strauss, and A. E. Attard. [1958] 4p. (AF 18(603)9) Unclassified

Presented at the Electrochemical Soc. Semiconductor Symposium, New York, Apr. 1958.

Recombination of excess carriers in n- and p-type InSb below 200°K is shown to take place primarily via bound states in the forbidden gap. The activation energies, concentrations and recombination parameters associated with these states are estimated from measurements of the dependence of photoconductive and photoelectromagnetic lifetimes on temperature, impurity concentration and light intensity.

INDIUM ANTIMONIDE INFRARED FILTER, by J. M. Powell and S. W. Kurnick. [1958] 3p. incl. diagrs. (AF 18(603)9) Unclassified

Published in Jour. Appl. Phys., v. 29: 1129-1130, July 1958.

N-type single crystal InSb of about 10^{17} donors cm^{-3} may be used as an infrared filter around room temperature. The transparency of this material is further increased by means of an anti-reflection coating of As_2S_3 . At 25°C the maximum transmission which occurs at 9 microns is increased from about 27% for no coating to about 53% with the anti-reflection coating, while at 0°C the maximum transmission rises to 60%.

THE ROLE OF TRAPS IN THE PHOTOELECTRO-
MAGNETIC AND PHOTOCONDUCTIVE EFFECTS,
by R. N. Zitter. [1958] [4]p. incl. refs. (AF 18(603)9)
Unclassified

Published in Phys. Rev., v. 112: 853-855, Nov. 1, 1958.

When carriers recombine through traps, the excess concentrations of mobile electrons and holes are not necessarily characterized by a single lifetime τ . Under the assumption that electrons and holes have separate lifetimes which in general are different, expressions for the steady-state PEM and PC currents are obtained which show that in certain cases the PEM current is determined by a lifetime different from the one determining the PC current. The results of the PEM-PC measurements can be used to evaluate the

parameters of any particular model which might be postulated for the recombination process. However, the theoretical treatment of the PEM-PC effects presented here is independent of such models and so can be used as a method for testing their validity. (Contractor's abstract)

Also published in Bull. Math. Biophys. v. 19: 209-235,
Sept. 1957.

The gate type non-carrier mechanism, an active transport model, is discussed. In this mechanism, the actively transported particle passes through the gate itself by means of a series of reorganizations of the active transport mechanism. The net rate of transport, the rate of transport in either direction, and the efficiency of this model are analyzed. It is shown that on the basis of these analyses alone, this mechanism cannot be distinguished from a carrier mechanism. Three generalizations which apply to many individual type active transport models are then discussed. These pertain to (1) the dependency of the flow in one direction on the concentration of the particles on the opposite side of the membrane, (2) the possibility of very high efficiencies for these models independent of the rate of the active transport, and (3) the methods whereby the energy expended in the active transport may be experimentally found. The effects of area and intensity on the critical flicker frequency, threshold, and reaction time are considered in terms of neural net theory. An attempt is made to develop a mechanism which can account for the phenomena associated with the empirically observed laws of Ricco, Granit, Talbot, and Ferry-Porter as well as observations on reaction time threshold. A simple model

gives results which are substantially in agreement with observation except for a few apparent discrepancies. Experimental procedures are suggested which can determine whether these are apparent or real. (Contractor's abstract)

FACTORS IN VISUAL ACUITY. I. NEURAL INHIBITION AND THE VISUAL PERCEPTION OF CONTOURS, by P. H. Greene. [1957] [15]p. incl. diags. (AFOSR-TN-57-456) (AF 18(600)1454) AD 136447 Unclassified

Also published in *Bull. Math. Biophys.*, v. 19: 147-156, June 1957.

Interpretations of the mechanisms of perception of contours or of Mach bands have stressed either the role of various spatial derivatives of light intensity at the retina or the importance of various forms of inhibitory effects between neighboring retinal elements. Evidence is presented in support of the latter type of interpretation. It is considered that the brightness contrast and perceived contours arise from neural elements, each of which is stimulated in proportion to the intensity of photoreceptor excitation at a point of the retina and inhibited in proportion to the mean intensity in some neighborhood of that point. The role of the spatial derivatives is best seen as a particular manifestation of the inhibitory mechanism. Predictions based upon this hypothesis appear to be consistent with experimentally observed evidence. (Contractor's abstract)

FACTORS IN VISUAL ACUITY. II. THE RELATION OF BLURRED RETINAL IMAGES AND NEURAL INHIBITION TO IRRADIATION, by P. H. Greene. [Jan. 13, 1958] 55p. incl. diags. refs. (AFOSR-TN-58-26) (AF 18(600)1454) AD 148065 Unclassified

It is known that the mode of variation of the apparent width of a bar with variation of its luminance depends upon the objective width of the bar. Common interpretations of this phenomenon are discussed and summarized. These interpretations refer to characteristics of the sloping retinal excitation distribution which results from the blurring, or "diffusion," of the luminance distribution of the bar. On the assumption that a Gaussian distribution results from the diffusion of an infinitely narrow bar, the blurred excitation distribution arising from a wider bar is calculated. Making use of this calculation, it is shown that none of the proposed interpretations of irradiation would explain its observed dependence upon the width of the bar unless the standard deviation of the Gaussian diffusion function exceeded

1.35", which is more than twice the standard deviation calculated on the basis of optical effects and threshold measurements. It is concluded that the larger standard deviation takes into account the further diffusion of the excitation distribution in the network of neurons responsible for determining the location of the contour. ON THE BIOPHYSICS OF VISION, by S. Kamiya. [1958] [45]p. incl. diags. refs. (AFOSR-TN-58-343) (AF 18(600)1454) AD 154248 Unclassified

Also published in *Bull. Math. Biophys.*, v. 20: 343-373, Dec. 1958.

A photochemical system is considered which is similar to that of S. Hecht but which includes an intermediate substance between visual purple and visual white. This intermediate is assumed to change the membrane voltage of the photoreceptors. A simple method is presented from which one may calculate the frequency of the impulses resulting from the application of light. It is found that this physicochemical model enables one to account for a considerable number of physiological phenomena of vision. Among these are the light and dark adaptation phenomena. By introducing a simple assumption regarding spatial interaction one can account for some psychological phenomena such as the effect of intensity, a light-dark ratio, shape, and area on the critical flicker frequency. A number of other phenomena are discussed in terms of the model. (Contractor's abstract)

The results of experiments performed by L. S. Stone and by R. W. Sperry on vision in salamanders are analyzed. A summary of Reichardt's theory, which originated in the researches of B. Hassenstein on insects, is given, and an application to salamanders is carried out. Introducing a simpler mathematical development based on the one-factor theory of excitation, the same formal results are obtained. A complete model, which includes those results and tries to fit the salamander behavior described by Stone, is elaborated and translated into Boolean terms. As a complementary consideration, it is pointed out that the functional rigidity of the visuomotor system, deriving from a biological molecular hysteresis, could be framed in the neuro-affinity principle, the spatial expression of which would turn out to be a biological field. FACTORS IN VISUAL ACUITY, by P. H. Greens. Aug. 25, 1958, 1v. incl. diagr. refs. (AFOSR-TR-58-88) (AF 18(600)1454; continued by AF 49(638)414) AD 238778 Unclassified

An interpretation is suggested for experimental results on the location of perceived contours in studies of Mach bands (sharply defined subjective bands seen in continuous luminance distributions), irradiation (change in apparent width of a bar with changes in luminance), and resolution distance (minimum distance separating two bars which can just be perceived as separate). An experiment based upon analysis of the Mach band experiments supports the view that contour-perception depends upon inhibitory influences between neighboring points in the visual pathway. Analysis of the irradiation experiments shows that the spatial extent of the blurring of the visual image owing to optical and neural effects must be at least twice the amount in the literature for the optical part of the blurring. Experimental results may be consistently interpreted by the hypothesis that a contour appears at a point where the difference between the local excitation intensity and the average intensity in a neighborhood of the point attains a threshold, or else at the point of maximum slope of the excitation distribution in case the difference nowhere attains its threshold. Resolution is shown to depend upon two factors: intensity

discrimination and the response of the inhibitory mechanism. The inhibitory mechanism can allow resolution of two bright bands even when they are so close together that their blurred excitation distribution is unimodal. (Contractor's abstract)

A CONTRIBUTION TO THE STUDY OF THE DIFFUSION OF NEUTRAL PARTICLES THROUGH PORES, by C. S. Patlak. Nov. 1958, 12p. incl. diagr. (AFOSR-TN-58-1075) (AF 49(638)414; continuation of AF 18(600)1454) AD 207454 Unclassified

Also published in *Bull. Math. Biophys.*, v. 21: 129-140, June 1959.

Diffusion through a flat pore into a large region is proportional to the linear dimension of the pore and not to its area. This was first explained by Brown and Escombe (1900) for a circular pore and is here generalized, by means of a dimensional argument, to include any type of regular opening. The problem is further generalized to include diffusion through pores of finite thickness, finite distance apart, and into finite regions. Since this problem cannot be solved exactly, an approximation method is introduced. Reasons for the credibility of the approximation are presented. It is then shown, by means of the approximation method, that the diffusive flow through a pore is equal to the total concentration difference divided by the resistance of the system. The resistance, in turn, is the sum of the resistances of all portions of the system, each of which is calculated. The result is compared with results which have been calculated exactly for limiting cases and found to agree very well. The results are then applied to a standard method of computing pore size in membranes, and it is shown that the correction factor is negligible. (Contractor's abstract)

ON SINGULAR INTEGRALS, by A. Zygmund. [1957] 38p. incl. refs. [AF 18(600)1111] Unclassified

Published in *Read. Matem. e Appl.*, v. 18: 468-506, 1957.

In former papers (e.g., *Acta Math.*, v. 88: 85-139, 1952; *Studia Math.*, v. 14: 249-271, 1954; *Amer. Math.*, v. 78: 289-309, 1956) A. P. Calderón and A. Zygmund have dealt with the extension of Hilbert's operator to singular integrals in the n -dimensional space E^n ($n > 2$); including that for periodic functions, i.e., the conjugate functions operator. The results were applied to potential theory. In the present paper, their main results and some of the proofs are given in a systematic and concise arrangement. (Probably a complete representation of the theory,

CHI.08:004 - CHI.08:007

Including the earlier work of other writers on the subject, in book form would be appreciated by mathematicians.) In § 1 the author starts from the classical Riesz theory on Hilbert's operator in E^1 . Then he states the results for the class L^p in E^n and gives examples for $n = 1, 2, 3$. In § 2, various generalizations in E^n are discussed, including transforms of infinite sequences of numbers and conjugate functions. In §§ 3-7 proofs of results are given; an essential tool for some of them is the Fourier transform in E^n . In § 8, application is made to the theory of the tentail. A short bibliographical note is added. It refers to the work of the writers who have raised the problem. (Math. Rev. abstract)

ON UNITARY REPRESENTATIONS OF NILPOTENT LIE GROUPS, by J. Dixmier. 1957 [2]p. (AFOSR-TN-57-506) (AF 18(600)1383) AD 218397 Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 43: 985-986, Nov. 1957.

Also published in Amer. Jour. Math., v. 81: 160-170, Jan. 1959.

If G is a locally compact separable unimodular group it is known that the regular representation of G may be expressed as a direct integral of factor representations U_χ where the χ run over a measure space Ω supplied with a positive measure μ . Furthermore if f is in $L_1(G) \cap L_2(G)$ and $U_\chi(f)$ is the operator corresponding to f in the representation U_χ , the Plancherel formula states that

$$(*) \int_G |f(x)|^2 dx = \int_\Omega \text{tr}(U_\chi(f) \circ U_\chi(f)) d\mu(x),$$

where dx is Haar measure on G . The following results are stated in the case that G is a simply connected nilpotent Lie group. (1) Ω can be chosen to be the complement of the zeroes of a polynomial in a real q -dimensional Euclidean space. (2) There is a fixed Hilbert space H and for each χ in Ω an irreducible representation U_χ of G on H ; for each f in $L_1(G)$, the Fourier transform of f defined by $U_\chi(f) = \int_G U_\chi(x) f(x) dx$ is strongly continuous and zero at infinity on Ω . (3) There is a positive measure μ on Ω defined by a regular differential form of degree q so that (*) is valid for f in $L_1(G) \cap L_2(G)$. (Math. Rev. abstract)

EXTENSIONS AND OBSTRUCTIONS FOR RINGS, by S. MacLane. [1958] [30]p. incl. refs. (AFOSR-TN-57-776) (AF 18(600)1383) AD 148006 Unclassified

Also published in Illinois Jour. Math., v. 2: 316-345, Sept. 1958.

An extension is defined by an epimorphism of algebras $E \rightarrow A$; when the product of any two elements of the kernel A is 0, the left multiplication (resp. right) by an element of E induced upon A a (A bimodule) structure. The author tries on one side to free himself from the hypothesis according to which the algebras considered have a body basis (in fact, the case of rings, i.e. algebras over \mathbb{Z} , is studied), which introduces obstructions of an additive character besides multiplicative obstructions. The case is also studied where the induced multiplication upon A is not zero. A new definition of the cohomology groups $H^n(A, K)$ with coefficients in a A bimodule K is given. It is proved that if K is a A -bimodule, the extension classes $0 \rightarrow K \rightarrow E \rightarrow A \rightarrow 0$ which define over K , this bimodule structure (the multiplication induced upon K being zero), are in bijective correspondence with $H^2(A, K)$.

[THE GEOMETRIC REALIZATION OF A TWISTED CARTESIAN PRODUCT] Die geometrische Realisierung eines schiefen kartesischen Produktes, by A. Dold. Sept. 12, 1957 [12]p. (AF 18(600)1383) AD 148141 Unclassified

Also published in Arch. der Math., v. 9: 275-286, 1958.

Intuitively a twisted Cartesian product of two semi-simplicial complexes F and B is almost a fibre space with projection map $\nu: E \rightarrow B$ and fibre F , where E is the total complex of the twisted Cartesian product. In this paper the author proves three main theorems. Theorem 1: Let (F, B, E) be a twisted Cartesian product which has a structural monoid complex H , such that $\pi_0(H)$ (the path components of H) form a group; then the geometric realization of the map $\nu: E \rightarrow B$ is a quasi-fibration, with total space the geometric realization of E , base the realization of B , and fibre the realization of F . Theorem 2: Let K be a semi-simplicial complex with base point, A a subcomplex with the same base point, and K/A the complex obtained by collapsing A to a point. Let $SP(K)$, $SP(K/A)$, and $SP(A)$ denote the infinite symmetric products of the complexes K , K/A , and A . Under these conditions there exists a twisted Cartesian product $(SP(A), SP(K/A), SP(K))$ with fibre $SP(A)$, base $SP(K/A)$, and total complex $SP(K)$. This twisted Cartesian product is principal with structural monoid $SP(A)$. Theorem 3: If Γ is an associative H -space with unit such that $\pi_0(\Gamma)$ is a group, then Γ has the same weak homotopy type as the space of loops in a connected space. The first of these theorems shows that one's intuition is correct: a twisted Cartesian product is almost a fibre space. The second is useful in abstracting the earlier work of the author and R. Thom on infinite symmetric products in the geometric case [A. Dold and R. Thom, Ann. of Math. v. 67: 239-281, 1958] to the semi-simplicial case. The third theorem is a further application of the first theorem. (Math. Rev. abstract)

 June 1959.

Let H be a topological space with a continuous multiplication which is associative and has a 2-sided unit. In analogy to the case of a topological group, the authors construct in this paper a universal quasi-fibration with fibre H . As an application, they obtain a classification of fibre bundles with respect to fibre homotopy equivalence. (Math. Rev. abstract)

adjoining a unit element to C and let $A = B \otimes_F C$. Then A is right hereditary but not left hereditary. The proof proceeds by showing that A is a regular ring (i.e., for any a there is an x such that $axa = a$); that in a regular ring every countably generated (right) ideal is projective; and that in A every right ideal is countably generated. Thus A is right hereditary. The author then produces a (non-countably generated) left ideal which is not projective. (Math. Rev. abstract)

Some questions were studied concerning projective modules which are the basic tool in the new field of homological algebra. A result obtained in this connection is the following: if M is a direct sum of (any number of) countably generated modules, then the same is true for any direct summand of M . This has a number of corollaries. One is that any projective module over a local ring is free. Another is the completion of a problem posed by Baer: if a torsion-free abelian group G is a direct sum of groups of rank one, then the same is true for any direct summand of G . Lie algebras were also dealt with. (Contractor's abstract, modified)

The tritium and He^3 contents of the Norton County stone meteorite were measured. At the time of fall (1948) the tritium activity of two different specimens were $(.28 \pm .02)$ and $(.25 \pm .02)$ dpm/g. The measured He^3 contents per gram were $(2.27 \pm .11)$ and $(2.35 \pm .11) \times 10^{-6}$ cc STP, respectively. Experiments were made which indicate that there has been no appreciable loss of He^3 . The amount of He^3 accumulated and the tritium production rate combined give apparent He^3 - He^3 ages for irradiation of 420 and 480 million years, respectively. If an assumption is made as to the direct production rate of He^3 by spallation these ages reduce to 240 and 280 million years. The $A^{40}\text{-K}^{40}$ age of this meteorite is 4200 ± 700 million years. The possible significance of this difference in age is discussed. (Contractor's abstract)

TRITIUM ASSAYS OF NATURAL WATERS MEASURED IN 1956-1957, by F. Begemann. Dec. 31, 1957, 1v. incl. diagrs. tables, refs. (AFOSR-TR-58-41) (AF 18(600)-564) AD 154131 Unclassified

Rain and snow samples were collected from Chicago (Ill.), Bern (Switzerland), Reykjavik (Iceland), and various locations in the Arctic to obtain more detailed information on the distribution of excess tritium. In addition, the tritium content of Mississippi water was measured to study its relationship to the tritium content of precipitation. The tritium content of one set of annual layers of snow from Greenland covering the period from 1944 to 1956 was measured to obtain the amount of Castle and Redwing produced tritium deposited in this particular area as well as the natural production rate of tritium. The results on 3 more sets of snow samples from the Antarctic confirmed the previous finding that no detectable amounts of bomb tritium are deposited in this area. Finally, to further investigate the usefulness of tritium for the study of hydrological problems, the measurements on samples from Steamboat Springs, Nevada, were continued. The tritium contents of South Steamboat well and Spring no. 16 appeared to follow closely the marked change in the tritium contents of rain water from artificially produced tritium. Spring no. 80 showed an entirely different behavior. No pronounced peaks in the tritium content could be detected. Instead, following Castle, the tritium content increased about 4 T units, but did not show any subsequent decrease.

THE MEASUREMENT OF VERY SLOW REACTION

RATES: DECARBOXYLATION OF ALANINE, by D. Conway and W. F. Libby. Feb. 1957 [35]p. incl. diagrs. tables, refs. (AFOSR-TN-57-60) (AF 18(600)663) AD 115100 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 80: 1077-1084, Mar. 5, 1958.

A method of measuring slow reactions using radioactive labelling and low level counting techniques has been applied to the decarboxylation of alanine at temperatures corresponding to half-lives from 0.1 to 10^4 years, the results being essentially in agreement with those which Abelson obtained at higher temperatures. The half-life for decarboxylation at room temperature is found to be about 10 billion years. A side reaction, which is most probably a short chain length radiation induced reaction, was controlling below 373°K and showed a half-life of about 10^5 years at room temperature at specific radioactivities of about 3 millicuries of C^{14} per mole of alanine. It also was found that O_2 attacks alanine to release carboxyl carbon at a rate corresponding to a half-life of about 20,000 years at room temperature.

C^{14} HOT ATOM CHEMISTRY OF n-PENTANE AND iso-PENTANE, by C. F. MacKay and W. F. Libby. May 1957, 16p. incl. tables, refs. (AFOSR-TN-57-217) (AF 18-(600)663) AD 126515 Unclassified

Also published in Jour. Amer. Chem. Soc., v. 79: 6366-6369, Dec. 20, 1957.

Reactions of C^{14} atoms of velocities corresponding to energies up to 40,000 electron volts have been studied in n-pentane and iso-pentane at about room temperature. C^{14} atoms were generated at the Argonne National Lab. pile through the reaction of thermal neutrons in the $\text{N}^{14}(n,p)\text{C}^{14}$ process. Aniline was most often used as a source of nitrogen, but substitution of aliphatic amines gave similar results indicating that products were characteristic only of the hydrocarbon. A wide variety of hydrocarbons was formed. Hexane and pentane isomers were identified. Hexane isomers predominate, yields of individual compounds being up to 12%. The type and yield of compounds formed from n-pentane differ from those formed from iso-pentane. A mechanism is proposed. (Contractor's abstract)

Orbits for cosmic-ray particles starting from the vicinity of the sun and passing through the geomagnetic dipole field were integrated by using the AVIDAC computer at the Argonne National Lab. The methods for integration used in Chicago and Göttingen were compared. Counting rates at the top of the atmosphere were calculated from the integrated orbits in order to make possible the analysis of cosmic-ray intensity increase during solar flares. Different source widths and declinations were assumed. The calculated counting rates are based on a flat rigidity spectrum at the source. This investigation shows that: (a) distinctive impact zones exist even for large source widths; (b) the position of these zones and the counting rates within these zones depend strongly upon the declination of the source; and (c) the earth's magnetic field produces a focusing effect especially at higher latitudes. SOLAR ORIGIN OF CHANGES IN THE PRIMARY COSMIC RADIATION, by J. A. Simpson. [1957] [15]p. incl. diagrs. [AF 18(600)666] Unclassified

Published in Proc. Nat'l. Acad. Sciences, v. 43: 42-56, Jan. 1957.

The observed nonperiodic changes of primary cosmic-ray intensity within the solar system are considered briefly. It is concluded that they are either the result of occasional, de novo production in the region of the sun or the modulation of pre-existent radiation from outside the solar system. These variations represent changes in the primary spectrum over a wide range of particle energies involving over 95% of all the cosmic radiation. Since the modulation mechanism which produces these spectrum changes has its origin in solar activity, it is clear that only during periods of extreme minimum solar activity will it be possible to record briefly the galactic spectrum at the earth. Further studies of cosmic-ray intensity may: (1) add to knowledge of the electrodynamics of the solar system, and the nature of geomagnetic storms specifically; (2) place upper limits on the production of cosmic rays at the sun; and (3) provide further information on the galactic spectrum.

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 192, Apr. 25, 1957.

Also published in Phys. Rev., v. 106: 568-571, May 1, 1957.

The low rigidity cutoff for primary particles in the cosmic-ray spectrum reappeared in 1956. From these new results and the earlier measurements in 1948, 1951, and 1954, it is clear that the shift of the low-rigidity cutoff to a very small value is restricted in time to an interval within which solar activity reached a minimum in the 11-year solar cycle. This effect was accompanied by other changes in the primary spectrum; namely (a), the total cosmic-ray intensity and (b) the exponent for the power law spectrum, both passed through maxima near the solar minimum in 1954. The 1956 results further support the view that these changes in the primary spectrum have their origin in a mechanism controlled by solar activity—most likely the diffusion of cosmic-ray particles through interplanetary disordered magnetic fields transported by plasma clouds of solar origin. If this is so, then only for a brief period near solar minimum is there

ACCELERATION OF COSMIC RAYS IN SOLAR FLARES, by E. N. Parker. [1957] [7]p. incl. table, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)666] and AFRC Geophysics Research Directorate) Unclassified

Published in Phys. Rev., v. 107: 830-836, Aug. 1, 1957.

It is shown that the white-light cosmic-ray solar flare of Feb. 23, 1956 expended of the order of 2×10^{32} ergs of energy, or 10^4 ergs/cm³. The energy apparently came from a 500-gauss force-free magnetic field initially occupying the site of the flare. It is shown that the 500-gauss field, besides supplying the flare energy, will produce fluid motions of sufficient velocity to accelerate ions from thermal to relativistic energies by Fermi's mechanism in about 2 min. The theoretical energy spectrum of the model is in agreement with the observed spectrum. About 1% of the total flare energy is converted to relativistic particles and the remainder

CHL12:031 - CHL12:033

is dissipated through thermal processes to produce the observed optical radiation. (Contractor's abstract)

NEWTONIAN DEVELOPMENT OF THE DYNAMICAL PROPERTIES OF IONIZED GASES OF LOW DENSITY, by E. N. Parker. [1957] [10]p. incl. diagrs. refs. [Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)666 and AFCRC Geophysics Research Directorate) Unclassified

Published in *Phys. Rev.*, v. 107: 924-933, Aug. 15, 1957.

The macroscopic dynamical equations of a tenuous ionized gas in a magnetic field are developed by averaging over the individual ion and electron motions, which do not necessarily possess an isotropic distribution. It is shown that the principal motion of the gas is related to the magnetic field by the usual hydromagnetic equations, as developed for conducting liquids and dense gases; the anisotropy of the individual particle motions shows up primarily as a coefficient multiplying the ponderomotive force exerted by the magnetic field on the plasma. The results reduce properly to the earlier work of Schlüter, Cowling, and Spitzer for isotropic pressure, and are in agreement with the recent developments from the Boltzmann equation. It is pointed out that the magnetic lines of force are permanently connected and move in the frame of reference of the electric drift. It is shown that near static equilibrium, when the principal motions vanish, there remain small macroscopic drift motions of the gas in the field of inhomogeneities. It is also shown that the field equations, obtained by assuming that the radius of gyration of the thermal motions is small compared to the scale of the field, are valid even near neutral surfaces, on which the field density vanishes. THE 24-HOUR INTENSITY VARIATIONS OF THE PRIMARY COSMIC RAYS, by A. M. Conforto and J. A. Simpson. [June 21, 1957] [11]p. incl. diagrs. [AF 18-(600)666] Unclassified

Published in *Nuovo Cimento, Serie X*, v. 6: 1052-1062, Nov. 1, 1957.

The data from nucleonic component detectors (neutron intensity monitors) are analyzed for the amplitude and phase of maximum intensity of the 24 hr variation at the geomagnetic equator and at 48°N. The same analysis covers 1953-55, which includes the time of solar cycle (sunspot) minimum in 1954. During 1954 it is known that the 24 hr variation possesses an anomalous behavior.

It is shown that during 1954 there is an interval of 9 mo or more when the solar daily variation appears to undergo a progressive phase shift whose time of maximum lies in the range of 0800-1000 hr on a sidereal time scale. This anisotropy certainly exists in the radiation falling upon the atmosphere, and it is likely, although not proven, that the anisotropy prevails even outside the terrestrial field. The question of whether this sidereal effect is spurious or real is discussed in relationship to the recent results on the modulation of cosmic ray intensity within the solar system.

INITIAL STAGES IN THE PROPAGATION OF COSMIC RAYS PRODUCED BY SOLAR FLARES, by R. Lüst and J. A. Simpson. [1957] [14]p. incl. illus. diagrs. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)666] and AFCRC Geophysics Research Directorate) Unclassified

Published in *Phys. Rev.*, v. 108: 1574-1576, Dec. 15, 1957.

The propagation of solar cosmic rays produced in the Feb. 23, 1956 flare have been studied from the time they leave the flare region to the time when the terrestrial cosmic-ray intensity reaches a maximum value. Within this interval there are observed not only strong anisotropies in the incident radiation, but also relatively large differences in time (≤ 9 min) between the commencements of the intensity increase in different parts of the world. This distribution of time delays is superposed upon the transit-time delay which all particles experience between production and detection. From these experimental results, and the calculations of orbits connecting the sun and earth at the time of the flare, it is shown that there are broad impact zones on the earth within the first 10 min of the cosmic-ray intensity increase. Using the recently deduced flare-particle spectrum, cosmic-ray intensities at the top of the atmosphere have been determined for the different impact zones. For this flare event the "2000 hr" impact zone becomes as important as the "0900" and "0300" hr impact zones. These results demonstrate that the first flare particles arriving at the earth were not of low energy, and that the low-energy particles arrived later - the delay being an inverse function of energy. This energy-dependent spread of first arriving particles is called the dispersion effect arising from the mode of particle propagation from the flare source to the earth. These conclusions show that back scattering from disordered magnetic fields beyond the orbit of the earth account for the time delays. Various alternatives are considered for production of this distribution of onset times. The most likely process appears to be propagation through magnetic fields by diffusion. Since the impact-zone data for all geomagnetic latitudes, including both polar regions, predict a distant source in the direction of the sun but of order one radian solid angle in the sky, and since

CHI.12:034 - CHI.12:037

sufficient diffusion around the earth to produce the required time delays would destroy the observed impact-zone effects, it is suggested that there may exist a diffusing envelope around the sun which accounts for both the apparent source size and the dispersion effect. Small irregularities in the general solar dipole field are invoked to produce the diffusion. Calculations show that the predicted dispersion effect agrees with the observations, and that other details following from diffusion are satisfied. There is evidence of a dispersion effect for the flare particles of Nov. 19, 1949. The implications of these results for possible magnetic-field distributions between the sun and earth are reviewed, and it is shown from the orbit calculations and the dispersion effects that the predictions are not in agreement with observations. There is a transition period between the time when impact zones are dominant and the time when isotropy sets in. The subsequent storage of the solar cosmic-ray particles is not further considered in this paper, except for the bearing of these observations at early times upon the character of the interplanetary storage magnetic fields. SWEET'S MECHANISM FOR MERGING MAGNETIC FIELDS IN CONDUCTING FLUIDS, by E. N. Parker. [June 4, 1957] [12]p. incl. diagr. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18-(600)666] and AFRC Geophysics Research Directorate)
Unclassified

Published in Jour. Geophys. Research, v. 62: 509-520, Dec. 1957.

Sweet's mechanism for the merging of two oppositely directed magnetic fields in a highly conducting fluid is investigated in a semi-quantitative manner. It is shown that two oppositely directed sunspot fields with scales of 10^4 km could be merged by Sweet's mechanism, if shoved firmly together in about two weeks; their normal inter-diffusion time would be of the order of 600 years. It is suggested that Sweet's mechanism may be of considerable astrophysical importance. It gives a means of altering quickly the configuration of magnetic fields in ionized gases, allowing a stable field to go over into an unstable configuration, subsequently converting much of the magnetic energy into kinetic energy of the fluid. ORIGIN AND DYNAMICS OF COSMIC RAYS, by E. N. Parker. [1958] [17]p. incl. diagr. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)666] and AFRC Geophysics Research Directorate)
Unclassified

Published in Phys. Rev., v. 109: 1328-1344, Feb. 15, 1958.

As a consequence of our inability to observe directly the origin of a cosmic-ray particle, we begin the development with a discussion of the limitations within which we can construct a cosmic-ray accelerator mechanism. We find that we are allowed only the betatron effect and Fermi mechanism. We review some of the many variations of these mechanisms which are to be found in the literature. Then it is shown that trains of oppositely moving hydromagnetic waves of large amplitude and with sharp crests can accomplish large and continued particle accelerations which are adequate to maintain the observed galactic cosmic-ray field. The large acceleration arises as a consequence of the simple fact that each wave tends to sweep up the cosmic-ray particles before it, so that head-on collisions of particles with waves are much more common than overtaking collisions. It is pointed out that the sharp crests of the waves are a natural consequence of the observed supersonic mass motions. Therefore, the acceleration by oppositely moving waves does not depend upon any special wave form, and we suggest that it is the naturally occurring acceleration process. By

CHI.12:038 - CHI.12:041

treating the cosmic rays as a gas with relativistic thermal motions, it is shown that the cosmic-ray gas is effectively coupled to the motions of the ordinary matter both parallel and perpendicular to the magnetic field. Thus the effective speed of sound must be computed in the composite cosmic-ray and ordinary gas. It is noted that with this composite speed of sound the irregular mass motions in the galactic disk and halo are approximately Mach one. It is suggested that this represents a general dynamic balance to be found in all sufficiently active regions of space, and explains how it is that we often observe prolonged mass motions in the galaxy and in stellar atmospheres which would otherwise be computed to be highly supersonic and dissipative. The dynamic balance comes about from the fact that increased cosmic-ray density would reduce the effective Mach number below one, allowing the sharp crests of the hydromagnetic waves to degenerate, and thereby halting the production of cosmic-ray particles. It is shown that when the thermal motions of a tenuous ionized gas are sufficiently anisotropic, the gas, and the initially uniform magnetic field which the gas is

assumed to contain, become unstable. One mode of instability occurs when the gas pressure is greater parallel to the field than perpendicular, and another mode when the pressure is greater perpendicular than parallel. It is suggested that such instabilities may be of astrophysical interest, particularly with regard to the configuration of the solar dipole field as it is drawn out into interplanetary space by ionized gas from the sun. CHANGES OF THE PRIMARY α -PARTICLE FLUX OF COSMIC RADIATION DURING HIGH SOLAR ACTIVITY (Abstract), by P. Meyer. [1958] [1]p. [AF 18(600)666] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in *Bull. Amer. Phys. Soc.*, Series II, v. 3: 221, May 1, 1958.

During the months of Aug. and Sept., 1957, the flux of the primary α -particle component was measured at the northern magnetic latitude of 61°. This report based on two flights which followed the sharp decrease of total cosmic-ray intensity on Aug. 30, 1957. It was found that from flight to flight the average proton and α -particle intensities undergo changes consistent with the concept that a common modulating mechanism is operating on both primary components. For each flight a detailed study of the intensity-time variations within 8 hr of observation reveals a large change in the α -particle flux not accompanied by a comparable variation in the proton intensity. We tentatively ascribe this to an anisotropy in the α -particle flux. Such an independent variation is not a consequence of any modulating mechanism so far considered.

INTERACTION OF THE SOLAR WIND WITH THE GEOMAGNETIC FIELD, by E. N. Parker. [1958] [17]p. incl. diagr. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)666] and AFCRC Geophysics Research Directorate) Unclassified

Published in *Phys. Fluids*, v. 1: 171-187, May-June 1958.

The dynamical properties of the solar wind blowing past the geomagnetic field are investigated by considering the effective viscosity and the resulting transition layer thickness. The collision of ions in the solar wind produce a negligible viscosity in the flow past the

geomagnetic field, but such an inviscid flow is shown to be unstable. The resulting disordered interface between the field and the wind yields Fermi acceleration of ions and consequently a not insignificant effective viscosity. The Fermi acceleration results in supra-thermal ions which may have an energy spectrum like that observed for primary auroral protons. The auroral zones and the agitated nature of the polar geomagnetic field are shown to follow from the depth of penetration of the solar wind into the geomagnetic field. The injection of gas into the geomagnetic field is studied. The effect at Earth of the distortion of the outer boundary of the geomagnetic field is computed; no matter how unevenly and anisotropically the outer field is distorted, the effect at Earth is a nearly uniform perturbation field which is closely parallel to the geomagnetic axis. Pushing in on the outer field increases the horizontal component at Earth, and pulling out decreases it; the total increase of the horizontal component is the algebraic sum of the pushing and pulling. The simultaneous worldwide onset and the main phase of a geomagnetic storm follow. The common tendency of large and/or violent bodies of plasma to produce supra-thermal particles is noted and suggested to be a general dynamical property. (Contractor's abstract)

COSMIC RAY MODULATION BY THE SOLAR WIND, by E. N. Parker. [1958] [5]p. incl. diagrs. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)666 and AFCRC Geophysics Research Directorate) Unclassified

Published in Phys. Rev., v. 110: 1445-1449, June 15, 1958.

It is shown that the hydrodynamic outflow of gas from the sun observed by Biermann results in a reduction of the cosmic-ray intensity in the inner solar system during the years of solar activity. The computed cosmic-ray energy spectrum so closely resembles the observed spectrum at earth that we suggest the outflow of gas to be the explanation for the 11-yr variation of the cosmic-ray intensity. It is also suggested that perhaps the Forbush-type decrease, which is a local geocentric phenomenon, is the result of disordering of the outer geomagnetic field by the outflowing gas from the sun. COSMIC-RAY PRODUCTION OF POSITRONS AND ELECTRONS IN THE GALAXY (Abstract), by F. C. Jones. [Nov. 1958] 1p. (AF 18(600)666) Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Nov. 28-29, 1958.

CHL12:047 - CHL12:049

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 362, Nov. 26, 1958.

The interaction of cosmic rays with interstellar hydrogen throughout the galaxy produces stable secondaries, such as γ rays and e^\pm . The electrons and positrons are derived from the sequence of reactions $N + N \rightarrow N + N + \pi^\pm$, $\pi^\pm \rightarrow \mu^\pm + \nu$, $\mu^\pm \rightarrow e^\pm + 2\nu$ (N = nucleon). Their flux has been calculated to be the same order of magnitude as the primary cosmic-ray proton flux but depends upon the density of interstellar hydrogen and galactic trapping magnetic fields. An approximate energy spectrum has been determined with a peak in the distribution well below 100 mev. The experimental determination of the electron-positron flux is of interest since the flux depends upon basic parameters of the galaxy. The existence of the geomagnetic field makes difficult the direct observation of such a low-energy particle distribution, and the low-energy charged particle cut-off recently shown to depend upon solar activity further limits the observational possibilities.

DYNAMICS OF THE INTERPLANETARY GAS AND MAGNETIC FIELDS, by E. N. Parker. [1958] [13]p. incl. diags. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)666 and AFCRC Geophysics Research Directorate)

Unclassified

Published in Astrophys. Jour., v. 128: 664-676, Nov. 1958.

We consider the dynamical consequences of Biermann's suggestion that gas is often streaming outward in all directions from the sun with velocities of the order of 500-1500 km/sec. These velocities of 500 km/sec and more and the interplanetary densities of 500 ions/cm³ (10^{14} gm/sec mass loss from the sun) follow from the hydrodynamic equations for a 3×10^6 K solar corona. It is suggested that the outward-streaming gas draws out the lines of force of the solar magnetic fields so that near the sun the field is very nearly in a radial direction. Plasma instabilities are expected to result in the thick shell of disordered field (10^{-5} gauss) inclosing the inner solar system, whose presence has already been inferred from cosmic-ray observations. It is shown that hydromagnetic waves propagating outward through the solar corona will convert all but a small portion of their energy into suprathermal particles. It is suggested that this is the source of the 3×10^{28} ergs/sec necessary to maintain 2×10^6 K solar corona with its continued expansion into solar wind. The temperature of the solar corona will then correspond to an ion thermal velocity of the same order of magnitude as the hydromagnetic wave velocity. (Contractor's abstract)

SUPRATHERMAL PARTICLES. III. ELECTRONS, by E. N. Parker. [1958] [7]p. incl. diags. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)666] and AFCRC Geophysics Research Directorate)

Unclassified

Published in Phys. Rev., v. 112: 1429-1435, Dec. 1, 1958.

Certain phenomena in nature, such as the 50- to 100 kev electrons of the aurora, suggest that there are plasma-dynamical processes which can quickly transfer the translational energy of the ions in a plasma stream to the electrons (some 20 kev/ion for a 2000-km/sec solar wind). It is shown that two interpenetrating streams of noncolliding and initially neutral plasma can achieve this energy transfer with a characteristic time comparable to $(M/m)^{1/2}$ times the plasma period. The process is closely analogous to the excitation of plasma oscillations by two interpenetrating electron streams, but of course proceeds to much greater electron energies because the ion components of the streams carry so much more kinetic energy than do the electron components. Hence, besides the auroral electrons, it is probably responsible for solar radio emission, rather than the electron streams implied in current theories. Further, the process is probably the dominant interaction in shock fronts, particularly in astrophysical cases where neither direct collisions nor the existing weak magnetic fields can give sharp fronts. The characteristic thickness of a shock front in the solar wind is of the order of 10^4 cm due to the above plasma excitation whereas the Larmor radius of the ions, which would

otherwise determine the shock thickness in the absence of collisions, is 100 km or more. (Contractor's abstract)

INADEQUACY OF RING CURRENT FOR MAIN PHASE OF A GEOMAGNETIC STORM, by E. N. Parker. [1958] [7]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)666 and AFCRC Geophysics Research Directorate) Unclassified

Published in Jour. Geophys. Research, v. 63: 883-889, Dec. 1958.

It is demonstrated that there is apparently not enough dissipation to allow significant diffusion, during a magnetic storm, of the magnetic fields in the vicinity of the earth. It is then demonstrated that a ring-current field can only increase the horizontal component of the geomagnetic field, and so cannot account for the main phase of a geomagnetic storm. Thus, other mechanisms must be sought.

A SYSTEMATIC STUDY OF HYPERFRAGMENTS PRODUCED BY 4.5 GeV π^- IN NUCLEAR EMULSION. I. π^- - MESIC DECAYS, by W. E. Slater. [July 9, 1958] [80]p. incl. diags. tables, refs. (AFOSR-TN-58-573) (AF 49(638)209) AD 158934

Unclassified

Also published in Nuovo Cimento, Series X, Suppl., v. 10: 1-40, 1958.

An experimental study was undertaken to establish the Λ -particle binding energies (B_{Λ}) for several hypernucleides with an accuracy comparable to the present uncertainty in the value of Q_{Λ} , the energy released in the decay of free Λ . Only events best suited to yield binding energies, those in which a negative pion is emitted, are considered. An emulsion stack of fifty 1-mm and thirty-five 0.6 mm Ilford G-5 pellicles, 4 in. by 6 in. in area, was exposed to a beam of 4.5 GeV π^- at the bevatron. The most energetic pion beam from the bevatron was chosen because in pion-nucleon collisions a substantial center-of-mass energy is produced from this beam. This increases the chance to produce a slowly

moving Λ hyperon which may become attached to a nuclear fragment. Two decay modes mass number (A) = 4 of the hydrogen hyperfragments, were identified. Twenty-one He_{Λ} decays, 2 Be_{Λ} decays, 5 Li_{Λ} decays, and 5 unidentified hyperfragments were also found. The binding energy increases monotonically with A through $A=9$, according to available reliable data. Because the density of nuclear matter is independent of A , the potential well in which the Λ is bound is expected to have a constant depth. No events with $A < 4$ were identified. Detection for the first time was made of mesic decays of both members of the $A=8$ doublet, Li_{Λ} and Be_{Λ} . (ASTIA abstract)

Excerpt published in Proc. 1958 Annual Internat'l. Conf. on High Energy Physics at CERN, European Organization for Nuclear Research, Geneva (Switzerland) (June 30-July 5, 1958), Geneva, CERN, Scientific Information Service, p. 327.

Also published in Nuovo Cimento, Series X, Suppl., v. 10: 68-90, 1958.

Existing surveys on hypernuclei are re-analyzed in an attempt to standardize procedures for identifying events and deducing binding energies. A detailed description of the salient features of the events considered and of the criteria adopted are presented. The following information is considered pertinent to the analysis of a hyperfragment decay: (1) data on the primary track, range, latitude, evidence for stopping (tapering or multiple scattering), charge (δ -ray count, or profile measurement), measured mass, and characteristics of the primary star; (2) data on the secondary star prongs, ranges, latitudes, longitudes, errors in these 3, and identities; and (3) thickness and density of the emulsions. The extraction of reliable hypernuclear binding energies is desired so all events decaying non-mesonically are ignored.

Published in *Nuovo Cimento, Series X, Suppl.*, v. 10: 41-67, 1958.

Hyperfragment decay without pion emission is analyzed. Only those events which originate from a primary star associated with a visible beam track are considered. The probable number of actual hyperfragments was estimated on a statistical basis under homogeneous conditions of production and detection. Careful measurements on the decay products of such events identified 44 non-mesic definite hyperfragments as specific hyper-nuclides. The non-mesic/mesic decay ratios can be estimated from the results. Definite hyperfragments are identified from the characteristics of the connecting tracks, e.g., thin-down, δ -rays, ionization, and scattering near the end of the range. This type of analysis is only possible for events having fairly long connecting tracks. The majority of the possible hyperfragments (GOKs) had connecting tracks shorter than 20 μ m. A total of 216 GOKs and 56 definite hyperfragments were found. Connected stars can be definitely classed as non-mesic decays of definite hyperfragments in a limited number of cases. These cases represent about 0.2 of the connected stars. Several methods were used to estimate the Z spectrum of the hyperfragments and the non-mesic to mesic ratio as a function of Z. The methods made use of the prong-number distribution of the decays and of the results of the analysis of the events with the aid of an IBM 650 computer. A forward to backward ratio of 2.2 ± 0.5 was found for the production of hyperfragments. (ASTIA abstract)

IMPURITY DIFFUSION IN COPPER (Abstract), by C. T. Tomizuka. [1957] [1]p. [AF 18(600)1489]

Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Published in *Bull. Amer. Phys. Soc., Series II*, v. 2: 123, Mar. 21, 1957.

In order to study the effect of the atomic size of diffusing elements on the impurity diffusion rate diffusion of silver and gold in single crystals of copper was measured. While gold atoms expand the copper lattice approximately 30% more effectively than silver atoms do, the diffusion rate of silver in copper was found to be 4 times faster than that of gold. The results can be expressed as $D = 0.69 \exp(-49\,700/RT) \text{ cm}^2/\text{sec}$ and $D = 0.23 \exp(-44\,000/RT) \text{ cm}^2/\text{sec}$ for the diffusion in copper of gold and of silver, respectively. Preliminary results on the diffusion of electropositive elements in copper will be reported.

EXPERIMENTAL DETERMINATION OF THE ELECTRICAL RESISTIVITY OF THE LIQUID ALLOYS Hg-In, Hg-Tl, and Ga-Sn, AND OF LIQUID GALLIUM, by L. G. Schulz and P. Splegler. Mar. 6, 1958 [14]p. incl. illus. tables, refs. (AFOSR-TN-58-149) (AF 18(600)1489) AD 152176 Unclassified

A potentiometric method was used to determine the resistivity and the temperature coefficient of the resistivity of several alloys which are liquid at room temperature. Pure Hg was used as the reference material. It was found that the solution of In or Tl in Hg caused a large decrease in the resistivity whereas the solution of In or Sn in Ga caused a slight increase. For solutions of Tl in Hg closely corresponding to Hg_5Tl_2 at room temperatures above 16°C there were no anomalies in the electrical properties. However, in the range of 16°C down to the melting temperature at 14.5°C the temperature

CHL13:012 - CHL13:016

coefficient decreases to zero at 14.5°C. The conclusions from electrical measurements are in general inconsistent with those from x-ray experiments which suggest that there is a more orderly atomic arrangement in the liquid at those compositions which correspond to compounds. The resistivity of liquid Ga was found to be in good agreement with that obtained by Bridgman. (Contractor's abstract)

ON HART'S THEORY ON THE ROLE OF DISLOCATION IN BULK DIFFUSION, by C. T. Tomizuka. Apr. 9, 1958 [8]p. incl. table. (AFOSR-TN-58-272) (AF 18(600)1489) AD 154173; PB 133964 Unclassified

Also published in Acta Metallurgica, v. 6: 660-661, Oct. 1958.

An analysis has been attempted of previously quoted experimental bulk diffusion data of antimony in silver in order to discover a gradual decrease of the activation energy with decreasing temperature as predicted by Hart's theory (Acta Metallurgica, v. 5: 597, 1957) of the short-circuiting effect of dislocations on the diffusion process. The change in slope between adjacent points of a $\log D$ vs $1/T$ plot has been examined for experimental data on single crystals which have values of D larger than 10^{-12} cm²/sec and only for those pairs of points with temperature intervals sufficiently large to give $\Delta(1/T) > 4 \times 10^{-5}$ /deg. The contributions of the short-circuiting elements amount to as much as 9% at 650°C for the diffusion of antimony in silver and 4% for the diffusion of silver in silver and are in general agreement with expectations.

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 139-140, Mar. 27, 1958.

Programs for computing all necessary one- and two-center integrals involving Slater-type atomic orbitals (AO's) for quantum numbers $n = 1, 2$ ($n = 3$ in the case of the one-electron integrals) have been written for the Scientific Univac and are now operating. Programs for the calculation of certain types of three-center integrals for almost any n , but for a maximum l of 7 are also operating. Description and discussion of results for the various integral programs are given. An SCF procedure for computation of LCAO molecular orbitals has been programed and is operating. This, coupled with the integral programs, provides a complete computational tool for the determination of "best-LCAO-MO" eigenfunctions (obtained by varying the exponents of the atomic orbitals and the coefficients of the LCAO-MO's) for ground and excited states of first-row homopolar, heteropolar, and hydride molecules. From these eigenfunctions (further improved by configuration interaction), calculation of molecular energies and other properties can be computed. Initial results are discussed.

Published in Jour. Chem. Phys., v. 27: 369-373, Aug. 1957.

An LCAO molecular orbital calculation using the full six-electron Hamiltonian has been performed on Li_2 at a nuclear separation equal to the experimental internuclear distance. The molecular wave function consisted of one antisymmetrized product made up of molecular orbitals formed as the best linear combinations of Slater $1s$, $2s$, and $2p$ atomic orbitals. The orbital exponents for these atomic orbitals were respectively 2.69, 0.64, and 0.53 as determined by a variational calculation on the lithium atom. In computing the molecular dissociation energy, the energy of two separated lithium atoms was taken to be that obtained by this variational calculation. The computed dissociation energy was found to be 0.33 ev compared with the experimental value of 1.05 (where a slight correction for zero-point energy has been made). The ratio of the computed molecular ground-state energy to the experimental is 0.9902 while the difference of these quantities is 4.00 ev. Certain other molecular constants are calculated and compared with available experimental data.

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 139, Mar. 27, 1958.

The ground state of a helium-like system is represented by a wave function of the form $\psi(r_1)\psi(r_2)\chi(r_{12})$, where ψ and χ are functions to be determined by minimizing the energy. Unlike many other approximate wave functions, a wave function of this form has the proper singularities for $r_1 \rightarrow 0$, $r_2 \rightarrow 0$, $r_{12} \rightarrow 0$ if ψ and χ have the right slopes at these points. An actual calculation was done for the helium atom. Simple expansions in terms of polynomials and exponentials were put forward for ψ and χ , and the energy was minimized with

CHI. 15:013, 014; CIN. 04:001

respect to the coefficients and exponents. The resulting wave function accounts for 92% of the correlation energy.

BROKEN BOTTLENECKS AND THE FUTURE OF MOLECULAR QUANTUM MECHANICS (Abstract), by R. S. Mulliken and C. C. J. Roothaan. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)471], Office of Naval Research, and National Science Foundation) Unclassified

Presented at annual meeting of the Nat'l. Acad. Sciences, Washington, D. C., Apr. 28-30, 1958.

Published in *Science*, v. 127: 1061, May 2, 1958.

In the early gold-rush days of quantum mechanics, the effort of theoretical physicists was largely concentrated in applying the new theory to the problem of the basic structure of atoms, molecules, solids, and liquids. Great advances were made, but quantitative progress toward understanding the electronic structure of extranuclear matter was frustrated for all but the simplest cases by the immensely complicated and laborious computations needed. The development of computationally practicable expressions for certain very difficult integrals has gone far recently toward breaking this computational bottleneck. A still more important new factor has been the programming for large electronic digital computers of the otherwise still excessively time-consuming numerical computation of these integrals. In our laboratory, machine programs have been completed for this purpose and for additional steps needed to obtain fairly good molecular wave functions for simple molecules. With these wave functions available, various molecular properties can be computed, and fundamental understanding of molecular and solid structures and of intermolecular forces can be advanced immensely. Computations on radicals, ions, and excited and activated states of molecules, which often are experimentally little accessible, will be especially valuable. We in this laboratory are now working in these directions. We believe the investigators in this field have crossed the threshold of a new era in the application of quantum mechanics to molecular physics and quantum chemistry.

IMPROVED MOLECULAR ORBITALS (COMPUTATIONS ON H_2), by P. E. Phillipson and R. S. Mulliken.

[1958] [2]p. incl. tables. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)-471 and National Science Foundation) Unclassified

Published in *Jour. Chem. Phys.*, v. 28: 1248-1249, June 1958.

Molecular orbital calculations using LCAO approximations have been carried out for the singlet and triplet excited states of H_2 using six values of the internuclear distances. It has been found that by means of selecting separately adjustable values of the parameter ζ for each molecular orbit the LCAO approximations yield better than expected agreement with self-consistent field molecular orbitals.

MOLECULAR STRUCTURE OF EPOXY POLYMERS AS A BASIS FOR ADHESION, by H. Alter and W. Soller. Mar. 27, 1957 [29]p. incl. illus. diagrs. table, refs. (Technical rept. no. 1) (AFOSR-TN-57-279) (AF 18(600)1141) AD 126580 Unclassified

Also published in *Indus. Engineering Chem.*, v. 50: 922-927, June 1958. (Title varies)

The adhesion properties of epoxy polymers were studied by means of the Cincinnati ultracentrifugal adhesion tester. The procedure involved dissolving Shell Epon 1001 in a mixture of organic solvents and curing the solution with amine curing agents. Samples of the polymer solution were dried, baked, and used to coat the replicate rotors of the ultracentrifuge. The rotors were made of 4340 steel and treated to yield a hardness of 50 to 52 Rockwell C. Before coating, the rotors were highly polished to effect the smooth surface desirable for a strong joint. The results indicated that in certain cases, adhesion was independent of the initial concentration of the polymer and of the extent of cure when coated, and that there was a minimum of adhesion at a viscosity of about 400 centipoise. The results of coating at constant polymer concentration with changing chain length indicated that adhesion decreased sharply with viscosity if the viscosity increase was due to the increasing chain length. If the chain length was constant and the concentration was increased, the adhesion increased with viscosity. Adhesion was inversely proportional to the amine content and could be changed by as much as 200 to 300 psi by changing the structure of the cured mass. Adhesion increased greatly when diethylene triamine was replaced by hexamethylene diamine as the curing agent, because the latter increased the flexibility of the cured polymer. A study of the isotherms of Frisch (*Jour. Phys. Chem.*, v. 57: 584, 1953, *ibid.*, v. 58: 507, 1954) and of Hobden and Jellinek (*Jour. Polymer Science*, v. 11: 356, 1953) indicated similarities between the factors governing adsorption and adhesion. (Contractor's abstract)

In view of the results of the experiments described in this report, two definite conclusions can be stated: (1) that the Davidson-Cole equation has broad application in the field of glassy state dielectric dispersion; and (2) that the favorite whipping boy for deviations from Debye behavior, namely dipole-dipole interactions, may not be blamed here. The first of these conclusions cautions investigators against accepting sparse data as indicating either the Debye equation or the Cole-Cole equation, since positive differentiation between these and the Davidson-Cole equation is difficult unless the manner in which the Cole-Cole plot approaches the axis of reals at ϵ_0 and ϵ_∞ is known. Judging from the materials investigated to date this involves measurements over a frequency range extending at least two decades on either side of the frequency corresponding to maximum loss factor. The second conclusion suggests that advancement of the general theory will best be served by turning consideration from detailed effects of local structure on the local field, and toward other approaches, such as the solution of the equations arising from Fröhlich's model when the frequency of activating collisions is not large compared to that of the applied field.

Double dienes and double dienophiles have been found to be capable of giving polymers in the Diels-Alder reaction. Most of the polymers were very insoluble materials with high softening or decomposition points. Their insolubility prevented molecular weight studies save in a few cases where probably lower molecular weight material was involved. In such cases the molecular weights were about 3,000. The bis-maleimides prepared for making the polymers were found to be cross linking agents in free radical copolymerizations although they have not been polymerized by themselves. Tetrachlorofulvenes were discovered to be inert in the Diels-Alder reaction. When p-6(1,2,3,4-tetrachloro)fulvylphenyl p'maleimidobenzoate was prepared the compound did not react with itself to give a polymer as hoped but was perfectly stable. It was red in color due to the fulvene structure and copolymerization with vinyl acetate gave a beautiful red polymer due to the polyfulvene units in the chain. Use of this compound and others like it to give colored copolymers is suggested. Many hitherto unknown compounds have been prepared in the course of this investigation. Samples of the bis-maleimides have been requested by Dr. Howard Bond of the U.S. Public Health Service for testing against cancer and some of these have been supplied. This type of compound is considered to be potentially good and the Public Health Service is starting a research program elsewhere solely to produce bis-maleimides for cancer testing.

The hydrogenations of some alkyl fluorides, chlorides, and bromides were studied with a catalyst consisting of PD on activated charcoal. Iso-PrF was quantitatively hydrogenated at 155°C to give C_3H_8 and HF. PrF was more difficult to hydrogenate. When a new and active catalyst was used, the reaction was quantitative at

COL.02:007 - COL.02:010

temperatures of 190°C and above. The maximum conversion of MeF and EtF to CH_4 and C_2H_6 was 10% at 240°C. At 240°C, 99.5% of MeCl was converted to CH_4 and HCl. Both EtCl and vinyl chloride hydrogenated easier than MeCl. MeBr, EtBr, PrBr, and iso-PrBr hydrogenated readily at 240°C. Catalytic hydrogenation of some simple olefins containing F, Cl, and Br occurred at a lower temperature than those involving the alkyl halides by being quantitative between 100° to 130°C. 1, 1-dichloro-2,2-difluoroethylene was reacted with H in a 1:5 molar ratio of 90°, 120°, 180° and 240°C. The reaction product formed at 90°C contained a small amount of a high-boiling material which could not be identified. The product at 120°C distilled over at -25°C; only a trace of high-boiling material was present. At 180° and 240°C, small amounts of HF were produced. After distillation, the materials obtained at 180° and 240°C contained 99.4 and 97.1% CF_2HCH_3 , respectively.

A second component boiling at -84°C was obtained. In a second series of runs at 120°C, a deficiency of H was used and the ratio of H to organic was varied. The substitution of H for Cl occurred before the H added to the double bond; no $\text{CF}_2\text{H-CH}_3$ was formed. Cl which is attached to an unsaturated C atom can be more readily substituted than if a saturated compound is involved.

REACTION HEATS OF ORGANIC HALOGEN COMPOUNDS. IX. THE CATALYTIC HYDROGENATION OF VINYL AND PERFLUOROVINYL BROMIDE, by J. R. Lacher, A. Kianpour and others. [1957] [2]p. incl. tables. (AF 18(600)1151) Unclassified

Published in Jour. Phys. Chem., v. 61: 1125-1126, Aug. 1957.

This paper deals with the catalytic hydrogenation of vinyl bromide and perfluorovinyl bromide. In the case of vinyl bromide, the reaction was quantitative, and calorimetric measurements could be carried out. In the case of the perfluoro compound, the activity of the catalyst varied. Initially the catalyst was sufficiently active to replace the bromine and saturate the double bond. With increasing use, it would continue to replace the bromine, but it would become less effective in saturating the double bond. Accurate calorimetric data could not be obtained.

Thermochemistry of organic halogen compounds: Catalytic hydrogenation reactions were performed on $\text{CClF}_2\text{CClF}_2$, CClF_2CF_3 , CCl_2F_2 and $\text{CCl}_2\text{FCClF}_2$. A few experiments were conducted on the hydrogenation of CH_3Cl and CH_2Cl_2 . An instrument which was constructed for the chromatographic analysis of gaseous products consisted of a carrier gas flow system, sampling system, chromatography columns, the sensing system. Each reaction was tested in a pilot plant in order to determine the nature and activity of a suitable catalyst, the correct rate of flow and optimum proportion reactants, and the best temperature. Photochemical studies: The polymerization of olefinic compounds was studied under the influence of UV light. The rate of the photochemical addition of Cl to trifluorochloroethylene was investigated at 3 different temperatures; a mechanism is proposed for the reaction at room temperature. Experiments were conducted on the reaction between Cl, O, and $\text{CF}_2 = \text{CFCI}$, which appeared to be a chlorine-sensitized oxidation of the olefin. The experiments were made in both static and flow systems. The gaseous mixtures appeared to undergo a rapid reaction in the dark with the production of light. The photobromination of trifluorobromoethylene was also studied. Preparation of organic compounds: Preparations are discussed of the compounds for calorimetric and photochemical studies and those prepared for the Bureau of Mines, the latter including benzyl fluoride, m-trifluoromethyl benzoic acid, and the 2,2'- and 4,4'-difluorobiphenyls.

ON PARABOLIC CONVERGENCE REGIONS FOR CONTINUED FRACTIONS, by W. J. Thron. [1958] 13p. (AFOSR-TN-58-289) (AF 49(838)100) AD 218710; PB 135988
Unclassified

Also published in Math. Zeitschr., v. 89: 173-182, 1958.

The author continues his study of parabolic convergence regions for continued fractions $a_1/1 + a_2/1 + \dots$. There is obtained an estimate of the error committed if the continued fraction is replaced by one of its approximants, a result which also gives information concerning the factors that influence the rapidity of convergence. A convergence neighborhood is found in which the convergence is proved uniform, even though the elements a_n are functions of any number of variables. Among other convergence theorems proved here, two results are established in which the a_n lie in different parabolas for different values of n. (Math. Rev. abstract)

and filter theories to guidance problems, recent developments in fixed and adaptive filtering, practical problems encountered in missile guidance and control design, application of methods of science to the problem of reliability reliability of guided missiles, laboratory vs flight evaluation of airborne guidance components, trends in field testing of guided missiles, low signal level missile instrumentation, on the way to automated processing of flight measurement, and paper on the guidance and control of missiles.

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 30, Jan. 30, 1957.

Approximately 1 μ g of I^{125} has been obtained by bombardment of tellurium by deuterous [$Te^{125}(d, 2n)I^{125}$ and $Te^{124}(dn)I^{125}$] and chemically synthesized into CH_3I^{125}

The absorption spectra of this molecule was then examined with a conventional stark modulated microwave spectrometer. Five absorption lines have been observed which can be fitted into a quadrupole hyperfine structure pattern of the $J = 2 - 1$ rotational spectrum assuming a nuclear spin for the I^{125} of $5/2$. The resulting quadrupole coupling constant is 2179.5 ± 1.0 mc, giving a ratio of quadrupole moments $Q_{125}/Q_{127} = 1.1270 \pm 0.0005$. The shift of the rotational frequency due to the isotopic substitution of I^{125} was 49.3 ± 5 mc in good agreement with that expected. The observed values of spin and quadrupole moment suggest a $d_{5/2}$ configuration for the ground state of the I^{125} nucleus similar to that of I^{127} . Preliminary measurements on the magnetic moment of I^{125} by Zeeman effects on the microwave spectrum also indicate this configuration. This technique is also being applied to determine the moments of other radioactive iodine nuclei.

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 44, Jan. 30, 1957.

Nuclear mass ratios determined from molecular spectra must be corrected for the contribution of higher electronic states induced by the rotation of the molecule. This correction can be made through a measurement of the molecular magnetic moment. To this end, measurement of the rotational frequencies of six isotopic species of CO have been made to an accuracy of about 0.004 mc near 110 000 mc and measurements of the magnetic moment of four isotopic species to an accuracy of about 1/5%. The correction to the nuclear masses calculated from the magnetic moment reduces the discrepancy between the presently measured $C^{14} - C^{12}$ mass difference (the worst case) and the mass difference calculated from nuclear reaction data from approximately 300 micro-mass units to about 40 micro-mass units. This remaining discrepancy is far outside the errors involved. A preliminary investigation of the effects of higher order perturbations on the electrons fails to disclose any explanation for this anomaly.

SOME MOMENTS OF RADIOACTIVE IODINE NUCLEI (Abstract), by P.[C.] Fletcher and E. Amble. [1957] [1]p. (Sponsored jointly by Signal Corps, Atomic Energy Commission, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64630])
Unclassified

microwave frequency is at the resonance center. Hence, for small E_2 , P is proportional to E_2 . In contrast to this situation, in a one cavity system the emitted power is proportional to E^2 for small E . Now if the cavity loss is proportional to E^2 , it can be shown that in the latter case, a threshold value for N is necessary to obtain a self-sustained oscillation. However, in a two cavity system, radiation is obtained in the second cavity for any value of N . The main ammonia 3-3 line and its magnetic satellites are observed experimentally.

FLUCTUATIONS IN AMPLIFICATION OF QUANTA WITH APPLICATION TO MASER AMPLIFIERS, by K. Shimoda, H. Takahashi, and C. H. Townes. [1957] [15]p. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-ac-64630] Unclassified

Published in Jour. Phys. Soc. Japan, v. 12: 686-700, June 1957.

Fluctuations in the amplification and absorption of waves by quantum processes are considered. Assuming for each quantum the probability (per unit time) a of producing another quantum, probability b of being absorbed, and assuming a probability c that a new quantum is introduced, a set of differential equations is obtained. By solving these equations, a complete expression for the probability of distribution of quanta is obtained, as well as expressions for the average values and fractional fluctuation. The expressions developed are applied in particular to maser-type amplifiers, and certain fluctuations in the amplification of electromagnetic waves are pointed out which are important when their quantum character becomes significant. This condition can occur in maser-type amplifiers, where thermal and extraneous noises may be very small. For such an amplifier, a is proportional to the number of excited molecules, whereas b consists of a term proportional to the number of molecules in the ground state plus terms due to certain other losses. The noise temperature of a maser-type traveling-wave amplifier is the "effective temperature"

$a(a-b)^{-1}h\nu/k$. In superregenerative and regenerative amplifiers using resonant cavities, the noise temperature is rather similar, if losses through the input coupling hole are excluded from b . In any case, the limiting noise for an ideal amplifier corresponds to a classical noise temperature of $h\nu/k$. (Contractor's abstract)

ELECTRONIC STRUCTURE OF OXYGEN BONDS IN MOLECULES (Abstract), by M. J. Stevenson. [1957] [1]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-ac-64630]) Unclassified

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 10-14, 1957.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts. 1957, p. 52.

The quadrupole hyperfine structure due to the O^{17} nucleus observed in microwave rotation spectra gives information on the bonds of various molecules containing oxygen. The value of the O^{17} quadrupole moment obtained from a measurement of the quadrupole coupling constant in HDO^{17} is $-.03 \pm .01 \times 10^{-24} \text{ cm}^2$, about six times greater than the value accepted thus far.

Therefore, the quadrupole spectrum of O^{17} should be resolvable in most molecules. The measurement of the hyperfine structure in the HDO^{17} rotational spectrum

yields $e \left(\frac{\partial^2 V}{\partial a^2} \right)_{\text{ave}} Q = -10.3 \text{ mc}$. A larger amount of

hybridization than previously expected is indicated by the small value of the asymmetry parameter $n = 4.72$. The molecular orbital calculations of Ellison and Shull will be compared with the experimental data. Nethercot and Rosenblum have obtained $eQ = +4.43 \text{ mc}$ for CO^{17} . This result is in disagreement with the MO calculations for CO, with the generally accepted valence bond picture of CO, and also with the measured eQ of OCS. Large amount of hybridization of the $2p\sigma$ oxygen orbital or inclusion of π bonded $C^+ - O^-$ structure is necessary to obtain the experimental value of eQ in CO. A comparison of the experimental and theoretical data on several molecules containing oxygen will be made.

COU.02:029 - COU.02:033

The nuclear quadrupole hyperfine structure resulting from O^{17} has been measured by A. H. Nethercot, Jr., and B. Rosenblum in the rotational microwave spectrum of the molecule CO^{17} . They find a quadrupole coupling constant eqQ which is positive in sign and appreciably larger than that found in OCS. Since neither its sign nor its magnitude can be reconciled with the present value of the quadrupole moment Q of O^{17} and accepted electronic structure of CO, the microwave spectrum of HDO^{17} is being investigated. Hyperfine structure in the rotational transition $2_{20} - 2_{21}$ has been observed. Its analysis should yield a determination of the quadrupole moment of O^{17} with more certainty than is allowed by the spectrum of OCS or CO because of the relative simplicity in the evaluation of field gradients from the electronic structure of HDO.

COMMENTS ON FREQUENCY-PULLING OF MASER OSCILLATORS, by C. H. Townes. [1957] [2]p. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-64630]) Unclassified

Published in Jour. Appl. Phys., v. 28: 920-921, Aug. 1957.

In a beam-type maser oscillator the cavity tuning "pulls" the oscillation frequency from the resonance frequency

v_0 of the molecules by an amount $(v-v_0)\alpha(n)$ which is of the order of unity, where n is the number of molecules entering the cavity per sec. For a Maxwellian distribution of velocities, Helmer and Lamb (Stanford U. Microwave Lab. Rept. no. ML-311, 1956) showed that $(v-v_0)$ increases initially as n increases, but Helmer's experimental results do not confirm this. The author briefly discusses the physical origin of the increase in $(v-v_0)$ and indicates a possible reason for its non-observance.

In a three-level maser, a transition between two energy levels is saturated in order to produce an induced emission of power at a lower frequency corresponding to a transition between an intermediate energy level and one or the other of the two saturated levels. In this paper, certain effects are discussed which cannot be predicted from a theory in which the population differences alone are considered in this process. For instance, it is shown that, in some cases it is possible to obtain for the same system an induced emission of power at two frequencies given by the resonances between the intermediate energy level and both of the saturated levels. Also, it is shown that, even in the absence of inhomogeneous broadening of the spectral line, one can obtain a net induced emission at some portions of a resonant line and a net absorption of other frequencies within the line widths. Such effects become important even in early stages of saturation in cases where $T_1 = T_2$ which is true

for ordinary gaseous systems and individual spin systems in a majority of very dilute paramagnetic solids. A complete theory is discussed for a gaseous system and extended to two limiting cases of paramagnetic materials with $T_1 = T_2$ and $T_2 < T_1$ for each individual spin system.

Furthermore, it is shown that for a saturating field of fixed frequency, the integral of induced power over the entire line is in full agreement with the results of a semiclassical treatment in which the population differences alone are considered. Some remarks are made as to the practicability of certain systems of this type. (Contractor's abstract)

COU.02:038; COU.19:001, 002

Coherent amplification of an electromagnetic wave as a result of interaction with matter can be shown to be impossible if the matter is in thermal equilibrium at any positive temperature. For an ensemble of systems with discrete energy levels, such equilibrium implies: (1) the population of one energy level is greater than that of a second level if its energy is lower; and (2) random phases of the systems. If either of these requirements are violated, the ensemble becomes unstable, and interaction with an electromagnetic wave may allow the ensemble to give up energy to the wave through stimulated emission, thus amplifying the wave.

The separation in energy (S) between the $2^2S_{1/2}$ and $2^2P_{1/2}$ states of singly ionized helium has been measured to high precision by a microwave method. Helium atoms in a resonant cavity are excited to the $2^2S_{1/2}$

state of the ion by bombardment with 300-v electrons. Rf power is applied to induce transitions between the two states and the 40.8-ev photon which arises from the decay of the $2^2P_{1/2}$ state to the $1^2S_{1/2}$ ground state of the ion is detected by a photomultiplier tube. A method of synchronous detection is employed to improve the signal-to-noise ratio. Twenty-six determinations of (S) have been made under differing experimental conditions in an attempt to uncover sources of systematic error. The value of (S) obtained for He^+ is $14\ 040.2 \pm 4.5$ mc/sec. The uncertainty is equal to three times the standard deviation plus an estimated 1.3 mc/sec for the uncertainty in various systematic corrections. The result is in agreement with previous determinations but differs significantly from the best available theoretical value of $14\ 056.8 \pm 3.0$ mc/sec. It is shown that this discrepancy might be resolved, without impairing the excellent arrangement in hydrogen, by a theoretical relativistic term of the form $\alpha(\alpha Z)^6 \ln(\alpha Z)$. Precision measurements of the $J = 1 - 0$ rotational frequencies and the molecular magnetic moments for various isotopic species of carbon monoxide have been made in order to determine isotopic mass ratios. A correction amounting to several hundred micromass units and evaluated from the magnetic moment has been applied for the fact that the electrons are not spherically distributed about their respective nuclei. It is also shown that the rapidly precessing electronic angular momentum causes a "wobbling" motion of the nuclei which in turn produces a stretching of the molecule ("wobble stretching") inversely proportional to the reduced mass of the molecule, but independent of J . This stretching cannot be accurately evaluated from theory and therefore appears to be the ultimate limitation on microwave determinations of mass ratios. This correction amounts to about 20 micromass units and is evaluated by the use of the nuclear reaction value for the $C^{14}-C^{12}$ mass ratio. The final mass ratios agree very closely with the nuclear reaction values. The sign of the electric dipole moment was determined from the relative magnetic moments of the several isotopic species and corresponds to the charge distribution, C^+O^- . This appears to be the first measurement of the sign of the electric dipole moment in any molecule. (Contractor's abstract)

Published in Phys. Rev., v. 109: 302-311, Jan. 15, 1958.

A series of experiments using paramagnetic resonance at microwave frequencies and in the 1-4°K temperature range on $Gd_2Mg_3(NO_3)_{12} \cdot 24H_2O$, $K_3Cr(CN)_6$, and $Cu(NH_4)_2(SO_4)_2 \cdot 6H_2O$ indicate the following characteristics for their relaxation: (1) It is the lattice-bath relaxation which limits the total rate of relaxation. (2) The spin-lattice relaxation time is several orders of magnitude smaller than the normally observed values of T_1 . (3) Breadth of the lattice modes is very much larger than the width of the resonances in diluted crystals, and in particular, for 1% paramagnetic concentration of the Cu salt, the breadth is several hundred of megacycles/sec. (4) Breadth of the lattice modes increases with increasing concentration of paramagnetic centers. (5) Two nearby resonances are rapidly brought to the same effective temperature by exchange of energy through the lattice modes. (6) The relaxation time T_1 is dependent on crystal size. Some consequences of these results are also discussed.

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 28, Jan. 29, 1958.

The rotational transition $J = 2 - 1$ has been observed for the molecule ClCN, using the maser techniques developed for ammonia. Since the population distribution of the molecules over the relevant quantum states is less favorable than for ammonia, a considerably more sensitive microwave detection system has been developed. The electric quadrupole coupling of the Cl and N produces a hyperfine structure for this transition; the observed line widths are of the order of 1.5 kc/sec. The detection system consists of a superheterodyne, phase sensitive amplifier with a band width of about one cycle. The power source is a stabilized klystron, swept at a slow rate over a range of about 10 kc/sec. A well stabilized klystron is essential for this type of spectroscopy. The klystron used has a long term stability sufficient for use with much narrower band widths, and a short term stability of better than 200 cycles/sec. In order to obviate the difficulties caused by the broadness of a conventional frequency standard marker, the frequencies of the observed lines are being measured using

the maser oscillation of the ammonia 3,3 inversion line as a standard. The measurements in progress will permit the calculation of the I-J coupling constant for the first time.

Unclassified

Published in Phys. Rev., v. 109: 1572-1589, Mar. 1, 1958.

The present experiment has yielded accurate information concerning the internuclear distances, rotational constants, vibration-rotation interaction constants, and the quadrupole coupling constants of the Tl, In, and Ga monohalides. The ionic character for diatomic halides involving Group IIIB elements is less than that for the alkali halides, in keeping with their greater electronegativity. The values of s character found for the Ga and In bonding orbitals, argue strongly for the presence of s-p hybridization in the ionic state. The quadrupole coupling data presented here show that the electronegativities of Tl, In, and Ga are the same and approximately equal to 1.4 which is in agreement with Gordy's values.

SPIN AND QUADRUPOLE MOMENT OF I^{125} AND THE MAGNETIC MOMENT OF I^{131} , by P. C. Fletcher and E. Ambler. [1958] [3]p. incl. illus. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-73279])
Unclassified

Published in Phys. Rev., v. 110: 536-543, Apr. 15, 1958.

The spin and quadrupole moment of I^{125} have been determined by observations on the microwave absorption spectrum of CH_3I^{125} . Five absorption lines have been observed which fit the quadrupole hyperfine pattern of the $J = 2 - 1$ rotational spectrum. The measurements indicate a spin of 5/2 and a quadrupole coupling constant of -2179 ± 1 mc/sec. Using this and other properties of the CH_3I molecule, the quadrupole moment of I^{125} is calculated to be $-0.66 \times 10^{-24} \text{ cm}^2$. This spin and quadrupole moment suggest a nuclear configuration for I^{125} similar to that of stable I^{127} , i.e., predominantly

COU.19:006 - COU.19:008

$d_{5/2}$. The magnetic moment of I^{131} has been measured by observation of the Zeeman splitting of the $F = 9/2 - 9/2$ ($K=1$) hyperfine line of the $J = 2 - 1$ rotational spectrum of CH_3I^{131} . The magnetic moment is found to be 2.56 ± 0.12 nuclear magnetons. The observations also confirm the previous results of Gordy et al for the spin of I^{131} of $7/2$ and quadrupole coupling constant, $eqQ = -974 \pm 1$ mc/sec. The magnetic moment measurement suggests a ground-state configuration similar to that of I^{129} which is predominantly $g_{7/2}$ in nature but with large admixture of other states. The significance of these results are discussed. (Contractor's abstract)

DESCRIPTION OF A RAMAN TYPE TWO-LEVEL MASER (Abstract), by A. Javan. [1958] [1]p. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-73279] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 213, May 1, 1958.

In a two-level system, if two photons of different frequencies are present with their frequency difference close to the energy separation of the two levels, in the presence of proper types of matrix elements, a transition can take place from the lower level to the upper

level in which the larger frequency photon is absorbed and the lower frequency photon is emitted. In the reverse transition, the role of absorption and emission of the photons is interchanged. This process, in the presence of a positive temperature, will produce amplification at the lower frequency. This effect will be treated quantum mechanically, and the probability of the spontaneous emission entering in the noise figure of this type of amplifier will be derived. Also the formula for magnetic susceptibility at the amplifying frequency for a paramagnetic ion of spin $\frac{1}{2}$ in an external magnetic field will be presented. The theoretical and practical application of this system to special cases of ferrites and systems with electric or magnetic dipole transitions will be discussed.

MOLECULAR BEAM STUDIES OF METASTABLE STATES OF MERCURY (Abstract), by W. Lichten and M. McDermott. [1958] [1]p. [Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-73279] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 186, May 1, 1958.

The atomic beam magnetic resonance method is being applied to measurements of the properties of the metastable electronic states of mercury. A beam of mercury atoms in the ground state is subjected to electron bombardment. A fraction of the atoms are excited to metastable states. All atoms are refocused upon a stop wire by the A and B deflecting magnets. Atoms undergoing a transition in the C region are defocused and strike a sodium coated secondary emission detector. The transitions $\Delta F = 0$, $\Delta m_F = \pm 1$ have been observed for the even isotopes and for all the hyperfine levels of the odd isotopes of mercury in the $(6s, 6p)^3P_2$ state. In particular, the signal to noise ratio in the single transition Hg^{201} , $F = 1/2$, $\Delta m_F = \pm 1/2$, indicates that measurements of the hfs are feasible. These measurements are in progress. Transitions $\Delta F = 0$, $\Delta m_F = \pm 1$ have been observed for another metastable state of mercury lying at higher energy, with $J = 3$, $g_J = 1.09 \pm 0.02$. These observations confirm an earlier report which indicated that the $(5d)^9(6s)^2 6p^3D_3$ state is metastable.

HYPERFINE STRUCTURE OF THE METASTABLE STATE OF SINGLY IONIZED HELIUM-3, by R. Novick and E. D. Commins. [1958] [19]p. incl. illus. diagrs. tables, refs. (Sponsored jointly by National Science Foundation, Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under [DA 36-039-sc-73279]) Unclassified

Published in Phys. Rev., v. 111: 822-840, Aug. 1, 1958.

The hfs splitting $\Delta\nu$ of the metastable state of singly ionized helium 3 is determined by an ion-beam method. The conventional inhomogeneous molecular-beams A and B fields are replaced by radio-frequency fields at 13 350 mc/sec. At this frequency transitions are preferentially induced between the $F = 1$ component of the $2^2S_{1/2}$ state and the short-lived $2^2P_{1/2}$ state. All those

ions which have made the transition decay immediately to the ground state. Thus, as the beam passes through such a field, state-selection is accomplished by selective quenching of the $F = 1$ metastable ions. Two types of detection have been used: photoelectric detection of the Lyman-alpha photons emitted in the second state selector, and metastable ion detection by the surface Auger effect. Eighty-six determinations of the hfs splitting have been made under a range of experimental conditions. The final result is $\Delta\nu = 1083.35499 \pm 0.00020$ mc/sec. This value is compared with the theoretical hfs splitting for a point nucleus, which includes the known electrodynamic, relativistic, and reduced-mass corrections, and which may be computed precisely,

since the atomic wave function of He^{3+} is hydrogenic and known exactly. The observed hfs splitting is smaller by 186 ppm than the theoretical value. This anomaly is attributed to the effects of finite nuclear and nucleon size, higher order radiative effects, and possibly also to nuclear interaction currents. Estimates are made of some of these effects. The hfs splitting $\Delta\nu(1s)$ of the ground state of He^{3+} is estimated on the basis of the present result to be $\Delta\nu(1s) = 8665.628 \pm 0.013$ mc/sec. The experimental result is also compared with the experimentally determined hfs splitting of the $1s2s$ (3S_1) state of the He^3 atom. The ratio of these two quantities yields a precise estimate of the electronic charge density at the nucleus of the 2^3S_1 state of the He^3 atom. Finally, the monoenergetic nature of the ion beam has allowed observation of a new molecular beams resonance power sharpening effect. (Contractor's abstract)

DETERMINATION OF NUCLEAR QUADRUPOLE MOMENTS, by C. H. Townes. [1958] [77]p. incl. diagrs. tables, refs. (Sponsored jointly by Signal Corps, Office of Naval Research, and Air Force Office of Scientific Research under DA 36-039-sc-73279) Unclassified

Published in Handbuch der Physik, v. 38/1: 377-453, 1958.

Since the two classes of phenomena involve quite different techniques and different theoretical approaches, they have been considered somewhat separately. Basic theory for interaction of nuclear quadrupole moments in atomic and molecular systems is the first to be presented,

COU.20:001 - COU.20:005

followed by a theoretical analysis of the many types of experiments which allow measurement of these interactions, and discussion of methods for evaluating quadrupole moments themselves from the measured coupling constant. The general theory of interactions between nuclear quadrupole moments and fast particles is then treated, and evaluation of quadrupole moments from measurement of such interactions are discussed. Actual numerical results of all determinations of quadrupole moments have been reserved for the final sections, where some of the determinations are discussed, and values of quadrupole moments are summarized and compared.

Also published in *Nature*, v. 179: 1101-1102, June 1, 1957.

The results of 2 experiments intended to provide evidence for the "law" of conservation of parity are described, both of which involve the direction of emission of the products of decay of radioactive particles relative to the orientation of the intrinsic angular momentum or spin of these particles. Weak interactions, meson, hyperon, and beta decay are investigated in verifying the non-conservation of parity. The consequences are discussed.

Also published in *Jour. Chem. Phys.*, v. 25: 860-876, Nov. 1956.

An analysis of the velocity distribution of the molecules which escape through an ideal aperture from an isothermal enclosure has been made for ten alkali halides (CsCl, CsBr, RbCl, KCl, KI, NaF, NaCl, NaI, LiCl, and LiBr). It is found that there is a significant abundance of dimers in all cases except those of the cesium salts, and that an observable concentration of trimers occurs

for NaF, LiCl and LiBr. Observation of the relative abundances of the polymers as the temperature of the effusing gas and the pressure within the source is varied permits the determination of the energy of dissociation of the dimer into two monomers and of the trimer into a monomer and dimer. Numerical errors have been found in the calculated data which appear in table X and have been corrected and appear as an errata publication in *Jour. Chem. Phys.*, v. 27: 981, Oct. 1957. Also published in Jour. Chem. Phys., v. 30: 517-527,
Feb. 1959.

A study has been made of the evaporation of alkali halide crystals directly into vacuum to determine (1) whether or not the velocity distribution of the evaporating molecules is Maxwellian, (2) the chemical composition of the vapor, and (3) the evaporation coefficients and heats of evaporation of the various molecular species. Single crystals of CsBr, CsI, LiF, and NaCl were used. The velocities of the evaporating molecules were analyzed by means of the rotating cylindrical velocity selector used by Miller and Kusch. It was found that within relatively narrow limits of error the velocity distributions were Maxwellian. The vapor of CsI was found to contain only monomers; the others contained polymers in abundances different from those found in saturated vapors. The heats of evaporation of NaCl monomers and dimers are, respectively, 61.7 ± 4.6 and 67.2 ± 4.6 kcal/mol, which yields heats of activation for evaporation of about 9 kcal/mol. Heats of activation also exist for LiF, but could not be determined from the data. The evaporation coefficients of the CsI and CsBr monomers are about 0.3; the evaporation coefficients of the polymers of NaCl and LiF are temperature dependent and are in the range 0.2 to 1. PARAMAGNETIC RESONANCE OF METHYL- AND CHLORO-SUBSTITUTED p-BENZOSEMIQUINONES, by B. Venkataraman, B. G. Segal, and G. K. Fraenkel. Oct. 16, 1958, 37p. incl. tables, refs. (Rept. no. CU-15-58-AF-1390-Chem.) (AFOSR-TN-58-905) (AF 18(600)1390) AD 204430; PB 140317

Unclassified

Also published in Jour. Chem. Phys., v. 30: 1006-1016, Apr. 1959.

Detailed measurements were made under conditions of high resolution on the paramagnetic resonance spectra of the negative radical ions of all the methyl- and chloro-substituted p-benzoquinones. All the spectra exhibited hyperfine structure which is accounted for in terms of interactions between the unpaired electron and all the protons in the radicals. No chlorine hyperfine splittings were observed. In some of the chlorine compounds anomalous lines, not attributable to the chloro-substituted p-benzoquinone ion, appeared. Microwave power saturation was encountered in all the spectra examined. Line widths of all the spectra were observed to depend markedly on the microwave power and on the concentration of the hydroquinone from which the semi-quinone was prepared. Separations of the hyperfine components were measured to a high degree of accuracy. Splitting constants for individual protons were calculated from measurements using the

method of least squares. The variation of the splitting constants with chlorine and methyl-group substitutions are shown to obey a nearly additive relation. (Contractor's abstract)

CORRELATION FUNCTION AND POWER SPECTRA OF RADIO LINKS AFFECTED BY RANDOM DIELECTRIC NOISE, by D. S. Bugnolo. [Nov. 3, 1958] [5]p. incl. diags, refs. (Technical rept. no. T-3 Sup.; rept. no. CU-4-59AF350-EE) (AFOSR-TN-58-968a) (AF 49(638)350) AD 220409 Unclassified

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-7: 137-141, Apr. 1959.

The correlation function and corresponding power spectrum of an electromagnetic wave affected by random dielectric noise is related to the power spectrum of the source by an extension of the notions of time-variable linear networks. It will be shown that in general, the power spectrum of the received signal can be regarded as the output of a network characterized by a time-variable transfer function. The results are applied to a long line of sight radio link and used to predict the error in the received signal in a mean squared sense. This will be used to show that the rate of a source is bounded such that there exists a maximum rate R given a bandwidth δ and scattering parameters of the atmosphere. (Contractor's abstract)

MULTIPLE SCATTERING OF ELECTROMAGNETIC RADIATION AND THE TRANSPORT EQUATION OF DIFFUSION (Abstract), by D. S. Bugnolo. [1958] [1]p. [AF 49(638)350] Unclassified

Presented at IRE-URSI Symposium, Washington, D. C., Apr. 23-26, 1958.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-6: 310, July 1958.

Multiple scattering of electromagnetic radiation by atmospheric and ionospheric turbulence is of considerable importance in long line-of-sight paths. The usual single scatter or Born approximation is of questionable value in such cases. Higher order Born approximations usually lead to equations of unusual complexity incapable of exact solution. Another possible method of solution is the transport equation of particle (photon) diffusion. The results of a single scatter or Born approximation can be used to construct an integral-differential equation in a six-dimensional phase space plus time. This method is of particular use in unbounded regions. The introduction of boundary conditions is usually untenable since the approximation is essentially scalar and the boundary conditions vector. The transport equation will be reviewed briefly and applied to a number of rather interesting long line-of-sight problems.

DISCONTINUOUS MARKOFF PROCESSES, by J. E. Moyal. Apr. 1957, 55p. refs. (AFOSR-TN-57-535) (AF 18(600)442) AD 136521 Unclassified

Also published in Acta Math., v. 98: 221-264, 1957.

Consider a non-homogeneous Markov process $\xi(t)$ and a sequence of jump times $0 = \eta_0 < \eta_1 < \dots$. Let x, X

denote resp. a point and a set in the state space, $n \geq 0$,

$$x(X, t | x_0, t_0) = \Pr\{\xi(t) \in X | \xi(t_0) = x_0\},$$

$$x_n(X, t | x_0, t_0) = \Pr\{\eta \leq t \leq \eta_{n+1} | \xi(t_0) = x_0\},$$

$$\psi_n(X, t | x_0, t_0) = \Pr\{\eta_n \leq t; \xi(\eta_n + 0) \in X | \xi(t_0) = x_0\}.$$

We have then

$$(*) \quad x(X, t | x_0, t_0) = x_0(X, t | x_0, t_0) + \int x(X, t | x, \tau) \psi_1(dx, d\tau | x_0, t_0).$$

Noting that x_0 is the probability of transition without

jump, we see that the well-known development by Feller (Trans. Amer. Math. Soc., v. 48: 488-515 (1940)) corresponds to the case where there is no change of state without a jump, so that x_0 is of a specifiable form. Observe

that these so-called "jumps" may be of a prescribed kind and need not include all ordinary jumps (of the sample function). The main point of the paper is to show that part of Feller's theory can be carried over painlessly (except for notations and formalities) to the present generality. E.g., we have $x_n = x_j * \psi_{n-j}$ in understandable

notation, and $x_R = \sum_{n=0}^{\infty} x_n$ can be obtained by the same

iterative procedure and represents a solution of (*) except that it may be "incomplete". In the latter case not all possible transition is via a finite number of jumps and Doob's continuation procedure [Trans. Amer. Math. Soc., v. 58: 455-473, 1945] can also be applied, etc. Because the presentation is analytical the scope of processes covered is not delineated. (Math. Rev. abstract)

TIGHTENED MULTI-LEVEL CONTINUOUS SAMPLING PLANS, by C. Derman, S. Littauer, and H. Solomon. [1957] [10]p. incl. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)442] and Office of Naval Research) Unclassified

Published in Ann. Math. Stat., v. 28: 395-404, June 1957.

The following generalizations of an inspection plan by Sieberman and Solomon (Ann. Math. Statistics, v. 26: 686-704, 1955) for continuous production are considered. The j th sampling level is said to be in use of every

(f^{-j}) th item is sampled. If i successive inspected items are free of defects, one adopts a higher level of sampling; if one defective item is found, one adopts a lower level of sampling. The previous paper moved sampling from the j th to the $(j+1)$ st or $(j-1)$ st level, while here one can move it to the $(j+s)$ th or, on the other hand, to either the $(j-r)$ th or the zeroth level (= 100% inspection). Most of

COU.06:025-029; COU.22:001

the paper is devoted to calculating the AOQ (average outgoing quality=fraction defective after sampling) in terms of the fraction defective in the original production process and to calculating the AOQL (average outgoing quality limit=maximum possible fraction defective after sampling) in terms of the parameters of the plan, always assuming that the process is in statistical control. The results follow from certain properties of Markov chains. (Math. Rev. abstract)

COU.10:018, 019

This paper is a statement of results relating the dimension, category, and geometric dimension of a group. If Π is a group, then Π is of dimension n if the cohomology

group $H^q(\Pi; A) = 0$ for $q > n$, where A is any Π module, and n is the least such integer. Let $K(\Pi)$ be a connected CW-complex such that $\pi_1(K(\Pi)) = \Pi$, and $\pi_q(K(\Pi)) = 0$

for $q > 1$, i.e., $K(\Pi)$ is a connected aspherical CW-complex with Π as fundamental group. The homotopy type of $K(\Pi)$ is an invariant of the group Π . The category of Π is defined to be the category of the complex $K(\Pi)$. The authors' definition of category differs from the usual one. They say that X is of category n , if n is the least integer such that X may be covered by open sets U_0, \dots, U_n such that each U_i is contractible in X . If no such integer exists, then the category of X is ∞ . Note that this is just the usual definition of category $n + 1$. Finally, the authors define the geometric dimension of a group Π as the least integer n for which there is a connected aspherical CW-complex $K(\mathbb{S})$ with Π as fundamental group which is of dimension n . Otherwise the geometric dimension of Π is ∞ . The main theorem of the paper is as follows. For any group Π

$$\dim \Pi = \text{category } \Pi = \text{geom. dim } \Pi$$

except possibly for the following three cases:

	A	B	C
dim	1	1	2
category	2	2	2
geom. dim	2	3	3. (Math. Rev. abstract)

ON THE DIMENSION OF MODULES AND ALGEBRAS, VIII. DIMENSION OF TENSOR PRODUCTS, by S. Eilenberg, A. Rosenberg, and D. Zelinsky. [1957] [23]p. incl. refs. (AF 18(603)67) Unclassified

Published in Nagoya Math. Jour., v. 12: 71-93, Dec. 1957.

A method using spectral sequences is applied to a study of the dimension of the tensor product $A \otimes_k \Gamma$ of two K -

algebras. Results are obtained when Γ is a ring of matrices, triangular matrices, polynomials or rational functions, so that in the first three cases $A \otimes_k \Gamma$ is,

respectively, the ring of matrices, triangular matrices or polynomials with coefficients in the arbitrary algebra A . Similar techniques yield additivity theorems for the dimensions associated with a tower of three algebras when one of the extensions is special. The domain of semi-primary rings is treated for the case when Γ is semi-simple.

THEORY OF TIME-VARYING SAMPLED-DATA SYSTEMS, by B. Friedland. Apr. 15, 1957, 204p. incl. diagrs. tables, refs. (Technical rept. no. T-19/B; rept. no. CU-31-57AF677-EE) (AFOSR-TN-57-183) (AF 18(600)677) AD 126478 Unclassified

Some of the theoretical aspects of linear, time-varying sampled-data systems are discussed. Chapter II shows that components may be characterized by means of infinite, triangular transmission matrices, H , and signals by means of infinite signal vectors, x . Extensions of the Z-transform (generating function) method commonly used for fixed sampled-data systems are discussed in Chapter III. A particularly convenient method of dealing with periodically varying systems is presented in Chapter IV. The design of time-varying filters for the least squares filtering and prediction of sampled random data is discussed in Chapter V. Appendices summarizing some of the classical theory of difference equations and Z-transforms are included.

DIGITAL CONTROLLERS IN FEEDBACK SYSTEMS, by J. R. Ragazzini. Mar. 15, 1957, 29p. incl. diagrs. table, refs. (Technical rept. no. T-18/B; rept. no. CU-30-57AF677-EE) (AFOSR-TN-57-205) (AF 18(600)677) AD 126502 Unclassified

Linear feedback control systems can be stabilized and compensated by means of digital controllers designed to implement a linear recursion formula. The constants in this recursion formula are chosen in such a manner as to produce a stable system whose stability is not dependent on a perfect knowledge of the system constants.

COU.10:020 - COU.10:023

This condition is achieved by including in the zeros of the overall pulse transfer function those zeros of the plant which have a magnitude equal to or greater than unity. Steady state response is controlled by causing the error sequence to tend toward zero in the steady state in response to test functions usually steps, ramps or constant accelerations. Finally, acceptable transient and ripple is achieved by applying design criteria which fulfill the specifications. Depending on which criterion is most important, minimum settling time, flexibility in response to a number of inputs or ripple-free operation, design techniques are available. Further flexibility in design can be attained by accepting digital controllers containing more than the minimum number of storage elements.

GENERAL SYNTHESIS PROCEDURE FOR COMPUTER CONTROL OF SINGLE AND MULTI-LOOP LINEAR SYSTEMS, by R. E. Kalman and J. E. Bertram. Aug. 10, 1957, 1v. incl. diags. table, refs. (Technical rept. no. T-20/B; rept. no. CU-33-57AF677-EE) (AFOSR-TN-57-504) (AF 18(600)677) AD 136587 Unclassified

Also published in Trans. Amer. Inst. Elec. Engineers, v. 77 (Part II): 602-609, Jan. 1959.

This paper is concerned with the problem of designing optimal systems for the control of a plant governed by a linear differential equation with constant coefficients. Control is exerted by means of piecewise constant signals which can change only at the "sampling instants". Optimality means here, as in some nonlinear problems, that the system achieves equilibrium with zero steady-state error from any initial state as quickly as possible. The sequence of signals required for optimal control in the above sense is usually a linear combination of the state variables of the plant being controlled. In the simplest regulator problem when all state variables are accessible, the optimal system is realized by a very simple multi-feedback arrangement in which the only unconventional component is the sample-and-hold element. When some states are not accessible, when the plant includes time delays, or when dealing with a followup problem, the physical realization of optimal control requires real-time analog or digital computation. The requirements of machine computation for control purposes are derived here in a general way; the theory presented includes as special cases many commonly used methods for control system synthesis. Also published in I.R.E. WESCON Convention Record, Pt. 4: 157-165, 1957.

This paper extends the standard methods of Z-transforms to problems (a) which arise when sampling switches close for a duration time which is too long for the process to be adequately described by impulse modulation, and (b) which arise when the sampling switches operate at different sampling rates. In the case of the finite width sampling it is shown that the sampler can be approximated to any degree of accuracy by a set of paralleled, idealized switches followed by triangular holds. The problem of having samplers operating at different sampling rates is treated similarly. Each sampling switch is replaced by an equivalent system of switches in parallel, all switches operating at the same rate. Having replaced the original feedback systems by their equivalent models, Z-transform methods are then applied to obtain the transfer characteristics from which stability of these systems can be studied. AN EXTENSION OF THE SAMPLING THEOREM TO THE CASE WHERE THE FREQUENCY SPECTRUM OF THE TIME FUNCTION EXISTS IN A FINITE NUMBER OF DISCRETE BANDS, by P. Oden and J. Gilmm. Sept. 15, 1957, 16p. incl. diags. (Technical rept. no. T-22/B; rept. no. CU-36-57AF677-EE) (AFOSR-TN-57-716) (AF 18(600)677) AD 136709 Unclassified

It is shown that a function of time whose Fourier transform is non-zero only in a finite number of frequency bands can be exactly reconstructed from its value at a select number of sampling points which occur at an average frequency equal to the sum of the frequency bands along the positive and negative frequency axis. If the Fourier transform of the time function is symmetrical about the frequency origin, the sampling frequency is given by twice the sum of the band widths along the positive frequency axis.

Also published in Trans. Amer. Inst. Elec. Engineers, v. 77(Part II): 75-81, May 1958.

Presented at Winter General meeting of the AIEE, New York, N. Y., Jan. 21-25, 1957.

Also published in Trans. Amer. Inst. Elec. Engineers, v. 76 (Part II): 28-31, Mar. 1957.

The problem considered is that of steering a missile toward a target by means of a closed-loop control system. The control system has a device which obtains samples of the system error (the angle between the line of sight and the actual heading) at a uniform rate. These samples are shaped by a steering controller and passed into a zero order hold circuit. The output of this hold circuit is steering command of the missile. The rudder is assumed to respond without delay to the steering command. The computations indicate that the system may be expected to perform reasonably well without compensation if at least 4 sampling intervals are available during the interception period and if the loop gain is properly adjusted. A compensator which ensures that there will be no terminal error may be realized by using only fixed components and amplifiers with time-varying gain.

A method is developed for the systematic synthesis of multiple control systems which is based on the application of certain system constraints. These constraints reduce the degrees of freedom of the system without, however, resulting in an undue restriction on system performance. A system transfer matrix is described which characterizes the system. Through the application of the constraints it becomes possible to solve this matrix for the controller transfer functions required to achieve specified performance. This permits the synthesis of multiple control systems in a manner similar to that presently possible for single-input and single-output system. (Contractor's abstract)

INPUT-OUTPUT ANALYSIS OF MULTIRATE FEED-BACK SYSTEMS, by G. M. Kranc. [1957] [8]p. incl. diagrs. (AF 18(600)677) Unclassified

Presented at meeting of the Amer. Inst. Elec. Engineers, New York, Feb. 2-7, 1958.

Presented at Western Electronic Show and Convention, Los Angeles, Calif., Aug. 1956.

Published in I.R.E. Trans. of Professional Group on Automatic Control, v. PGAC-3: 21-28, Nov. 1957.

Also published in Trans. Amer. Inst. Elec. Engineers, v. 77(Part II): 177-182, Sept. 1958.

When digital transducers are introduced into a sampled-data system, an error is produced which is a result of quantization. The error is bounded by replacing every quantizer with a unity gain element and an input which is equal in magnitude to the greatest error possible in the element. The magnitude of the output of the system resulting from all these inputs is an upper bound on the error. This bound is conservative because the signs of the error tend to alternate. The result provides a means for comparing various computing schemes and serves to select a value for the quantizing interval.

A general analytical technique described in this paper permits the extension of Z-transform methods to sampled-data systems containing synchronized switches which do not operate with the same sampling rate. Sampling periods of each switch are first expressed in the form $T/p_1 \dots T/p_n$ (where $p_1 \dots p_n$ are integers not equal to zero) and then it is shown that each switch with a period T/p can be replaced by a system of switches and advances and delay elements where each switch operates with a sampling period T . In this way, the original sampled-data system can be represented by an equivalent system containing switches operating with the same sampling rate. The general solution of such equivalent systems is outlined in this paper. (Contractor's abstract)

no. T-25/B; rept. no. CU-39-57AF677-EE) (AFOSR-TN-58-24) (AF 18(600)677) AD 148063 Unclassified

Also published in *Information and Control*, v. 1: 297-313, Dec. 1958.

The design of a linear, least squares filter or predictor H for nonstationary sampled-data is shown to entail the inversion of an $n \times n$ matrix for the n^{th} row of the "transmission matrix," H which characterizes the device. By the use of an "ensemble-shaping" technique the computation required is reduced to tractable proportions. It is shown that even when the input data is stationary the filter which is optimum for all instants (and not only in the steady-state) is a time-varying device which approaches the optimum steady-state filter as the filterizing time becomes infinite.

THE EFFECTS OF QUANTIZATION IN FEEDBACK SYSTEMS, by J. E. Bertram. Mar. 15, 1958, 68p. incl. diagrs. refs. (Technical rept. no. T-28/B; rept. no. CU-44-56AF677-EE) (AFOSR-TN-58-323) (AF 18(600)-677) AD 154227; PB 137726 Unclassified

The linear sampled data system has been formulated in terms of the state variables of the system - a set of

numbers which completely summarizes the past history of the system. Using this formulation, the solution to any arbitrary input can be expressed by means of the fundamental matrix. The equations obtained permit an easy determination of the upper bound on the error in the state variables due to quantization. The same formulation has also proved useful in obtaining sufficient conditions for global stability for several classes of nonlinearities as well as the desirable operating conditions for a random quantizer.

LINEAR MODULAR SEQUENTIAL CIRCUITS, by B. Friedland. Apr. 15, 1958, 20p. incl. diagrs. (Technical rept. no. T-29/B; rept. no. CU-45-58AF677-EE) (AFOSR-TN-58-555) (AF 18(600)677) AD 158373 Unclassified

Also published in *I.R.E. Trans. of Professional Group on Circuit Theory*, v. CT-6: 61-68, Mar. 1959.

Sequential amplifier, unit delay, and modulo p summer circuits are considered in terms of a modular field description using vectors and matrices defined on this modular field. The sequential circuit is defined in terms of the vector equations relating the input $X(n)$, the output $Y(n)$, and the state of the circuit $S(n)$ at the time of the n th observation: (1) $Y(n) = F[S(n), X(n)]$ and (2) $S(n+1) = G[S(n), X(n)]$ where F and G represent arbitrary functions. Equality is interpreted as congruence, modulo p . It is shown that linear circuits, which are represented by linear equations, meet the additivity criterion of linear systems. The behavior of the circuit is described by trajectories in a space of k dimensions and p^k states. If the vector input is the null vector and the coefficients in the equation are constants, then the equation exhibits periodic trajectories of maximum period $p^k - 1$. Examples are provided to show that a linear sequential circuit may be treated by transform methods.

CROSS-COUPLED MULTI-DIMENSIONAL FEEDBACK CONTROL SYSTEMS, by P. E. Sarachik. May 15, 1958, 119p. incl. diagrs. refs. (Technical rept. no. T-30/B; rept. no. CU-46-58AF677) (AFOSR-TN-58-556) (AF 18(600)677) AD 158374; PB 137446 Unclassified

Research was conducted on a study of cross-coupled multi-dimensional control systems. The following major aspects of the system are considered in this work. Mathematical description: The differential equations describing the system are derived and represented rather simply in vector matrix notation.

Stability: The proper performance requirements of the over-all system are identified with the stability properties of a "reduced system." Three stability theorems are then proven, 2 of which are applicable to 2-dimensional systems and one to the n-dimensional case.

Dynamic behavior and synthesis: The linearized equations in the vicinity of equilibrium are derived, and a synthesis procedure is suggested which combines the nonlinear methods required to establish stability in the large with linear designs for good dynamic behavior. (Contractor's abstract, modified)

In this way, a connection is established between some quantitative measure on one hand and the structure of the graph on the other. To this end, a new matrix in the theory of linear graphs has to be introduced and its properties studied. These properties are derived and given in terms of a number of theorems. They include (1) a relation between the path matrix and the vertex matrix, (2) the rank of the path matrix, and (3) the correspondence of the non-singular submatrices in the path matrix and the path cut sets. The probability of failure then is expressed in terms of the path matrix and is in fact given by the probability of the union of the "basis-cut-set products." (Contractor's abstract)

Also published in Jour. Franklin Inst., v. 268: 453-463, Dec. 1959.

The concepts of linear graph theory are applied to the study of feedback systems. Two topological matrices, called the exit and entrance matrices, are defined and the transmission matrix of the system is expressed in terms of these matrices. The properties of these matrices are examined, and a relation between non-singular submatrices and nontouching feedback loops is established. Graph theory and the theory of determinants allow a rigorous derivation of Mason's general gain formula. A systematic method, based on the topological formulas derived in the paper, of finding all forward paths and feedback loops without drawing the graph of the feedback system is demonstrated. Unclassified

The state periodicity of unexcited, linear modular sequential circuits characterized by the vector-matrix equation $s(n+1) = A s(n)$ over $GF(p)$ is considered by application of Galois field theory. It is shown that if the minimal polynomial $m'(x)$ of A of degree k' is irreducible, the set of all matrix polynomials in A of degree k' form a Galois field isomorphic to $GF[p, m'(\lambda)]$, and consequently that the state period is equal to the period (order) of the subgroup generated by λ in $GF[p, m'(\lambda)]$. If the minimal polynomial is reducible, it is shown that the matrix period is the least common multiple of the periods generated by λ in $GF[p, m_i(\lambda)]$ where $m_i(x)$ are the irreducible factors of the characteristic polynomial of A , and that every state period is a divisor of the matrix period. STABILITY AND PHYSICAL REALIZABILITY CONSIDERATIONS IN THE SYNTHESIS OF MULTIPOLE CONTROL SYSTEMS, by H. Freeman. [1958] [5]p. incl. diagrs. refs. (AF 18(600)677) Unclassified

Presented at meeting of the Amer. Inst. Elec. Engineers, Montreal, Que. (Canada), June 24-28, 1957.

Published in Trans. Amer. Inst. Elec. Engineers, v. 77 (Part II): 1-5, Mar. 1958.

With the use of the canonical form for a multipole control system as the starting point, the characteristic equation of the system is derived and its roots related to the poles and zeros of the given plant. Conditions are established which must be imposed on the plant to permit the design of a stable system having an arbitrary response. This is followed by the development of a technique which, by imposing constraints on the over-all response, enables the system designer to achieve a stable design even when certain of the plant's poles and zeros lie in an unstable region of the complex frequency plane. The method permits the direct stability design of multipole control systems in a manner similar to that presently possible for the conventional 2-pole systems. It is applicable to continuous-data systems as well as to sampled-data systems. The conditions for the physical realizability of the controllers of a multipole control system designed for a specified over-all response are investigated, and it is shown that, except for the introduction of certain delays, physical realizability can always be achieved.

ON VIBRATIONS OF CONICAL SHELLS, by G. Herrmann and I. Mirsky. Apr. 1957 [31]p. incl. diagrs. (Technical note no. 4; rept. no. CU-14-57AF1247-CE) (AFOSR-TN-57-181) (AF 18(600)1247) AD 126453 Unclassified

Frequencies of truncated conical shells are determined using a Rayleigh-Ritz procedure. Sinusoidal mode shapes are assumed, which satisfy the equation of motion of a corresponding cylindrical shell. The approximate values should therefore have good accuracy for small semi-vertical angles, or small "conicity." It was found that for short shells the conicity lowers the frequency somewhat, while for long shells the frequency increases appreciably with conicity. This influence is strongest if

the number of circumferential waves is 3. As may be expected, the frequency of thin shells and the lowest frequency are more sensitive to changes in shape. It is shown further that the equations of motion may be integrated in terms of known tabulated functions in several special cases. (Contractor's abstract)

ON VIBRATIONS OF CYLINDRICAL SHELLS OF ELLIPTIC CROSS-SECTION, by G. Herrmann and I. Mirsky. Dec. 1957 [24]p. incl. illus. (Technical note no. 5; rept. no. CU-17-57AF1247-CE) (AFOSR-TN-57-734) (AF 18(600)1247) AD 136721; PB 138602

Unclassified

Frequencies of free vibration of thin elastic cylindrical shells of constant thickness and elliptic cross-section are determined for several modes of motion. It is shown that purely longitudinal motions, for small ellipticities, are governed by a Mathieu equation and that the square of the frequency of a slightly elliptic shell with semi-axes a and b is the arithmetic mean of the squares of the frequencies of 2 circular shells with radii a and b , respectively. Purely torsional motion appears to be unaffected by ellipticity, while purely transverse motion (breathing mode) does not exist in elliptic cylinders. Flexural motions are studied by energy methods. It is found that in the absence of nodal lines parallel to the generator, the ellipticity increases the frequency considerably for shells of like cross-sectional area. If cylindrical shells of like circumference, that is of like mass, are compared with one another, the influence of ellipticity is stronger. (Contractor's abstract)

A variational principle for linear thermoelasticity, corresponding to Castigliano's theorem of classical linear elasticity, is established. The proof of the principle is based on Biot's formulation of the equations of the thermoelasticity which include the effect of entropy displacement. The author's principle constitutes a counterpart of the variational principle established by Biot for the thermoelastic linear case. The author promises that a less restricted proof of the present principle will be given in the future and that a more general variational principle for thermoelasticity will be formulated to correspond to Reissner's variational principle for both stresses and displacements in classical elasticity.

THE TEMPERATURE DEPENDENCE OF FLOW AND FRACTURE IN COATED ZINC SINGLE CRYSTALS, by L. C. Weiner. July 16, 1957 [18]p. incl. diagrs. table, refs. (AFOSR-TN-57-385) (AF 18(600)898, Task I) AD 132460
Unclassified

Also published in Trans. Metall. Soc. AIME, v. 212: 253-256, Apr. 1958.

For zinc single crystals, $\chi_0 = 3^\circ$, a copper coating raises both the cleavage and yield strengths over a large temperature range. Two ductile to brittle transition temperatures are observed, one associated with slip after completion of twinning, the other, with twinning. Surface films have no effect on the higher transition temperature, while they lower the other. For crystals $\chi_0 = 83^\circ$, a surface film decreases the cleavage strength, making it independent of temperature, and also raises the transition temperature. These observations and effects are described on the basis of a dislocation-pile-up-at-a-barrier model; in crystals $\chi_0 = 3^\circ$ the number and distribution of twins play a vital role.

Also published in Trans. Metall. Soc. AIME, v. 212: 342-343, June 1958

The effects were studied of solid environments on the brittle fracture of Zn single crystals. Results are given of gaseous and liquid environments on cleavage strength. N, H, He, and CO₂ did not react with the Zn crystals to produce a surface coating and did not effect σ_F , the normal fracture stress. HCl and H₂S reacted to form a uniform, adherent surface layer of ZnCl₂ and ZnS, respectively. The films were of sufficient thickness to cause an increase in σ_F of the same order of magnitude as that of initially coated specimens. An O atmosphere increased σ_F similar to that noted with coated crystals, but no coating was visible. However, specimens treated in an O atmosphere and subsequently etched in dilute HNO₃ gave a value of σ_{FM} (mean value) of 2475 psi.

A ZNO surface film of sufficient thickness was formed to cause this large increase in σ_F . A gaseous

liquid environment will only increase the cleavage strength of initially clean Zn single crystals, when the medium reacts to form an adherent surface film of a thickness greater than a few hundred angstroms.

BENDING OF COATED ZINC CRYSTALS, by L. C. Weiner. Aug. 29, 1957, 3p. (AFOSR-TN-57-560) (AF 18(600)898, Task I) AD 136551
Unclassified

Also published in Acta Metallurgica, v. 6: 135-136, Feb. 1958.

In studying the effects of solid environments on the tensile brittle fracture of Zn single crystals, experiments were conducted to determine whether similar effects occur in bending. Both clean-surfaced and electrodeposited-Cu-coated (2000 to 4500 Å) specimens were used. The results failed to show any significant effect of a solid environment. For 21 clean crystals the mean value of S was 8900 ± 535 psi as compared with a mean value of 9200 ± 655 psi observed with 23 coated specimens. The orientation of the basal plane relative to the axis of loading was not important, since the test results indicated no difference between crystals, both clean and coated, tested

COU.14:008; COU.15:003; COU.17:005

with their basal planes either parallel or normal to the axis of loading. A 48% decrease in cleavage strength was observed in tension for crystals $\chi_0 = 83^\circ$ possessing a surface film. In bending, no effect due to a solid environment was found. The mean value of S for clean and coated crystals was observed to be 2000 ± 340 psi and 2250 ± 640 psi, respectively. In crystals oriented $\chi_0 = 3^\circ$, twinning was the predominant mode of plastic deformation in regions of tension, while for specimens of the other orientation, $\chi_0 = 83^\circ$, twinning occurred in regions of compression. The results indicated that tensile tests at appropriate testing temperatures rather than bend tests are necessary for a study of the brittle behavior of materials which exhibit twinning.

INVESTIGATION OF THE ROLES OF ABSOLUTE GRAIN SIZE AND NUMBER OF GRAINS IN THE CROSS-SECTION AS FACTORS CONTROLLING FLOW AND FRACTURE STRESSES AT LOW TEMPERATURE, by J. W. Hill. Feb. 28, 1958, 18p. incl. diagrs. tables, (AFOSR-TN-58-882) (AF 18(600)898; Task I) AD 162215; PB 138107 Unclassified

An investigation was conducted to determine whether the absolute grain size or the number of grains in the cross-sectional area is the controlling factor in determining flow and fracture stress at low temperatures. As-rolled ferrites containing 0.03 C, 0.53 Mn, and 0.19 Si, were subjected to cold working and machined to contour specimens having diam at min cross section of about 0.045, 0.075, and 0.090 in. The specimens were mechanically polished, cleaned by re-centerdrilling and washing with benzene, and heat treated. Two to $3\frac{1}{2}$ hr were required at 700°C to produce ASTM grain sizes of about 6, 5, and 4. The specimens were immersed in either a single vacuum dewar of liquid nitrogen or double dewar containing liquid nitrogen in the outer dewar and liquid helium in the inner dewar. At these low temperatures, the specimens were pulled with an Instron tensile testing machine at a crosshead speed of 0.1 in. min. The upper yield, lower yield, and fracture loads were taken from the Instron recorder as the highest load before drop in load at yield, the lowest load occurring immediately after the drop in load at yield, and the load at which the specimen broke. A plot of the square of the stress vs the reciprocal of the average grain diam is a single straight-line relationship. All the low-temperature data for the reduction of area vs the reciprocal of the average grain diam also shows a straight-line relationship. These results indicate that the absolute grain size and not the number of grains in the cross section determines tensile properties at low temperatures.

THE DRIVING FORCE FOR RECRYSTALLIZATION IN BENT SINGLE CRYSTALS OF SILVER, by J. W. Semmel, Jr. and E. S. Machlin. [1957] [15]p. incl. illus. diagrs. tables, refs. [AF 18(600)899] Unclassified

Published in *Acta Metallurgica*, v. 5: 582-598, Oct. 1957.

During an experimental study of recrystallization of bent single crystals of silver, in which measurements of dislocation density were made, it was found that the energy associated with the dislocations comprised but a small fraction of the driving energy for recrystallization. Experimental evidence was obtained to support the theory that excess point defects produced by the bend deformation, in particular vacancies, provide the major source of the driving energy for recrystallization under the present experimental conditions. Two annealing stages were found during which the driving energy for recrystallization decreased to values below that necessary to achieve recrystallization on subsequent heating to high temperatures. This process is called "degradation." Specimens bent to 12% outer fiber strain or less degraded much more rapidly than specimens bent to 23% outer fiber strain. It is postulated that the vacancy-sinks are not infinite and that the longer degradation time is a measure of the time required for the excess vacancies to diffuse to the specimen surface. GRAIN GROWTH IN DILUTE ALLOYS OF COPPER, by S. Weinig and E. S. Machlin. [1957] [3]p. incl. diagrs. table. [AF 18(600)965] Unclassified

Published in *Jour. Metals*, v. 9: 843-845, July 1957.

An experimental study of grain growth in dilute binary alloys of copper was performed. It was found that the growth law $D = Kt^n$ fit most of the data, the grain growth exponent n decreased with solute content until a saturation value was obtained at slightly under 0.2 for both silicon and aluminum solutes. It is concluded that the grain growth exponent n depends upon solute adsorption at the grain boundaries. An estimate of the activation energy was made and it was found that the activation energy decreased with temperature. The activation energies for grain boundary migration compare well with values obtained from internal friction studies on identical alloys. This contributes strong experimental support for the two-step mechanism for complete boundary stress relaxation. (Contractor's abstract)

GRAIN BOUNDARY SLIDING IN COPPER BI-CRYSTALS
(Abstract), by J. Intrater and E. S. Machlin. [1957] [1]p.
[AF 18(630)965] UnclassifiedPresented at meeting of the Inst. of Metals Div.,
A.I.M.E., Chicago, Ill., Nov. 3-7, 1957.

Published in Jour. Metals, v. 9: 31, Oct. 1957.

The phenomenon of grain boundary sliding (motion of grains along a common boundary) was studied in bi-crystals of copper which were oriented to minimize slip in the adjoining grains. It was found that sliding occurred within a very narrow zone. Prior plastic deformation is not necessary to achieve boundary sliding; however, when specimens were plastically deformed prior to grain boundary sliding, a decrease in the flow resistance of the region adjoining the grain boundary to shear stress parallel to the boundary was observed. Sliding is spasmodic with no incubation time and occurs with an activation energy of 40,000 cal/mol when tested in a vacuum of 5×10^{-4} mm Hg and 20,000 cal/mol when tested in hydrogen. Cracks along the boundary are found on bi-crystals test in vacuum and isolated voids are found on testing in hydrogen. The number of voids is directly dependent upon the amount of grain boundary sliding and is independent of temperature. It is believed that during grain boundary sliding pure sliding occurs along the straight sections of the boundary between the boundary projections (jogs). High stresses are developed at these jogs, indicating local plastic deformation. After sufficient plastic deformation fracture occurs, producing voids.

GRAIN BOUNDARY STRESS RELAXATION AND
SLIDING; SOLUTES AND INTERACTIONS. [1958]
[16]p. incl. refs. (AFOSR-TR-58-123) (AF 18(606)965)
AD 202924; PB 139821 Unclassified

The mechanism of grain boundary stress relaxation was investigated. The effects of dilute solute elements were investigated to provide an experimental basis for induction of potential mechanisms. Complete grain boundary stress relaxation was deduced to result from 2 dependent processes: (1) grain boundary migration controlling in pure metals, and (2) grain boundary sliding controlling in alloys. Testing of grain boundary sliding in bicrystals was conducted. Two phenomena, zone shear and pure sliding, produced relative motions of grains tangential to their common boundary. The time and temperature dependence, and the morphology of pure sliding were measured. Theories for zone shear

and pure sliding were devised. Voids were produced along the bicrystal boundaries subjected to sliding at the elevated temperature. The number of voids produced depended monotonically upon the amount of grain boundary sliding solely. This number of voids per amount of grain boundary sliding was found to be independent of temperature, but strongly dependent upon the jogged character of the boundary. The study, demonstrated the predominance of the grain boundary sliding mechanism of creep rupture, and the unimportance of vacancy condensation. A beginning was achieved toward providing a basis for alloy design to withstand high temperature failure.

RECOMBINATION LIGHT EMISSION IN GERMANIUM. Final technical rept. [1958] 12p. diagrs. (AFOSR-TR-58-38) (AF 61(514)1148) AD 154118 Unclassified

The basic experiment consisted of passing current forward through a rectifying junction and observing which photons were emitted from the outside of the semiconductor specimen. Experiments were also conducted on Si with a Benoit-Weierstrass sphere. Al wire alloy junctions on n-type Si were used as well as P-diffused junctions on a p-type sample. A modified Klipp symmetrical double monochromator and the Perkin-Elmer monochromator were used in the experiments. A system was developed for studying accurately how the energy emitted at a given wavelength depends on current through the junction. A typical recording of the emitted light with current density of a few hundred amp/cm² indicated the existence of 2 peaks in the emitted radiation, one of which was the band-to-band gap at a wavelength of about 1.74 μ at 77°K. The second peak, centered at about 2.30 μ , was observed only below about 200°K. The amount of trap radiation was found to be approximately linearly related to the dislocation density, as a result of experiments with Ge. Measurements were made of radiative efficiency by passing a signal through a spectrometer and measuring the peak intensity at 0.52 eV with approximately 50 ma through the junction.

At 20°K, a weak peak 15.10⁻³ eV on the high-energy side of the band-to-band peak was observed on an Sb-doped Ge specimen. Measurements of recombination light in Si were initiated.

RESPONSES IN SINGLE OPTIC TRACT FIBERS OF

CAT TO MONOCHROMATIC LIGHT. CORRELATION WITH CONDUCTION VELOCITY, by M. A. Lennox. [1957] [2]p. [AF 61(514)1194] Unclassified

Presented at meeting of the Scandinavian Physiol. Soc., Stockholm (Sweden), Aug. 25, 1957.

Published in Acta Physiologica Scandinavica, v. 42: Suppl. 145, 1957.

In chloralose-urethane anesthetized cats, a just supra-maximal electrical stimulus was applied to one optic nerve just behind the intact eye and the response recorded with a gross and an immediately adjacent glass capillary microelectrode from the contralateral optic tract. Responses were then recorded in these same fibers by flashing the intact eye with light which could be varied independently with respect to intensity, color, duration, and frequency. The responses to light evoked in single optic tract fibers in the cat were of the three types, "on," "off," and "on-off," and the response type of any one fiber was a fixed characteristic. The majority of the optic tract fibers were off fibers, and these appeared to be the only units allowing discrimination of the brightness of light. The "on" responses differed according to the color of the light, and these differences were correlated with the conduction velocity along the fiber.

SINGLE FIBER RESPONSES TO ELECTRICAL STIMULATION IN CAT'S OPTIC TRACT, by M. A. Lennox. [1958] [8]p. incl. diagrs. tables, refs. (AFOSR-TN-58-430) (AF 61(514)1194) AD 158234 Unclassified

Also published in Jour. Neurophysiol., v. 21: 62-69, Jan. 1958.

The properties of the optic tract in the cat have been the cause of occasional disagreement. This experiment was performed to examine the evidence obtainable from single fiber responses to electrical stimulation of the contralateral optic nerve. Twenty-six animals were used (2- 2.5kg.) under deep chloralose-urethane anesthesia, and this report concerns 73 units obtained from 14 successful experiments. By means of KCl-filled glass microelectrodes with tip diameters of 0.15-0.4 μ , unit responses were found. For comparison, the gross response was recorded with an immediately adjacent unipolar or concentric electrode. In the axons, each stimulus above threshold evoked a single spike of constant amplitude and latency at all stimulus strengths. The single fiber response was always positive and usually monophasic; the amplitude varied between 0.5 and 10 mv. The duration of the rising phase tended to be correlated with latency and thus with conduction velocity and fiber size, being the shorter, the faster the conduction velocity. The refractory period was longer in fibers with slow

than in those with rapid conduction velocity. Calculated for the mean measured distance between stimulating and recording electrodes (41 ± 1 mm), the three significant latency groups correspond to conduction velocities of about 52, 37, and 16 m/sec.

COP.01:003

STUDY OF THE ORGANIZATION OF THE VISUAL SYSTEM IN RESPECT TO COLOR, by M. A. Lennox. Final technical rept. Jan. 1-Dec. 31, 1957 [10]p. incl. refs. (AFOSR-TR-58-24) (AF 61(514)1194) AD 152199 Unclassified

The correlation of conduction velocity with response to light, especially to the color of the light, of single units (optic tract fibers) was studied. The experimental animals were cats under chloralose-urethane anesthesia. The only correlate with the conduction velocity was the differential response of the units to the 2 colors, blue and red. Slow fibers were more responsive to blue and fast fibers to red. Responses after cessation of brief light flashes were more common than any other type of response. These occurred in 60% of the single units. Three types of responses were seen: those in which the number of spikes was determined sensitively by the quantity, those in which the number of spikes was only in general related to the quantity of light, and mixed types of response with both components. No correlation was noted between type of response and conduction velocity, nor did these units respond differently to blue and to red. An electroencephalographic and followup study of candidates for jet pilot training in 1953 to 1955 confirmed earlier findings of a correlation between marked or paroxysmally abnormal EEG's and service performance that the crash rate was 3 times as high in trainees with as in those without such abnormalities.

THE ON RESPONSES TO COLORED FLASH IN SINGLE OPTIC TRACT FIBERS OF CAT. CORRELATION WITH CONDUCTION VELOCITY, by M. A. Lennox. Apr. 1957 [37]p. incl. diagrs. tables, refs. (AFOSR-TR-58-24a) (Sponsored jointly by Danish State Research Foundation and Air Force Office of Scientific Research under AF 61-514)1194) AD 202485 Unclassified

Also published in Jour. Neurophysiol., v. 21: 70-84, Jan. 1958.

Eighteen on responses of on (11) or on-off (7) units to various intensities and durations of red, blue, and white light were obtained. In 13 of these units, responses to optic nerve stimulation were also obtained. The type of response of each fiber was found to be a fixed character-

istic for any one unit. The on responses of on and of on-off units differed in general from each other with respect to latency, spike number, and frequency of the response to light, with respect to color sensitivity, and with respect to fiber size. The pure on fibers were less "active" in response to light, more apt to be blue sensitive, and tended to belong to the slower conduction velocity groups. By less "active" is meant that the latency of the response to light was longer, the number of spikes fewer, and the discharge frequency lower. The on-off fibers were more "active" in their response, they included the only two red sensitive units found, and they belonged preferentially in the fast conduction velocity groups. The only consistent correlation with conduction velocity was the differential response of the unit to the two colors, blue and red; fibers with low conduction velocities responded more actively to blue than to red, while those with high conduction velocities responded more actively to red. These findings contribute to the evidence that not only peripheral, but also central nervous mechanisms are involved in the reception of color.

CENTRAL NERVOUS MECHANISMS IN COLOR VISION, by M. A. Lennox. Jan. 27, 1958, 8p. incl. diagrs. (Sponsored jointly by the Danish State Research Foundation and Air Force Office of Scientific Research under AF 61-514)1194) Unclassified

Presented at meeting of the Danish Neurological Soc., Jan. 27, 1958.

In this neurophysiological study using cats, an attempt was made to discover what happens in the brain when the color of a light (stimulus) is changed. Recordings were made of the response from the cortex when the cat's eye was flashed with blue, green, yellow, and red light. At high intensities, the response occurred earlier when the light was red, later when it was yellow, and latest when it was blue or green. Tests verified that the photochemical reaction took place fastest in the eye when the light was red and that the red-sensitive receptors were connected with large fibers which conducted the impulse faster in the central nervous system than in the case of the other light stimuli. For a response of a given size, the arrival time is 5 msec earlier when the light is red or yellow than when it is blue or green. It is concluded that the arrival time of an impulse offers a possibility to the brain to judge the quality (color) of the stimulus. In addition, it is pointed out that the eye is always making small scanning motions, and that without these motions, color cannot be seen. Thus, this scanning motion may provide the brain a means of comparing latencies.

THE HYPERCIRCLE METHOD APPLIED TO THE SOLUTION OF THE BIHARMONIC EQUATION. I, by V. G. Hart. Dec. 1957, 62p. incl. diagrs. (AFOSR-TN-58-172) (AF 61(514)1163) AD 152203 Unclassified

The hypercircle technique utilizes a function-space representation in which the point of intersection of two orthogonal linear subspaces corresponds to the solution (which we suppose unique) of a boundary-value problem. General points on the two subspaces correspond to solutions of the original problem with some conditions relaxed and may be easily found. A point is selected on each subspace, and an attempt is made to draw each point close to the point of intersection by means of a least square procedure. Then provided that the metric of function-space is positive-definite (which will always be the case in the subsequent work), the point of intersection of the subspaces is located on a geometrical figure called a hypercircle. When the hypercircle has been found, the method provides upper and lower bounds on a certain functional involving the solution of the problem under consideration. Also it is possible to estimate the mean-square error involved at all stages of the process, this quantity being represented by the square of the radius of the hypercircle. In this work pointwise bounds on the solution of a boundary-value problem are not obtained, but methods are available for such a process if desired. (Contractor's abstract)

MULTI-RING PLATES, A STEP FUNCTION APPROACH, by P. M. Quinlan. Jan. 1958, 26p. incl. diagrs. (Technical note no. 2) (AFOSR-TN-58-211) (AF 61(514)1163) AD 154112; PB 134277 Unclassified

By introducing suitable functions a single, discontinuous, differential equation is written for the symmetrical bending of an elastic plate consisting of a number of concentric discs, each of constant thickness. The concentrated uniform ring load is taken as the fundamental load type, from which all other loading can be derived by integration. The case of a concentrated ring torque is obtained by applying an appropriate limiting technique to the ring load. The case of a disc of variable thickness is obtained by letting the number of discs in the plate become infinite, thereby making the solution of the problem depend on obtaining a particular integral of a second order differential equation with variable coefficients. Solutions are given for a hollow disc, where the thickness varies as some power (not necessarily an integer) of the radius. Finally, a theory of the bending of prestressed concrete circular slabs is developed, in which the solution involves concentrated ring loads and torques both of

which have been obtained in the present paper. (Contractor's abstract)

RECTANGULAR PLATES. A NEW APPROACH, by P. M. Quinlan. Jan. 1958 [47]p. incl. diagrs. (Technical note no. 3) (AFOSR-TN-58-259) (AF 61(514)1163) AD 154163; PB 134511 Unclassified

A Fourier double sine series expansion is obtained for the deflection in a simply supported rectangular plate. This is done by introducing a delta function into the plate equation for a concentrated load, then adding the series to produce a singly infinite series. Solutions are obtained for plates fixed horizontally along a pair of opposite edges by means of suitable complementary functions. Formulas are established for transverse bending moments, and suitable asymptotic series are introduced to improve the convergence of the series involved. The case of a concentrated torque is obtained by applying an appropriate limiting technique to the concentrated load case. Influence diagrams are given for transverse moment at the center of a simply supported rectangular plate with $b = 2a$, for both concentrated loads and torques. This is repeated for the same rectangular plate when fixed along two opposite edges. The solution to the case of a loaded semi-infinite strip is obtained by taking the limit of the previous solutions as b/a tends to infinity. The case where the strip is fixed horizontally along all finite edges is shown to lead to a singly infinite set of simultaneous equations, and is presented as the limiting case of the finite rectangle fixed along all edges. Solution to the problem of the loaded infinite strip follows in a similar manner. Finally, a complete theory of the bending of rectangular prestressed bridge slabs is developed. TORSION OF SEMI-ELLIPTIC AND HOLLOW-ELLIPTIC SECTIONS, by P. M. Quinlan. July 1958, 23p. incl. diagrs. tables. (Technical note no. 4) (AFOSR-TN-58-883) (AF 61(514)1163) AD 203905; PB 138739 Unclassified

Conformal mapping is used to reduce the torsion problem for hollow-elliptic and semi-elliptic sections to a potential problem in a rectangle. In each case both the appropriate stress function and the torsional rigidity are obtained in series form, and the appropriate asymptotic form of the series for the stress components is given for use where greater precision is required. Solutions developed for the hollow elliptic tube and the prolate semi-elliptic shaft check with existing solutions

obtained by other methods. Solutions are also given when the above sections are cracked; the crack in each case being along the major axis extending respectively through the thickness of the tube, and to the focus of the shaft. The torsion of an oblate semi-elliptic shaft is also included. Calculations were performed to evaluate the effects of cracking on the sections, and the results are presented in tabular form. ON THE COEFFICIENTS IN CERTAIN FOURIER SERIES, by P. B. Kennedy. [1958] 24p. (Technical note no. 1) (AFOSR-TN-58-171) (AF 61(514)1399) AD 152198 Unclassified

Also published in Jour. London Math. Soc., v. 33: 196-207, Apr. 1958.

The following problem is considered. A function satisfies a Lipschitz condition, in the strong sense, in a set of positive measure. Also the Fourier series of the function is subject to a gap hypothesis. What conclusion can be drawn regarding the order of magnitude of the Fourier coefficients of the function in question? The results obtained are roughly best-possible, and shed some light on a conjecture advanced by M. E. Noble in 1954 [Mth. Annalen, v. 128: 55-62, 1954]. Remarks are made concerning the possibility of working with a weak Lipschitz condition; it is shown that the results do not extend to this case, even in a somewhat modified form. As an incidental result, it is pointed out that a function may satisfy a strong Lipschitz condition in a set of positive measure without satisfying such a condition in any interval. (Contractor's abstract)

REMARKS ON CONTINUITY CONDITIONS, by P. B. Kennedy. [1959] 8p. (Technical note no. 2) (AFOSR-TN-58-586) (AF 61(514)1399) AD 162107; PB 138974 Unclassified

Also published in Proc. Amer. Math. Soc., v. 10: 203-204, Apr. 1959.

A simple method is elaborated for Lipschitz conditions in intervals and sets of positive measure. Let E be any subset whatever of $(0,1)$. Let $\omega(k)$ be positive and monotonic increasing in $(0,1)$ and satisfy $\omega(k) \rightarrow 0$ as $k \rightarrow 0$. Then there exists a function $f(x)$ defined in $(0,1)$ such that (1) $\omega(k)$ is a modulus of continuity of $f(x)$ in E and (2) $f(x)$ is discontinuous at every interior point of the complement of E . THE DIVERGENCE OF TRIGONOMETRIC SERIES, by P. B. Kennedy and S. O'Shea. [1958] 13p. (Technical note no. 3) (AFOSR-TN-58-634) (AF 61(514)1399) AD 162164; PB 138975 Unclassified

A method due to Steinhaus, for the construction of everywhere-divergent trigonometric series with coefficients tending to zero, is generalized in a simple way. The generalization leads to some information concerning a theorem due to Zygmund, on the power of the set of points of convergence of certain trigonometric series with gaps. (Contractor's abstract)

THE USE OF A SINGLE-PULSE SHOCK TUBE FOR THE STUDY OF HIGH-SPEED CHEMICAL KINETICS, by H. S. Glick, J. J. Klein, and W. Squire. [1956] 5p. (AF 18-(600)1332) Unclassified

A new shock tube technique for studying high-speed chemical kinetics has been developed at the Cornell Aeronautical Lab. With this technique, a reactive gas sample can be processed through a single high temperature pulse, which has amplitudes up to 10,000°K, durations from 0.1 to 10.0 msec, and cooling rates on the order of 10^6 K/sec. The gas sample can be withdrawn from the shock tube after the experiment and the "debris" formed by the high temperature pulse can be analyzed by the most convenient means. The single-pulse shock tube has been used to study the kinetics of the formation of nitric oxide from air between 2000° and 3000°K. The reaction rates, activation energy, and mechanism of the nitric oxide reaction have been determined. (Contractor's abstract)

SHOCK TUBE STUDY OF DISSOCIATION RELAXATION IN OXYGEN, by H. S. Glick and W. H. Wurster. [1957] [3]p. incl. illus. diagr. (AF 18(600)1332) Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 47, Jan. 30, 1957.

Published in Jour. Chem. Phys., v. 27. 1224-1226, Nov. 1957.

A schlieren optical system and a high purity level shock tube have been used to study relaxation phenomena in oxygen at temperatures from 1200°K to 4000°K. Vibration and dissociation relaxation zones have been observed, and the data has been correlated with other experiments and existing theory. The measured vibrational relaxation times are in reasonable agreement with those measured by Blackman up to 3000°K. At higher temperatures, another non-equilibrium zone appears which is believed to be due to dissociation relaxation. The dissociation relaxation times, however, are several orders of magnitude shorter than those predicted by the theory of Bethe and Teller. The short dissociation relaxation times observed in the present experiments are corroborated by chemical kinetics studies of the formation of nitric oxide, and it is therefore believed that the theoretical model of dissociation kinetics for oxygen required refinement. Theoretical studies, based on the work of Rice, are being carried out in an effort to reconcile theory and experiment. (Contractor's abstract)

The principles of a single temperature pulse shock tube which was developed for the study of high-speed chemical reactions are discussed. The shock tube enables a reactant gas to be processed by a predetermined temperature pulse of variable amplitude and duration; both the reaction rates and activation energies are determined by analyzing the resulting data. The kinetics of the $N_2 + O_2 \rightleftharpoons 2 NO$ reaction were investigated between 2000° and 3000°K and were proven to be consistent with the chain mechanism proposed by Zeldovich (Acta Physicochimica U.R.S.S., v. 21: 577, 1946). An activation energy of 74 ± 5 kcal/mol was measured. Measurements of the relaxation time for O dissociation between 2000° and 4000°K yielded values which confirmed the validity of the chain mechanism for the NO reaction. The complementary use of high-speed spectrographic techniques in reaction studies is discussed.

THE SHOCK TUNNEL AND ITS APPLICATIONS TO HYPERSONIC FLIGHT, by A. Hertzberg. June 1957 [45]p. incl. illus. diagrs. refs. (Rept. no. AD-1052-A-5; AGARD rept. no. 144) (AFOSR-TN-57-268) (AF 18(603)-10) AD 126567 Unclassified

Presented at Eleventh meeting of the AGARD Wind Tunnel and Model Testing Panel, Scheveningen (Netherlands), July 8-12, 1957.

This paper discusses the application of the shock tube to the study of the problems of hypersonic flight. The development of the shock tube into a short-duration wind tunnel for the study of supersonic air flow is reviewed historically. Modifications of the conventional shock tube which extend the shock tube into a tool for the study of hypersonic flows are described. The problems of operation and technique which these modified shock tubes introduce are discussed. The techniques of instrumentation for the brief flow durations of hypersonic shock tunnels are outlined. In particular, a technique is described for accurately measuring heat transfer within the short testing times available in shock tunnels. The results of preliminary experiments carried out to explore the effects of shock attenuation on the operation of shock tunnels are presented. Since the attenuation becomes so severe at high shock Mach numbers, shock tubes of more sophisticated design are being studied which promise to increase the testing time per unit length of shock tube up to twenty-five times that of the existing shock tubes, and hence alleviate the attenuation problem. A new technique for generating strong shock waves required for shock tunnel operation is described. (Contractor's abstract)

SHOCK TUBE DRIVER TECHNIQUES AND ATTENUATION MEASUREMENTS, by C. E. Wittliff and M. R. Wilson. Aug. 1957, 34p. incl. diagrs. refs. (Rept. no. AD-1052-A-4) (AFOSR-TN-57-546) (AF 18(603)10) AD 136531
Unclassified

The development of the hypersonic shock tunnel at the Cornell Aeronautical Lab., Inc. has been accompanied by a study of various techniques for producing strong shock waves to drive the shock tunnel. The results of this study are described as to technique and relative efficiency of different driver gases, and the resultant attenuation of the shock wave in the low pressure tube. It has been found that as the strength of the shock wave increases so does the amount of attenuation. Furthermore, the more efficient a given driver technique is in producing a shock wave, the larger the degree of attenuation that is observed. A survey of the presently available theories on shock wave attenuation indicates that the theories do not accurately predict the attenuation of shock waves having Mach numbers greater than 2, whereas all of the experimental data reported herein are for shock wave Mach numbers greater than 4. This serves to illustrate the need for a better understanding of the attenuation of strong shock waves. (Contractor's abstract)

A METHOD FOR IMPROVING THE PERFORMANCE OF SHOCK TUBES, by A. Russo and A. Hertzberg. Apr. 1957 [11]p. incl. diagrs. (AF 18(603)10)
Unclassified

Also published in *Jet Propulsion*, v. 27: 1191-1193, Nov. 1957.

Modifications of the basic shock tube are considered in order to improve the performance of shock tubes and, in particular, to extend the use of hydrogen to the generation of strong shock waves in air. These modifications are the double-diaphragm shock tube with monatomic buffer gases and the shock tube with an area change at the diaphragm station. The results of this investigation indicate that the use of a shock tube with an area discontinuity and the proper monatomic buffer gas should permit the generation of strong shock waves, using cold hydrogen as a driver gas, with over-all pressure ratios comparable to those required for existing combustion drivers. In addition, by using a buffer gas with the proper atomic weight, it is possible to control the downstream diaphragm pressure ratio to minimize the mass of the downstream diaphragm. SIMILITUDE OF HYPERSONIC FLOWS OVER THIN AND SLENDER BODIES - AN EXTENSION TO REAL GASES, by H. K. Cheng. Feb. 1958 [19]p. incl. diagrs. refs. (Rept. no. AD-1052-A-6) (AFOSR-TN-58-87) (AF 18(603)10) AD 148136
Unclassified

On the basis of the governing equations and boundary conditions, similitude in the hypersonic inviscid flow fields over thin or slender bodies is examined, wherein the restriction to ideal gas with constant specific heats is removed. When local thermal (vibrational and chemical, etc.) equilibrium prevails, i.e., when the properties of gas are determined nearly by the thermodynamic properties corresponding to the local pressure and temperature (or density), the parameter $M_\infty \tau$ of Tsien and Hayes remains the controlling parameter for the similar fields of hypersonic flows past thin or slender bodies. However, general correlation of similar flows of real gases are possible only between flows under the same free-stream atmosphere, i.e., with the same p_∞ , ρ_∞ (or T_∞) and initial gas composition, say $(X_i)_\infty$'s. Examples of correlation are given for flows of real gases over wedges. (Contractor's abstract)

MODIFICATIONS OF THE BASIC SHOCK TUBE TO IMPROVE ITS PERFORMANCE, by A. Russo and A. Hertzberg. Aug. 1958, 43p. incl. diagrs. tables, refs. (Rept. no. AD-1052-A-7) (AFOSR-TN-58-716) (AF 18(603)10) AD 162251
Unclassified

Basic modifications are considered which would improve the performance of shock tubes in producing higher shock strengths and extend the use of hydrogen in generating strong shock waves in air. These modifications are the double-diaphragm driver with monatomic buffer gases and an area contraction at the diaphragm station. The results of this investigation indicate that the use of a shock tube with an area contraction and the proper monatomic buffer gas will permit the generation of strong shock waves, using cold hydrogen as a driver gas, with overall pressure ratios comparable to those required for combustion drivers. It is also shown that, by using a buffer gas with the proper atomic weight, the downstream diaphragm pressure ratio may be controlled to minimize the mass of the downstream diaphragm. SUBJECT TO THERMAL OR CHEMICAL RELAXATION, by W. E. Gibson and F. K. Moore. Dec. 1958 [61]p. incl. diagrs. refs. (Rept. no. HF-1056-A-2) (AFOSR-TN-58-1057) (AF 18(603)19) AD 206988 Unclassified

A theory of acoustic propagation in a gas subject to relaxation phenomena is presented. An acoustic equation is obtained for small disturbances from an equilibrium state of rest; this equation applies equally well to unsteady 1-dimensional waves or to steady 2-dimensional disturbances. The problem of a 2-dimensional airfoil in a supersonic flow of relaxing gas is considered. From the acoustic equation, the law of decay of shock waves and the values of the flow properties on the surface of the airfoil are derived. The asymptotic behavior of the flow field is obtained far from the airfoil so that the formation of an equilibrium wave is described. The acoustic equation involves the 2 wave operators which can be defined on the basis of the frozen and equilibrium sound speeds. The closeness of the sound speeds allows a simplification of the full equation to a variant of the telegraph equation. This approximate equation is uniquely determined by the requirements that the shock decay law and the exact value of the equilibrium sound speed be preserved. An explicit solution for the flow field is presented and proved to be in close agreement with the exact solution on the surface of the airfoil and in the asymptotic range. (Contractor's abstract)

STUDIES OF A PROTOTYPE WAVE SUPERHEATER FACILITY FOR HYPERSONIC RESEARCH, by W. E. Smith and K. C. Weatherston. Dec. 1958, 115p. incl. illus. diagrs. table, refs. (Rept. no. HF-1056-A-1) (AFOSR-TR-58-158) (AF 18(603)19) AD 207244 Unclassified

Research was concerned with the development of a wave superheater which produces a continuous supersonic flow of air or other gases at temperatures and pressures needed for realistic hypersonic testing in the laboratory. A prototype, designed to generate 3000°R in air and 5500°R in argon, starting from room temperature, was built and successfully demonstrated the principles of wave superheater operation. The unique flow conditions, characterized by homogeneity, purity, and high temperature, pressure, and velocity, that are generated in hypersonic shock tubes and shock tunnels for short periods can be sustained for many seconds in a wave superheater. Many shock tubes are mounted on a rotating drum and fired cyclically in a manner to produce an uninterrupted jet of uncontaminated, superheated gas that is collected and expanded through a nozzle and test section. The test flow, being at typical shock tunnel conditions, reproduces the aerophysical phenomena, especially the high heat fluxes, associated with launching, gliding and re-entering hypersonic vehicles. The wave superheater is adaptable to full-scale

materials and structures testing, to high-speed aerodynamic research, and to studies of such basic processes as molecular dissociation and recombination as well as the interaction of electromagnetic radiation with ionized flow. A helium driven, preheated wave superheater was designed to superheat 4.3 lb of uncontaminated air/sec to 9000°R, or 12 lb of argon/sec to 17,000°R.

MEASUREMENTS OF FLOW PROPERTIES IN A

DISSOCIATED GAS (Abstract), by C. E. Treanor, T. C. Golian, and A. Hertzberg. [1958] [1]p. [AF 49(838)289] Unclassified

Presented at meeting of the Fluid Dynamics Div. of the Amer. Phys. Soc., Lehigh U., Bethlehem, Pa., Nov. 25-27, 1957, v. 3: 289, June 19, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 289, June 19, 1958.

Direct measurements of the speed of sound have been performed in dissociated gases. The sound wave is produced by an abrupt expansion in the shock tube, and the velocity of the expanding cylindrical wave is determined from a schlieren photograph taken a known time later. A comparison of these results with calculated values of the speed of sound indicates that waves produced in this manner propagate as though vibration and dissociation do not participate.

ELECTROANALYTICAL METHODS IN TRACE ANALYSIS, by W. D. Cooke. Feb. 1957 [35]p. incl. diagrs. refs. (Technical rept. no. 10) (AFOSR-TN-57-90) (AF 18(800)486) AD 120438 Unclassified

Published in Physical Methods in Chemical Analysis, v. III: 71-105, 1956.

In recent years scientists in widely different fields of endeavor are becoming increasingly aware of the important role of minor constituents in various phenomena. Extremely small quantities of material, sometimes as low as $10^{-6}\%$, can exert profound chemical and catalytic influences. The effect of microgram quantities of vitamins and hormones has been known for a long time. Traces of various metals are also of great importance in biological systems as well as in various aspects of technology. A review is presented of electroanalytical methods in trace analysis. Topics discussed are: (1) separation of minor constituents; (2) polarography; (3) amperometric procedures; (4) titration methods; and (5) anodic stripping of deposited metals. Sixty domestic and foreign references are included covering a time period from 1932 to 1956.

POLAROGRAPHIC DETERMINATION OF SUBMICROGRAM QUANTITIES OF MOLYBDENUM, by W. D. Cooke. May 23, 1958, 15p. incl. table. (Technical note no. 11) (AFOSR-TN-58-468) (AF 18(800)488) AD 158278 Unclassified

An analytical method which was capable of determining submicrogram quantities of molybdenum in highly purified salts was needed. A highly sensitive method employing catalytic reduction wave for molybdate had been reported. A comparison of the various procedures is undertaken here in order to find which method would have the widest applicability to the problems at hand. Two different supporting electrolytes, nitric acid and perchloric acid were found to give a catalytic effect in the polarographic reduction of molybdate. The effect of foreign electrolytes on the height of the polarographic waves is briefly touched upon. A summary of the results obtained in those cases where difficulties were experienced which were caused by large quantities of interfering elements is presented. The proposed methods were checked on synthetic samples or by standard additions of molybdenum and an accuracy of 5% was considered to be acceptable.

A mass spectrometer was used to analyze vapors in equilibrium with alkali fluoride condensed phases. Monomers, dimers, and trimers were detected in all alkali fluoride vapors. In addition to monomers and dimers characteristic of pure condensed phases, mixed dimers were found in equilibrium with mixed condensed phases. A method for determining the difference in dimerization energies for constituents in a mixed vapor was formulated, and dimerization enthalpies for alkali fluoride species are presented. Mass spectrometric studies of the gaseous species produced in the vaporization of NaOH and KOH have shown that in the temperature range 270°C to 450°C, the vapor phase of these compounds consists largely of dimer molecules. The gaseous species effusing from a Knudsen cell containing a condensed hydroxide phase were subjected to electron bombardment for subsequent ion detection in a 12-in. 60° direction-focusing mass spectrometer. Through a study of positive ions produced, appearance potentials, ion current ratios, and dependence of ion currents on experimental conditions the neutral molecular species in the vapor have been identified and thermochemical data have been obtained. Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 132, Mar. 21, 1957.

Also published in Jour. Chem. Phys., v. 27: 940-952, Oct. 1957.

The radial Schrödinger equation for arbitrary values of the angular momentum is solved exactly with a repulsive R^{-4} potential energy, the solutions being Mathieu functions whose arguments are linear functions of $\log R$. These solutions are then applied to the problem of vibrational relaxation in the distorted wave approximation. Emphasis is given to the case in which the energy which is exchanged in the inelastic collision, ϵ_0 , is very much greater than the smaller of the energies of the incident and emergent waves. It is found that in this case the energy exchange probability per collision is proportional to a sinusoidal factor which may have a value anywhere between 0 and 1, depending on the precise magnitude of ϵ_0 ; to a factor which decreases as the exponential of $\epsilon_0^{-1/2}$; and to a factor which depends on the angular momentum quantum number, l , and on the smaller of the incident and emergent wave numbers, k . This last factor is evaluated for fixed l with k^{-1} much less than the effective range of molecular interaction; for fixed l with k^{-1} much greater than the effective range; and for l large with k fixed. The relaxation time is obtained and both its magnitude and temperature dependence are discussed. Over an appropriate range of temperature it is found to decrease

COR. 15:002-004; COR. 18:001

as the exponential of $-T^{1/3}$, which is not the same as the Landau-Teller exponential of $T^{-1/3}$. The temperature dependence found in the present work is in better agreement with the observed high-temperature vibrational relaxation of oxygen, and essentially perfect agreement is obtained when the present approximation methods are applied with an exponential interaction energy. The magnitude of the relaxation time, however, is not predicted nearly so well as is its temperature dependence. (Contractor's abstract)

Also published in Jour. Chem. Phys., v. 28: 309-310, Feb. 1958.

A solution is given to the radial Schrödinger equation with a repulsive R^{-4} potential by means of the transformation to a standard Mathieu equation. The associated characteristic exponent in the Mathieu equation is an important parameter in determining the properties of the solution. Values of this exponent have been calculated for the six lowest angular momentum states and for a range of energies of interest in molecular dynamics. (Contractor's abstract, modified)

RELAXATION OF THE STRING OSCILLATOR, by B. Widom. [1958] 26p. incl. diag. (Technical note no. 3) (AFOSR-TN-58-12) (AF 18(603)111) AD 148051
Unclassified

Also published in Jour. Chem. Phys., v. 28: 918-925, May 1958.

A single collision between an oscillator and an impinging particle usually consists of a multiplicity of impacts. If the oscillator is a particle on an inextensible string (mechanically equivalent to a particle in a box), and if it interacts impulsively with particles of identical mass incident along its line of oscillation, then each collision either consists of a single impact, in which case momentum is exchanged, or of a double impact, in which case there is no net momentum exchange. The transition probability is calculated exactly, and the resulting integro-differential equation for the oscillator distribution function is solved explicitly. It is shown that the approach to equilibrium is

not in general exponential in the time, even in its last stages, but that it may be made so with a special initial distribution. The effect of impact multiplicity on the time of relaxation is discussed. (Contractor's abstract, modified)

ONE-DIMENSIONAL INELASTIC COLLISIONS WITH IMPULSIVE INTERACTIONS, by B. Widom. [July 1958] [31]p. incl. diagrs. (AFOSR-TN-58-895) (AF 18(603)111) AD 162229
Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-28, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 140, Mar. 27, 1958.

Also published in Jour. Chem. Phys., v. 30: 238-245, Jan. 1959.

A linear oscillator interacting impulsively with a free particle incident along its line of oscillation will in general suffer a change in state; and this model may be taken to represent an inelastic molecular collision. It is pointed out that this picture is substantially equivalent to that used by Castellan and Hulbert, with one modification. The problem is formulated for both quantum and classical mechanics. Explicit transition probabilities are calculated for two extreme cases: (i) the mass and momentum of the incident particle are small, while its energy is fixed; (ii) the mass of the incident particle is small and its energy is large, while its momentum is fixed. The quantum form of approximation (i) is essentially the approximate theory of Castellan and Hulbert. In the present paper the emphasis is on approximation (ii), for which it is shown that in both the classical and quantum theories the average energy transferred to an oscillator of mass m by an incident particle of momentum p is $2p^2/m$, whatever the law of force of the oscillator and whatever its initial state. It is also shown in this approximation that the classical transition probability for the harmonic oscillator may be recast in a pseudoquantum form so as to allow direct comparison with the quantum mechanical transition probability over the whole range of momenta of the incident particle. The dissolved chromic species formed when chromous perchlorate is oxidized in aqueous solution by molecular oxygen is shown by visible spectrum and behavior toward a cation exchange resin to be the same as the hydrolytic polymer which forms first when chromic solutions are refluxed. Analysis of the solution for chromium, perchlorate, and free acid shows the species to have a charge of +2 per Cr atom. Ion exchange experiments indicate that +4 is the most likely charge for the entire species, which is consistent with its being a dinuclear Cr(III) species with the two Cr atoms bound by either an O or two OH bridges. This same product can be formed by oxidation of Cr^{++} with Ti^{+3} and in lower yield by ClO_3^- , HClO , Cr_2O_7 and H_2O_2 . It is absent when the oxidation is performed with Fe^{+3} , Cu^{++} , Cl_2 , or Br_2 . It is believed that the dimer results from reaction of the intermediate Cr(IV) with Cr^{++} . Presented at Conference on Ultrasonic Energy Losses in Crystalline Materials, Brown U., Providence, R. I., Sept.

4-6, 1956 and at Canadian Metal Physics Conference, Kingston, Ont., Sept. 3-5, 1957.

Also published in part in Jour. Appl. Phys., v. 29: 1210-1214, Aug. 1958.

Equipment and techniques were developed for measuring the internal friction and Young's modulus of pure Cu crystals between 4° to 300°K by using longitudinal vibrations at a frequency of 38 to 42 kc. Measurements were also made on crystals containing various concentrations of Au or Ni. In the 99.99% pure, annealed, single crystals, the background decrement decreased monotonically with decreasing temperature. A sharper decrease near room temperature was observed in Au-doped annealed, single crystals, but not in the Ni-doped crystal. A peak at 180°K was observed in Au- or Ni-doped annealed reeds. Cold work generally increased the background decrement up to a 2% reduction after which it had little effect; the temperature dependence was less pronounced than in annealed crystals. The greatest amplitude dependence of the internal friction occurred in the pure, annealed, single Cu crystals. The addition of Au to Cu reduced the amplitude dependence appreciably. Ni produced the same result, but to a lesser degree than Au. Cold work also systematically reduced the amplitude dependence. The Bordoni peak is not present in annealed samples, either pure or doped. The peak is introduced by cold working the sample. Cross rolling had a more pronounced effect on the height of the peak than continued rolling in one dimension in excess of a 3% reduction. Increased cold work shifted the peak temperature to slightly higher values. Impurities of sufficient concentration decreased the peak height, shifted the peak temperature to slightly lower values, and increased the peak width. A second peak was observed in Cu samples at 40°K but was much smaller than the Bordoni peak. A peak at 20°K occurred in cross rolled Mg, but was not present in semi-annealed stock material. A HORIZONTAL, CONTINUOUS FLOW CRYOSTAT, by H. L. Caswell. [July 1957] [3]p. incl. diagr. (AF 18-(600)1000)
Unclassified

During an investigation of internal friction at low temperatures, it was found desirable to have a cryostat in which samples of up to seven inches in length could be mounted horizontally and in which measurements could be made at controlled temperatures from 5°K to 370°K. Since certain temperature ranges were of special significance, it was important to be able to regulate the rate of increase or decrease of temperature and to cover the same range of temperature more than once at any time during the experiment. It has been found that conventional cryostats were not suitable for this

COR.02:007 - COR.02:009

application. A continuous flow cryostat having the desired characteristics was developed and is described in this report.

REMARKS ON THE THEORETICAL INTERPRETATION OF THE BORDONI PEAK (Abstract), by V. K. Paré. [1957] [1]p. (AF 18(600)1000) Unclassified

Presented at the Canadian Metal Physics Conference, Kingston, Ont., Sept. 5-7, 1957.

The most promising explanation of the Bordoni low-temperature internal friction peak is that of A. Seeger, since it predicts that the temperature at which the peak occurs should be independent of the treatment of the sample. However, it also predicts a much narrower peak than is observed, and a marked dependence on strain amplitude, also not observed. Various possible sources of broadening of the peak are considered, and it is shown that a distribution of activation energies must exist. The shape of the distribution is inferred from the data presented by H. L. Caswell in the previous paper. To explain this, a distribution of internal stresses is postulated, and is found to reduce the strain amplitude dependence and also provide a distribution of activation energies. The results are compared with Caswell's data. A brief discussion is given of the possibility of applying Seeger's more elaborate theory in this way. (Contractor's abstract)

SOME EXPERIMENTAL RESULTS ON THE BORDONI INTERNAL FRICTION PEAK IN COPPER (Abstract), by H. L. Caswell. [1957] [1]p. (AF 18(600)1000) Unclassified

Presented at Canadian Metal Physics Conference, Kingston, Ont., Sept. 5-7, 1957.

The effect of cold work and subsequent annealing on the height and shape of the Bordoni internal friction peak at about 80°K in a 99.999% pure single crystal of copper has been studied at a frequency of 40,000 cps. It was found that no peak was present in the annealed crystal, but that as the crystal was subjected to increasing amounts of cold work, higher peaks occurred. Those phenomena are independent of the stress amplitude. Subsequent annealing reduced the amplitude of the peak. The addition of small amounts of nickel and gold was found not to seriously effect the height or shape of the peak. The result of freezing in a surplus of vacancies was also investigated. EXPERIMENTAL AND THEORETICAL STUDY OF LOW-TEMPERATURE INTERNAL FRICTION IN COPPER, by V. K. Paré. July 1, 1958, 1v. incl. illus. diagrs. tables, refs. (Technical rept. no. 4) (AFOSR-TR-58-92) (AF 18(600)1000) AD 162133; PB 138958 Unclassified

Measurements were made of internal friction in cold-worked copper single crystals as a function of temperature from 4°K to 300°K and at strains ranging from 10^{-7} to 2×10^{-5} . Flexural vibration was used at frequencies in the neighborhood of 5 kc. Particular attention was given to the Bordoni peak, a prominent maximum at about 80°K in the curve of internal friction versus temperature, apparently representing a thermally-activated relaxation process. The activation energy of the process was estimated as 0.18 ev by comparison of the data with that of other investigators at different frequencies. A theory of Seeger, Donth, and Pfaff is discussed which describes the interactions of dislocations with thermal stress waves and with the periodic potential giving rise to the Peierls force. The applicability of this theory and of some modifications introduced by the author is shown in terms of the activation energy and breadth of the Bordoni peak, and its dependence on the amplitude of oscillating strain employed in the measurement. INTERNAL FRICTION IN COPPER SINGLE CRYSTALS AT LOW TEMPERATURES (Abstract), by V. K. Paré, T. R. Cuykendall, and H. S. Sack. [1958] [1]p. [AF 18(600)1000] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 122, Mar. 27, 1958.

The internal friction maximum first observed by Bordoni at about 80°K is of interest because it may provide information on lattice barriers to dislocation motion. Results of measurements on cold-worked copper single crystals vibrated at 4 kc are described and compared with the 40 kc data of Caswell (item no. COR.02:005) on some of the same samples. The effects of frequency, mode of deformation, impurities, and aging on the position, height, and shape of the peak are discussed. The theory of Seeger, Donth, and Pfaff predicts the correct general behavior but gives a peak which is

much too narrow and shifts with changes in strain amplitude. Taking into account the internal stresses in cold-worked metal eliminates the latter effect and broadens the peak in a way which depends on the relaxation model used.

The method used in a previous paper on the Phragmén-Lindelöf theorem is applied to some other boundary conditions. The prescribed growth functions in the resulting theorems form successive steps of a logarithmic scale. The existence theorem in this paper is treated by means of the Poisson formula. ON THE PHRAGMÉN-LINDELÖF THEOREM AND SOME APPLICATIONS, by H. Rademacher. Aug. 1957, 20p. (Rept. no. 66) (AFOSR-TN-57-453) (AF 18(600)-685) AD 136443; PB 135990 Unclassified

Also published in Math. Zeitschr., v. 72: 192-204, 1959.

The Phragmén-Lindelöf theorem for a parallel strip is usually enunciated for a single function and contains a multiplicative constant possibly depending on the function. Here a statement of the theorem is evolved which is valid uniformly for an infinite set of functions and which is sharp. The basic idea is to use a special subharmonic function for a lower estimate of a harmonic function. Applications are made to families of $L(s, \chi)$ - and $\xi_k(s)$ -functions with new results.

AN EXTREMUM PROBLEM, by H. Widom. Sept. 1957, 12p. (Rept. no. 69) (AFOSR-TN-57-536) (AF 18(600)-685) AD 136522; PB 135984 Unclassified

Let $f(\theta)$ be non-negative and integrable on $(-\pi, \pi)$, and $|a| < 1$. G. Szego has shown that the infimum of

$$(1) \quad \frac{1}{2\pi} \int_{-\pi}^{\pi} |P(e^{i\theta})|^2 d\theta,$$

taken over all polynomials P with $P(a) = 1$ is given by

$$(2) \quad \exp\left(\frac{1}{2\pi} \int_{-\pi}^{\pi} \log f(\theta) \frac{1-p^2}{1-2p \cos(\theta-\gamma) + p^2} d\theta\right)$$

where $pe^{i\gamma} = a$. In this paper the following result was: Let L be a linear functional on the space of polynomials; then we find the infimum of (1) taken over all P with $L(P) = 1$. The actual form of the result is somewhat complicated (in fact the formula takes different forms depending on the behavior of f and L) but (2) drops out of it quite easily. (Contractor's abstract)

A THEOREM ON POWER SERIES WHOSE COEFFICIENTS HAVE GIVEN SIGNS, by W. H. J. Fuchs. [1957] [7]p. (AF 18(600)685) Unclassified

Published in Proc. Amer. Math. Soc., v. 8: 443-449, June 1957.

The well-known theorem of Hurwitz and Pólya (Acta Math., v. 40: 179-183, 1915) says that if $\sum a_k z^k$ is a power series with finite radius of convergence then it is possible to find a sequence $\{e_k\}$ ($e_k = \pm 1$) such that the series $\sum e_k a_k z^k$ has the circle of convergence as natural boundary. In the present paper the following sort of converse to the above results is proven. If $\{e_k\}$ is a sequence with $e_k = \pm 1$ then there is always a power series $\sum a_k z^k$, $a_k > 0$, of finite radius of convergence such that the series $\sum e_k a_k z^k$ can be analytically continued across a semi-circle on its circle of convergence. It is shown that the semi-circle cannot be replaced by a larger arc. It remains an open question to find a corresponding theorem for the case in which e_k is a given sequence of complex numbers of absolute value one. (Math. Rev. abstract)

SINGULAR INTEGRAL OPERATORS, AND DIFFERENTIAL EQUATIONS, by A. P. Calderón and A. Zygmund. [1957] [21]p. (AF 18(600)685) Unclassified

Published in Amer. Jour. Math., v. 79: 901-921, Oct. 1957.

Let $P(u)$ be a linear partial differential operator with smooth coefficients and of homogeneous order m . Then $P = HA^m$ where A is a square root of the Laplacian and H is a singular operator. With each singular integral operator there is associated a function in a one-to-one fashion. This correspondence is linear and pseudo-multiplicative in the sense that, modulo a class of regular operators, singular integral operators can be multiplied (in the sense of operator composition) by simply multiplying their symbols. The regular operators in that class have the property of remaining bounded after being multiplied on the left or on the right by A . A detailed study is presented of the properties of singular integral operators in their connection with the operator A .

ON THE PARTITION FUNCTION OF A ONE-DIMENSIONAL GAS, by M. Kac. Mar. 1958 [10]p. (Rept. no. 75) (AFOSR-TN-58-201) (AF 18(600)685) AD 152234; PB 140050 Unclassified

Also published in Phys. Fluids, v. 2: 8-12, Jan.-Feb. 1959.

The grand-partition function of a one-dimensional gas is calculated with the potential $V(x)$ given by the formula

$$V(x) = \begin{cases} +\infty, & 0 < x < \delta, \\ -ae^{-\gamma x}, & x \geq \delta. \end{cases}$$

The crucial feature of the potential responsible for the success of the calculation is that $e^{-\gamma|x|}$ is the correlation function of a stationary, Gaussian, Markoffian process (the Ornstein-Uhlenbeck process).

OPTIMUM DESIGNS IN REGRESSION PROBLEMS, by J. Kiefer and J. Wolfowitz. Feb. 1959, 35p. incl. refs. (Rept. no. 79) (AFOSR-TN-58-389) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)685 and Office of Naval Research) AD 154298; PB 140048 Unclassified

Also published in Ann. Math. Stat., v. 30: 271-294, June 1959.

Computational procedures are developed for finding optimum designs in regression problems of estimation and testing hypotheses. The theory is developed for the case where the desired inference concerns just one of the regression coefficients; illustrative examples are given. The theory for the case of interference on several coefficients is also developed. The problem of global estimation is treated for the regression function rather than that of the individual coefficients.

INVERSION OF TOEPLITZ MATRICES, by A. [P.] Calderón, F. Spitzer, and H. Widom. Mar. 1958, 16p. (Rept. no. 76) (AFOSR-TN-58-489) (AF 18(600)685) AD -58297; PB 140047 Unclassified

Also published in Illinois Jour. Math., v. 3: 490-498, Dec. 1959.

Conditions are found for the invertibility of the Toeplitz matrix $T = (c_{j-k})$, $j, k = 0, 1, \dots$. In case $\sum_{k=0}^{\infty} |c_k| < \infty$, T is a bounded operator on the space of bounded sequences and a necessary and sufficient condition for the invertibility of T is found, and the matrix T^{-1} is produced. As a consequence of the theory a Tauberian theorem is proved. In case $\sum_{k=0}^{\infty} c_k e^{ik\theta}$ is in $L_{\infty}(-\pi, \pi)$, T is a bounded operator on the space of square summable sequences and a sufficient condition is found for the invertibility of T . MINIMAX FUNCTIONS, CONFIGURATION FUNCTIONS AND PARTITIONS, by R. P. Agnew. May 1958, 27p. incl. tables. (Rept. no. 77) (AFOSR-TN-58-490) (AF 18(600)685) AD 158298; PB 140068 Unclassified

Two classes of functions defined by R. W. Murphy (IBM Jour. Research and Development, v. 1: 158-170, 1957) are investigated: class F_n of minimax functions, and class G_n of functions called configuration functions. Each function is continuous of F_n and in G_n . When $n > 2$, G_n contains discontinuous as well as continuous functions. Proof is presented of Murphy's conjecture that each continuous function in G_n is continuous in F_n so that $F_n = CG_n$ where C is the class of continuous

COR.05:076 - COR.05:078

functions, and the results show how the values of a function g in CG_n determines the f in F_n to which it is equal. A partition problem which was originated by Dedekind and which is related to the determination of the number of free distribution lattices having n generators is presented.

ON RAPIDLY MIXING TRANSFORMATIONS AND AN APPLICATION TO CONTINUED FRACTIONS, by M. Kac and H. Kesten. June 1958, 5p. (Rept. no. 78) (AFOSR-TN-58-491) (AF 18(600)685) AD 158299

Unclassified

Also published in Bull. Amer. Math. Soc., v. 64: 283-287, Sept. 1958.

Proof is presented of the theorem: Let Ω be a measure space (of total measure 1) and let T be a measure preserving transformation in the sense that $\mu(T^{-1}(A)) = \mu(A)$, where $T^{-1}(A)$ denotes the inverse image of A (not assuming that T is necessarily one-to-one). Let

$$V(\omega) = \begin{cases} 1, & \omega \in B \\ 0, & \omega \notin B \end{cases} \text{ and consider } \sum_{k=1}^n V(T^k \omega).$$

Under suitable conditions on T , the conditional measure

$$\mu \left\{ \frac{\sum_{k=1}^n V(T^k \omega)}{n} \in \mu(B) \pm \frac{\epsilon}{n}, \omega \in B \right\}$$

approaches, as n tends to infinity, $\frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\frac{u}{\sigma\sqrt{2\pi}}} e^{-\frac{u^2}{2\sigma^2}} du$

where σ is, in general, not known explicitly. The condition imposed on T is that of exponential rapid mixing. If ν is a measure absolutely continuous with respect to the invariant measure μ then, for every measurable set A , $|\nu(T^{-k}(A)) - \mu(T^{-k}(A))| =$

$$|\nu(T^{-k}(A)) - \mu(A)| \leq H_\nu e^{-\epsilon k} \mu(A),$$

where $\epsilon > 0$ is an absolute constant and H_ν a constant which may depend on the measure ν . (ASTIA abstract)

THE MAXIMUM ACHIEVABLE LENGTH OF AN ERROR CORRECTING CODE, by J. Wolfowitz. [1958] [5]p. (AFOSR-TN-58-533) (In cooperation with Technion-Israel Inst. of Tech., Haifa) (AF 18(600)685) AD 158349

Unclassified

Also published in Illinois Jour. Math., v. 2: 454-458, Sept. 1958.

The author uses results described in previous articles (Ill. Jour. Math., v. 1: 591-606, 1957, and Ill. Jour. Math., v. 2: 137-141, 1958) to obtain bounds for the size of an error-correcting block code in a discrete channel with memory m . The bounds do not involve the statistical nature of a source feeding to the channel. That is, there exists a functional J of the channel error probabilities which has the following property. Let $\epsilon > 0$ and $\lambda > 0$ be arbitrary, and let n be sufficiently large. Then there exists a block code of block length n which handles $2^{n(J-\epsilon)}$ code sequences with probability of error less than λ each, but no code of block length n and error bound λ contains more than $2^{n(J+\epsilon)}$ code sequences. If the channel capacities for independent [Markov, ergodic stationary] sources are C_0, C_1, C_2 , respectively, then $C_0 \leq C_1 \leq C_2 \leq J$. The author conjectures that $C_1 < J$ when $m > 1$. He reduces the problem for $m > 0$ to the memoryless case ($m = 0$) by considering subblocks of suitable length and discarding the small fraction (essentially, ϵ in $J \pm \epsilon$) of received symbols at the end of each subblock which produce memory between subblocks. Thus the spread of $O(1)$ of bounds for the case $m > 0$ is larger than the corresponding spread $O(n^{-1/2})$ the author has obtained in the case $m = 0$ [above references]. (Math. Rev. abstract)

ASYMPTOTIC MINIMAX CHARACTER OF THE SAMPLE DISTRIBUTION FUNCTION FOR VECTOR CHANGE VARIABLES, by J. Kiefer and J. Wolfowitz. [1958] [27]p. (AFOSR-TN-58-534) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)685 and Office of Naval Research) AD 158350

Unclassified

Also published in Ann. Math. Stat., v. 30: 463-489, June 1959.

The authors, in a joint paper with (Dvoretzky, Kiefer, and Wolfowitz, Ann. Math. Statistics, v. 27: 642-669, 1956) have shown that for a very general class of weight functions the sample distribution is an asymptotically minimax estimator of the distribution of a real valued random variable. In the present paper similar results

COR.05:079 - COR.05:081

are obtained for (finite dimensional) vector-valued random variables. The method of the quoted paper must be greatly modified since the "distribution-free" properties of the sample d.f. no longer hold. The authors utilize their previous results (Trans. Amer. Math. Soc., v. 87: 173-186, 1958) on the deviation of the sample d.f. from the true d.f. in the multi-dimensional case. From the uniformity of approach of the d.f. of the normalized maximum deviation to its limit the authors deduce the existence of an approximately least favorable distribution and proceed hence to prove the following result: Let $W(r)$, for $r \geq 0$, be continuous, non-negative, non-decreasing, not identically zero and satisfy (*) $\int_0^\infty rW(r)e^{-cm'r^2} dr < \infty$ (c_m being a positive constant depending only on m); then the sequence of sample d.f. is asymptotically minimax relative to the sequence of weight functions

$$W_n(F, g) = W(n \sup_z |g(z) - F(z)|)$$

and the family of all m -dimensional d.f. F . A similar result with c_m replaced by 2, is proved for integral weights $W_n(f, g) = \int W(n|F(x) - g(x)|) dx$. Generalizations to other loss functions, etc., are indicated. (Math. Rev. abstract)

UNIQUENESS IN THE CAUCHY PROBLEM FOR PARTIAL DIFFERENTIAL EQUATIONS, by A. P. Calderón. [1958] [21]p. Incl. refs. (AF 18(600)685)
Unclassified

Published in Amer. Jour. Math., v. 80: 16-35, Jan. 1958.

The problem of distinguishing all the types of partial differential equations, whose solutions are uniquely determined by Cauchy data, is of widespread current interest. In the paper under review, considerable advances are made in the general solution of this problem on the hypothesis that the (real and complex) characteristics of the equations considered are non-multiple. Linear equations first are considered, then systems of linear equations, and finally non-linear equations and systems reduced by well known methods to the linear case. The smoothness required of the coefficients in the linear cases, and of the differential equations in the non-linear cases, is light. Uniqueness in Cauchy's problem then is established for second and third order equations in any number of independent variables (the second order case is already known from Aronszajn, Jour. Math. Pures Appl., v. 36: 235-249, 1957), for equations of any order not in three independent variables, and for systems of equations not in three or four independent variables. The method is based on the fact that a linear differential operator Au of homogeneous order m defined on all Euclidean space and with bounded coefficients is

representable as $Au = H\Delta^m u$, where Δ is a square root of the negative of the Laplacian, and H is a singular integral operator. This fact, in the light of properties of Δ and H previously established by Calderón and Zygmund (Amer. Jour. Math., v. 79: 901-921, Oct. 1957), makes possible the reduction of the uniqueness problem to a relatively simple form. (Math. Rev. abstract)

ASYMPTOTIC DISTRIBUTION OF STOCHASTIC APPROXIMATION PROCEDURES, by J. Sacks. [1958] [33]p. Incl. refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)685] and Office of Naval Research)
Unclassified

Published in Ann. Math. Stat., v. 29: 373-405, June 1958.

The asymptotic behavior is studied of the Robbins-Munro and Kiefer-Wolfowitz procedures. The result concerning Robbins-Munro is reproduced. Let: (1) $M(x)$ be Borel-measurable, $(x - \theta)(M(x) - \alpha) \geq 0$ and $|M(x) - \alpha| < K|x - \theta|$ for all x , $M(x) = \alpha + \alpha_1(x - \theta) + o(|x - \theta|)$ as $x \rightarrow \theta$, with $\alpha_1 > 0$ and $\inf |M(x) - \alpha| > 0$ over every compact interval not containing θ ; (2) $Z(x)$ be, for every x , a random variable, $\sup_x Z(x) < \infty$, $EZ^2(x) = \sigma^2$ as $x \rightarrow \theta$ and $\lim_{R \rightarrow \infty} \lim_{\epsilon \rightarrow 0} \sup_{|x-\theta| < \epsilon, \int_{|Z(x)| > R} Z^2(x) dP = 0$; (3) $a_n = A/n$ with $A > 1/(2\alpha_1)$. Then if $EX_1^2 < \infty$ and $X_{n+1} = X_n - a_n[M(X_n) - \alpha + Z(X_n)]$, it follows that $n^{1/2}(X_n - \theta)$ is asymptotically normally distributed with mean 0 and variance $A^2\sigma^2/(2A\alpha_1 - 1)$. The first results of this nature were proved by K. L. Chung [Ann. Math. Stat., v. 25: 463-483, 1954]. Chung and his followers used the method of moments; this paper utilizes instead a central limit theorem for dependent random variables and this enables him to obtain asymptotic normality under more general conditions than hitherto. Some remarks on "best possible" aspects of the results are made and the multidimensional case is also treated. (Math. Rev. abstract)

A THEOREM ON THE NEVANLINNA DEFICIENCIES OF MEROMORPHIC FUNCTIONS OF FINITE ORDER, by W. H. J. Fuchs. [1958] [7]p. (AF 18(600)685)

Unclassified

Published in Ann. Math., v. 68: 203-209, Sept. 1958.

The author proves the following theorem. Let $f(z)$ be a meromorphic function of finite lower order λ , and set $q = \max(2, \lambda)$. Then if δ_k are the defects in the sense of Nevanlinna, we have $\sum (\delta_k)^{\frac{1}{2}} \leq (Aq \log q)^{\frac{1}{2}}$. No other inequality of such generality is known, apart from the Nevanlinna defect relation $\sum \delta_k \leq 2$. The author states that an example of A. A. Goldberg [Dokl. Akad. Nauk. SSR, v. 98: 893-895, 1954] can be modified to show that the index $\frac{1}{2}$ cannot be replaced by any smaller number. Also $q \log q$ cannot be replaced by anything smaller than q . The proof is surprisingly simple and depends on an estimation of the variation of $\log |f(z)|$ on the circle $|z| = r$. (Math. Rev. abstract)

X-ray reflection curves were recorded and analyzed as a function of heat-treatment for thin Cu films of nominal thicknesses 35, 75, 120, 150, and 200A. The films were evaporated onto glass substrates; both Pyrex and soft glass substrates were used. The soft glass exhibited a surface layer of reduced density, about 50A of 20% reduction; for Pyrex glass, there was little if any such evidence. Fresh Cu films on soft glass showed an intensity minimum near ϵ_c , the cut-off angle bounding the region of total reflection. Films on Pyrex did not show this minimum, possibly due to the difference in the substrate surface and in its influence on the film structure. As a function of the heat-treatment up to 400°C, the general trend in the shapes of the curves and in the values of ϵ_c were similar. For the 120A and 150A

films, initial treatments up to 100°C caused ϵ_c to decrease

slowly. After treatment at 130°C, ϕ_2 decreased rapidly to a value well below that predicted for Cu_2O or CuO . For the 75 Å films, the rapid decrease in ϕ_2 occurred at about 100°C. Continued heat-treatments above about 200°C caused ϕ_2 to increase slightly to an apparent saturation value. At about 300°C, a ϕ_2 pronounced low angle minimum developed in the reflected intensity for films on soft glass and became progressively deeper with additional heat-treatments. Reflection curves for thick-fresh Cu, Al and Au are discussed with respect to the determination of the dispersion constants used in the theoretical calculations. (ASTIA abstract)

CORRECTION OF COMPLEX SPECTRA FOR INSTRUMENTAL RESOLVING POWER. PART II (Abstract), by J. O. Porteus and L. G. Parratt. Feb. 1, 1957 [1]p. [AF 18(600)300] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 55, Jan. 30, 1957.

In Part I (item no. COR.07:013) the general problem is stated and a solution outlined for certain model windows. For Part II, a different solution is given, one having greater practical generality. The observed spectrum is regarded as a superposition of the true spectrum and a perturbation function. The present solution is practical in almost all actual cases; however two formal conditions must be met: (a) a unique solution must exist and (b) the perturbation function must be expressible as a series of "correction functions" having uniformly decreasing amplitudes. These correction functions are calculated directly by taking successive "folds" (convolutions) of the spectral window (assumed to be known) with the observed spectrum. The calculation can be readily performed on a digital-type computer, or even on a desk calculator if a low order of correction is satisfactory. Estimates of the accuracy of the corrected spectrum, point by point, are provided by the correction functions themselves. Illustrative examples are given for an ideal simple spectrum and for complex x-ray emission and absorption spectra as observed with a two-crystal spectrometer.

NOTES ON THE PROSPECTIVE USE OF THE ORBIT-RADIATION OF A HIGH-ENERGY SYNCHROTRON IN

X-RAY PHYSICS IN THE 0.1 TO 20Å REGION, by L. G. Parratt. May 1, 1958 [13]p. incl. diagrs. table. (Technical rept. no. 12) (AFOSR-TN-58-473) (AF 18(600)300) AD 158284 Unclassified

Also published in Rev. Scient. Instruments, v. 30: 297-299, Apr. 1959 (Title varies).

It is proposed to use the "very costly" orbit radiation for irradiation experiments, structure analysis, fluorescence spectroscopy, radiography, etc. This radiation, which is a waste product of a synchrotron, is shown theoretically to be much more intense for a 6 bev machine than the x-rays obtained from conventional x-ray tubes. For the 1 bev machine the orbit radiation is of about the same intensity as that from a conventional tube for wavelengths of about 1Å. For longer wavelengths the intensity of advantage goes up rapidly until at 10Å it is about 10^4 .

A STUDY OF EVAPORATED ALUMINUM FILMS BY X-RAY TOTAL REFLECTION, by R. C. Duncan and L. G. Parratt. Aug. 21, 1958, [100]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 13) (AFOSR-TN-58-680) (AF 18(600)300) AD 162212; PB 137433

Unclassified

The nature of the surface of thick aluminum films evaporated onto glass substrates has been studied by the method of total reflection of x-rays. Films freshly deposited, then heat treated in successive steps up to 400°C or anodized in successive steps up to an oxide thickness of about 625Å, have been studied. Details of the alignment of the reflectometer and of the preparation and treatment of the films are given. The theory of reflection based on homogeneous media accounts reasonably satisfactorily for the shape of the reflection curves near the critical angle for total reflection, but it seems necessary for the heat treated and anodized films to introduce a surface model which contains inhomogeneities in order to account for the shapes of the curves at smaller glancing angles. X-ray small-angle scattering from such inhomogeneities is discussed. (Contractor's abstract)

X-RAY ABSORPTION COEFFICIENTS AND GEOMETRICAL COLLIMATION OF THE BEAM, by L. G. Parratt, J. O. Porteus and others. Sept. 1, 1958, 14p. incl. diagrs. table, refs. (Technical rept. no. 14) (AFOSR-TN-58-755, (AF 18(600)300) AD 201614; PB 138143 Unclassified

COR.07:024 - COR.07:027

Also published in *Rev. Scient. Instruments*, v. 30: 344-347, May 1959.

In order to achieve high angular collimation of an intense x-ray beam in a measurement of an absorption coefficient, most investigators have used the action of a high-resolving-power monochromator to provide the collimation. If the absorber exhibits small-angle scattering (including multiple scattering) of significant intensity in a scattering cone as large as a few seconds of arc, the value of the coefficient depends upon the absorber-position with respect to the monochromator. A few measurements are reported with a two-crystal spectrometer to illustrate the points discussed. (Contractor's abstract)

THEORY OF SCATTERING OF X-RAYS AT ULTRA-SMALL ANGLES, by A. W. K. Metzner and L. G. Parratt. Sept. 14, 1958, 28p. incl. diagrs. tables, refs. (Technical rept. no. 15) (AFOSR-TN-58-780) (AF 18-(600)300) AD 202001; PB 137537 Unclassified

The theory of small-angle x-ray scattering was developed mathematically with an attempt to clarify the picture in the ultra-small-angle region. Interparticle interference effects are observed to play a dominant role. The theory of small-angle scattering as developed is somewhat equivocal about this ultra-small angular region, the region within about 10 sec of arc of the axis of symmetry. No theory based on just the single scattering process was found to predict the experimental scattering curve correctly in this region, and multiple scattering theory has not been developed to the point where interparticle interference effects are considered.

DENSITY MEASUREMENTS OF THIN COPPER FILMS (Abstract), by N. Wainfan, M. Hommel and others. [1958] [1]p. [AF 18(600)300] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in *Bull. Amer. Phys. Soc., Series II*, v. 3: 192, May 1, 1958.

A series of "smooth" copper films, evaporated onto optically flat Pyrex substrates, was investigated. Film thickness was determined from the multiple-beam x-ray interference patterns formed on reflection near the critical angle using equations based on an ideal three media model. Mass per unit area was measured by a

chemical colorimetric method. In the range between 500 and 1100 Å, films smooth enough to exhibit the x-ray interference pattern were found to have bulk density. Present results for the above thickness range yield a density of 9.03 ± 0.36 g/cc. The values compiled by Foote and Jette for bulk copper are between 8.814 and 8.953 g/cc. Comparisons of x-ray thickness determinations with those obtained by optical interference methods are discussed.

NEW TYPE OF X-RAY ENERGY LEVEL DIAGRAM (Abstract), by L. G. Parratt. [1958] [1]p. [AF 18(600)-300] Unclassified

Presented at meeting of the Amer. Phys. Soc., Ithaca, N. Y., June 19-21, 1958.

Published in *Bull. Amer. Phys. Soc., Series II*, v. 3: 263, June 19, 1958.

Each level in the conventional diagram is based on a theoretical ionization state, i.e., a state in which the inner electron has been ejected to "infinity" and all the remaining electrons in the system have assumed adjusted but unique positions. In application, this diagram is confusing on several counts: (1) "infinity" is not a practical reference position, especially in a solid, (2) the ejected electron may remain bound, albeit lightly, to the positive hole it left behind, giving rise to an excitation state (or exciton), and (3) the other electrons in the system may not assume unique positions for a given inner vacancy. The confusion is greatest in solid-state spectroscopy. Some attempts have been made to include the excitation states in the diagram, but then the indicated energy differences are not correct for actual transitions. A new type of diagram, qualitative at the present state of our knowledge, is proposed in which there are many different energy states associated with each inner electron vacancy.

RESOLVING POWER CORRECTION IN PRECISION MEASUREMENTS OF COMPLEX STRUCTURE (Abstract), by J. O. Porteus and L. G. Parratt. [1958] [1]p. [AF 18-(600)300; continued by AF 49(638)403] Unclassified

Presented at meeting of the Amer. Phys. Soc., Ithaca, N. Y., June 19-21, 1958.

Published in *Bull. Amer. Phys. Soc., Series II*, v. 3: 263, June 19, 1958.

An observed spectral curve is always the convolution of the true curve and a resolving power smearing function.

In case the resolving power smear is rather large (e.g., width of the spectral window larger than the width of a component in the true curve), it is imperative that the correction procedure be such as to minimize the final uncertainty in each true-curve point. Uncertainties arise because of experimental errors and finite interval spacings in the observed curve and in the smearing function. An optimum correction method is discussed and applied to the case of the x-ray chlorine K absorption spectra in crystalline KCl as an example in which two resolving power functions are treated successively, i.e., instrumental resolving power and then the smearing by the x-ray K-state, to arrive at a density-of-states curve of the solid. The method, practical if a digital computer is available, is sufficiently general that it may be applied to many other experimental problems requiring an optimum solution of the convolution integral.

STUDIES ON THE SEPARABILITY OF SIZE EFFECTS IN ELECTRON DIFFRACTION FROM SINGLE CRYSTAL SURFACES, by H. P. Furth, J. A. Krumhansl, and B. M. Siegel. Apr. 1, 1958 [21]p. incl. illus. diagrs. refs. (Technical rept. no. 7) (AFOSR-TN-58-284) (AF 18(600)674, Task 1) AD 154185 **Unclassified**

Reflection electron diffraction at low angles from very smooth surfaces of solids give an interface pattern which is produced by electrons scattered from only a few net planes of atoms parallel to the surface. An analysis is attempted of the information that can be obtained on the character of the diffraction phenomena from these surface net planes, conditioned by the nature of the investigations of surfaces by electron diffraction. The relaxation of the Laue conditions caused by the limited extent of the atomic arrays producing a given coherent interference will be the overriding factor in determining the type of diffraction pattern obtained from low angle electron diffraction from very smooth surfaces. The relaxation phenomena are analyzed through the use of a semi-dynamical model, which can lead to a method for investigating the possible lattice contraction of crystals in the surface planes. STRUCTURE OF COPPER FILMS (Abstract), by B. M. Siegel. [1958] [1]p. [AF 18(600)674, Task 1] **Unclassified**

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3 102, May 1, 1958.

The structure of thin films of copper deposited by vacuum evaporation on mica substrates has been studied utilizing a technique in which transmission electron microscopy, surface replication, and electron diffraction observations can be made on the same film. Investigations have been made on films of thicknesses from 15 to 1000A in which the deposits were made on freshly cleaved mica kept at temperatures ranging up to 450°C during deposition. When the copper is deposited on the mica at the higher temperatures there is crystallite growth which upon examination produces an interesting array of electron interference phenomena. The patterns obtained are interpreted in terms of defect structures such as stacking faults and dislocations.

STUDIES ON THE STRUCTURE OF EVAPORATED METAL FILMS WITH THE ELECTRON MICROSCOPE (Abstract), by B. M. Siegel. [1958] [1]p. (AF 18(600)-674, Task 1) **Unclassified**

Presented at meeting of the Electron Microscope Soc. Amer., Santa Monica, Calif., Aug. 7-9, 1958.

Published in Jour. Appl. Phys., v. 29: 1619, Nov. 1958.

The electron microscope has been used in a study of evaporated metal films (mainly copper), investigating with different modes of operation and methods, the structure of the deposit, the surface, the crystallite defect structure, and the mass density. Transmission electron microscopy gives important information on the defect structure of the crystal lattice which is not shown by surface examination by replication. The inelastic scattering at very low angles has been investigated as a method for determining the mass density of evaporated films and correlated with the structure observed by other methods.

THE ADSORPTION OF NICKEL AND ZIRCONIUM ON A CLEAN MOLYBDENUM SURFACE IN THE FIELD EMISSION MICROSCOPE, by E. C. Melvine and R. C. Bradley. May 1, 1957, iv. incl. illus. diagrs. table, refs. (Technical rept. no. 5) (AFOSR-TN-57-151) (AF 18(600)-674, Task 1) AD 126440 **Unclassified**

An investigation of two adsorption systems, nickel on molybdenum and zirconium on molybdenum, is compared with theoretical considerations of adsorption phenomena. Nickel was found to adsorb coherently on molybdenum, preferentially on the (111) planes of the substrate. For coverages of about 1/5 of a monolayer, the following activation energies were determined:

COR.08:011 - COR.08:013

- $Q_d = (2.10 \pm .05) \text{ ev}$ (desorption)
- $Q_m = (1.31 \pm .08) \text{ ev}$ (surface migration 1/4 completed)
- $Q_m = (1.42 \pm .05) \text{ ev}$ (surface migration 1/2 completed)
- $Q_m = (1.48 \pm .06) \text{ ev}$ (surface migration 3/4 completed)

The desorption energy did not vary with degree of completion. Heavy adsorbed layers of nickel were investigated. The equilibrium position of heavy layers was found to be field-dependent. Zirconium adsorbed incoherently, in small spots on the (100) planes. Activation energies for zirconium on molybdenum were:

- $Q_d = (4.10 \pm .15) \text{ ev}$ (desorption)
- $Q_m = (2.90 \pm .15) \text{ ev}$ (field-free surface migration)
- $Q_m = (1.36 \pm .15) \text{ ev}$ (field-enhanced surface migration).

The results of D'Asaro's molybdenum-zirconium alloy studies were reinterpreted to be indicative of purely surface phenomena. (Contractor's abstract)

FIELD EMISSION MICROSCOPE STUDIES OF Zr ON Mo (Abstract), by R. C. Bradley and E. C. McIrvine. [1957] [1]p. [AF 18(600)674, Task II] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Also presented at Field Emission Symposium, Penn. State U., University Park, June 27-29, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 214, Apr. 25, 1957.

The field emission microscope has previously been used to investigate the surface conditions of an alloy of a few percent of zirconium in molybdenum. The results were interpreted on the basis of a volume diffusion process, for which an activation energy was measured. To test this interpretation, Zr was evaporated onto a Mo field-emission point and an activation energy for surface migration was measured. The agreement between measured activation energies plus the similarities in the emission patterns obtained in the two different ways suggest that in the case of the alloy the rate-controlling mechanism was also surface migration, the Zr coming from sources (presumably grain boundaries) along the shank of the point. It is thought that the initial high-

temperature flash, used primarily to clean the emitting surface of the alloy, also served to replenish these sources. Activation energies for desorption of Zr from both the alloy and the Mo surface have also been obtained and are in good agreement.

SURFACE STUDY OF EVAPORATED ALUMINUM BY X-RAY TOTAL REFLECTION METHOD (Abstract), by R. C. Duncan, and L. G. Parratt. [1957] [1]p. [AF 18(600)674, Task II] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 215, Apr. 25, 1957.

Aluminum films 5000A thick, evaporated onto optically flat Pyrex glass substrates, have been studied by the x-ray total reflection method. Somewhat different rates of evaporation and different residual gas pressures were used. Five films were subjected to repeated heat treatments in atmospheric air at temperatures up to 400°C for periods up to 12 hr. Without exception they showed a marked and progressive drop in x-ray reflectivity over the entire "total" reflection region, accompanied by a very slight decrease in the critical angle and by the appearance of patches of blister-like spots over a large portion of the film surface. The most pronounced decrease in reflectivity occurred at small glancing angles, producing there a reflectivity minimum which grew progressively deeper with successive heatings. Similar films, aged at room temperature or oxidized by anodization, exhibited no such effects. The anodized film showed an increasing critical angle approaching that expected for the higher density oxide. Various sensitive parameters of the changing reflection curves appear to be better correlated with number of heatings than with temperature or length of heat treatment.

SURFACE STUDY OF EVAPORATED COPPER BY X-RAY TOTAL REFLECTION METHOD (Abstract), by N. J. Scott and L. G. Parratt. [1957] [1]p. [AF 18(600)-674, Task II] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 215, Apr. 25, 1957.

Thin copper films (35 to 150A thick) evaporated onto

glass substrates were studied. Contrary to observations with soft glass substrates, similar "fresh" copper films on Pyrex do not show a minimum near the critical angle. Films of 75, 120, and 150A on Pyrex were subjected to successive heat treatments up to 400°C in laboratory air. After treatment to about 130°C, the critical angle θ_c was observed to be greatly reduced, even well below the value predicted for Cu_2O on glass.

Then, continued heat treatments above about 200°C caused θ_c to increase slightly to an apparent saturation value. Similar treatments with 75A films on soft glass caused the minimum near the critical angle to "wash out" completely by the time θ_c reached its minimum

value. A pronounced low-angle dip, as observed for aluminum, developed at 300°C for films on soft glass substrates only and became progressively deeper with additional heat treatments. Theoretical dispersion calculations based on the simplest film model (having uniform density) predict only the qualitative shape of the reflection curve for either fresh or heat treated films.

SPUTTERING OF MOLYBDENUM BY INERT GAS IONS OF LOW ENERGY (Abstract), by R. C. Bradley, R. C. Stabler, and A. Arakengy. [1957] [1]p. [AF 18(600)674, Task II] Unclassified

Presented at meeting of the Amer. Phys. Soc., Notre Dame U., South Bend, Ind., June 20-22, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 269, June 20, 1957.

A high vacuum 6-in. radius 60° sector field mass spectrometer has been used to study particles ejected from a molybdenum surface under bombardment by inert gas ions of low energy (< 1000 ev). The method is similar to one described recently by Honig, and has general applicability both for the analysis of surfaces of solids and for the study of sputtering. Despite the relatively large energy spread of the ejected particles, the seven isotopes of Mo could be clearly resolved in both the Mo and the MoO_2 peaks. An important feature of the method

is that there is inappreciable heating of the sample due to the ion bombardment; thus target temperature is left as an independent variable. Energy thresholds for sputtering were measured as a function of target temperature and are in good agreement with Wehner's "velocity-of-sound" formula. For a given ion energy, the sputtering was observed to decrease monotonically as the target temperature was increased. A surprising result was the high percentage of ejected particles which bore a positive charge.

FIELD EMISSION FROM MAGNESIUM DEPOSITED ON TUNGSTEN (Abstract), by K. Scharf. [1957] [1]p. (Sponsored jointly by Wright Air Development Center and Air Force Office of Scientific Research under [AF 18-(600)674, Task II]) Unclassified

Presented at Field Emission Symposium, Penn. State U., University Park, June 27-29, 1957.

Field emission patterns have been observed from magnesium deposited on a clean tungsten point. The effective work functions, measured after annealing the point at different temperatures show changes as may be expected from the changing coverage of the point. An abrupt change of the effective work function from approximately 2.5 ev to 3.5 ev has been observed, when the magnesium has spread over the whole point. The latter value compares favorably with values measured by photoelectric methods.

ADSORPTION OF NICKEL ON MOLYBDENUM IN THE FIELD EMISSION MICROSCOPE, by E. C. McIrvine and R. C. Bradley. [1957] [7]p. incl. illus. diagrs. tables, refs. [AF 18(600)674, Task II] Unclassified

Presented at meeting of the Amer. Phys. Rev., Washington, D. C., Apr. 25-27, 1957.

Also presented at Field Emission Symposium, Penn. State U., University Park, June 27-29, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 215, Apr. 25, 1957.

Published in Jour. Chem. Phys., v. 27: 646-652, Sept. 1957.

The adsorption characteristics of Ni on a clean Mo surface have been investigated using a sealed-off field emission tube with provisions for evaporating Ni onto the Mo emitter. The location of adsorbate agrees with predictions based on the geometrical fit of coherently adsorbed material. Activation energies for desorption (Q_d) and surface migration (Q_m) were determined for coverages corresponding to about 0.2 of a monolayer. The experimental Q_d is the minimum value of Q_d for any region of the emitter, 2.10 ± 0.05 ev. In the surface migration case, the experimental Q_m varies according to the degree of completion of the migration processes: 1.31 ± 0.08 ev (1/4 completed), 1.42 ± 0.05 ev (1/2 completed), and 1.48 ± 0.06 ev (3/4 completed). For heavier

COR.08:017 - COR.08:020

coverages of adsorbate, built-up areas were observed which gave enhanced emission. At an elevated temperature which allowed migration, the equilibrium position of these areas changed reversibly upon application of the field. Other observations of heavy adsorbed layers are presented. (Contractor's abstract)

AN ULTRA-HIGH VACUUM MASS SPECTROMETER FOR THE STUDY OF THE SURFACES OF SOLIDS, by R. C. Bradley. Mar. 1, 1958, 1v. incl. illus. diagrs. tables, refs. (Technical rept. no. 6) (AFOSR-TN-58-97) (AF 18(600)674, Task II) AD 148148 Unclassified

A new ultra-high vacuum mass spectrometer for the study of the surfaces of solids is described. Surface atoms are removed either by ion bombardment or by evaporation and are mass analyzed in a 60° sector field mass spectrometer with a six-in. radius of curvature. The design, construction, and operation of the instrument and its associated apparatus are discussed in some detail. The results of certain experiments on the surfaces of the three refractory metals, molybdenum, tantalum, and platinum, are presented in order to indicate both the potentialities and the limitations of the instrument in its present form. SECONDARY POSITIVE ION EMISSION FROM METAL SURFACES, by R. C. Bradley. Sept. 1, 1958 [32]p. incl. diagrs. refs. (Technical rept. no. 8) (AFOSR-TN-58-642) (AF 18(600)874, Task II) AD 162174; PB 138503 Unclassified

Also published in Jour. Appl. Phys., v. 30: 1-8, Jan. 1959.

Secondary positive ions ejected from surfaces of Mo, Ta, and Pt under bombardment by inert gas ions of low energy (< 1000 ev) were studied in high vacuum ($< 10^{-8}$ mm of Hg of background gases) using a 60° sector field mass spectrometer with a 6-in. radius of curvature, the object being to explore this as a technique for investigating solid surfaces in general. Ion species characteristic of the base metal, of surface compounds, and of a few bulk impurities were found. Quantitative analyses based on abundance ratios of the ions are unreliable owing to the enormous and essentially unknown differences in ionization efficiencies for the various species. Application of the technique to the investigation of surface kinetics seems highly promising, and as an illustration certain observations on the formation of PtO_3 on a Pt surface and its desorption at high temperatures

are presented. Another possible application is to the study of sputtering, although some of the properties of secondary ions are shown to be quite different from those of sputtered particles in general. The secondary ions characteristic of the base metal comprise only a small fraction (0.1% for Pt) of the total sputtering yield, are principally singly charged and monatomic, have a low average energy (4 to 5 ev) and energy spread, and may result either from physical sputtering of the base metal or from the dissociation of surface compounds or both. MASS SPECTROMETRIC STUDIES OF PARTICLES SPUTTERED FROM TANTALUM AND PLATINUM SURFACES (Abstract), by A. Arakengy and R. C. Bradley. [1958] [1]p. [AF 18(600)674, Task II] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 193, May 1, 1958.

A mass spectrometric study of secondary ions sputtered from a Mo surface in high vacuum has previously been reported by Bradley, Stabler, and Arakengy. This work has now been extended to a study of Ta and Pt surfaces. The secondary ion yield as a function of surface temperature is quite different for the three metals: it increases with increasing temperature for Pt^+ , decreases for Mo^+ , and shows a marked hysteresis effect for Ta^+ . For the Pt surface, (the only case where neutral sputtered particles were also studied) it is estimated that secondary ions comprise about 0.1% to 1% of the total yield of sputtered particles. Thermionic and secondary emission of positive ions of alkali metal impurities in the Pt have also been investigated and have led to a determination of the following activation energies: for desorption of the Na from the surface, 1.9 ± 0.1 ev; for bulk diffusion of Na, 4.7 ± 0.1 ev; for bulk diffusion of K, 4.4 ± 0.1 ev.

TRANSMISSION SPUTTERING IN THIN METAL FOILS (Abstract), by R. C. Bradley. [1958] [1]p. [AF 18(600)-674, Task II] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 193, May 1, 1958.

The discovery of G. K. Wehner that sputtered particles

COR. 18:021; COR. 17:001, 002;
COR. 12:006

are ejected preferentially along the directions of close packing of metal crystals suggests the possibility that during ion bombardment energy might be propagated a considerable distance into a crystal along these same-close packed directions, and might in fact lead to the ejection of atoms from the back side of thin metal foils. Study has been made of this effect for 0.0002 in. foils of gold and aluminum under bombardment by inert gas ions of 800 ev energy. For the gold foils the results indicate that approximately one gold atom was ejected

from the back face for every 10^3 - 10^4 ions incident on the front face, that 0.1% of these were positively charged, that their energy was low (< 4 ev), and that the total yield was greatest for bombardment by Xe ions, less for A ions, still less for He ions, and undetected for bombardment by electrons of the same energy. For the aluminum foils, no transmission sputtering was detected and hence must have been less than 1 ejected Al atom for 10^8 incident ions.

SECONDARY ION EMISSION FROM METAL SURFACES (Abstract), by R. C. Bradley. [1958] [1]p. [AF 18(600)-674, Task II] Unclassified

Presented at meeting of the Amer. Phys. Soc., Ithaca, N. Y., June 19-21, 1958.

The emission of positive ions from Mo, Ta, and Pt surfaces under bombardment by inert gas ions of moderate energy (< 1000 ev) has been studied in high vacuum using a 60° sector field mass spectrometer. These ions are characteristic of the metal itself and of its surface and bulk impurities. Qualitative surface analyses are thus possible by this technique. Quantitative surface analyses are difficult, however, owing to the large differences in surface ionization probabilities for the various species. For example, the Na^+ peak from a platinum target was comparable to the Pt^+ peak even though according to spectroscopic analysis sodium could not have been present as an impurity in the solid in an amount greater than 1 part in 10,000. These studies also give information on the sputtering process itself, in particular on the energy spread and on the state of aggregation of the ejected particles. The effect of surface temperature on secondary ion emission is interesting: The Mo^+ peak from molybdenum decreases rapidly with increasing temperature whereas the Pt^+ peak from platinum increases. Certain activated processes such as diffusion and desorption of impurities have also been studied with the instrument and some results are described. (Contractor's abstract)

ULTRA-SMALL-ANGLE X-RAY SCATTERING, by L. G. Parratt, J. O. Porteus and others. Dec. 20, 1958 [15]p. incl. diagrs. table, refs. (Technical rept. no. 2) (AFOSR-TN-58-781) (AF 49(638)402; continuation of AF 18(600)300) AD 202002; PB 137936 Unclassified

Discussion is given of the extension of the conventional small-angle scattering techniques to angles in the range of a few seconds of arc. The magnitudes of the scattered intensity in this range are large. A new double two-crystal spectrometer is proposed for this work. It is believed that with this instrument, with a high-energy synchrotron as an x-ray source, with either perfect crystals on the spectrometer for the ultra-small angles or with deliberately imperfect crystals for the conventional angular range, and with the newly developed unfolding procedures to correct for the residual instrumental effects, the techniques of small-angle scattering would be advanced to new levels of usefulness in many problems of structural analysis. Interpretive theory, now undeveloped in the ultra-small-angular range and in some respects also in the conventional angular range, would probably not lag far behind.

THE LAMINAR BOUNDARY-LAYER FLOW ON ROTATING CYLINDERS. PART I. FLAT PLATE, by S.-W. Liu. June 1957, 1v. incl. illus. tables, refs. (AFOSR-TN-57-298, pt. 1) (AF 18(600)1523) AD 132369 Unclassified

The boundary-layer equations for a cylindrical blade rotating with a constant angular speed about an axis perpendicular to the cylindrical axis are re-examined, and from the existing solutions for rotating blades an extension is made to allow the axis of rotation to be arbitrarily located with respect to the leading edge of the blade. The present report is limited to the case of a flat plate with the axis of rotation perpendicular to the plane of the plate. Two parameters are used to construct the boundary-layer flow at various locations on the plate with respect to the location of the axis of rotation. A perturbation procedure is set up by expressing the velocity components in series expansions of the parameters. Successive orders in the velocity components are obtained by numerical integration. The results show that the development of the boundary layer from the leading edge, as indicated by the relative deviation of any particular streamline from the potential streamline, is apparently unaffected by the location of the axis of rotation. Comparison with earlier first-order calculations is limited to cases where there is no eccentricity of the axis of rotation. Such first-order results are shown to give good approximations in regions where chordwise distance is much less than spanwise distance ($\frac{x}{y} \ll 1$). The streamlines of the boundary layer so calculated have smaller curvature than the more exact solutions which include higher-order terms.

THE LAMINAR BOUNDARY-LAYER FLOW ON ROTATING CYLINDERS. PART II. THIN CYLINDERS, by S.-W. Liu. June 1957, 1v. incl. illus. tables. (AFOSR-TN-57-298, pt. 2) (AF 18(600)1523) AD 210156; PB 145479 Unclassified

The boundary-layer equations for a cylindrical blade of small thickness rotating with a constant angular speed

about an axis perpendicular to the cylindrical axis are re-examined, and from the existing solutions, an extension is made to allow the axis of rotation to be located arbitrarily with respect to the leading edge of the blade. The cylindrical symmetry is represented by assuming a universal velocity polynomial in terms of the chordwise coordinate for the chordwise potential flow. As in the flat-plate case, solution is obtained by means of series expansions in terms of appropriate parameters. In the present case, series expansion is also made in terms of the chordwise coordinate. The perturbation due to small local taper of the cylinder is also included. The deviations of the results from infinite-cylinder flow are found to be caused mainly by the modification of the outstanding pressure-gradient terms. Such effects on the chordwise flow can be favorable or adverse, depending on the location of the axis of rotation. For example, when the axis is well behind the leading edge, the pressure gradient may become so unfavorable as to cause reversal of the chordwise flow component very near the leading edge; this is interpreted to mean leading-edge separation. The correction due to taper is again found to be small. (Contractor's abstract)

THE INTERACTION OF A REFLECTED SHOCK WAVE WITH THE BOUNDARY LAYER IN A SHOCK TUBE, by H. Mark. June 1957, 149p. illus. tables, refs. (AFOSR-TN-57-345) (Sponsored jointly by Air Force Office of Scientific Research and Office of Naval Research under AF 18(600)1523) AD 132418 Unclassified

Condensed version published in Jour. Aeronaut. Sciences, v. 24: 304-305, Apr. 1957.

Analysis in which simplifying assumptions are made for the interaction of the shock reflected from the closed end of a shock tube with the boundary layer of the initial shock after-flow. It is predicted that interactions of several different types will exist in different ranges of initial shock Mach number, and it is shown that the cooling effect of the wall on the after-flow boundary layer accounts for the change in interaction type. An experiment verifies the existence of several interaction regions and shows that they are satisfactorily predicted by theory.

potential, an integral equation for the required source distribution in the upwash region is derived. Without having to solve this equation, it is shown that the potential for a point in the tip region can be obtained in terms of an integration of known source distributions over the blade surface only. The case of a twisted flat plate of particular planform is treated, and a sample calculation is made of the pressure distribution over the blade's tip region. (Contractor's abstract)

Steady, plane flow of incompressible fluid past thin cylindrical obstacles is treated, with two different orientations of the undisturbed, uniform magnetic field; viz., parallel and perpendicular, respectively, to the undisturbed, uniform stream. In the first case, the flow of an infinitely conducting fluid is shown to be irrotational and current-free except for surface currents at the walls of the obstacles. With large but infinite conductivity the surface currents are replaced by thin boundary layers of large current density. In the second case, for infinite conductivity the flow field is made up of an irrotational current-free part and a system of waves involving currents and vorticity extending out from the body. For large, finite conductivity these waves attenuate exponentially with distance from the body. In both cases the forces on sinusoidal walls and on airfoils are calculated. (Contractor's abstract)

Equations of magnetohydrodynamic channel flow are developed and the results are applied to rocket propulsion with unlimited energy supply. Two rocket configurations are described in which the energy is limited to the energy supplied by the fuel of the rocket. Rocket payload energy is increased for a given rocket fuel energy by redistributing this energy: magnetohydro-

dynamics is a feasible way to accomplish the redistribution. Descriptions are presented of a magnetohydrodynamic generator, 2 magnetohydrodynamic devices of aerodynamic interest, a hypersonic wind tunnel, and a diffuser.

A NUMERICAL METHOD FOR SOLVING BOUNDARY-LAYER EQUATIONS, by S.-W. Liu. [1958] [2]p. [AF 18(600)1523] Unclassified

Published in Jour. Aero/Space Sciences, v. 25: 598-599, Sept. 1958.

In this paper, a method is outlined which has been used with considerable success in obtaining numerical solutions to equations commonly encountered in boundary-layer problems, and which is particularly adaptable to the high-speed computers currently in use. One advantage of this method is that the formulas used are simple and direct, with minimum of arbitrariness.

A THREE-DIMENSIONAL THEORY OF AXIAL COMPRESSOR BLADE ROWS - APPLICATION IN SUBSONIC AND SUPERSONIC FLOWS, by J. E. McCune. [1958] [17]p. incl. diagrs. tables, refs. [AF 18(600)1523] Unclassified

Presented at the Twenty-Sixth Annual meeting, IAS, New York, Jan. 27-30, 1958.

Published in Jour. Aero/Space Sciences, v. 25: 544-560, Sept. 1958.

A small-perturbation theory for the description of the steady-state flow fields of axial compressor blade rows is developed by superposition of cylindrical wave functions. The relation between the full three-dimensional solution and the usual strip-theory (cascade) approximation for blade rows having a large number of blades is determined, and a similarity law for three-dimensional correction effects is provided. Numerical data necessary for the application of the general solution to configurations of arbitrary hub ratio and large blade number are presented, and this information is used in computing numerical examples in subsonic and supersonic cases. THE TRANSONIC FLOW FIELD OF AN AXIAL COMPRESSOR BLADE ROW, by J. E. McCune. [1958] [11]p. Incl. diagrs. refs. [AF 18(600)1523] Unclassified

Presented at the Twenty-Sixth annual meeting, IAS, New York, Jan. 27-30, 1958.

Published in Jour. Aero/Space Sciences, v. 25: 616-626, Oct. 1958.

The general three-dimensional theory for compressible flow through axial compressor blade rows is applied to transonic cases. Because of the occurrence in the transonic range of acoustic resonance, the theory is modified to include first-order viscous and heat-conduction effects. This approach is adequate to bring most transonic compressor problems within the realm of linear treatment. Numerical examples of the behavior of a transonic blade row are presented and discussed. The results indicate a smooth transition from the subsonic to the transonic, or mixed-flow, regimes—i.e., the degeneracy encountered in two-dimensional transonic applications of the small-perturbation theory is completely absent. At the same time, the results emphasize the failure of any strip theory, or "blade-element," approximation in the transonic range and thereby cast serious doubt upon the usefulness of transonic cascade studies. NON-PARAMETRIC MULTIPLE-DECISION PROCEDURES FOR SELECTING THAT ONE OF K POPULATIONS WHICH HAS THE HIGHEST PROBABILITY OF YIELDING THE LARGEST OBSERVATION, by R. E. Bechhofer and M. Sobel. Preliminary rept. Oct. 1957, 1p. (Rept. no. 11) (AFOSR-TN-57-604) (AF 18(600)331) AD 136593 Unclassified

Presented at meeting of Inst. of Math. Stat., Los Angeles, Calif., Dec. 27-28, 1957.

Abstract published in Ann. Math. Statistics, v. 29: 325, Mar. 1958.

Let X_i be chance variables with a density function $f_i(x)$, and $p_i = \text{Prob}\{X_i > \max_{j \neq i} X_j\}$, ($i = 1, \dots, k$); then $\sum_{i=1}^k p_i = 1$. Let $p_{[1]} \geq \dots \geq p_{[k]}$ be the ranked p_i ; let θ^* , $P^* (1 < \theta^* < 1, k > P^* > 1)$ be specified constants:

select the population associated with $p_{[k]}$ by a procedure which guarantees the requirement, $\text{Prob}\{\text{correct selection} | p_{[k]} \geq \theta^* p_{[k-1]}\} \leq P^*$. At the m^{th} stage of experimentation take the vector observation $\bar{x}_m = (x_{1m}, \dots, x_{km})$ where the x_{ij} ($j = 1, 2, \dots$) are independent observations from the i^{th} population. Consider the vector $\bar{y}_m = (y_{1m}, \dots, y_{km})$ which is obtained by replacing the largest component of \bar{x}_m by unity, and all other components by zero; then \bar{y}_m is an observation from a multinomial distribution with probability p_i associated with the i^{th} component ($i = 1, 2, \dots, k$). The requirement is guaranteed with procedures previously proposed (Ann. Math. Statistics, v. 27: 861). If $f_i(x) = g\left(\frac{x-\mu_i}{\theta}\right)$, ($i = 1, 2, \dots, k$), then the procedure can be used to select the population associated with the largest μ_i for any θ , known or unknown.

Similar non-parametric multiple-decision procedures in which pairs of observations are taken from each population at each stage of experimentation, and which employ the range of each pair can be used for selecting that one of k populations which has the highest probability of yielding the largest sample range. If $f_i(x) =$

$$h \frac{x-\mu_i}{\theta}, (i = 1, 2, \dots, k)$$

than these latter procedures can be used for selecting the population associated with the largest θ_i for any set of μ_i , known or unknown. (Contractor's abstract)

A SINGLE-SAMPLE MULTIPLE-DECISION PROCEDURE FOR SELECTING THE MULTINOMIAL EVENT WHICH HAS THE HIGHEST PROBABILITY, by R. E. Bechhofer, S. Elmaghraby, and N. Morse. Dec. 1957, 26p. Incl. tables. (Mechanical engineering rept. no. 12) (AFOSR-TN-57-710) (AF 18(600)331) AD 136704 Unclassified

Also published in Ann. Math. Statistics, v. 30: 102-119, Mar. 1959.

The problem of selecting the multinomial event with the highest probability is formulated as a multiple-decision selection problem. Taking θ as the true ratio and P as the true probability of a correct selection, θ^* is the smallest value of θ worth detecting and P^* is the smallest acceptable value of P when $\theta \geq \theta^*$. A single-sample procedure is proposed which guarantees that $P \geq P^*$ whenever the true, but unknown, ratio of the largest to the second largest of the population probabilities is equal to or greater than θ^* . The basis of the procedure is the proper choice of N , the number of trials.

COR.13:015-017; CWC.01:001

Two methods of determining N are described. The first is exact and is to be used when N is small; the second is approximate for cases when N is large. Tables and sample calculations are included.

SEQUENTIAL MULTIPLE-DECISION PROCEDURES FOR RANKING PARAMETERS OF KOOPMAN-DARMOIS POPULATIONS WITH SPECIAL REFERENCE TO RANKING MEANS OF NORMAL POPULATIONS, by R. E. Bechhofer and M. Sobel. Mar. 17, 1958 [188]p. incl. tables. (AFOSR-TN-58-260) (AF 18(600)331) AD 154164 Unclassified

The general theory for the procedures is developed where it is assumed the frequency functions associated with the k populations all have the same known form and differ at most in the value of a single parameter τ . One population is better than another when it has a larger τ -value. The correct pairing of the ordered τ -values with the populations is unknown, as are the τ -values themselves. Six forms of Koopman-Darmois populations including normal populations with unknown means and a common known variance, and binomial populations with unknown probabilities of "success" are treated in detail, in part I. Part II contains special theoretical results for two populations. Part III describes experimental samplings and the results obtained which were conducted to simulate (by Monte Carlo methods) the application of the basic procedure (and several of the other proposed procedures) to the selection of the T best populations without regard to order for Koopman-Darmois normal populations with unknown means and a common variance. Part IV contains a statement of some of the more important unsolved problems, and an indication of the directions future research may take.

A study of gaseous fuel ignition in transient flow by

means of a "heated wall" mounted in the test section of a shock tube is the subject of this report. The process was followed photographically by means of schlieren apparatus and a high speed Fastax movie camera. Pressure in the test section and in the immediate vicinity was followed by means of high frequency pressure recorders. The results establish the existence of an ignition time delay considerably longer than in steady flow and indicate a marked dependence of ignition time delay on surface roughness and turbulence level in the air stream. Pressure pulses produced by combustion are always greater than those produced if the flow was completely blocked and are further strengthened as they travel upstream. The dependence of the ignition delay time and to some extent the dependence of the peak of the pressure pulse on various physical parameters has been studied.

A theoretical analysis for turbulent flow of non-Newtonian fluids through smooth round tubes has been performed for the first time, and has yielded a completely new concept of the attending relationship between the pressure loss and mean flowrate. In addition, the analysis has permitted the prediction of non-Newtonian turbulent velocity profiles, a topic about which the published literature is entirely void. To confirm the theoretical analysis, experimental data were taken both on polymeric gels and solid-liquid suspensions under turbulent flow conditions. Fluid systems with flow-behavior indexes between 0.3 and 1.0 were studied at Reynolds numbers as high as 36,000. All of the fully turbulent experimental data supported the validity of the theoretical analysis. The final resistance law correlation represents a generalization of von Karman's equation for Newtonian fluids in turbulent flow, and is applicable to all non-Newtonians for which the shear rate depends only on shear stress, irrespective of their rheological classification. All the turbulent experimental data were for the non-Newtonian systems correlated by this relationship with a mean deviation of 1.9 percent. Some polymeric gels are shown to deviate from the above relationship, possibly due to elasticity effects. (Contractor's abstract)

A METHOD FOR CALCULATING THE TORSIONAL STRAIN VS STRESS ON AN ALREADY AXIALLY LOADED THIN WALLED CYLINDER, by H. Payne, S. J. Czyzak, and W. Lucas. Mar. 1, 1958 [10]p. incl. diagr. table. (AFOSR-TN-58-248) (AF 18(600)1466) AD 154151; PB 133960 Unclassified

of θ and ρ , and the resulting tensors averaged over all the orientations, an elastic strain tensor can be obtained which represents the aggregate. From this aggregate strain tensor, a tensile and torsional stress tensor can be computed. From this aggregate stress tensor, a theoretical stress-strain relation can be obtained which can then be compared with experimental data on polycrystalline aggregates of aluminum. Such a comparison would serve as a critical test of the validity of this slip theory of plasticity.

A new method of calculating the superposed torsional strain is described. This is an extension of T. H. Lin's method for the uniaxial case. Contrary to earlier calculations it was found that a displacement in a given slip system which is opposite in sense to one previously occurring is due to plastic, as well as elastic strain.

DEVELOPMENT OF A MATHEMATICAL THEORY OF PLASTICITY BASED ON THE CONCEPT OF SLIP, by H. Payne and S. J. Czyzak. Oct. 1, 1958, 41p. incl. diagrs. tables. (AFOSR-TN-58-779) (AF 18(600)1466) AD 202000 Unclassified

The application of Lin's modification to Taylor's method permits a means by which the stress-strain relation in a polycrystalline solid may be determined for any stage of loading. Both Taylor's method and Lin's modification compare favorably with experiment when the loading is simple tensile or compressive loading. The purpose of this paper is the investigation of the application of Lin's modification to the more critical case of a torsional load superposed on an already existing tensile or compressive load. The mathematical method used in performing the calculations, is based on the work of Payne, Czyzak, and Lucas. Little can be said at present regarding the results of the calculations. When the calculations for all 44 orientations have been completed, a comparison between the average of these values and experimental values may be made.

The model developed by Taylor for calculating the stress-strain relation for a polycrystalline material following a non-linear strain path is reviewed and extended. This theory is applied to the problem of a thin wall cylinder which is subjected to an incremental torsional strain on an already existing tensile or compressional strain.

Storage and retrieval devices are differentiated from computers within the general class of automatic data handling devices. The basis for this differentiation is both negative and positive; negative in that the identity of computers and computer logic with automata and the logic of automata in general is shown to be in error; and positive in that the specific logic of storage and retrieval automata is shown to be the algebra of classes as distinct from the propositional calculus which is the logical instrument for the analysis of computers and computer circuits. As a final point, the time sequence in computer operation is shown to be analogous to non-commutative pairs in the algebra of classes.

THE DESCRIPTIVE CONTINUUM. A "GENERALIZED" THEORY OF INDEXING, by F. Jonker. June 1957, 26p. incl. diagr. (AFOSR-TN-57-287) (AF 49(638)91) AD 132358
Unclassified

Also published in Proc. Internat'l. Conf. on Scientific Information, Washington, D.C. (Nov. 16-21, 1958), Washington, Nat'l Acad. Sciences, v. 2: 1291-1311, 1959.

The degree of adequacy and total cost of indexing systems in mechanized information retrieval is studied in search of general criteria for the systems. The history of information control is traced from the earliest classification

systems through subject heading systems to recent developments (Uniterm indexing) in an attempt to establish a "generalized theory" of indexing. A theory of indexing looks on all systems as a "descriptive continuum" with "entry" length chosen as the main parameter. The continuum ranges from keyword indexing through subject heading indexing to hierarchic classification. Other parameters are potential depth of indexing, permutability of indexing criteria, degree of hierarchical definition of indexing, potential need for a coordinating mechanism, retrieval noise, size of the access apparatus, false coordinations and capacity for handling semantic indeterminacy. The theory indicates that with the determination of the main parameter, other system properties are fixed. For the information collection, an optimal continuum position can be related to the degree of diffuseness of the field's information.

MATHEMATICAL FOUNDATIONS FOR A STORAGE AND RETRIEVAL THEORY, by A. Kreithen. June 1957, 15p. (AFOSR-TN-57-400) (AF 49(638)91) AD 132475
Unclassified

Some of the fundamental concepts of a mathematical basis for a storage and retrieval theory are noted, and a terminology and notation are developed for representation by set theory. The possible ways in which a collection of information can be organized for storage and retrieval are presented, and the properties of each form of organization are outlined. The resulting effect on the theory is studied of the incorporation of certain relations between terms, such as meaning and order. The problems, which include nonmathematical as well as logical or mathematical relations, in a formal theory are discussed, and some consequences are pointed out for the storage requirements of realizable systems. The properties of specific indexing schemes are closely represented by particular mathematical systems. (Contractor's abstract)

THE RELATION OF THE SIZE OF THE QUESTION TO THE WORK ACCOMPLISHED BY A STORAGE AND RETRIEVAL SYSTEM, by M. Taube and L. B. Hellprin. Aug. 1957 [13]p. (AFOSR-TN-57-483) (AF 49(638)91) AD 136476 Unclassified

Presented at Amer. Chem. Soc., Chemical Literature Session, New York, Sept. 1957.

Definitions given by Kreithen (item no. DOC.01:004) of code element, coding field, bit, character, word, item, store, and question are extended. Work accomplished in a search is defined as the set of items in a store selected by matching the terms in the question against the terms recorded in a store to describe the items. The bearing of this concept of work on the design of storage and retrieval devices (especially the Rapid Selector and the Minicard System) is discussed. A mathematical analysis is appended in which the unit of work accomplished is defined as the matching of 1 word in the question against 1 word in the store and the unit of search power is 1 search work unit per unit time. Results indicate that (1) in any search of an information store by either sequential or parallel matching, the sequential search work is less; (2) search time saved by a parallel instead of a sequential search is proportionately less than the increase in search power required to save the time; and (3) asking an ordered question involves either more units of work or more memory capacity than asking a question in which order of terms is immaterial.

MATHEMATICAL MODEL OF INDEXING, by L. B. Hellprin. Aug. 1957 [24]p. incl. diagr. (AFOSP-TN-57-484) (AF 49(638)91) AD 136477 Unclassified

The main problems in storage and retrieval of an item of information are indexing, coding, and mechanization. Jonker has recently presented a theory of indexing (item no. DOC.01:003). According to the theory all indexing systems can be located on a "descriptive continuum" the parameter for which is average length of indexing terms. This paper develops a mathematical model from Jonker's theory. The descriptive continuum is mathematically equivalent to the range between complete dependence and independence of indexing terms. The main task is to find functional forms for the variables. Some new concepts are introduced: number of search paths, ideal indexing system, permutability noise, hierarchical noise. An indexing equation is derived: $RH = n(1-M)$ where R is retrieval power, H is degree of hierarchical classification, n is the maximum number of independent indexing terms per item, and M

is hierarchical noise. The "ideal case" in which $M = 0$ corresponds to Jonker's original concept. Suggestions are given for use of the model in indexing system design. (Contractor's abstract)

INFORMATION STORAGE AND RETRIEVAL THEORY, SYSTEMS, AND DEVICES; AN AFOSR SYMPOSIUM, Washington, D. C. (Mar. 17-18, 1958), ed. by M. Taube and H. Wooster. New York, Columbia U. Press, 1958, 228p. incl. diagr. table, refs. (AFOSR-TN-58-190) (AF 49(638)91) AD 152236 Unclassified

This book is divided into 2 parts. Part I is an orientation to the subject matter prepared prior to the symposium. It deals with the scope, history, present state and future of information storage and retrieval. Part II is a condensation of the introductory remarks and discussions at the symposium in the following general areas: (1) the relation of storage to retrieval; (2) the relation of physical to symbolic systems; (3) the logic of retrieval devices; (4) digital coding for information retrieval; (5) the grouping and arrangement of terms, items and their codes; (6) the environment and requirements of a system; and (7) indexing, language, and meaning. A summary is included.

THE COMAC. AN EFFICIENT PUNCHED CARD COLLECTING SYSTEM FOR THE STORAGE AND RETRIEVAL OF INFORMATION, by M. Taube. Oct. 1957, 20p. incl. diagr. (AFOSR-TN-58-365) (AF 49(638)91) AD 154271 Unclassified

Also published in Proc. Internat'l. Conf. on Scientific Information, Washington, D. C. (Nov. 16-21, 1958), Washington, Nat'l. Acad. Sciences, v. 2: 1245-1254, 1959.

An analysis of the theory of using punched card sorters and collators for the storage and retrieval of information is given. The general logical requirements of storage and retrieval systems involving, efficient input, compact storage, rapid search and freedom from machine constraints on the intellectual operations of document analysis is also discussed. A new system of punched card devices is presented which is adequate for collections of information of any size and complexity. There is thus achieved the description of a general purpose information storage and retrieval device called the COMAC. This device can match codes on one punched card against codes on another punched card, and punch the codes for the logical product or sum on a third card. The COMAC devices should decrease search time, allow multiple access to the store, eliminate refiling, reproduce

A COMPARISON OF CONVENTIONAL GROUPING AND INVERTED GROUPING OF CODES FOR THE STORAGE AND RETRIEVAL OF CHEMICAL DATA, by E. Miller, D. Ballard and others. May 1958 [23]p. incl. illus. diags. tables. (AFOSR-TN-58-366) (AF 49(638)91) AD 154272
Unclassified

Also published in Proc. Internat'l. Conf. on Scientific Information, Washington, D. C. (Nov. 16-21, 1958), Washington, Nat'l. Acad. Sciences, v. 1: 671-685, 1959. (Title varies)

Direct experimental comparison of the operation of two different information storage and retrieval systems using conventional and inverted groupings respectively has been carried out using the U. S. Patent Office punched-card index to steroid patents. Identical Patent Office index terms were used in both systems. Equal search results were thus obtainable from both systems. Comparison is made on the basis of equipment cost and operating time to put in the same material and find the same answers to a series of queries. An IBM sorter and a modified Type 101 machine were used for the conventionally grouped material, while a "Matrex" device was employed for the inverted group arrangement. The Matrex approach was somewhat more costly on input, but far more economical in both equipment cost and presentation of answers to queries. These differences are magnified as the size of the collection grows. A side result shows that the IBM sorter improves in efficiency over the Type 101 machine as the size of the collection increases. Basic and applied parameters for the design of information storage and retrieval devices are discussed. A distinction is made between primary design considerations of a more abstract nature, and less abstract secondary considerations. The primary design considerations are used as a framework for classifying the various types of information storage and retrieval systems. This classification is a practical frame of reference to allow similarities and differences to be seen, and to apply systematic thinking to the problems of information storage and retrieval machines. It may help create some

AN EVALUATION OF USE STUDIES OF SCIENTIFIC INFORMATION, by M. Taube. Dec. 1958, 23p. incl. refs. (AFOSR-TN-58-1050) (AF 49(638)91) AD 206987; PB 138260
Unclassified

An evaluation of the existing literature on use studies is attempted. The conclusions drawn by other surveys of use studies which appeared before the International Conference on Scientific Information in November 1958 are accepted, and these conclusions are brought up to date by abstracting and evaluating the studies prepared for the conference. An attempt is made to analyze the reasons for the generally accepted failure of use studies by establishing a distinction between consumer services and professional services. It is concluded that the organization and dissemination of scientific information is a professional activity, the value of which cannot be measured by consumer responses, and that such responses cannot supply directions for the design of more effective scientific information and reference systems. The abilities of various extensive shower arrays to detect possible departures from isotropy of the directions of incidence of very high-energy cosmic-ray primaries are analyzed. The effects of angular resolution, selectivity of total energy and sensitivity to the nature of the primary are discussed. A simple method of analyzing variation in intensity with declination is given and applied to some recent experimental results. It is shown that in two well-known cases, these are not consistent with the hypothesis of isotropy of incoming directions. (Contractor's abstract)

ON THE ZEROS OF THE DERIVATIVES OF SOME ENTIRE FUNCTIONS, by R. M. McLeod. June 1957, 25p. refs. (AFOSR-TN-57-353) (AF 18(800)1341) AD 132426 Unclassified

Also published in *Trans. Amer. Math. Soc.*, v. 91: 354-367, May 1959.

Let f be an entire function. Let $\{L_k\}$ be a set of points z such that to each disk D centered at z , there corresponds a sequence of integers $\{n_k\}$ and a sequence of points $\{z_k\}$, $z_k \in D$, such that $f^{(n_k)}(z_k) = 0$. Polya (*Math. Zeitschr.*, v. 12: 38-60, 1922) determined $\{L_k\}$ for functions of f of finite order greater than or equal to 2 with only a finite set of zeros; these results are extended by relaxing the restriction on the set of zeros of f . Let $f(z) = \varphi(z) \exp(cz^q + dz^{q-1})$, $q \geq 2$, where $M(\log|\varphi|, 0, r) = o(r^{q-1})$, and let $\{R_k\}$ be the set made up of the q rays emanating from the point $-d/(qc)$ and passing through $-d/(qc) + \alpha_k(c)^{1/q}$, $k = 0, 1, \dots, q-1$. Polya proved that $\{L_k\} = \{R_k\}$ if f has a finite set of zeros; by application of his result to functions approximating to an f with an infinite set of zeros, it is found that zeros of f influence $\{L_k\}$ only in the directions $\alpha_k(c)$; for f of the classes $\{F\}$ and $\{G\}$ again $\{L_k\} = \{R_k\}$.

The proof is a simplified version of Polya's procedure:

(1) the asymptotic behavior of $f^{(n)}(z)$ in certain sectors is found by a modification of a generalization of Stirling's formula due to Hayman (*Jour. Reine Angew. Math.*, v. 196: 69, 1956); and (2) a theorem of Ganelius (*Ark. Matem.*, v. 3: 33, 1954) is applied which gives an estimate from below on the number of zeros in certain neighborhoods. (ASTIA abstract)

DUK.04:002 - DUK.04:006

A discussion is presented of the numerical calculation of mathematical functions. The calculation of elementary functions is discussed with certain conclusions drawn as the result of considerable theoretical study and extensive experimentation on the Oracle computer. Generally speaking the most usual method is the evaluation of truncated power series because they are easy to produce, their theory is simple, and they have no extreme properties, being neither fast nor slow; they are simple to code and offer simple problems in error analysis. Continued fractions, on the other hand present difficult problems in error analysis and programming. The most commonly used techniques are discussed. These fall into the analytical methods which include the truncated series expansions, expansion in orthogonal functions, addition formulas, and analytic continuation; and the numerical methods which include interpolation from tabulated values, successive approximation, numerical quadrature, numerical integration of differential equations, and Monte Carlo techniques.

AN ANALYSIS OF CARRY TRANSMISSION IN COMPUTER ADDITION, by S. G. Campbell and G. H. Rosser, Jr. Sept. 1957 [25]p. incl. diagrs. tables. (AFOSR-TN-57-

707) (AF 18(600)1539) AD 136701 Unclassified

Methods of facilitating carry transmission in binary addition were considered by introducing some operations of the classical 2-valued logic in which events are true or false, a pair of steady states which can be represented by 1 and 0, respectively. The operations considered are conjunction ($a \cdot b$ or ab), negation (inversion \bar{a}), inclusive disjunction ($a \vee b$), and exclusive disjunction ($a \oplus b$). Various methods are presented for handling carry transmission that make it possible to transform immediately any information about binary carry into equivalent information about any transformed circuit.

GAUSSIAN INTEGRATION FOR THE DIGITAL COMPUTER, by S. G. Campbell. Sept. 1957, 32p. (AFOSR-TN-57-708) (AF 18(600)1539) AD 136702 Unclassified

Possible increase in the efficiency of an automatically produced code is considered from the standpoint of numerical quadrature. The general quadrature problem is studied for suggestions applicable to machine application which are to be inferred from classical techniques of approximation. The importance of numerical integration is emphasized for physical problems for which analytical methods fail. The numerical quadrature problem consists in, if $f(x)$ is given, finding $\int_a^b f(x) dx$ in terms of values of $f(x)$ for $a \leq x \leq b$. In particular, expressions of the form: $\int_a^b w(x)f(x) dx \approx \sum_{i=1}^n W_i f(x_i)$

where the x_i are real and $a \leq x_i \leq b$ for each i are considered. Gaussian quadrature formulas are also discussed and general purpose numerical integration programs are studied for characteristics which would lend themselves to a more optimal programming. To this end, various integration formulas are analyzed.

Erlandsson and W. Gordy. [1957] [13]p. incl. diagrs. tables, refs. (AFOSR-TN-57-47) (Bound with its Quarterly progress rept. no. 16, Nov. 1, 1956-Feb. 1, 1957) (AF 18(600)497) AD 115086 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 212, Apr. 25, 1957.

Also published in Phys. Rev., v. 106: 513-515, May 1, 1957.

The $J = 0 - 1$ rotational transition of $N^{14}D_3$ has been measured at a wavelength of 0.97 mm. This transition is split into two components by inversion doubling of the ground vibrational levels. The frequencies of the two components were found to be 306 735.0 mc/sec and 309 909.35 mc/sec. Their separation, 3174.4 mc/sec, is equivalent to the sum of the inversion frequencies of the upper and lower states. The relative intensities of the upper and lower frequency components were found to be about 10 to 1, in agreement with theory. The B_0 value, 154 162.7 mc/sec, is obtained from the arithmetic mean of the two components, with the infrared value, $D_J = 3.4$ mc/sec. The B_0 value is consistent with a bond length of 1.0144 Å and a bond angle of 107°. Superimposed upon each of the inversion components is a triplet hyperfine structure caused by the N^{14} quadrupole moment. This structure was measured for the higher frequency component, and the value, $eQq = -4.20 \pm 0.15$ mc/sec, was obtained for the N^{14} coupling. (Contractor's abstract)

electron can give specific information about the radiation damage in proteins, nucleic acids and many other biologically significant chemicals. The structures of their electron resonances show that free radicals of various types are formed from the different amino acids and simpler peptides by ionizing radiations. However, in numerous proteins only two structural patterns are obtained, either separately or in combination. One of these is like the common pattern obtained for cysteine, cystine, and glutathione and is believed to arise from an unpaired electron (electron hole) on the protein sulfur. The other pattern (obtained alone in proteins which have no sulfur) is a doublet characteristic of the interaction of the electron spin with the spin of a single proton. The latter appears to arise from an electron on a carbonyl oxygen interacting with a proton of the hydrogen bridge, or possibly on a -CH- of the peptide chain which has lost an R side group. There is no evidence that the ionizing radiation breaks the polypeptide backbone structure of the proteins. The results seem to require that an electron hole or vacancy created at a given location in the protein molecule can migrate to other locations where it has lower energy.

The hypothesis set forth in this note is that free radicals produced outside the body may find their way into the body and produce mutations and/or cancer. The evidence for support of this hypothesis is the presence of radicals as detected by microwave paramagnetic resonance in several carcinogenic agents, and the fact that free radicals are now recognized by radiobiologists as being responsible for a large portion of mutagenic and carcinogenic effects of ionizing radiations.

ELECTRON SPIN RESONANCE IN X-IRRADIATED PLASTICS AND SYNTHETIC FIBERS (Abstract), by H. Shields, W. B. Ard, and W. Gordy. [1957] [1]p. (Sponsored jointly by Office of Ordnance Research and Air Force Office of Scientific Research [under AF 18-(600)497]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 227, Apr. 25, 1957.

Microwave paramagnetic resonance has been used to study the effects of ionizing radiation on various plastics and synthetic fibers. The strength of the resonances obtained was found to depend on the degree of crystallinity. A sample of ordinary polyethylene gave no resonance signal after x-irradiation, whereas a similarly irradiated sample of polyethylene (supplied by Phillips Petroleum Company) which has a crystallinity above 90% gave a strong resonance with a seven-component proton hyperfine structure. Strong resonances have been obtained for x-irradiated polystyrene (single sharp line), Teflon (eight-component F^{19} hyperfine structure), Kel-F (unresolved hyperfine structure of several components), polyvinyl fluoride and chlorotrifluoethylene (broad single resonances), polystyrene (single sharp resonance), nylon (asymmetric structure of four components), and Orlon (unresolved hyperfine structure of several components).

ELECTRON SPIN RESONANCE OF RADICALS PRODUCED BY ULTRAVIOLET IRRADIATION (Abstract), by H. N. Rexroad and W. Gordy. [1957] [1]p. [AF 18-(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 227, Apr. 25, 1957.

The radicals produced by ultraviolet irradiation of solutions of various substances in the mixture ether, isopentane, and alcohol (EPA) and frozen at 77°K have been investigated by their microwave electron spin resonance. The EPA mixture, one commonly employed as a solvent by optical spectroscopists, was itself found to give no resonance under uv irradiation at 77°K. At 0.1 M solution of toluene ($C_6H_5CH_3$) in EPA showed a quartet resonance of 80 gauss spread which can be attributed to the CH_3 radical and a single component which might arise from the radical C_6H_5 . Thus the results indicate that the uv simply breaks the C C bond which ties the CH_3 to the ring. Interestingly, similar results are obtained for phenol, C_6H_5OH , in EPA. Tentatively, we interpret this to mean that the OH radical is produced by the uv but that it immediately attacks the EPA to form the CH_3 radical and an alcohol. A single moderately sharp resonance is obtained for benzoyl chloride, $C_6H_5(CO)Cl$. This is believed to arise from the C_6H_5CO radical. Probably the Cl produced at the same time would escape through the EPA.

The $J = -0\ 1$ line of CO was the first spectral transition measured in the 2-3 mm wave region. Further improvements in harmonic generators and detectors have made possible more precise measurements of this and higher rotational transitions occurring in the submillimeter region with a video-type spectrometer employing a slow sweep and high fidelity amplifier. We have obtained

$$\begin{aligned} \nu_0(J = 0 - 1) &= 115\ 271.195 \pm 0.015 \text{ mc/sec} \\ (J = 1 - 2) &= 230\ 537.974 \pm 0.030 \text{ mc/sec} \\ (J = 2 - 3) &= 345\ 795.900 \pm 0.090 \text{ mc/sec} \end{aligned}$$

for $C^{12}O^{16}$ in the ground vibrational state. These yield

$$B_0 = 57\ 635.965 \pm 0.008 \text{ mc/sec}$$

$$D_0 = 0.1838 \pm 0.0005 \text{ mc/sec}$$

From infrared wavelength measurements, Rank has obtained $B_0 = 1.922521 \pm 0.0000035 \text{ cm}^{-1}$ for $C^{12}O^{16}$. The ratio of our B_0 value to his yields the velocity of light as

$$c = 299\ 793.7 \pm 0.6 \text{ km/sec}$$

which is in good agreement with the value, $c = 299\ 793.0 \pm 0.3 \text{ km/sec}$, recommended by DuMond and Cohen. Actually the microwave B_0 of $C^{12}O^{16}$ is now known to an accuracy better than that of c , and further improvement in the infrared measurements could lead to a significant improvement in the value of the velocity of light.

SUBMILLIMETER WAVE SPECTROSCOPY: DC1 (Abstract), by M. J. Cowan and W. Gordy. [1957] [1]p. [AF 18(600)497] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 212, Apr. 25, 1957.

The $J = 0 - 1$ rotational transitions in $DC1^{35}$ and $DC1^{37}$ have been measured in the wavelength region of 0.93 mm. Nuclear hyperfine structure was observed for both the Cl and D nuclei. Preliminary results are

	For $DC1^{35}$	For $DC1^{37}$
$\nu_0(J = 0 - 1)$	323 295.70	322 349.48
in mc/sec	± 0.65	± 0.65
B_0 in mc/sec	161 656.09	161.182.93
r_0 in A	1.28125	1.28124
B_e in mc/sec	163 340.1	162 859.0
r_e in A	1.27462	1.27463
$eQq(Cl)$ in mc/sec	-67.3	-53.1

The values of r and of B employ the infrared D_0 and α_e

values by Pickworth and Thompson. Measurements and analysis of the deuterium hyperfine structure are not yet complete.

SUPERCONDUCTIVITY AT MILLIMETER WAVE FREQUENCIES (Abstract), by G. S. Blevins, W. Gordy, and W. M. Fairbank. [1957] [1]p. (Sponsored jointly by Office of Ordnance Research and Air Force Office of Scientific Research [under AF 18(600)497])

Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 183, Apr. 25, 1957.

The development at Duke University of refined millimeter wave techniques for the 0.5 to 5 mm region made possible investigations of the temperature dependence of the surface resistance of superconducting tin in the frequency region where $h\nu \approx kT$. In the first experiments the onset of superconductivity, as evidenced by a noticeable change in the high-frequency surface resistance, was found to depend on the frequency. These measurements have been extended to different types of surfaces. More sensitive methods have been developed for ascertaining small changes in resistance near the transition temperature. A new cryostat and microwave system has been constructed which makes possible a significant extension of the measurements to frequencies above 150 kmc/sec. In both plated surfaces and surfaces made from the bulk metal, the transition temperature was found to shift to lower temperatures as the frequency was increased above 50 kmc/sec in agreement with the earlier measurements. However, the amount of the shift was found to be less in the bulk metal surface than in the plated surface. It possibly depends on the width of the intermediate state.

CHARACTERISTIC ELECTRON-SPIN RESONANCES OF FREE RADICALS WITHIN SOLIDS (Abstract), by W. Gordy. [1957] [2]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18-(600)497] and Office of Ordnance Research)

Unclassified

Published in Program for Symposium on The Formation and Stabilization of Free Radicals, Nat'l. Bur. Standards, Washington, D. C. (Sept. 18-20, 1957), Washington, Nat'l. Bur. Standards, 1957, p. K1-K2.

Hydrocarbon free radicals have been produced by x and UV irradiation of numerous organic and biological substances in the solid state, and their characteristic electron spin resonances observed by various members of the Duke Microwave Lab. Nuclear hyperfine structure and other factors allow reasonably definitive identification of certain of the radicals, including the methyl and ethyl radicals and reasonably good guesses as to the identity of others. Our rather extensive observations revealed that the isotropic Fermi-type interaction with the proton spins is much larger in aliphatic hydrocarbon radicals than had previously been supposed and that the orientation-dependent dipole-dipole coupling is less significant than was thought. In fact, the isotropic coupling due to s orbital occupancy of the H atoms by the odd electron is generally much larger than the residual direct dipole-dipole interactions. It is this fortunate but unexpected circumstance which allows one to resolve the numerous hyperfine patterns in polycrystalline or amorphous solids. Another surprising fact is that symmetrical patterns indicating equivalent coupling of four or more protons in a single radical is often observed. To get the geometrical symmetry apparently needed to account for the equivalent coupling of an even number of protons in a simple aliphatic radical, charged radicals such as $(C_2H_4)^+$

were first postulated. However, the problem of accounting for the equivalent coupling of an odd number of five or more protons in radicals where a static geometrical symmetry does not appear possible. It is now thought that hydrogen exchange between adjacent carbons in aliphatic radicals occurs, and at a sufficient frequency to equalize the coupling of the protons during the lifetime in the spin states. Such an exchange could account for equalization of coupling of hydrocarbon radicals with even as well as odd numbers of hydrogens and could also account for much of the reduction in the dipole-dipole coupling already mentioned. Other motions of the radicals as well as the delocalization of the wave function of the odd electron also help to reduce the anisotropic dipole-dipole coupling. Hydrogen exchange between C atoms in radicals, if it occurs as indicated, should have important consequences in organic chemistry and biology. Results at elevated, medium and low temperatures and upon single

crystals as well as upon polycrystalline materials will be reported.

Free radicals produced by x-irradiated dipeptides and tripeptides have been investigated by the use of electron spin resonance methods. The hyperfine interaction with the hydrogen nuclei has been used to identify some of the radicals. Each peptide has generally been found to have characteristic resonance patterns. Oxygen has been found to kill or alter the pattern and sulfur or tyrosine rings act as protective agents against radiation damage to the rest of the protein or polypeptide.

Characteristic electron spin resonance patterns have been found for all the basic amino acids. Many of these patterns arise from the hyperfine interaction with the hydrogen nuclei. A g factor anisotropy gives rise to similar patterns for cysteine, cystine, and glutathione and it is believed that the odd electron is localized on the sulfur atom. Tyrosine and tryptophan do not have resolvable structure patterns which suggests that the odd electron migrates within the unsaturated rings. Sulfur groups and tyrosine and tryptophan rings serve to protect against radiation damage to the molecule. Some of the free radicals have been tentatively identified.

A MOLECULAR-ORBITAL TREATMENT OF ISOTROPIC HYPERFINE INTERACTIONS IN SIMPLE ALIPHATIC RADICALS, by D. B. Chesnut. [1958] [18]p. incl. diagrs. tables, refs. (AFOSR-TN-58-352) (Bound with its Quarterly progress rept. no. 21, Feb. 1, 1958-May 1, 1958) (AF 18(600)497) AD 154257 Unclassified

Also published in Jour. Chem. Phys., v. 29: 43-47, July 1958.

The problem of isotropic hyperfine interactions in the EPR spectra of aliphatic free radicals is approached from the molecular-orbital picture of hyperconjugation. The ethyl, methylethyl, and 1,1-dimethylethyl radicals are treated by this approximation; with a reasonable choice of parameters, the results can be correlated rather well with our present knowledge of aliphatic radicals. The calculated coupling constants of methyl group hydrogens are of the order of 15 to 25 gauss, do not decrease radically with the presence of additional methyl groups, and are very nearly proportional to the molecular-orbital unpaired electron density at the central carbon atom. ELECTRON SPIN RESONANCE STUDIES OF RADIATION DAMAGE TO PROTEINS, by W. Gordy and H. Shields. [1958] [35]p. incl. diagrs. refs. (AFOSR-TN-58-353) (Bound with its Quarterly progress rept. no. 21, Feb. 1, 1958-May 1, 1958) (AF 18(600)497) AD 154258 Unclassified

Also published in Radiation Research, v. 9: 611-625, Dec. 1958.

The present study represents a continuation of an earlier investigation of the effects of ionizing radiation on the proteins with the method of electron spin resonance. It includes a number of proteins not in the preliminary work and gives further observations of certain ones which are in the earlier report. An orientation dependence of the resonance has been observed for silk strand and feather quill. Most, though not all, proteins investigated give

DUK.03:089 - DUK.03:091

either a doublet resonance characteristic of glycyl glycine, a field-dependent resonance characteristic of cystine, or a combination of the two. This is a surprising observation when one considers that the individual proteins are generally composed of some twenty different amino acids, almost all of which give characteristically different resonance patterns. The simpler peptides also give a variety of resonance patterns not found for the proteins. From the many types of long-lived spin resonances obtained for the amino acids and simpler peptides, one might predict extremely complex, probably unresolvable patterns for all proteins, patterns representing the superposition of several different radicals produced from different side groups or side chains of the proteins. The fact that this does not occur reveals a property of the proteins which may be important to the understanding of some of their biological functions as well as their reaction to ionizing radiations. References to the methods and theory of electron spin resonance are given in the other papers. (Contractor's abstract)

Also published in Jour. Chem. Phys., v. 30: 399-403, Feb. 1959.

The radical produced by x- or γ -irradiation of polyfluoroethylene (Teflon) in a high vacuum is shown to have five F atoms with nuclear coupling to the electron spin, four with equivalent coupling of 33 gauss each and a fifth with coupling of 92 gauss. The radical is probably of the form XCF_2CF_2Y , where X and Y represent the continuing

Teflon chains with no significant electron spin density. Molecular oxygen was found to combine with undetectable radicals or ions in the irradiated Teflon to produce a new resonance. Carbon monoxide alters the latter resonance to a different one while H_2 , NO, and ionized air kill it. The resonance of the fluorocarbon radical is also nullified by H_2 and NO. When Teflon is irradiated under an atmosphere of NO gas, a triplet resonance structure apparently arising from N^{14} nuclear interaction is produced. The triplet can also be produced by admission of NO to a sample of Teflon previously irradiated in a vacuum. (Contractor's abstract)

Observations have been carried out on 12 normal subjects demonstrating that in the horizontal position intravenous atropine causes a considerable increase in cardiac output, primarily due to increased heart rate. In the passive upright position, despite even greater increases in heart rate, cardiac output is altered only slightly from the control observations in the upright position. Application of an antigravity suit in part restores cardiac responsiveness in the passive upright position. These data support the thesis that the central venous reservoir is an important determinant of cardiac responsiveness. (Contractor's abstract)

VASODEPRESSOR SYNCOPE: ACUTE CIRCULATORY DISORGANIZATION. AN EXPERIMENTAL STUDY OF FACTORS INFLUENCING CARDIAC OUTPUT, by A. M. Weissler, J. V. Warren and others. [Mar. 1957] [27]p. incl. diagrs. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)-1542, American Heart Association, and National Institutes of Health)
Unclassified

Also published in *Circulation*, v. 15: 875-882, June 1957. (Title varies)

Postural syncope can be produced with facility by 60° headup tilt with the aid of sodium nitrite. Syncope so induced is similar to spontaneous vasodepressor syncope, and offers an experimental technique for the study of blood pressure and cardiac output regulation. The cardiac output in vasodepressor syncope tends to fall slightly. During recovery, the cardiac output rises at times to supernormal levels. Of particular interest, is

the failure of the cardiac output to compensate for the fall in peripheral resistance during syncope. The occurrence of either neurogenic myocardial inhibition, or markedly limited venous inflow were investigated as possible explanations for this finding. Atropinization prevents the relative bradycardia during syncope, but does not alter the cardiac output response. Antigravity suit inflation or negative pressure breathing rapidly reverses the syncopal reaction. The improvement following antigravity suit inflation is associated with a rise in cardiac output, and insignificant changes in peripheral resistance. Albumin infusions were found to prevent syncope. The arterial CO₂ constant falls at the height of syncope.

This fall is probably secondary to the hyperventilation during syncope, and contributes to the circulatory embarrassment by further lowering peripheral resistance and cerebral blood flow. The major circulatory event of vasodepressor syncope would appear to be not only widespread loss of peripheral resistance, but its occurrence in the face of inability of the heart to compensate by an increase in output. Present evidence favors the causative role of limited inflow in restricting the cardiac output response. (Contractor's abstract)

EFFECTS OF POSTURE AND ATROPINE ON THE CARDIAC OUTPUT, by A. M. Weissler, J. J. Leonard, and J. V. Warren. [1957] [7]p. incl. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1542, American Heart Association, and National Institutes of Health)
Unclassified

Published in *Jour. Clin. Invest.*, v. 36: 1656-1662, Dec. 1957.

The cardiac output response to tachycardia induced by the intravenous administration of atropine sulfate has been studied in twelve normal subjects in recumbency and tilted head up at 60 degrees. In four instances the effects of antigravity suit compression on the response to atropine in tilted subjects were studied. In five subjects the effects of peripheral venous pooling of blood on the response to atropine were also observed. Significant increases in cardiac output, primarily the result of increased heart rate with little change in mean stroke volume, occurred in recumbent subjects. Only slight elevation of cardiac index, despite even greater tachycardia associated with a fall in mean stroke volume, occurred in the tilted group. Similar results following atropine were seen during peripheral pooling of blood. Sustained antigravity suit inflation restored, in part, the cardiac responsiveness to atropine in tilted subjects. These data support the thesis that the central venous reservoir is an important determinant of cardiac responsiveness.

"NORMAL VOLUNTEER SUBJECTS": THEIR PERSONALITY PROFILES (Abstract), by M. D. Bogdonoff, J. J. Combs, Jr. and others. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1542, American Heart Association, and National Institutes of Health) Unclassified

Published in Clin. Research, v. 6: 309, Apr. 1958.

A series of comprehensive personality interviews of the "volunteers" have been conducted. These interviews have consisted of a biographical account of family and home development, an inventory of feelings and attitudes, and reasons for volunteering. Twenty "volunteer" male subjects were studied. All were university students who were informed of the experiments either by word-of-mouth communication in the dormitories, or by a bulletin board announcement. Four subjects presented history patterns indicative of serious personality disorders, two with marked psychoneurotic patterns, and two with depressive illness. In 13 subjects, there was a history of one parent's being an extremely overbearing, aggressive individual, and these subjects universally reported the inability adequately to express their own feelings of hostility and aggression. Two of these individuals indicated a "need to experience pain and toughen up." Two subjects reported volunteering for these experiments shortly after undergoing intensely stressful difficulties in life adjustment. Six reported home backgrounds characterized by elements of intense discord. Life histories of 5 of the subjects appeared unremarkable. The incidence of

personality adjustment problems in "normal volunteer subjects" indicates that in the study of relationships between affect state and physiologic changes, the nature of the subject group must be taken into consideration.

THE EFFECT OF INDUCED ANXIETY AND HOSTILITY ON CARDIOVASCULAR FUNCTIONS (Abstract), by J. J. Combs, Jr., G. N. Bryant and others. [1958] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1542, American Heart Association, and National Institutes of Health) Unclassified

Published in Jour. Clin. Invest., v. 37: 885, June 1958.

Although it is recognized that affect states may influence cardiovascular function, there is little information regarding the pattern of response and its mechanism of production. It may well be that such factors play an important role in determining the manifestations or even presence of organic cardiovascular disease. To study this problem, the authors observed the response of 23 normal male volunteers to induced variation in affect state produced by verbal and electrical stimuli. Heart rate, respiratory rate, arterial and central venous pressure were monitored on a photographic recorder. Cardiac output was determined by the dye technique. Following control determinations, change in affect state was attempted by suggesting an endangering personal situation or by a noxious stimulus (electric shock). Further circulatory observations were made at the point of apparent maximum emotional response. Conversational material was tape recorded, including a focused interview of the subject by an objective examiner immediately after the maximum response observations. These data were then reviewed for evaluation of affect state and only later correlated with the hemodynamic response. The magnitude of cardiovascular response varied directly with the evaluated intensity of the affect state, but could not be correlated with personality patterns derived from personal history. In both affect states the pattern of response was similar, and in some respects resembled that associated with epinephrine administration.

An atrial gallop sound is a frequent finding in hypertensive cardiovascular disease, myocardial infarction, and in the presence of a prolonged atrioventricular conduction time. In view of evidence relating this sound to a ventricular pressure wave resulting from atrial contraction, modification of this hemodynamic event was studied by means of tourniquet pooling of blood in the extremities. In the eighteen patients studied, this maneuver caused striking changes in the intensity and timing of the atrial gallop. Analysis of these changes helps explain the frequent appearance of this triple rhythm in severe hypertensive cardiovascular disease. (Contractor's abstract)

in patients with mitral stenosis and may be used as evidence in weighing the advisability of operation. In the present study, delayed appearance of the first heart sound was often noted in patients with hypertensive vascular disease as well. The mechanism for these changes as well as their significance in the phonocardiographic evaluation of patients with combined valvular disease and hypertension is discussed. (Contractor's abstract)

Published in British Heart Jour., v. 20: 502-506, Oct. 1958.

The peripheral pooling of blood by venous occlusive tourniquets, with resultant alterations in pressure flow relationships within the heart, causes a diminution or disappearance of the ventricular gallop sound in most instances. This procedure may be useful in differentiating a ventricular gallop from an opening snap or a split second sound.

APPLICATION OF THE CLOSED-CYCLE PRINCIPLE TO AIRCRAFT PROPULSION SYSTEMS. VOLUME VI. GENERAL He-NAP CONSIDERATIONS, by A. Burgdorfer, R. Tognoni, and W. Spillmann. July 21, 1957, 1v. incl. diags. (Rept. no. Sp-AK-57-045; Z no. 5-862-619) (AFOSR-TR-58-30) (AF 61(514)985) AD 152239 **Unclassified**

A closed-cycle nuclear aircraft-propulsion plant is discussed. The plant consists of a main engine with a cooling fan, a reactor, a high-pressure turbine, a recuperator, a cooler, and a compressor. The propulsion system consists of 4 ducted fans driven by 4 low-pressure turbines in parallel. The cycle has neither intercooling nor reheat. To reduce the dimensions of the cycle components, a high-pressure level was selected (about a 1000-psi maximum cycle pressure). The nature of the gas, the high pressure, and the stress levels determine the smallest feasible power output to 51,000 hp which results in a heat-generating requirement of about 100 megawatt for the helium reactor. The dimensions of the turbo-machinery components are small, but removal of 6.24×10^4 Btu/sec requires a large cycle cooler. The ducted fans may be installed at any location in the aircraft. An aircraft for which the power plant would be suitable was sized and compared with the DC-8.

TO AIRCRAFT PROPULSION SYSTEMS. VOLUME VII. GASEOUS WORKING MEDIA FOR CLOSED CYCLE POWER PLANTS, by W. Spillmann and B. Speckert. July 21, 1957, 1v. incl. diags. tables. (Rept. no. Sp-AK-57-046; Z no. 5-862-620) (AFOSR-TR-58-31) (AF 61(514)985) AD 152240 **Unclassified**

The comparative data of various gases were studied with respect to their behavior in thermal cycles. He, N₂, and CO₂ are feasible as working media in nuclear power plants. For a nuclear air-propulsion plant, He is the best suited gas with respect to radiation stability and plant size. The excellent heat-transfer properties of He are of prime importance for the size of the heat-transfer equipment, which should be kept as small as possible.

The penalties for a double circuit in which heat is added by a heat exchanger in connection with an external heat source were investigated. For actual designs, the

ESC.02:005, 006; EXP.01:002

double-loop system needs a pumping power of 10 to 20% of useful power output. Where the reactor temperature is not limited, the thermal efficiency of the double loop is 4 to 9% lower than that for a single circuit in which the heat source is in the gas-turbine cycle itself. For a given maximum allowed reactor outlet temperature (1030°K), the thermal efficiency is up to 16% smaller than the efficiency of the simple direct cooling cycle. The absolute maximum efficiency can be the same for all gases because the pressure losses are smaller for gases with higher specific heat ratio. Thermal and pumping power losses are of such a magnitude in the double loop that single-loop systems are to be preferred for all applications where high efficiency is of primary interest.

Helium in a gas-turbine cycle requires turbo machinery with a large number of stages because of the small molecular weight of the helium. Higher tip speeds can be obtained with helium because of the high sonic velocity. The use of titanium which has the strength of steel but a density of only 4.5 would allow an appreciable increase in rpm and a decrease in the number of stages.

SUPERSONIC COMBUSTION TUNNEL, by R. A. Gross. Design rept. Oct. 1, 1957, 38p. incl. illus. diagrs. tables. (AFOSR-TN-57-677) (AF 49(638)15) AD 136667 Unclassified

The major features incorporated in a supersonic combustion-research tunnel which was designed to permit experimental exploration of chemical energy release in supersonic flow are summarized. The tunnel, which is designed for steady-state operation, accelerates a homogeneous mixture of fuel and air to a test section at about $M = 3$. The tunnel is of fixed geometry, and the test section has an axial gradient from $M = 3.0$ to 3.5 . Inlet stagnation temperature in the tunnel can be varied from 300° to 1200°F , and inlet stagnation pressure can be varied from ambient to 140 psia. Test area in the tunnel is about 5 by 3 in.; the throat is about 1 by 3 in. Detailed information is provided on the aerodynamic design, heat transfer, structural design, operating analysis, and instrumentation associated with the tunnel. (Contractor's abstract)

MAGNETOHYDRODYNAMIC EFFECTS IN COMBUSTION, by R. A. Gross, W. Chinitz, and T. J. Rivlin. Feb. 15, 1958, 23p. incl. diagrs. table, refs. (AFOSR-TN-58-120) (AF 49(638)15) AD 152028 Unclassified

Also published in Jour. Aero/Space Sciences, v. 27: 283-290, Apr. 1960. (Title varies)

One dimensional steady flow with heat addition in the presence of a plane magnetic field transverse to the direction of motion is studied. The basic equations are derived and solved for a variety of ideal conditions. Particular emphasis is given to the singular solution (the analogue of the Chapman-Jouguet detonation). The presence of a magnetic field alters the classical conditions. The effects of variable fluid properties and finite electrical conductivity are discussed. The electrical conductivity of the product gases of hydrogen-air detonations is presented. The experimental implications of this analysis are examined and lead to the conclusion that large magnetohydrodynamic effects in combustion can be produced in the laboratory under special conditions. THEORETICAL CALCULATIONS IN GASEOUS DETONATION, by C. L. Elsen, R. A. Gross, and T. J. Rivlin. Mar. 15, 1958, 93p. incl. diagrs. tables, refs. (AFOSR-TN-58-326) (AF 49(638)15) AD 154230; PB 135266 Unclassified

Also published in Combustion and Flame, v. 4: 137-147, Mar. 1960.

This study treats one dimensional steady flow combustion in the Mach number range of 0 to 10. Original data are presented for a wide variety of hydrocarbon fuels burning with air. Particular attention is given to the classical Chapman-Jouguet point. The results include the effect of dissociation and ionization. Non-dissociative results are also presented for both subsonic and supersonic flow and compared with the dissociative data. The effects of fuel-air ratio, initial temperature, and initial pressure are considered. Curves are presented which show not only the Chapman-Jouguet point, but the strong and weak detonation branches. Comparisons are made with other published works. These data were generated by the successful development of an automatic digital computer program. The program is applicable to any hydrogen, carbon, oxygen and nitrogen system. The theory, equations and method of solution are presented. The accuracy of the computation is discussed. These calculations are believed to be the most extensive of their kind ever made. RESEARCH ON THERMIONIC EMISSION OF BORIDES,
by R. Steinitz. Final rept. May 1, 1957, 34p. incl. illus.
diags. tables, refs. (AFOSR-TN-57-312) (AF 18(600)-
1504) AD 132383 Unclassified

Thermionic emission measurements were performed on most of the transition metal diborides, gadolinium hexaboride, and dense and porous tungsten cathodes. With the exception of the dense tungsten, which was used to standardize the test equipment, all samples were prepared by powder metallurgical techniques. The necessary vacuum system and electrical circuits were constructed to fit the requirements. The emission constant and work function for each of the above metals has been calculated from the emission data. However, in view of the above discussion, the reliability of the data is questionable. A simple solution to most of these problems has been planned for the future. Preliminary measurements performed on a tungsten cathode with 26% porosity showed a 32-fold improvement of emission over the 100% dense sample. This property was readily reproducible in each of three independent runs. The values for the thermionic emission of the transition metal diborides, which were obtained in this investigation, are not accurate or reliable enough to try to correlate them into the electronic structure of these materials or to draw conclusions about the nature of the bond between the boron and the metal atoms.

FUNDAMENTAL ASPECTS OF PHOTSENSITIZATION. INTERCOMBINATIONS IN MOLECULES. SPIN-ORBITAL COUPLING IN ATOMS AND MOLECULES, by I. G. Ross. July 20, 1958, 69p. incl. diagr. (Technical rept. no. 3) (AFOSR-TN-58-603) (AF 18(600)678) AD 162128 Unclassified

The first half of this paper deals with the theory of spin-orbital coupling in atoms, and is largely a restatement of some relevant parts of Condon and Shortley: "The Theory of Atomic Spectra". The theory of spin-orbital coupling in molecules is in its infancy, but a most important question concerns the selection rules for mixing of states due to this interaction. This topic is dealt with at sufficient length so that the reader may have a better understanding of the way in which the multiplicity classification of molecular state wave function is broken down. Finally, a brief account is given of the few quantitative treatments of molecular spin-orbital interaction that have so far been published.

SPIN ORBITAL INTERACTION IN N-HETEROCYCLIC MOLECULES: GENERAL RESULTS IN A CYLINDRICAL POTENTIAL APPROXIMATION, by E. Clementi and M. Kasha. [1958] [10]p. incl. tables, refs. (AF 18(600)-678) Unclassified

Published in Jour. Molecular Spectroscopy, v. 2: 297-307, June 1958.

The method for calculation of spin-orbital interaction in benzene, developed by Mizushima and Koide, is extended to N-heterocyclic molecules in which both (π, π^*) states are excited. Using the L.C.A.O.-M.O. approximation, the general matrix elements of the interaction are expanded to matrix elements involving A.O.'s. The cylindrical form of the potential used by Mizushima and Koide, and one-center integrals only, are adopted as approximations. The method is applied to the case of pyridine, and evaluation of the matrix elements is carried out on the basis of symmetry considerations. The net result is a prediction that the absolute value for the transition probability of the lowest triplet (n, π^*) - singlet transition in pyridine would be of the same order of magnitude as the transition probability of the analogous $\pi - \pi^*$ transition. Analysis of the results in terms of f-number ratios, and comparison with a parallel study based on a spherical potential, confirm a proposal of enhancement of spin-orbital interaction for (n, π^*) states. INTRAMOLECULAR TWISTING EFFECTS IN SUBSTITUTED BENZENES. II. GROUND-STATE PROPERTIES, by E. G. McRae and L. Goodman. [1958] [13]p. incl. diagrs. tables. (Bound with its AFOSR-TN-58-477; AD 158288) [AF 18(600)678] Unclassified

Also published in Jour. Chem. Phys., v. 29: 334-336, Aug. 1958.

The effects on ground-state properties of twisting a substituent-ring bond in substituted benzenes are discussed from the viewpoint of semiempirical MO theory. The ground-state properties are discussed with reference to a parameter θ , which generally increases as the substituent is twisted. The substituent-ring bond order varies approximately as $\cos \theta$, and the following vary approximately as $\cos^2 \theta$: the resonance energy, charge densities, ring C-C bond orders and the π -electronic dipole moment. The θ dependence of the total dipole moment is discussed. Numerical applications to N,N-dimethylaniline and related molecules are described, including a detailed treatment of the dipole moments of N,N-dimethylaniline and some of its orthosubstituted

FLA.01:011 - FLA.01:013

derivatives. A brief discussion of the valence state of the dimethylamino group is included. (Contractor's abstract)

SOLVENT EFFECTS ON MEROCYANINE SPECTRA, by E. G. McRae. [1958] [39]p. incl. diagrs. tables, refs. (Bound with its AFOSR-TN-58-477; AD 158288) [AF 18(600)878] Unclassified

Also published in Spectrochimica Acta, v. 12: 192-210, Sept. 1958.

Solvent effects on the visible absorption spectra of three merocyanine dyes are described. The dyes comprise two (I and II) of exceedingly high polarity, and a third (III) less polar than I and II but still highly polar by ordinary standards.

The absorption curves, values of the extinction coefficient and frequency at the absorption maxima (ϵ_{max} and ν_{max} respectively) and oscillator strengths are given for I dissolved in pure solvents, and for dyes II and III in a variety of both pure and mixed solvents. For each dye, ϵ_{max} and ν_{max} undergo pronounced solvent effects, but the oscillator strengths are insensitive to solvent perturbations. The results are discussed in terms of a simple theory in which the combining states are considered as superpositions of a polar and a non-polar resonance structure. A more detailed theory is applied in the interpretation of the frequency shifts induced by non-hydrogen bonding solvents. (Contractor's abstract)

ENERGY TRANSFER IN MOLECULAR COMPLEXES OF SYM-TRINITROBENZENE WITH POLYACENES. I. GENERAL CONSIDERATIONS, by S. P. McGlynn and J. D. Boggus. [1958] [32]p. incl. diagrs. tables, refs. (Bound with its AFOSR-TN-58-477; AD 158288) [AF 18(600)878] Unclassified

Also published in Jour. Amer. Chem. Soc., v. 80: 5096-5101, Oct. 5, 1958.

The emission spectra of π -complexes of aromatics with sym-trinitrobenzene have been studied. It is shown that after irradiation in the charge-transfer band, two emissions occur: one the reverse of the charge-transfer absorption, the other from a triplet level of the uncomplexed aromatic. Absorption spectra of complexes, their total emission spectra and delayed emissions are described. Theoretical considerations of the processes involved lead us to presume that after excitation in the charge-transfer band, some intersystem crossing occurs to a dissociative triplet level of the complex. The resultant production of uncomplexed aromatic in its lowest triplet state then gives rise to the observed phosphorescence. State correlation diagrams and plots of ionization potential of aromatic versus the energy of the charge-transfer absorption are also described. (Contractor's abstract)

INTRAMOLECULAR TWISTING EFFECTS IN SUBSTITUTED BENZENES. I. ELECTRONIC SPECTRA, by E. G. McRae and L. Goodman. [1958] [56]p. incl. diagrs. tables, refs. (Bound with its AFOSR-TN-58-477; AD 158288) [AF 18(600)878] unclassified

Also published in Jour. Molecular Spectroscopy, v. 2: 464-493, Oct. 1958.

The electronic spectral effects of twisting a substituent group about the substituent-ring bond in substituted benzenes are analyzed from the viewpoint of semi-empirical MO theory including zeroth and first order configuration interaction. The substituent orbital ϕ_s^0 is expressed as a linear combination of two functions, ϕ_x and ϕ_y , which are respectively anti-symmetric and symmetric with respect to reflection in the ring plane: $\phi_s^0 = \cos \theta \phi_x + \sin \theta \phi_y$. Transition energies and intensities are discussed with reference to the twisting parameter θ . Ordinarily, θ increases as the substituent is twisted, and can be evaluated explicitly when the molecular geometry is known. The treatment is carried through both with and without cognizance of the nearest-neighbor overlap integrals, and the inductive effect of the substituent is discussed. Particular attention is given to the question of self-consistency. The theory applies especially to those transitions which correspond to transitions observed in the spectrum of benzene ("benzene-analogue" transitions). Three possible types of θ -dependence of transition energies are distinguished, and the conditions under which each might be realized are specified. Of the four benzene-analogue singlet-singlet transitions considered, the two of lowest energy

FLA.02:001-004; FLU.02:001, 002

are ordinarily predicted to suffer a decrease of intensity as θ increases, while the intensities of the remaining two transitions are predicted to be insensitive to twisting perturbations. "Charge transfer" transitions are also considered, though in less detail. The theory is applied in a detailed discussion of the ultraviolet absorption spectra of *N,N*-dimethylaniline and related molecules in which the dimethylamino substituent is twisted as a result of ortho substitution or intramolecular bridge formation. The meaning of an x-ray attenuation coefficient is considered from the point of view of an experimental determination of its value. Consideration is given to the factors which affect the precision of its measurement including (1) those arising from the absorbers, (2) those arising from the x-ray spectrometer's resolution in energy, and (3) those arising from the detection of the x-ray beam. A MODERATELY VERSATILE PROGRAM CIRCUIT FOR COUNTING EXPERIMENTS, by R. D. Deslattes and D. L. Clemmons, Jr. 1958 [13]p. incl. diagrs. (Technical rept. no. 3) (AFOSR-TN-58-601) (AF 18(603)64) AD 162126
Unclassified

A device is discussed which was designed to execute various measurements in absorption and emission spectroscopy utilizing a two-crystal x-ray spectrometer. Its versatility is such, however, as to suggest applications to counting experiments in general. Its design is open, so that sequential procedures of arbitrary complexity may be executed by means of simple extensions of the circuitry. (Contractor's abstract)

Precise values for the total attenuation coefficients were obtained at approximately 1 kv intervals from 8 to 30 kv for 15 pure elements using a two-crystal spectrometer of high resolving power. These span the range of atomic numbers from 12 to 79. (Possibly disturbing effects of small-angle scattering were investigated.) The resulting values of μ for some elements may be assigned an average standard deviation of 0.2%. (Contractor's abstract)

Two of the soluble, linear polymers obtained from monomers of the general formula $[(CH_2 = CHCH_2)_2NR_2]^+ Br^-$ have been degraded by well-known methods. Both mono-(diallylammonium bromide) and poly-(diallyldimethylammonium bromide) have given products resulting from the cleavage of piperidinium bromide rings present in the structures. The results confirm the structure previously proposed for these polymers. (Contractor's abstract)

The polymerization of acrylic anhydride in solution has been accomplished to yield a series of saturated linear polymers with molecular weight up to 95,000. The polymerization occurred through the means of alternating intramolecular-intermolecular mechanism and has led to a poly-3(5)-methylene glutaric anhydride structure. The polyacrylic acid obtained by hydrolysis has been shown by means of its degree of crystallinity to have a more regular structure than normal polyacrylic acid. (Contractor's abstract, modified)

Also published in Chem. and Indus. (London), No. 3: 88-89, Jan. 17, 1959.

Me_2SO (I) (3 vols) oxidizes 1 vol $\text{BrCH}_2\text{CO}_2\text{Et}$ (II) to OCHCO_2Et in 70% yield. Me_2S (III) formed may react with (II) to give $(\text{Me}_2\text{SCH}_2\text{CO}_2\text{Et})\text{Br}$ (IV), and there may be Me exchange between III and IV. I may also react with the HBr formed to give III, water, and Br. Addition of MeBr and 1,2-epoxy-3-phenoxypropane represses these side-reactions. Also prepared by this reaction are AcCO_2Et from $\text{MeCHBrCO}_2\text{Et}$ and $\text{CO}(\text{CO}_2\text{Et})_2$ from $\text{CHBr}(\text{CO}_2\text{Et})_2$. The ease of oxidation of $\text{RR}'\text{CHX}$ increases when X is varied from Cl to Br and I, and when R and R' are electron attracting. Although an induction period is observed, radical scavengers are ineffective, and the reaction is thought to proceed by a polar mechanism through an intermediate, $(\text{Me}_2\text{SOCHRR}')\text{X}$, which collapses to III, HX, and $\text{RR}'\text{CO}$.

ELECTRON SPIN RESONANCE STUDIES OF PHOTOCHROMIC SOLIDS, by H. S. Gutowsky, R. L. Rutledge, and I. M. Hunsberger. [1958] [2]p. Incl. diagr. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)127, Office of Naval Research, and Public Health Service) Unclassified

Published in Jour. Chem. Phys., v. 29: 1183-1184, Nov. 1958.

Electron resonance studies were made of tetrachloro-1-oxonaphthalene (the structure of this compound is either 2,3,4,4-tetrachloro-1(4H)-naphthalenone or 2,2,3,4-tetrachloro-1(2H)-naphthalenone), N-(3-pyridyl) sydnone, the anils of salicylaldehyde with p-bromoaniline and 2-naphthylamine, and 2-(2,4-dinitrobenzyl) pyridine. In only the sydnone was an electron spin resonance detected. On exposure to a Hg vapor lamp, the white crystals turned blue. A detectable spin resonance absorption was detected later with an intensity depending on the temperature of the sample and the presence or absence of air. In evacuated samples no resonance was detected at room temperature until air was admitted. The blue color faded to a yellow green while the absorption increased and reached a maximum. The sydnone provides long-term storage of photochemical energy in a form readily available for chemical reaction.

Gelatin solutions shrink as water evaporates from the gel. If the shrinkage is prevented, tensile stresses develop. A technique is described for measuring the tensile stress developing in the plane of edge-clamped gelatin films during drying. It is based on measurement of the elastic deformation of the film when stressed normally to the plane of the film. At 50% relative humidity, stresses of 4,000 to 5,000 lb/sq in. were observed in several films. The reality of these stresses was confirmed by a completely independent method.

IRREVERSIBLE STOCHASTIC THERMODYNAMICS AND THE TRANSPORT PHENOMENA IN A REACTING PLASMA, by H. J. Kaeppler and G. Baumann. Final rept. Nov. 1956, 104p. incl. diagrs. tables, refs. (AFOSR-TR-57-20) (AF 61(514)939) AD 120462; PB 150688 Unclassified

The investigations presented in this report are a first venture in attempting a theory of transport phenomena in a reacting plasma at elevated and high temperatures. As an essential basis for such studies, the equilibrium behavior of a plasma is treated. These equilibrium considerations concern the influence of electrostatic microfields on plasma properties, termination of the electronic partition function, and determination of the plasma composition. Entering into the problem of energy transport, the classical diffusion theory of transport is discussed. Then, an attempt is made at establishing the rudiments of a stochastic description of plasma physics, the thermodynamics of transport phenomena in particular. It is shown that the theory includes the purely statistical methods. For the calculation of internal energy transport, the formal kinetic theory due to Wang-Chang and Uhlenbeck is extended, and approximate methods for integration of the collision integrals are derived. Finally the energy transport in the presence of chemical reactions is treated. (Contractor's abstract)

INELASTIC PROTON SCATTERING FROM PHOSPHORUS, by D. M. Van Patter, C. P. Swann and others. [1956] [1]p. [AF 18(600)1320] Unclassified

Presented at Internat'l. Conf. on Nuclear Reactions, Amsterdam (Netherlands), July 2-7, 1956.

Published in *Physica*, v. 22: 1125-1126, Nov. 1956.

Using a 180° double-focusing magnetic spectrometer, the inelastic proton spectrum from zinc phosphide targets bombarded by 3.055 mev protons has been observed at 90°. For a region of excitation from 0 to 1.42 mev, only one inelastic proton group was observed, corresponding to a level in ^{31}P at 1.264 ± 0.004 mev. No other inelastic groups were observed with an intensity greater than 15% of the intensity of this group. By the use of higher bombarding energies, of 3.12 and 4.65 mev, this survey has been extended to 3.55 mev excitation. Three additional inelastic groups have been observed, corresponding to ^{31}P levels at 2.23, 3.13 and 3.29 (± 0.01) mev. In the region from 0 to 1.26 mev excitation, no inelastic groups were observed with an intensity greater than a few percent of the first excited state group. In addition, inelastic groups corresponding to the first excited state of ^{64}Zn , ^{66}Zn and ^{68}Zn were observed, corresponding to level energies of 0.99, 1.04 and 1.08 (± 0.01) mev, respectively.

LEVELS IN Cr^{50} , Cr^{52} , Cr^{53} , AND Cr^{54} , by W. C. Porter, D. M. Van Patter and others. [1958] [7]p. incl. diagrs. tables, refs. [AF 18(600)1320] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 38, Jan. 29, 1958.

Also published in Phys. Rev., v. 112: 468-474, Oct. 15, 1958.

Inelastically scattered proton spectra from targets of natural chromium and targets enriched in Cr^{50} , Cr^{53} , and Cr^{54} have been studied for bombarding energies in the region of 4.3 to 4.6 mev using a double-focusing magnetic spectrometer, at angles of observation of 91.5° and 136.2°. The enriched targets were prepared by the vacuum evaporation of Cr_2O_3 from a small carbon crucible mounted on a tungsten filament onto gold-leaf backings. Surveys were taken up to at least 2.0-mev excitation. The following level energies in kev were determined: Cr^{50} , 780 ± 3; Cr^{52} , 1432 ± 5; Cr^{53} , 562 ± 3, 1006 ± 4, and 1287 ± 5; Cr^{54} , 842 ± 6. The new level in Cr^{50} occurs at the energy expected for the first 2+ state. Inelastically scattered proton groups corresponding to the known second excited states of Cr^{52} and Cr^{54} were not sufficient intensity to be observed. (Contractor's abstract)

ENERGY AND SPIN SYSTEMATICS OF EVEN-EVEN NUCLEI WITH $22 \leq N < 50$ (Abstract), by D. M. Van Patter. [1958] [1]p. [AF 18(600)1320] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 212, May 1, 1958.

Recently, new information regarding the energy levels of even-even nuclei has become available, indicating that the energy ratio E_2/E_1 of the second to first excited state drops below 2 in the region $30 \leq N \leq 40$, as has been pointed out. Examination of the evidence concerning the energies and spins of the second and third excited states of nuclei in the region $22 \leq N < 50$ has revealed a possible systematic trend for the spin of the second excited state. For nuclei with $22 \leq N < 30$, the spin of the second excited state is always 4+ when measured. For nuclei with $32 \leq N < 50$, the spin of the second excited state is always 2+ when measured, omitting the low-lying 0+ states in Ge^{70} and Ge^{72} . There is some indication that the 4+ and 2+ levels may cross over at $N = 30$ to 32. Some implications of these possible systematic trends will be discussed.

PROPOSED SYSTEMATICS FOR E2 TRANSITION PROBABILITIES OF EVEN-EVEN NUCLEI, by D. M. Van Patter. [1958] [3]p. [AF 18(600)1320] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago U., Ill., Nov. 26-29, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 360, Nov. 28, 1958.

Also published in Jour. Franklin Inst., v. 266: 411-413, Nov. 1958.

A survey has been made of all available data concerning lifetime determinations and Coulomb excitation cross sections for the first two 2+ levels of even-even nuclei. A pronounced correlation has been found between the reduced transition probability for decay, $B(E2)$, and the energy E_1 (in mev) of the first excited state. One way of demonstrating this correlation is to consider the quantity $B(E2)/Z^2$. For nuclei with $A = 46-132$, the

reduced transition probability for decay can be well represented (to about ± 25 percent) by $B(E2)/Z^2 = 2.2 \times 10^{-5} E_1^{-1.4}$ (in units of $e^2 \times 10^{-48} \text{ cm}^4$). For nuclei with $A = 146-202$, a similar expression is obtained: $B(E2)/Z^2 = 0.9 \times 10^{-5} E_1^{-1.3}$. However, it should be pointed out that this apparent correlation is not unique, for similar correlations between the favored factor F , or $FA^{5/3}/Z^2$, and E_1 can be demonstrated. Another interesting feature has been noticed for isotopes of W, Os, and Pt. The measured values of $B(E2)$ and the E2 transition between the second and first 2+ levels are consistent with the second expression given above.

FURTHER CONSIDERATIONS ON THE DUCTILITY OF IRON AT 4.2°K, by R. L. Smith and J. L. Rutherford. [1957] [2]p. incl. diag. (AF 18(600)1581) Unclassified

Published in Acta Metallurgica, v. 5: 761-762, Dec. 1957.

In a recent letter to the editor, Basinski and Sleswyk showed three tensile curves for Ferrovac iron tested at 4.2°K. Each of these curves was for a different grain size. The authors observed that there was always a number of constrictions in the specimen—corresponding to the no. of serrations in the stress-strain curve. Smith and Rutherford have tested a large no. of iron specimens at 4.2°K and have found no correlation between the no. of constrictions and the no. of serrations. These authors believe that the heat generated by plastic deformation causes a localized decrease in strength during deformation due to the very low heat capacity together with the large temperature dependence of the yield stress at these temperatures. Their explanation for serrations seems unreasonable since one can obtain the same serrated curve for iron tested in tension at -196°C. Smith, Spangler and Brick found that the ductility in tension at low temperatures was determined by the grain size. The authors apparently overlooked the fact that ductility was greater for the specimen nearest the purest end of the zone-refined iron, even though the grain size was much larger than that at the impure end. It is important to note that at no time have Smith and Rutherford drawn any conclusions on the general ductility of very pure iron (as inferred by Basinski and Sleswyk). They have only concluded that iron is not brittle in simple tension. To date, their results on zone-purified iron have always shown that it still has less ductility at 4.2°K, as measured by uniform strain in tension, than it does at higher temperatures.

EVIDENCE OF DISLOCATION LOOPS AND SPIRALS IN ZINC, by V. Damiano and M. Herman. [July 1958] 7p. (AF 18(600)1581) Unclassified

Crystals of pure zinc and zinc alloyed with small amounts of cadmium were cleaved, etched, and examined under the light microscope. The loops and spirals observed appear as configurations predicted by Frank and Read. They proposed that a dislocation pinned at its end may bow out and generate a continuous spiral; and that if the dislocation is pinned at both ends, it will collapse upon itself and generate closed dislocation loops. It is concluded that the observed etch patterns revealed on zinc represent dislocations in the metal.

MAGNETIC EXAMINATION OF THE INITIAL PRECIPITATION IN A GOLD-NICKEL ALLOY, by A. E. Berkowitz and P. J. Flanders. May 1957 [28]p. incl. diags. tables, refs. (Interim technical rept. no. 1-A2026-1) (AFOSR-TN-57-314) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under AF 49(638)59) AD 132385 Unclassified

Magnetic measurements of gold-nickel alloy in the initial stages of precipitation have been analyzed in terms of the structure and growth behavior of the nickel-rich precipitate, and the mechanisms of magnetization of these particles. The magnetic measurements include

the field and temperature dependence of the saturation magnetization, torque, rotational hysteresis, and remanence. The structural properties of the precipitate particles derived from these measurements are shape and size distributions, degree of precipitation, coherency, and orientation. After 206 min at 400°C when approximately one percent of the equilibrium precipitate had developed, the particles were randomly oriented, not coherent, and of the order of 1,000Å. The nearly spherical particles grew relatively rapidly and were magnetized by a non-uniform process. The more acicular precipitate particles could be described by a uniform magnetization process. The temperature dependence of the magnetic properties also reflected the shape dependence of the mechanism of magnetization. (Contractor's abstract)

MAGNETIC MEASUREMENTS ON SOME PRECIPITATING SYSTEMS, by A. E. Berkowitz and P. J. Flanders. [1958] [3]p. [AF 49(638)159] Unclassified

Published in Jour. Appl. Phys., v. 29: 314-316, Mar. 1958.

In the systems Au-Ni and β -brass-Fe, ferromagnetic precipitate particles develop in a nonmagnetic matrix. Single crystal samples of these alloys have been examined by measuring saturation magnetization, torque curves, rotational hysteresis, and remanence. The data on the Au-Ni system have been analyzed to infer particle anisotropy distributions, orientation of the "easy" axes of the particles, and other features of the precipitate particle system. Electron micrographs of the precipitate particles are in general agreement with this analysis. The measurements on the β -brass-Fe system indicated that the precipitate particles were single crystals with the same crystal habit as the matrix, and were elongated in the $\langle 111 \rangle$ directions. The temperature dependence of the torque curves was identified with the temperature dependence of shape and magnetocrystalline anisotropy. (Contractor's abstract)

COMPARISON BETWEEN NEGATIVE CARBON REPLICAS AND SILICON MONOXIDE REPLICAS (Abstract), by I. G. Greenfield and H. G. [F.] Wildorf. [1957] [1]p. [AF 49(638)162] Unclassified

Presented at annual meeting of the Electron Microscope Soc. Amer., Massachusetts Inst. of Tech., Cambridge, Sept. 9-11, 1957.

Published in Jour. Appl. Phys., v. 28: 1375, Nov. 1957.

Negative carbon and silicon monoxide replicas are considered to be almost suitable for high resolution work. Since resolution measurements are known for silicon monoxide replicas but not for carbon replicas, a comparison between the two replica methods appeared to be desirable. In order to prevent the occasional ejection of carbon particles, the generally used carbon source was slightly modified. Carbon and silica replicas were taken from metals and inorganic crystals, and their properties determined. This includes a comparison of those properties which are imperative for high resolution, for instance, surface migration and inherent structure, as well as the properties important for handling of the replicas and for special purposes. A discussion of the merits of the two replica methods will be given.

THE "DECORATION" OF DISLOCATIONS IN α -BRASS, by R. Sun and H. G. F. Wilsdorf. [1958] [3]p. incl. illus. [AF 49(638)162] Unclassified

Published in Jour. Franklin Inst., v. 265: 413-415, May 1958.

It has been known for several years that dislocations can be "decorated" by impurity atoms. This is usually done by adding a predetermined quantity of impurities in solid solution, straining, and then heat treating. In metals, two processes are then possible: (1) the diffusion of impurity atoms to the dislocations, producing the so-called "atmospheres", and (2) the nucleating of precipitates at dislocation sites. Through subsequent etching, the atmospheres or the precipitates, and thereby the dislocations, can be revealed with the use of an electron microscope. This technique was used to decorate dislocations in Cd doped α -brass crystals. Observation of a single crystal which had been elongated 4% revealed that its surface was covered with etch pits which were immediately interpreted in terms of dislocations. They were arranged in rows, parallel to the active slip planes and appeared in distinct groups. Observation and measurement of the isolated dislocation pile ups occurring in slip lines offered proof that etch pits indeed mark dislocation sites, and that the theoretical calculations applying elasticity theory are well founded. Further, the data were in good agreement with the theoretical concept that dislocations form pile-ups against obstacles in the course of plastic deformation.

DISLOCATION PATTERNS IN DEFORMED ALPHA-BRASS, by H. G. F. Wilsdorf. [1958] [4]p. incl. illus. [AF 49(638)162] Unclassified

Published in Proc. Symposium on Internal Stresses and Fatigue in Metals, Detroit and Warren, Mich. (Sept. 4-5, 1958), Amsterdam, Elsevier Publishing Co., 1959, p. 178-181.

The mechanism of plastic deformation in Cd-doped α -brass crystals was investigated. The dislocation patterns were observed with the use of an electron microscope. The comparison of distances between dislocations in a discrete pile-up with theoretical values yielded the result that there is a 1:1 correspondence between etch pits and dislocations. Counting the number of dislocations in these deformed regions, a dislocation density in the order

of $\rho = 4 \cdot 10^8 \text{ cm}^{-2}$ was found. The micrographs also showed that the pile-ups were headed in one direction mainly, indicating an excess of dislocations of one sign in any one area. A direct determination was made of n , the average number of dislocations in each group, and σ , the average number of groups per unit area. These values together with data obtained previously; namely s , the average glide for a slip line, and d , the average distance between slip lines, made it possible to calculate the average length of the path of a dislocation l , the average distance between dislocation groups, a , and the number of groups per slip line, N_{gr} . The following values were obtained: $l = 80\mu$; $a = 13\mu$; and average $N_{gr} = 23.3$. The experimental results were in excellent agreement with predictions made by Kuhlmann.

SURFACE STRUCTURE OF THERMALLY ETCHED SILVER (Abstract), by I. G. Greenfield. [1958] [1]p. [AF 49(638)162] Unclassified

Presented at meeting of the Electron Microscope Soc. Amer., Santa Monica, Calif., Aug. 7-9, 1958.

Published in Jour. Appl. Phys., v. 29: 1625, Nov. 1958.

The crystallographic faces that appeared on thermally etched silver are in general low index faces of the type $\{111\}$ and $\{100\}$. Electron micrographs indicated that the perfection of these planes depended on the temperature, length of time of thermal etching, and the orientation of the lattice with respect to the surface of the specimen. Rod-like structures which were aligned parallel to each other appeared on the surfaces of some of the specimens.

A BIBLIOGRAPHY ON GAS-LUBRICATED BEARINGS, by E. B. Sciulli. Dec. 1, 1957, 80p. (Interim rept. no. I-A2049-1) (Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-234200) AD 147733 Unclassified

This partially annotated bibliography of 124 references on gas-lubricated bearings was compiled in an effort "to evaluate the present state of the art and to establish a library of available technical papers to serve as ready references of work done in this field." Foreign, e.g., British, French, German, and Japanese, as well as domestic, literature sources have been reviewed. Though most of the references are from open literature, i.e., books, technical journals, patents, a few report references are included, and some theses are cited. The entries range in time from 1828 through 1957. The following indexes are included: personal author index; subject index; "composite index" (consisting of a series of columns arranged so that most of the pertinent information concerning a reference will appear on one horizontal line); year of publication; and corporate author index. Appendixes contain additional references, associated-subject references, and notes of interest in the field of gas-lubricated bearings.

[ON THE MOLECULAR THEORY OF BROWNIAN MOTION] Sur la théorie moléculaire du mouvement Brownien, by I. Prigogine and R. Balescu. [1957] [14]p. incl. refs. (AFOSR-TN-58-101) (AF 61(514)957) AD 148150 Unclassified

Also published in *Physica*, v. 23: 555-568, June 1957.

The theory of Brownian motion for weakly coupled systems has been derived from first principles for systems in which it is possible to trace the development of a single degree of freedom which is out of equilibrium. Two cases are studied in detail: (1) weakly coupled oscillators as are found in the theory of slightly anharmonic solids or in radiation theory; and (2) gases interacting through weak long-range forces such as gravitational or electrostatic forces. The first case is solved completely but not the second. The approach to equilibrium of the system is found to be governed by non-Gaussian Markoff processes.

ON IRREVERSIBLE PROCESSES IN NON-UNIFORM

SYSTEMS, by I. Prigogine and J. Philippot. [1958] [16]p. (AFOSR-TN-58-247) (AF 61(514)957) AD 154149

Unclassified

Also published in *Physica*, v. 23: 569-584, June 1957.

The irreversible phenomena in inhomogeneous systems are studied. In the classical approach there remains a basic dissymmetry between evolution in the geometric space (reversible flow) and in energy space (irreversible collisions). The new terms derived in this paper introduce a complete symmetry into the problem. Both the motion in angle-spaces and in action space are governed by irreversible equations. Brownian motion is described here as a non-Gaussian Markoffian process which may be reduced to Kramer's equation for Brownian motion. An appendix is included which gives characteristic times and thermal conductivity of solids in relation to their thermodynamic properties. A very simple and explicit formula of thermal conductivity is given.

[THEORETICAL STUDY OF A SYSTEM CONTAINING AN AMPHOTERIC PRODUCT IN THE PRESENCE OF pH GRADIENTS AND OF AN ELECTRICAL POTENTIAL] Étude théorique d'un système contenant un produit amphotérique en présence de gradients de pH et de potentiel électrique, by W. G. Kauman. 1957, 1v. incl. diagrs. tables, refs. (AFOSR-TN-58-648) [AF 61-(514)957] Unclassified

The distribution of an ampholyte is calculated for the stationary state when it is simultaneously in the presence of pH gradients and an electric potential. It is shown that in the case where the gradients act in opposite directions, the ampholyte will be strongly concentrated in the vicinity of the region where the pH of the solution corresponds to the isoelectric point. The intensity of this concentration increases if one or both of the two

gradients are increased. Several numerical examples are given. The approach to the stationary state resulting from an initial arbitrary distribution is calculated and it is shown that the relaxation time for this approach is of the order of several minutes.

ON THE ELECTROPHORETIC SEPARATION OF AMPHOLYTES IN A MEDIUM OF NON-UNIFORM pH, by W. G. Kauman. [1957] [15]p. incl. diagrs. table. (AFOSR-TN-58-651) [AF 61(514)957] AD 162183 Unclassified

Also published in *Bull. Acad. Roy. de Belgique, Cl. Sci., Series 5*, v. 43: 854-868, Dec. 7, 1957.

The behavior of amphoteric electrolytes under the combined action of a gradient of pH and air electrostatic potential is investigated theoretically. It is shown that ampholytes may be separated and concentrated if the positive electrode is placed on the acid side of the pH gradient. Results are presented which show that under these conditions, the distribution of the ampholyte at the stationary state will vary approximately as a Gaussian error function of distance with the maximum at the isoelectric point. The "Bandwidth" of the maximum is found to depend inversely on the magnitudes of the gradients. The relaxation time for the approach to the stationary state is calculated and found to be of the order of a few minutes. (Contractor's abstract)

ON IRREVERSIBLE PROCESSES IN QUANTUM MECHANICS, by I. Prigogine and M. Toda. [1958] [15]p. (AFOSR-TN-58-652) [AF 61(514)957] AD 162184 Unclassified

Also published in *Molecular Phys.*, v. 1: 48-62, Jan. 1958.

A general theory of irreversible processes in weakly coupled systems based on classical mechanics has been extended to the study of quantum mechanical systems. In this procedure the density matrix is divided into a slowly varying and an oscillatory part, and asymptotic equations are established for the matrix elements. In the representation in which the unperturbed Hamiltonian is diagonal, these equations take a particularly simple form for weakly coupled systems in which the matrix elements lying on diagonal parallel to the principal diagonal undergo separate transformations. A particular case is that in which the diagonal elements are transformed to yield the Pauli equations. As an illustrative example the problem of the frictional forces on

GRAVITATIONAL FORCES AND DYNAMIC FRICTION, by R. Balescu. [1958] [4]p. [AF 61(514)957] Unclassified

Published in Proc. Internat'l. Symposium on Transport Processes in Statistical Mechanics, Brussels (Belgium) (Aug. 27-31, 1958), N. Y., Interscience Publishers, Inc., 1958, p. 33-38.

Irreversible processes are studied by a master equation derived by Brout and Prigogine for classical weakly coupled systems. The application is to the gases of point stars with long-range interactions between the particles. As a result of the interactions, it is shown that any incident star will be systematically decelerated in the direction of its motion, a phenomenon described as dynamic friction which is evaluated by the quantity

$\overline{dv_0/dt}$. The Hamiltonian of the isolated global cluster is used to develop the master equation:

$$\frac{\partial \rho}{\partial t} = \frac{A}{\gamma} \sum_{i < j} \int dk \frac{1}{k} k \left(\frac{\partial}{\partial v_i} - \frac{\partial}{\partial v_j} \right) \delta[k \cdot (v_i - v_j)] k \cdot \left(\frac{\partial}{\partial v_i} - \frac{\partial}{\partial v_j} \right) \rho$$

with $A = 2G^2 m^2$ and v = volume of the system. The situation is analyzed for the limiting situations of the divergence for $k \rightarrow 0$ and $k \rightarrow \infty$. The upper cutoff for $k \rightarrow 0$ is placed approximately equal to $k_D = 1/R_0$ and

$$\text{for } k \rightarrow \infty, \text{ one obtains } \frac{dv_0}{dt} = - \int dv_0 \phi(v_0) \eta(v_0) v_0 =$$

$-\overline{\eta(v_0)} v_0$, exhibiting the coefficient of dynamic friction

$$\eta(v_0) = 16\pi^2 nA \ln q v_0^{-2} \cdot \frac{1}{v_0^3} \int_0^v dv v^2 f(v).$$

CYCLIC PROCESSES IN IRREVERSIBLE THERMODYNAMICS, by I. Prigogine and R. Balescu. [1958] [3]p. [AF 61(514)957] Unclassified

Published in Proc. Internat'l. Symposium on Transport Processes in Statistical Mechanics, Brussels (Belgium) (Aug. 27-31, 1958), N. Y., Interscience Publishers, Inc., 1958, p. 343-345.

Cyclic rotation processes around a stationary state are considered from a thermodynamic standpoint. A variational principle is postulated for Glandsdorff and Prigogine's theorem: The total differential of the entropy production P is written as $dP = d_X P + d_V P$, with $d_X P = \sum V_i dX_i$ and $d_V P = \sum X_i dV_i$ (V_i, X_i are rates and affinities of the irreversible processes). Along every path followed by the system during its evolution, $d_X P \leq 0$, for time-independent boundary conditions. The value 0 corresponds to the stationary state. From Volterra's model using the analysis of two coexisting mutually predatory biological species A and B, $d_X P/dt = (B - \epsilon_1) \dot{A} + (\epsilon_2 - A) \dot{B} = -\nu \leq 0$, which is comparable to imposing a sense of rotation around the stationary state. This provides a means of studying $d_X P$ as a variational principle, in spite of its non-integrability as a general case.

A MASS SPECTROMETRIC METHOD FOR THE DETERMINATION OF DISSOCIATION ENERGIES OF DIATOMIC MOLECULES, by J. Drowart and R. E. Honig. [1957] [16]p. incl. diags. tables, refs. (AF 61(514)868) Unclassified

Published in Jour. Phys. Chem., v. 61: 980-985, July 1957.

By combining experimental data obtained in a mass spectrometer with thermochemical computations, dissociation energies of various diatomic molecules have been determined. This method has been applied to the Group IB and IVB dimers, and estimates have yielded values for Group IIIB and some other elements. To produce atomic and diatomic species of a given element, a milligram sample was vaporized in a mass spectrometer from a small, electrically-heated crucible. Ion intensity ratios were measured as a function of temperature, after the particles had been ionized, accelerated, mass analyzed, and collected. The dissociation energies computed by the Absolute Entropy Method are based on the

FRE.03:005 - FRE.03:008

following quantities: ion intensity ratios; internuclear distances, estimated from known crystal spacings; electronic partition functions; and vibrational frequencies reported recently in band spectral studies. The values found agree well with those obtained by the so-called Slope Method which utilizes directly the measured heats of vaporization of monomers and dimers, and they fall within the upper limits set by band spectral data. VAPORIZATION OF COMPOUNDS AND ALLOYS AT HIGH TEMPERATURE, by P. Goldfinger and J. Drowart. Final technical rept. Oct. 1957, 25p. incl. diags. tables, refs. (AFOSR-TR-58-5) (AF 61(514)868) AD 148038; PB 133279 Unclassified

Accurate thermodynamic data for the vaporization of elements and compounds were obtained by means of mass spectrometry. Molecular species as Cu_2 , Ag_2 , and Au_2 were found during an investigation of the vapor phase; the dissociation energies of the molecules were determined. No such molecules were observed in the vapor phase of the transition elements. Study of the vapor phase evaporating from the III-V compounds, GaAs and InP, yielded new data on the dissociation energies of the tetramer molecules of group V elements. The maximum of stability was observed for As_4 or Sb_4 .

The partial decomposition pressures of GaAs, InP, CdSe, and CdTe allowed the calculation of the heat of formation, the free energy of formation, and the standard entropy of these compounds, as well as the dissoci-

ation energies of the molecules As_4 , P_4 , Sb_4 , Se_2 and Te_2 .

MASS SPECTROMETRIC STUDIES OF THERMODYNAMIC PROPERTIES OF GROUP III-V AND II-VI COMPOUNDS AND GROUP V AND VI ELEMENTS, by P. Goldfinger and M. Jeunehomme. Sept. 1958, 24p. incl. diags. tables, refs. (AF 61(514)868) Unclassified

Presented at the Mass Spectrometry Conference, London (England), Sept. 24-26, 1958.

The mass spectrometric investigation of the evaporation of InAs, GaSb and ZnS enabled thermodynamic data regarding these substances to be obtained. The dissociation energies of tetramer to dimer of the Group V elements were found: $D(\text{As}_2-\text{As}_2) = 69.6 \text{ kcal/mol}$ and $D(\text{Sb}_2-\text{Sb}_2) = 63.4 \text{ kcal/mol}$. These are in good agreement with the values obtained previously from the evaporation of GaAs and InSb. ZnS decomposes when heated near 1000°K, and Zn and S_2 evaporated in equivalent amounts; a lower limit $D(\text{S}_2) \geq 78 \text{ kcal/mol}$ was calculated. The evaporation of gray Se was investigated and was found to contain at about 480°K some 10 percent molecules Se_8 and perhaps Se_7 .

[THERMODYNAMIC STUDY OF GROUP III-V AND GROUP II-VI COMPOUNDS BY MASS SPECTROMETRY] Étude Thermodynamique des Composés III-V et II-VI par Spectrométrie de Masse, by J. Drowart and P. Goldfinger. [Apr. 4, 1958] [12]p. incl. diags. tables, refs. (AF 61(514)868) Unclassified

Published in Jour. de Chimie Physique, v. 55: 721-732, Oct. 1958.

Partial decomposition pressures were measured for the group III-V compounds GaAs, InP, and InSb and for the group II-VI compounds CdSe and CdTe. The latter made it possible to calculate the heat of formation, the free energy of formation, and the entropies as well as the dissociation energies. In contrast to methods employed in prior research, the apparatus was adapted so that the molecular rays traveled perpendicular to the ionic and electronic tubes rather than parallel. This prevented collision with the walls; it prevented formation of deposits, and it enabled the surfaces of the specimens to

GAS-LIQUID SYSTEMS FOR USE IN A GAS BUBBLE CHAMBER, by B. Hahn and J. Fischer. [1957] [5]p. Incl. illus. (AFOSR-TN-57-427) [AF 61(514)1262] AD 136416 Unclassified

Also published in Rev. Scient. Instruments, v. 28: 656-657, Aug. 1957.

Several new liquids in combination with CO_2 were tried in a gas bubble chamber which is operated at room temperature. The chamber is filled with a liquid which is saturated under pressure with a gas. The gas-liquid system when expanded ionizes particles that give rise to gas bubble formation along their path. Propane, butane, pentane, isopentane, hexane, heptane, triethylamine, silicone 0.65 centistoke, and silicon 5.0 centistoke were used successfully with CO_2 . In order to determine the life of bubble nuclei the chamber was irradiated by a pulsed gamma ray source at various moments before beginning the expansion. Preliminary results for isopentane, hexane, and silicones put an upper limit to the life of bubble nuclei to about 100 μsec .

FLUOROCARBON GAS BUBBLE CHAMBER, by B. Hahn and G. Riepe. [1958] 4p. Incl. illus. table. (AFOSR-TN-58-8) (AF 61(514)1262) Unclassified

Also published in Rev. Scient. Instruments, v. 29: 184-185, Feb. 1958.

It is known that almost any chemically stable and transparent liquid will yield visible bubble tracks due to ionizing radiation when put under proper working conditions in a bubble chamber. An ethforane (C_2F_6) - proforane (C_3F_8) gas-liquid system was operated successfully at room temperature in a "dirty" bubble chamber 4 cm in diam and 5 cm in depth. Bubble densities as high as 100 bubbles per cm were produced for minimum ionizing electrons upon heating the chamber to 29°C ($p_{\text{eq}} \sim 15 \text{ atm}$). From the experimental data available on several existing bubble chambers and the help of some theoretical arguments, the operating temperatures and pressures for some pure fluorocarbons in a "dirty" bubble chamber were estimated to be: C_3F_4 (43°C , 13 atm); C_4F_{10} (79°C , 11.5 atm); and C_5F_{12} (115°C , 10.5 atm). In addition to the fluorocarbons, sulfur hexafluoride (SF_6), certain freons (e.g., CClF_3), and some of the fluoroethers are suggested as attractive liquids for use in a gas bubble chamber.

RECORDING OF EMOTIONAL STRESS (Abstract), by C.
W. Sem-Jacobsen. [1957] [1]p. (AF 61(514)1201)

Unclassified

Presented at meeting of the Aeromedical Association,
Denver, Colo., May 6-8, 1957.

Published in Jour. Aviation Med., v. 28: 217-218, Apr.
1957.

Rapidly mounting emotional stress or sudden fear encountered by most people may in some instances leave the person "stiff" for a short period, during which he is not able to react or respond to outside stimuli in a rational way. It has long been a challenge to record these experiences with physiological equipment. In the course of intracerebral recordings, there were recorded short periods of flattening of the depth tracings, indicating a blocking of the brain activity in response to frightening of the patient by a sudden sharp noise. In a thoroughly examined non-epileptic patient, a buildup to a convulsive seizure was recorded in response to sudden mounting emotional stress. The findings are related to animal study and may be related to the sudden strange behavior of, for instance, tree surgeons treating tall, decayed trees. There has also been some speculation regarding the possibilities of extreme emotional stress or sudden fear, being responsible for some of the fatal crashes of low flying jet planes. Examples from unexplained jet crashes are presented.

ELECTROENCEPHALOGRAPHIC RECORDING IN
SIMULATED COMBAT FLIGHT IN A JET FIGHTER
PLANE. THE PILOT'S LEVEL OF CONSCIOUSNESS,
by C. W. Sem-Jacobsen, O. Nilseng and others.
[1958] 2p. (Sponsored jointly by Air Force Office of
Scientific Research under [AF 61(514)1201] and Royal
Norwegian Air Force) Unclassified

Presented at AGARD meeting in Paris, France,
June 16-17, 1958.

Also published in EEG Clin. Neurophysiol., v. 11:
154-155, Feb. 1959.

In this aeromedical study, a standard 8-channel EEG
(electroencephalogram) transistor apparatus was modified and installed in a Royal Norwegian Air Force T33.

Operational flights showed that this apparatus tolerated an altitude of 20,000 ft, a temperature of 45°C, a force of 8 g's, and rolls and other flying maneuvers. In flight EEG recordings were made of pilots and backseat passengers. Though little data have been collected, they indicate that a pilot's level of consciousness during operational flight varies, and that these changes can be recorded using EEG methods.

STATISTICAL STUDIES ON THE TURBULENT STATE
OF MOTION. PART I. KINEMATICS, by H. Gebelein
and E. Svenson. Mar. 1957, 42p. (Technical note no. 1)
(AFOSR-TN-57-278) (AF 61(514)925) AD 126539
Unclassified

In this report a new systematical account on some parts of the statistical theory of turbulence is presented. The main subject is the "correlation tensors" $\hat{R}(X(P), Y(P'))$ for two random quantities $X(P)$ and $Y(P')$ at two arbitrary control points P and P' . The quantities in question are the pressure, the local velocities with their dyadical products and their gradients, and the vorticity components. In order to present this analysis in a rational way, the common tensor calculus is completed for tensors up to the fourth order in strict analogy to vector calculus. The investigation starts with the classical case of homogenous and isotropic turbulence of an incompressible fluid. These three conditions are analyzed thoroughly and it is shown how the results change when the suppositions are lessened. Anisotropic but homogenous turbulence is treated in detail in strict analogy to the presentation of isotropic and homogenous turbulence with particular attention to the correlations of the velocity gradients and the vorticities.

PROCEEDINGS OF THE MEETING ON TURBULENCE,
11-14TH OF MAY 1957 IN THE MATHEMATICAL RE-
SEARCH INSTITUTE AT OBERWOLFACH, ed. by H.
Gebelein. June 1957, 24p. (AFOSR-TN-57-529)
(AF 61(514)925) AD 136514; PB 135584 Unclassified

Abstracts of papers are presented on turbulence theory with discussions on its dynamics, the effects of viscosity, transition probabilities, and applications of statistical and symbolic tensor calculus to the theory. In the course of this conference, the main traits of the research work under contract have been discussed, and by comparison of the results with those from other theoretical approaches a valuable survey on the actual situation of turbulence research was obtained.

STATISTICAL STUDIES ON THE TURBULENT STATE OF MOTION. PART II. CONTRIBUTIONS TO DYNAMICS, by H. Gebelein and E. Svenson. Nov. 1957, 31p. incl. refs. (Technical note no. 2) (AFOSR-TN-58-45) (AF 61(514)925) AD 148085; PB 136189

Unclassified

Contributions to dynamics of turbulence are treated, and the relationship between the statistical concept of turbulent motion and the classical hydrodynamic equations is discussed. A systematic account is made of dynamical facts of homogeneous turbulence, and the problems of shear turbulence are treated.

FORMATION OF FREE RADICAL SOLIDS USING BEAM TECHNIQUES (Abstract), by W. L. Fite. [1958] [1]p. (AF 49(638)301)

Unclassified

Presented at Symposium on Unstable Chemical Species, Los Angeles, Calif., June 23-24, 1958.

Experiments now in progress are attempting to produce solids in which atomic hydrogen is stabilized at 4°K and below, by condensation of atomic beams. By using modulated atomic beam techniques so that sampling of the beam can be made through ionization and mass analysis, detailed knowledge of the relative fractions of various species striking the condensing surface is ensured. In addition, these techniques, along with usual stagnation detection of the beam, promise to allow study of various processes of importance in the condensation process, e.g., thermal accommodation coefficient, sticking coefficient, and probability of reassociation of the atoms into molecules. A discussion is presented of the experimental approach as well as early results of these experiments.

This volume contains up-to-date and pertinent reports and discussions on crystal phenomena, polymer crystallization, and crystallization of simpler molecules. Organic, inorganic, and polymeric substances are investigated from the standpoint of crystal perfection, formation and structure of whiskers, presence of dislocations, and the mechanism of crystal growth from the melt, solution and vapor. Several reports emphasize the important differences and points of similarity between polymer and ordinary crystallization. Special features are presented which relate crystal growth in metals to that of growth in polymers and other types of solids; bring together literature on whisker phenomena dating back to 1574; summarize present understanding of crystal growth; and introduces the many advances made in the field since the Faraday Society Discussions of 1949.

An attempt is made to simplify the physical picture of a nucleus by assuming that electrons and positrons, the elementary particles, are the building stones of the nucleon (proton and neutron). An exponential function of the distance is introduced with a linear coupling factor which is computed from the electrostatic charge of the elementary particle and its mass. By this function the character of the Coulomb Law in the nuclear field is substantially changed, thereby providing the possibility of obtaining electrostatic equilibrium between any number of electrons and positrons. This new idea is first applied to the dynamics of the mass point.

words) have equal probabilities. Results show that the number of words, of cost less than u , may be written as: $r(u) = V[\exp(b' u - b' C_0) - 1]$. The number V , which was

neglected by Shannon, is the inverse of the information per word and plays the role of the volume in the present thermodynamical theory. Several types of syntax were also considered. Results show that the formula

$p(r) = (B-1) V^{B-1} (r + V)^{-B}$ holds, whatever the syntax, as soon as the volume V and the temperature $1/B$ are large. A theory of the law of Pareto was presented. The main tool is the definition of the Pareto-Lévy variables and sequences. A theory of entropy and a theory of divisibility were added to the author's approach to the foundations of thermodynamics. TECHNOTICS; A STUDY OF EFFECTIVE COMMUNICATION OF TECHNICAL AND SCIENTIFIC KNOWLEDGE, by J. S. J. Hlobil. July 10, 1957, 34p. incl. diagrs. refs. (Rept. no. TEX-101) (AFOSR-TR-57-45) (AF 49(638)-174) AD 132473 Unclassified

Technotics, as proposed in the current study, is a systematic method of increasing the effectiveness of communication of technical and scientific knowledge by attenuation of noise in the communication channels. Noise in the communication channels is described as including any distracting element which prevents the preparation of a clear message, clear delivery of a message, and a clear reception of a message. For practical application, especially for decision-making meetings, use of TechnOrient (a Technotics orientation chart) is advocated.

METABOLISM OF CYSTEAMINE, by R. A. Salvador, C. Davison, and P. K. Smith. [1957] [19]p. incl. diags. tables, refs. (AFOSR-TR-57-41) (Sponsored jointly by Atomic Energy Commission under AT(30-1)1107 and Air Force Office of Scientific Research under AF 18-(600)853) AD 132414 Unclassified

Inorganic sulfate, taurine, cysteamine and cystamine were demonstrated in the urine of normal and x-irradiated male mice receiving S^{35} -cysteamine. These findings corroborate reports of its degradation in rats. There appears to be no difference in the metabolism of this agent as a result of its presence during x-irradiation. Excretion of radioactivity, however, was significantly slower in the x-irradiated animal. In man, as in the mouse, sulfate and taurine constituted the largest portion of the urinary excretory products. Several metabolites present in human urine were not seen in mouse urine. In man, the urinary end products differed under hypoxic conditions. (Contractor's abstract)

INFLUENCE COEFFICIENTS FOR CIRCULAR CYLINDRICAL SHELLS WITH LINEARLY VARYING WALL THICKNESS, by M. B. Sledd. Apr. 10, 1957, 22p. incl. diags. refs. (Rept. no. 2) (AFOSR-TN-57-196) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1459—continued by AF 18(600)-1462 at Lehigh U. Dept. of Physics, Bethlehem, Pa.—and Office of Naval Research) AD 126491 Unclassified

An analysis is presented of a thin-walled, elastic, right circular cylinder loaded on one edge with a uniformly distributed shearing force H_2 and a bending moment M_2 , and with the other edge free. For purposes of subsequent comparison, expressions are recorded for the influence coefficients of the shell with constant wall thickness and semi-infinite axial length, and for a shell with constant wall thickness and finite axis length. Consideration is then given to expressions for varying thickness, including the following: radial displacement, rotation, horizontal stress resultant, and bending moment—all as functions of axial distance. These expressions are used to obtain coefficients for a shell loaded along its thicker edge. The results are expressed in terms of Kelvin functions, and compared graphically with those previously recorded for shells of constant thickness.

[DEVELOPMENT OF OXIMETER], by K. Kramer, N. J. Nilsson and others. Apr. 7, 1955 [23]p. (AFOSR-TR-58-7) (In cooperation with Marburg U. (Germany)) (AF 61(514)427) AD 148050 Unclassified

The new oximeter described here utilizes the property of selenium cells to give logarithmic responses to change in light intensity when used in open circuits. Since the O_2 -saturation of the blood in the flushed ear is a logarithmic function of transmitted light it has been possible to obtain oximetric readings directly proportional to the O_2 -saturation. The linearity has been shown to hold within the entire range from 100 to 25% saturation. A method has been elaborated which enables individual calibrations of the ear pieces without blood sampling and chemical analyses. The accuracy is of the same order of magnitude as that of commonly used oximeters. Other new technical items are special arrangement and spectral sensitivity of photocells and a method for arresting blood flow to the examined ear area. (Contractor's abstract)

To take recordings of actions potentials of single units in the nucleus supra opticus the following preparatory studies were carried out: (1) Histological studies of the basal hypothalamic area revealed basal position and disk shaped form of the nucleus, its high vascularization and dense population of fairly great cells; (2) Several types of microelectrodes were tested. A modification of Hubels tungsten wire electrolytically sharpened

was found to be the electrode most suitable for our purpose. Insulation of electrode was obtained by quartz evaporation; (3) The subcortical approach to the nucleus supra opticus made necessary a modification of the classical stereotactic device; and (4) Examples of microelectrode recordings in the nucleus supra opticus are shown. Local discharge patterns show pulsatory rhythms sometimes closely related to heart rate. In other cases rhythms are independent but under vagal control. (Contractor's abstract)

ESTIMATIONS OF ERROR FOR NONLINEAR ELLIPTICAL DIFFERENTIAL EQUATIONS, by A. Meyer. Oct. 1956, 49p. incl. diags. tables. (AFOSR-TN-57-2) (AF 61(514)880) AD 115032 Unclassified

It is shown that for many nonlinear differential equations, the boundary value problem with an elliptical differential equation is of monotonous type and that, therefore, bounds can be obtained for its solution. The second boundary value problem is considered in addition to the first and third boundary problem. Formulas which allow the estimation of error are given and applied to some examples.

are constructed by Mehrstellen methods. A systematical examination is made of the corresponding Taylor expansions to find the appropriate finite equations. All formulas are tailored for quadratic grids; in numerical examples they are much more accurate. The first boundary problem is covered in 3-dimensional space. The finite expressions are generalized for inner points of a cubic net with Taylor balance up to h^5 ; for net points close to the boundary, a Taylor balance up to at least h^3 is obtained. The ordinary finite difference method, with Taylor balance up to h^2 , which substitutes
$$\frac{u(x-h,y,z) - 2u(x,y,z) + u(x+h,y,z)}{h^2}$$
 for $\frac{\partial^2 u}{\partial x^2}$ as a special case. Numerical examples for the formula are worked out.

INTERCONTINENTAL FREQUENCY COMPARISON BY VERY LOW-FREQUENCY RADIO TRANSMISSION, by J. A. Pierce. Feb. 15, 1957 [36]p. incl. illus. diagrs.

(Technical rept. no. 220) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186607) AD 126051 Unclassified

Presented at Symposium on Propagation of Very-Low-Frequency Electromagnetic Waves, Boulder, Colo., Jan. 23-25, 1957.

Also published in Proc. Inst. Radio Engineers, v. 45: 794-803, June 1957.

Studies of signals from Rugby, England, at 16 kc/s and 60 kc/s have given evidence that a single source of standard frequency can be made available at VLF on a world-wide basis. At a distance of 5200 kilometers the doppler effects in transmission seldom exceed ± 3 parts in 10^9 , and a measurement can be made to 1 part in 10^9 in a few minutes. Accuracies exceeding 1 part in 10^{10} are consistently obtained by observation over several hours. Data contributed by Allan, Cromble, and Penton, of the New Zealand Dominion Physical Laboratory, indicate that at 16 kc/s the diurnal doppler effects at 18,700 km have normal maxima of the order of $1/10^8$, and that a measurement of 3 or 4 parts in 10^9 can be made in an hour or less. These results are described and some of the effects of solar flares and magnetic disturbances are discussed. In addition, a brief description is given of four mechanisms that have been found useful in comparing the frequency of a local oscillator with that of a VLF standard transmission. RECENT LONG-DISTANCE FREQUENCY COMPARISONS, by J. A. Pierce. Sept. 10, 1958, 7p. incl. illus. (Technical rept. no. 270) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186607) Unclassified

Since March 1, 1958, a number of comparisons were made between the frequency of an Atomichron at Cruft Laboratory and the frequencies of other Atomichrons in Boulder and Washington. Comparisons were also made with the cesium resonator at the National Physical Laboratory at Teddington, England. A limited number of daily direct comparisons with Boulder had a standard deviation of 1.4 parts in 10^{11} . This value may be determined by the uncertainties of the phase of the LF transmission at 60 kc, or by changes in the Atomichrons. Comparisons with Washington and Teddington using a VLF carrier had a standard deviation of about $2/10^{10}$ that was apparently controlled by vagaries of the crystal oscillator at the transmitter. The vagaries of HF WWV transmission, even under the best conditions, limited

the standard deviation at about $4/10^{10}$. It appears that the average frequencies of different Atomichrons, aligned and operated in different ways, may be in very close agreement or may differ by as much as 3 parts in 10^{10} . (Contractor's abstract)

with which to compare the experimental data that are presented in the companion report. (Contractor's abstract)

SIGNALS AND NOISE IN A FREQUENCY MODULATION RECEIVER. PART II. EXPERIMENTAL DISCUSSION, by H. W. Fuller. Feb. 1, 1957, iv. incl. illus. (Technical rept. no. 243) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 129258

Unclassified

The experimental methods and equipment are described in Chapter IV together with figures showing the performance of the individual units of the system. The more interesting circuit features of two analog multipliers, a negative feedback limiter, and a balanced modulator-type discriminator are discussed in detail. Reasons are listed for believing that the FM receiver output in some cases presents an unusually difficult measurement problem. Sample estimates are made of the errors encountered in experimental continuous spectrum analysis for spectra of the kind found at the output of an FM receiver. The accumulated experimental results are displayed and discussed in Chapter V. Sample waveforms simultaneously photographed at the limiter and receiver outputs for a variety of operational conditions are interpreted in terms of the statistical quantities that describe them. Absolute total mean power output measurements (with no post-detection filtering) are compared with theoretical curves. A large number of output spectra for various operational conditions and for three different IF filter characteristics are shown together with theoretical data where these are available. Relative peak spectral intensities for related cases, derived from the recorded spectra, are normalized and plotted with theoretical curves where possible. Chapter VI summarizes the main features of the experimental investigation. The gratifying agreement between theory and experiment, proclaims, in general, the adequacy of the mathematical models of the FM receiver and random noise, as well as the intermediate operations and calculations. Specifically, the noise-alone arbitrary-limiting results of Chapters II and III of the companion report are substantiated, as well as the limiter output results. The simpler cases as well are quite uniformly verified. The few discrepancies that turned up are classified in accordance with their probable explanations. Experimental results unchallenged by theoretical predictions are given for the cases of intermediate signal-to-noise ratio and arbitrary limiting, a narrow-banded limiter, and an off-tuned discriminator. SIGNALS AND NOISE IN A FREQUENCY MODULATION RECEIVER. PART I. THEORETICAL DISCUSSION, by H. W. Fuller and D. Middleton. Feb. 1, 1957 [89]p. incl. diagrs. refs. (Technical rept. no. 242) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 129257

Unclassified

This report first reviews the theoretical description of the frequency modulation receiver available in the literature: in particular, the effect of the FM receiver on a received wave consisting of a signal and random noise. In Chapter II an abbreviated theoretical development of the FM receiver is presented, generally following the combined works of Middleton, and using the results obtained by Davenport for the output of an infinite limiter. The development assumes an idealized discriminator and normal random noise of the fluctuation type. The development features an arbitrary limiter dynamic characteristic (that is later specialized), a modulated carrier, an arbitrary signal-to-noise ratio, and arbitrary limiting. A closed-form expression for the total mean power output of the FM receiver is obtained, in the course of the presentation, for a receiver input of noise alone. Compact forms are found of the expressions for the output correlation function and spectrum in the case of a receiver input of noise along with arbitrary limiting. The results for arbitrary limiting are critically reviewed and appropriate modifications are made. Simple expressions for the infinite limiter output correlation function are obtained from Davenport's results for the cases of weak and strong carriers. In Chapter III a discussion of various IF filter characteristics is given and three specific characteristics are chosen for further consideration on the basis of experimental and analytical expediency. A further discussion of the modified results for the noise-alone arbitrary-limiting case is given, and the results are verified by a comparison between calculations made from two different expressions for the total mean power output. Expressions for the output correlation function and spectrum for the noise-alone arbitrary-limiting case are obtained using both synchronous-tuned double and rectangular IF filter characteristics. Output spectra of the infinite limiter are found for the gauss-shaped and synchronous-tuned double IF filter characteristics. A number of calculated curves are presented for the three chosen IF filter characteristics to supplement the extensive results given by Middleton for the gauss-shaped IF filter, and to furnish theoretical findings

THEORY OF THE CORNER DRIVEN SQUARE LOOP ANTENNA, by R. King. Feb. 1, 1957 [14]p. incl. diagrs. refs. (Technical rept. no. 222) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 126000 Unclassified

Also published in Electromagnetic Wave Theory Symposium, p. 393-407, 1957.

The general problem of determining the distribution of current and the driving point impedances of a square loop or frame antenna is formulated when arbitrary driving voltages are applied at each corner or when up to three of these voltages are replaced by impedances. The loop is unrestricted in size and account is taken of the finite cross-section of the conductors. Four simultaneous integral equations are obtained and then replaced by four independent integral equations using the method of symmetrical components. These equations are solved individually by iteration and first-order formulas are obtained for the distributions of current and the driving-point admittances. By superposition the general solution for the arbitrarily driven and loaded loop is obtained. Interesting special cases include a corner-reflector antenna and the square rhombic (terminated) antenna. An application of the principle of complementarity permits the generalization of the solution to the square slot antenna in a conducting plane when driven from a double-slot transmission line at one corner. THE SECONDARY EMISSION PULSE CIRCUIT: ITS ANALYSIS AND APPLICATION, by J. A. Narud. Apr. 5, 1957 [42]p. incl. diagrs. table, refs. (Technical rept. no. 245) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 131984 Unclassified

Also published in I.R.E. Trans. of Professional Group on Electronic Computers, v. EC-9: 439-451, June 1960.

In the fields of high-speed computers, guided missile tracking systems and nuclear physics there has lately been an increasing demand for nonlinear active circuits capable of generating pulses in the millimicrosecond range at high repetition rates. In such circuits thermionic secondary emission tubes show great promise of replacing the ordinary vacuum tube. The reasons for this are twofold: First, these tubes have a much higher ratio between saturation current and electrode capacitance than ordinary vacuum tubes, resulting in a smaller rise time for the same voltage level. Second, with these tubes it is possible to design a positive feedback configuration that has a small loop delay so that the interval between the times it is possible to turn the circuit on and off can be minimized. This paper describes a regenerative pulse circuit using a single secondary emission tube that is able to generate pulses having a rise time of 6m s and a width continuously variable from 25m s to 12 s. First, a theoretical discussion of the circuit is given in which expressions for pulse width and resolving time are derived. Then various practical realizations of the circuit are presented. Among others these include a millimicrosecond pulse generator and a fast pulse-height discriminator. (Contractor's abstract)

CYLINDRICAL ANTENNA IMMERSSED IN A DISSIPATIVE MEDIUM (INPUT IMPEDANCE), by M. S. Macrakis. May 1, 1957, 10p. incl. illus. (Technical rept. no. 256) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 135165 Unclassified

Hallen's linearized integral equation (Theory of Linear Antennas by R. W. P. King, 1956) has the following form for a cylindrical antenna immersed in a dissipative medium in which the conductivity is very small:

$$\int_{-h}^h I(z') K(z | z') dz' = -\frac{14\pi}{\epsilon_0} [C \cos \beta z + \frac{1}{2} V_0 \sin \beta |z|]$$

with $K(z|z') = e^{-\beta R} / R$, $R = [(z-z')^2 + a^2]^{1/2}$, $\beta = \beta' - j\beta''$.

Investigation is made of the case of $\beta'' \ll 1$, and

$e^{-j\beta R} \pm (1 - \beta'R)e^{-j\beta'R}$, or a Taylor's expansion in β' for the impedance can be introduced. The iteration and variational methods of solving the integral equation are studied. The simplest is the variational method with Taylor's expansion in β' for the impedance. The short antenna in a dissipative medium is discussed as a special case. (ASTIA abstract)

AN EXPERIMENTAL SYSTEM FOR STUDYING THE ZEROS OF NOISE, by G. M. White. May 15, 1957 [53]p. incl. illus. diagrs. tables, refs. (Technical rept. no. 261) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 135934

Unclassified

For many years, researchers in the field of statistical communications have been interested in the zeros problem, i.e., the statistical distributions of the times a random voltage waveform passes through zero value. One of the most common waveforms investigated experimentally and theoretically is Gaussian noise. In this report an experimental system for generating and measuring the zeros of Gaussian noise is described. Various zero-crossing distributions found in the literature are briefly derived and calculations performed for the spectra that were experimentally synthesized. When the calculated distributions were checked with the experimental distributions from the system described, close agreement was reached. (Contractor's abstract)

Magnetic resonance experiments have been carried out at low-power levels on nickel ferrite single crystals at temperatures down to 1.57°K. The frequency of these measurements was 24,000 Mc/s (K-band). Line widths, first and second order anisotropy constants, and g-values were obtained. At low temperatures the line width became a strong function of the orientation of the applied d-c field, exceedingly narrow and exceedingly broad lines having been observed with the same sample. Subsidiary resonances of the Walker type were found at the lowest temperatures. Resonance measurements at

very high r-f power levels were also carried out on nickel ferrite at temperatures down to 4.2°K, using 9000 Mc/s (X-band). Changes in the magnetization were observed, and the relaxation time τ_1 determined following Bloembergen and Wang. The predictions of the Suhl nonlinear theory are verified with respect to the critical field for the decline of the main resonance and the position of the subsidiary absorption. Oscillograms showing the growth of the parasitic spin waves are presented. The relaxation time is also evaluated for the very long spin waves excited at the subsidiary absorption. It is shown that the relaxation time is relatively independent of temperature and of the wave number of the spin waves concerned. An explanation of this behavior is suggested. In Cruft Laboratory technical report no. 261 (item no. HAR.03:020), an experimental system was described for use in accurately locating in time the zeros of noise for 2 broad band power spectra. Later, this system was used to obtain experimental curves of:

- $W(N, T)$, the probability of having N zero-crossings in a time interval T ;
- \bar{N} , the average number of zero-crossings in a time interval T ; and
- $\overline{N^2}$, the average of the square of the number of zero-crossings in a time interval of length T , where Gaussian noise having a spectral shape of

$$\frac{1}{1 + \left(\frac{f}{Q}\right)^2 - 2\left(\frac{f}{f_0}\right)^2 + \left(\frac{f}{f_0}\right)^4}$$

was employed. This study presents a description of the additional equipment built and graphs of the resulting curves. Broad band noise ($Q = 1/2$ and $1/\sqrt{2}$), narrow band noise ($Q = 10$), and intermediate cases ($Q = 6$ and 10) were considered. The curves obtained that could be checked [\bar{N} and $\overline{N^2}$] were found to agree closely with the calculated curves; the other $W(N, T)$ were found to agree with theoretical predictions. It is hoped that theoreticians, by examining the curves given will gain some insight into the solution of the zero-crossing problem for noise alone. (Contractor's abstract)

THE SCATTERING OF CONDUCTION ELECTRONS BY IMPURITIES IN METALS, by L. M. Roth. June 25, 1957, 112p. incl. diags. tables, refs. (Technical rept. no. 267) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 147173

Unclassified

The scattering of electrons by impurities in metals is studied in this report by a Green's function method which takes into account the band structure. The Green's function for an electron in a periodic potential is used to demonstrate the form which the scattered waves take far from the scattering center. The method is specifically applied to the case of a spherically symmetric impurity confined to one atomic cell in a monovalent metal, where an approximate generalization of the method of partial waves is derived, which includes the effect of the crystalline field as well as the type of impurity. This result is extended by a perturbation method to include the effect of a potential tail outside of the impurity cell. It is proved that Friedel's sum rule, which relates the phase shifts to the excess charge introduced about the impurity, holds for the case of a spherical energy surface. These results are applied to the case of monovalent impurities in monovalent metals, and a generalization of Mott's square well approximation is obtained, which includes the effect of the crystalline field in the band edge approximation. The residual resistivity of noble metal alloys is computed using the calculation of Kambe for the wave functions. When the scattering due to the lattice strain is also included, the agreement with experimental results is found to be considerably better than in the Mott approximation. The effect of including the polarization of the conduction electrons is discussed, and it is found that this correction, while important, is not so drastic as in the Mott approximation. The results are also applied to the thermoelectric power in one case. Preliminary results are given for the residual resistivity of alkali metal alloys. (Contractor's abstract)

Unclassified

Also published in Jour. Phys. Chem. Solids, v. 5: 241-255, 1958.

Measurements of the pressure dependence of the Knight shift in Li, Na, Rb, Cs, Cu, and Al have been made at room temperature in the pressure range 1 to 10,000 kg/cm². The volume dependence of $\langle |\psi_F(0)|^2 \rangle = P_F$ has been deduced from these data using Pines' collective electron picture for the paramagnetic susceptibility of the conduction electrons. The results of recent calculations of the volume dependence of P_F are presented and compared with the experimentally deduced results. The Knight shift is shown experimentally to be an explicit function of the temperature at constant volume. A theory, which takes into account semi-quantitatively the effect of the lattice vibrations on P_F , is proposed. Comparison is made between this theory and the experimental observations. Many of today's electronic devices, such as computers, radar units and television systems, require synchronized waveforms the frequencies of which are a submultiple of some master frequency. A great variety of different circuits, commonly called "frequency dividers," have been designed for that purpose and described in the literature. It is the purpose of this paper to introduce and to describe two simple and very reliable divider schemes for a fixed input frequency using a delay line, on the one hand, and a sawtooth generator, on the other, to produce the timing waveform. A description is given of experimental equipment and methods used to study some recently observed effects in nuclear magnetic resonance centering around the transverse relaxation time at high r-f fields in solids

with two kinds of nuclear spins. Studies are reported of these effects with regard to the Cs^{133} nuclei in the cesium halides; the effects can be observed with other insulating crystals providing certain conditions are fulfilled. The equipment described was primarily designed to measure the transverse relaxation time T_{2e} in the presence of high r-f fields, as well as the spectrum of the steady-state transverse nuclei magnetization which is produced in a new-type of double resonance experiment. Each kind of measurement is briefly discussed.

THREE NOTES ON SOME ELECTRON FLOW PROBLEMS, by G. Kent. Aug. 30, 1957 [22]p. incl. illus. diags. refs. (Technical note no. 273) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186616) AD 146084 Unclassified

Part I. Stability of Double Stream Flow. The question of whether or not a two-velocity electron beam which can support exponentially growing space-charge waves is stable in time is examined. On the basis of a simple mathematical model, it is shown that the entrance condition of zero excitation implies zero wave amplitudes. Part II. A Collector for Improving the Efficiency of a Hollow Beam Klystron. A collector which returns to the power supply a large portion of the energy remaining in the beam of a hollow beam klystron is suggested. In the ideal case, 99 per cent of the energy is theoretically extracted from the spent beam, although not necessarily at useful voltage levels. Part III. Internal Emitters. A statistical analysis of plane and cylindrical emitters is presented. Although the analysis is restricted to equilibrium conditions, some of the experimentally known properties of internal emitters may be inferred. These properties lead to the conclusion that such emitters are seldom suitable for cathodes in practical vacuum tubes. (Contractor's abstract)

THE RECTIFICATION OF NON-GAUSSIAN NOISE, by J. A. Mullen and D. Middleton. [1958] [25]p. incl. diags. tables, refs. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under [Nonr-186616]) Unclassified

Published in Quart. Appl. Math., v. 15: 395-419, Jan. 1958.

The types of noise functions considered are of the type

$V_N(t) = \sum_j v_j(t - t_j)$, where $\{t_j\}$ are the instants of a Poisson process of density ν , and $v_j(t) = h(t) \cos(\omega_0 t + \alpha_j)$, $\omega_0 > 1$, where either (i) $h(t) = e^{-t}$, $t > 0$, (ii) $h(t) = e^{-t^2}$, or (iii) $h(t) = 1$, $0 < t < 1$. The stochastic process of interest is $I(t) = g[V_N(t) + A_0 \cos \omega_0 t]$, where $g(V) = \beta \{\max(0, V)\}^\nu$, $\nu > 0$; the magnitude A_0 corresponds to the signal strength. A number of approximations are computed to the correlation function of $I(t)$, corresponding to low and high ν , and low and high signal strengths. Their expressions become more tractable when $\nu = 1$ or 2 , but even then are quite complicated. A number of the formulas are represented graphically, and a qualitative discussion of the results is given. (Math. Rev. abstract)

PRESSURE DEPENDENCE OF THE PURE QUADRUPOLE RESONANCE FREQUENCY IN METALLIC GALLIUM (Abstract), by T. Kushida and G. B. Benedek. [1958] [1]p. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under [Nonr-186616]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 167, May 1, 1958.

The pure quadrupole resonance of the Ga^{69} nucleus in metallic gallium has been studied under hydrostatic pressure in the range 1 to 8000 kg/cm^2 at 0°C , -29.8°C , -75°C . It was found that ν varies linearly with the pressure at all temperatures. $(d\nu/dP)_T$ is 16.1×10^{-3} kc/hg/cm^2 , 15.8×10^{-3} kc/hg/cm^2 , 15.4×10^{-3} kc/hg/cm^2 at 0° , -29.8° , and -75°C , respectively. No appreciable change was found in the line width as the pressure was increased. In view of the anisotropy in the thermal expansion, the probable anisotropy of the compressibility and the absence of knowledge as to the size of the asymmetry parameter, a detailed analysis of these results cannot now be given. However, a semiquantitative analysis of the results in terms of the volume dependence of the effective field gradient tensor components will be offered. This analysis will be applied to a discussion of the possible sources of the field gradient.

ZERO-FIELD SPLITTING IN NICKEL FLUOSILICATE (Abstract), by W. M. Walsh, Jr. [1958] [1]p. (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under [Nonr-186616]) Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 178, May 1, 1958.

Paramagnetic resonance measurements of the zero-field splitting D in single crystals of $\text{NiSiF}_6 \cdot 6\text{H}_2\text{O}$ have been made as a function of hydrostatic pressure P, and uniaxial stress U, the latter being applied along the crystalline symmetry axis. The results are

$$1/D(\partial D/\partial P)_T = 1.60 \times 10^{-4} \text{ (kg/cm}^2\text{)}^{-1} \text{ and}$$

$$1/D(\partial D/\partial U)_T = 3.18 \times 10^{-4} \text{ (kg/cm}^2\text{)}^{-1} \text{ respectively.}$$

The anisotropic changes in sample dimensions due to these forces as well as the thermal expansion have been measured. Combining these data with the temperature dependence of D permits a phenomenological calculation of the zero-field splitting dependence on unit cell shape and volume and of the explicit temperature dependence due to lattice vibrations.

Harvard U. [Cruft Lab.] Cambridge, Mass.

NUCLEAR MAGNETIC RESONANCE IN THE CESIUM HALIDES, by N. Bloembergen and P. P. Sorokin. [1958] [11]p. incl. illus. diagrs. tables. refs. [Technical rept. no. 274] (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under [Nonr-186616] AD 218457 Unclassified

Also published in Phys. Rev., v. 110: 865-875, May 15, 1958.

The chemical shifts, the spin-lattice relaxation times, the isotropic exchange coupling A, and the pseudo-dipolar exchange coupling B between cation and anion nuclear spins have been determined in a single crystal of CsBr. The results are: $\sigma_{\text{Cs}} = (-1.9 \pm 0.4) \times 10^{-4}$, $\sigma_{\text{Br}} = (-2.5 \pm 0.3) \times 10^{-4}$, $(T_1)_{\text{Cs}} = 1050 \pm 40 \text{ sec}$, $(T_1)_{\text{Br}} = 0.105 \pm 0.020 \text{ sec}$, $h^{-1} |A| = 55 \text{ sec}^{-1}$, $h^{-1} B = 15 \text{ or } -89 \text{ sec}^{-1}$. Similar, but less complete, data have

been obtained for a single crystal of CsI and a CsCl powder. The results are discussed in terms of existing theories for the chemical shift and exchange interactions in solids. An average of 25% covalent bonding per ion is deduced. The large ratio of T_1 for Cs and Br, respectively, sets an upper limit to the quadrupole moment of Cs^{133} : $|Q| < 0.004 \times 10^{-24} \text{ cm}^2$. This large difference in the spin-lattice interactions between the nuclear species is responsible for some new effects.

The decay time T_{2e} for the transverse Cs^{133} magnetization is proportional to $H_1^2(\nu_{\text{Cs}})$ for a wide power range of the ratio-frequency field at the Cs^{133} Larmor frequency. It is furthermore possible to build up a transverse Cs^{133} magnetization by applying, simultaneously with $H_1(\nu_{\text{Cs}})$, a radio-frequency field $H_1^{\text{Br}}(\nu)$

at a frequency $\nu = \nu_{\text{Br}} \pm \nu_{\text{Cs}} H_1^{\text{Cs}}/2\pi$. Here ν_{Br} is the bromine precession frequency. A theory of these effects shows that the relatively weak interaction constants A and B between cesium and halogen spins can be determined with much higher accuracy than would have been possible from the usual second moment determinations.

GERMANIUM SURFACE STUDIES, by A. B. Fowler. July 1, 1958 [72]p. incl. diagrs. tables, refs. (Technical rept. no. 275) ([Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research] under Nonr-186616) AD 204469 Unclassified

This report on germanium surface studies is divided into three parts: I. Introduction; II. P-N Junction Measurements; and III. Interpretation of Results on P-N Junctions. Part I discusses work function, surface states, surface potential and statistics, cleaning of surfaces, adsorption of gases, and physical measurements of cleaned surfaces. Part II presents the introduction, germanium samples, the reference, the experimental tube, the vacuum system, measurement of contact potential, measurements of the photovoltage, temperature measurements, cleaning of the samples in vacuum, measurements on Argon-bombarded surfaces, results of simultaneous bombarding and annealing, and the effect of gaseous contamination. Part III discusses the cleanliness of surfaces, estimates of the number of surface states, and the effect of oxygen adsorption.

Also published in *Phys. Rev.*, v. 114: 467-475, Apr. 15, 1959.

By applying the Mie-Gruneisen equation of state to measurements of the compression of solids by strong shock waves, it is possible to determine the volume dependence of the cohesive energy. The method for carrying out this deduction is presented along with a detailed exposition of the underlying assumptions. The method is applied to six metals, Be, Al, Co, Ni, Cu and Ag, for which the experimental data are most extensive. The volume dependence of the cohesive energy for these six metals is presented in both analytical and graphical form. (Contractor's abstract)

ENERGY BANDS IN SOLIDS - THE QUANTUM DEFECT METHOD, by H. Brooks and F. S. Ham. Dec. 15, 1958 [18]p. incl. tables, refs. (Technical rept. no. 295) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under Nonr-186616) AD 213444

Unclassified

Also published in *Phys. Rev.*, v. 112: 344-361, Oct. 15, 1958.

This paper describes a procedure for the calculation of electron energy bands in certain solids from spectroscopic data for the corresponding free atom. This method is an improved version of one used by Kuhn and Van Vleck to calculate the energy bands of sodium, potassium, and rubidium. It avoids explicit construction of a one-electron potential to represent the interaction between the valence and core electrons. It is assumed that the interaction between a valence electron and an ion in the crystal is approximately the same as in the isolated atom. If the interaction is accurately represented by a Coulomb potential outside the ion core, one may express solutions of the radial differential equation in this region as linear combinations of standard Coulomb functions. The combination corresponding to the solution which is well-behaved at the nucleus involves a coupling constant which depends upon the ion potential through a parameter that is a slowly varying function of the energy. At an eigenvalue this parameter can be evaluated from the quantum defect. Hence if the eigenvalue spectrum is known, we may obtain this parameter by extrapolation for arbitrary nearby energies, and the regular solution of the radial equation is consequently determined explicitly, outside the core. This is

sufficient information for the calculation of energy bands with available techniques. An approximate formula is established for the ratio of the amplitude of the wave function near the nucleus to its value at a point outside the core. For an *s* function this relation involves only the nuclear charge, standard Coulomb functions, and the aforementioned parameter derived from spectroscopic data. It therefore provides a convenient means of calculating P_F and P_A , the squared amplitudes at the

nucleus appropriate to the Knight shift and the atomic hyperfine splitting, respectively. In the latter case the result is identical with a formula given by Fermi and Segrè, which gives reasonable agreement with experiment. Arguments are presented in support of the thesis that the quantum defect method takes very general account of exchange and correlation interactions between the valence electron and core electrons. Relativistic effects, including spin-orbit coupling are also included naturally. Modifications are discussed of the method to take into account deviations of the ion or crystal potential outside the core from Coulomb form. Tables of the essential data, including improved polarization corrections, are given for the alkali metals. (Contractor's abstract)

A STUDY OF MAGNETRON DIODE OSCILLATIONS, I, by J. M. Osepchuk. Dec. 30, 1957, 45p. incl. diags. refs. (Technical rept. no. 271) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-186632) AD 159663

Unclassified

This work is concerned with the velocity-resonance type of oscillations which have been observed in magnetron diodes. In Chapter I the anomalous effects which are believed to be associated with these oscillations are reviewed and are shown to be in conflict with the classical steady-state theories of the magnetron diode even when emission velocities of electrons are taken into account. An explanation of these effects is shown to require either a state of statistical disorder in the space charge or a state of organized oscillations. In Chapter II the small-signal theory of a perturbed Brillouin state is treated with a review of previous work on this subject. Under the usual assumptions in the case of a small cathode, it is found that the space charge is stable with real frequencies of oscillation. This result is valid only if the space-charge cloud extends to a radius much greater than the cathode radius. In the general case with special conditions at the cathode, instability may be found. The central importance of the Hahn boundary condition in the theory of "M" type space-charge waves is shown. The derivation of this condition is reexamined with a clear statement of the conditions for its validity. An investigation is made of the effect of a finite boundary layer on the nature of the

HAR.09:002 - HAR.09:005

space-charge waves. Under special assumptions an instability if found, however, does not correspond to velocity-resonance oscillations. The results of this theoretical study are used (in Part II) (TR-272) to interpret the results of experiments which were conducted with a series of magnetron diodes. (Contractor's abstract)

This report presents the results of an experimental study of oscillations in several magnetron diodes of varying dimensional parameters. Coupling to the oscillations was effected by the use of coupling slots in the anodes of the magnetrons. Frequency and power measurements were made over the ranges of voltage and magnetic field common to C-W magnetrons. The power measurements were related to interaction space $r-f$ fields (assuming a slightly disturbed bounded cloud of space charge) with the results of a calculation of slot coupling (Appendix A). The frequency measurements are compared with the results of several theories which were studied in a previous report (TR-271). Although the measured frequencies are in best agreement with a formula of Guénard and Huber it is concluded that a satisfactory understanding of the mechanism of the oscillations is still lacking. The frequency measurements as a function of voltage and magnetic field, do confirm, however, the oscillations as a type of "velocity-resonance" oscillations. The power measurements lead one to conclude that a considerable proportion of the space charge is present beyond the bounding radius of the space-charge cloud in the classical steady-state theories. The detected signals were observed to be "noisy" at high cathode temperatures and "clean" at low cathode temperatures. It is probable that "clean" oscillations occur with a temperature-limited state in the magnetron. (Contractor's abstract)

The directional characteristics of a complete array are only approximately given by patterns in the 2 principal planes. Minor lobes occur outside these principal planes, which are approximately as large as those occurring in the principal planes. Thus, in designing arrays for low minor lobes the patterns outside the principal planes should be considered. The factor which limits the amount the principal maximum can be moved by varying t_p (the phase difference between elements in fractions of a period), while still obtaining a useful pattern, is the shape of the pattern of the basic unit. No attempt has been made to determine the optimum realizable shape for the pattern of the basic unit, but this would be a useful piece of information. Some very useful information concerning t_{pm} can be

HAR. 09:006; HAR. 04:015;
HAR. 05:002, 003

obtained by choosing fixed γ (the azimuthal angle measured from the x axis) and θ (the elevation angle measured from the z axis) and determining the pattern as a function of t_p . This is frequently easier to do than computing the pattern as a function of angle. A basic unit consisting of a unidirectional end-fire couplet permits a wide variation of t_p with small effects upon the principal maximum but "back lobe" becomes important as the limiting factor. The basic unit pattern from a dipole placed $\pi/4$ in front of a conducting screen has no "back lobe" but the range of variation of t_p is limited by the resulting change in the height of the principal maximum. Owing to the significance of the pattern of the basic unit in determining the pattern of a complete array, the properties of a non-uniform array may be expected to resemble qualitatively the uniform array discussed here.

LIPSCHITZ CONDITIONS FOR HARMONIC AND DISCRETE HARMONIC FUNCTIONS, by J. L. Walsh and D. Young. July 1957, 21p. (In cooperation with Maryland U., College Park) (AFOSR-TN-57-404) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1461 and Office of Ordnance Research under DA 36-034-ord-1486) AD 132482 Unclassified

Also published in *Jour. Math. and Phys.*, v. 36: 138-150, July 1957.

Proof is given that if a function $u(x,y)$ is harmonic in a square or rectangle, and if boundary values of $u(x,y)$ are continuously assumed and satisfy on the boundary a Lipschitz condition of order α ($0 < \alpha < 1$): $|u(x_1, y_1) - u(x_2, y_2)| \leq L \delta^\alpha$, $\delta^2 = (x_1 - x_2)^2 + (y_1 - y_2)^2$, $\delta \geq 0$, so also does $u(x,y)$ in the closed region, with a suitable modification of the constant L . The expression is written as $u(x,y) \in \text{Lip } \alpha$. Proof is also given for the analogous result for discrete harmonic functions with uniformity of the Lipschitz condition for all mesh size. These results are applied to degree of convergence in a closed rectangle of the solution of the Dirichlet problem. Poisson's integral for the half plane is employed to obtain the results, and these in turn are used to solve the Dirichlet problem for a semi-infinite strip. A new vertical accordion process of folding a semi-infinite strip is introduced to cover infinitely often a square and thus to solve the Dirichlet problem for the square. These procedures with suitable modifications apply to both harmonic and discrete harmonic functions.

Also published in *Trans. Amer. Math. Soc.*, v. 91: 231-245, May 1959.

A systematic study is presented of the common properties relating to oscillation of the difference $f(x) - p_n(x)$ of polynomials $p_n(x)$ of given degree n ($n \geq 0$) of best approximation to a given real function $f(x)$ on a given real finite point set E . Juxtapolynomials to a given real function $f(x)$ on a given real finite point E are defined as the closest polynomials to that function on that point. The totality of extremal polynomials for the classical deviations and unspecified positive weights is identical with the totality of juxtapolynomials. The striking relation between juxtapolynomials and weak oscillation of $f(x) - p_n(x)$ on E is discussed. A study is made of the properties of boundedness, closure, and connectedness of the set of juxtapolynomials, and of the characterization of juxtapolynomials relative to the special classical norms of $p > 1$, of Chebyshev, and of $0 < p < 1$.

THE THEORY OF SQUARE INTEGRABLE DIFFERENTIALS ON OPEN RIEMANN SURFACES, by L. V. Ahlfors. Jan. 1958, 52p. (AFOSR-TN-57-790) (AF 18(600)1461) AD 148021 Unclassified

Various orthogonal decompositions are shown to play a central role in the theory of differentials. In these cases the restrictions are not imposed on the Riemann surface. Generality is achieved by focusing the attention on certain subclasses of differentials. The following are discussed: (1) square integrable differentials, (2) Weyl's lemma, (3) DeRham's decomposition, (4) orthogonal complements, (5) periods, (6) finite surfaces, (7) semi-exact differentials, (8) Schottky differentials, (9) harmonic measures, (10) canonical homology bases, (11) isolated singularities, (12) closed singular differentials, (13) harmonic singular differentials, (14) canonical differentials, (15) period differentials, (16) modular differentials, and (17) Abel's theorem.

THE COMPLEX ANALYTIC STRUCTURE OF THE SPACE OF CLOSED RIEMANN SURFACES, by L. V. Ahlfors. [1957] [22]p. (AF 18(600)1461) Unclassified

Published in *Analytic Functions; a Conference, Inst. for Advanced Study, Princeton, N. J.* (Sept. 2-14, 1957), Princeton, Princeton U. Press, 1960, p. 45-66.

Let M_g be the set each element of which consists of a compact Riemann surface of genus g , together with a

fixed homotopy basis for the surface. Teichmüller has defined a metric, taking as the distance between 2 elements of M_g the logarithm of the infimum of the maximal dilation of all quasi-conformal maps (in the proper homotopy class) between the two surfaces. The author has shown that M_g is homeomorphic to $(6g - 6)$ -dimensional Euclidean space. In the present paper he establishes the following theorem: The space M_g of canonical Riemann surfaces of genus $g > 1$ permits 1 and only 1 complex analytic structure over the Teichmüller topology with respect to which all elements τ_{ij} of the Riemann matrix are analytic functions. The complex dimension of this structure is $3g-3$. Explicit calculations are made of the variations of the τ_{ij} under infinitesimal quasi-conformal maps. (Math. Rev. abstract)

Also published in *Trans. Amer. Math. Soc.*, v. 87: 467-484, Mar. 1958.

Methods are presented of approximating a given function of a complex variable by means of simpler functions. The principal results of recent theoretical studies are given in broad outline and also in some detail. One case deals with a function $f(z)$, analytic on a closed point set E , with a geometric degree of convergence. A second problem deals with weaker properties (as, for example, existence of derivatives and Lipschitz conditions) of a function $f(z)$ which is not analytic on E and which has a slower than geometric degree of convergence. The third problem concerns weaker properties of $f(z)$ not on E on a closed set E_1 which contains E and is contained in a region D . In this case $f(z)$ is analytic on E but not throughout E_1 and the degree of convergence on E is geometric but expressed with various refinements depending upon the properties of $f(z)$ on E_1 . The Taylor development of $f(z)$ is discussed. Approximation by polynomials and approximation by rational and analytic functions are described. Generalizations and extensions include geometric situations, continuity classes, other norms besides the Chebyshev norm as e.g., the p^{th} power integrals with or without a weight function, interpolation by functions of least norm, and extremal problems.

APPROXIMATION ON A LINE SEGMENT BY BOUNDED ANALYTIC FUNCTIONS. PROBLEM β , by J. L. Walsh. [May 1958] 6p. (AFOSR-TN-58-393) (AF 18(600)1461) AD 154302

Unclassified

Also published in Proc. Amer. Math. Soc., v. 10: 270-272, Apr. 1959.

The problem β is the study of the degree of approximation on a closed bounded point set E to a function $f(z)$ analytic on E , by functions which are analytic and bounded in a region D containing E . The function $f(z)$ is supposed not necessarily analytic throughout D , but possesses certain continuity properties on the boundary of a suitable region of analyticity which contains E and whose closure lies in D . Recent progress has been made in the case in which E is bounded by analytic Jordan curves; the present paper discusses the case in which E is a line segment.

ON CANONICAL CONFORMAL MAPS OF MULTIPLY CONNECTED REGIONS, by J. L. Walsh and H. J. Landau. May 1958 [25]p. (In cooperation with Bell Telephone Labs., Inc., Murray Hill, N. J.) (AFOSR-TN-58-394) (AF 18(600)1461) AD 154303

Unclassified

Also published in Trans. Amer. Math. Soc., v. 93: 81-96, Oct. 1959.

An application of the following theorem is made: Let D be a region of the extended z -plane whose boundary consists of mutually disjoint Jordan curves $B_1, B_2, \dots, B_\mu; C_1, C_2, \dots, C_\nu, \mu\nu \neq 0$. There exists a conformal map of D onto a region Δ of the extended Z -plane, one

to one and continuous in the closures of the two regions, where Δ is defined by

$$1 < |T(Z)| < e^{\frac{1}{\tau}}, \quad T(Z) = \frac{A(z-a_1)^{M_1} \dots (z-a_\mu)^{M_\mu}}{(z-b_1)^{N_1} \dots (z-b_\nu)^{N_\nu}},$$

with $M_i, N_j, \tau > 0, \sum M_i = \sum N_j = 1$. The purpose is to show, using closely related methods, that the theorem extends to the case of domains in which the sets

$U_i = \bigcup_{j=1}^{\mu} B_j$ and $U_j = \bigcup_{i=1}^{\nu} C_i$ are made up of Jordan curves that are not necessarily disjoint. The development is carried out by using several preliminary definitions and the result is applicable in the study of approximation by rational and by bounded analytical functions.

A GENERALIZATION OF FABER'S POLYNOMIALS, by J. L. Walsh. May 1958, 21p. (AFOSR-TN-58-417) (AF 18(600)1461) AD 158220

Unclassified

Also published in Math. Ann., v. 136: 23-33, 1958.

Faber's method is modified for application to the problem of the simultaneous expansion in several disjoint Jordan regions of a function analytic in those regions. This procedure involves (1) the use of a suitable sequence of interpolation polynomials convergent in the interior of a lemniscate leading to a series similar to that of Jacobi, and (2) the conformal mapping of the exterior of the lemniscate onto the exterior of given closed

HAR.05:012 - HAR.05:014

Jordan regions: the expansion of this mapping function yields the new polynomials. These functions are considered a generalization of Faber's polynomials because (1) they are defined by an interpolation series expansion of the first member of

$$\frac{\psi'(\tau)}{\psi(\tau) - z} = \frac{b_0(z)}{\tau - \alpha_1} + \frac{b_1(z)}{(\tau - \alpha_1)(\tau - \alpha_2)} + \dots$$

where $z = \psi(w)$ is a schlicht map onto the complement of E (E is the union of mutually disjoint continua, none of which is a single point, in the z -plane, and each of whose complements is an infinite region) so that

(1) the expansion $f(z) = \sum_0^{\infty} a_k b_k(z)$ becomes the classical Faber expansion if $\nu = 1$ and becomes the Taylor expansion if E is a circular disk; (2) if $f(z)$ is analytic on E the expansion (2), like the Faber expansion, converges to $f(z)$ on E with the greatest geometric degree of convergence; (4) the $b_n(z)$ are unchanged if E is replaced by E_σ (the point set $|U(z)| < \sigma$; and (5) the relation $\limsup \sup [\max |b_n(z)|, z \text{ on } E]^{1/n} = \delta(E) = \mu$ is satisfied.

NOTE ON APPROXIMATION BY BOUNDED ANALYTIC FUNCTIONS (PROBLEM α), by J. L. Walsh. Aug. 1958, 12p. (AFOSR-TN-58-701) (AF 18(600)1461) AD 162235; PB 137873
Unclassified

Also published in Math. Zeitschr., v. 72: 47-52, 1959.

Problem α is a study of the relation of the degree of approximation of a function $f(z)$ on a point set E to the continuity properties on E of the function when the difference between the function and $f_n(z)$ is bounded by $n^{-p+\alpha}$ and $f_n(z)$ is bounded by R^n in a region D which contains E . A relationship is given between the function defined above and the existence of polynomials which approximate $f(z)$ such that the difference between $f(z)$ and $p_n(z)$ is bounded by $n^{-p+\alpha}$. This relationship presented is important due to the presently existing theory on problem α for polynomials and the possibilities of enlarging the region D in which $f_n(z)$ satisfy the needed approximation of $f(z)$.

APPROXIMATION BY BOUNDED ANALYTIC FUNCTIONS: GENERAL CONFIGURATIONS, by J. L.

Walsh. Aug. 1958, 10p. (AFOSR-TN-58-703) (AF 18(600)1461) AD 162237; PB 137872
Unclassified

Also published in Proc. Amer. Math. Soc., v. 10: 280-285, Apr. 1959.

A proof is presented of a theorem regarding the topological properties of point sets. Let $B = \bigcup_{j=1}^{\nu} B_j$ and $C = \bigcup_{j=1}^{\nu} C_j$ be a set of mutually disjoint ana-

lytic Jordan curves. Let D be a bounded open set whose boundary is all of C plus a subset of B_j (not necessarily proper), and let each maximal subregion of D be bounded by a non-empty subset of B_j plus a non-empty subset of C . Let C not separate D . Let E be a closed set disjoint from D whose boundary is B , but E need not be the closure of an open set. Let $D + E$ be connected. Let $u(z)$ be the harmonic function in D , continuous in the closure of D , equal to zero on B and unity on C . Let Γ_σ , $0 < \sigma < 1$, denote generically the locus $u(z) = \sigma$ in D , and let D_σ denote the set $0 < u(z) < \sigma$. Let the function $f(z)$ be analytic in the interior points of E , continuous on E , and analytic in D_σ , where Γ_σ has no multiple points. Let $f(z)$ be of class $L(p, \alpha)$ on Γ_σ . Then there exists functions $f_n(z)$ analytic in the interior points of $D + E$ and continuous on E , satisfying the following inequalities:

$$(1) |f(z) - f_n(z)| \leq \frac{A_1 e^{-n\rho}}{n^{p+\alpha}}, z \text{ on } E,$$

$$(2) |f_n(z)| \leq \frac{A_2 e^{n(1-\rho)}}{n^{p+\alpha}}, z \text{ in } D + E, (n = 1, 2, \dots).$$

EXPANSIONS IN SERIES OF HOMOGENEOUS POLYNOMIAL SOLUTIONS OF THE GENERAL TWO-DIMENSIONAL LINEAR PARTIAL DIFFERENTIAL EQUATION OF THE SECOND ORDER WITH CONSTANT COEFFICIENTS, by D. V. Widder. Sept. 1958, 8p. (AFOSR-TN-58-706) (AF 18(600)1461) AD 162240; PB 137863
Unclassified

Also published in Duke Math. Jour., v. 26: 599-603, Dec. 1959.

The region of convergence of series solutions of polynomials for the linear second order partial differential equation has been studied. If the equation is hyperbolic, the solutions are convergence in a rectangular region and possible on the extended diagonals of the rectangle as shown (see item no. HAR.05:015). If the equation is

HAR.05:015 - HAR.05:016

elliptic, the region of convergence is an ellipse given in terms of a limit term of the series coefficients, plus perhaps certain points outside the ellipse, such as diameters extended beyond the boundary. In the parabolic case the region of convergence is an infinite strip whose sides are characteristics plus perhaps portions of a single line extended beyond the strip through the origin.

EXPANSIONS IN SERIES OF HOMOGENEOUS POLYNOMIAL SOLUTIONS OF THE TWO-DIMENSIONAL WAVE EQUATION, by D. V. Widder. Sept. 1958, 14p. (AFOSR-TN-58-707) (AF 18(600)1461) AD 162241; PB 137864 Unclassified

Also published in Duke Math. Jour., v. 26: 591-598, Dec. 1959.

The convergence of the solutions of the two-dimensional wave equation given as an expansion in homogeneous polynomials has been investigated. Absolute convergence for the Taylor series expansion has been found in a rectangular region which is given in terms of the coefficients of the series and possible for the extended diagonals of the rectangle. A brief discussion is given of the relation of the above results to the Cauchy problem for the wave equation.

SOLUTION OF THE DIRICHLET PROBLEM FOR THE ELLIPSE BY INTERPOLATING HARMONIC POLYNOMIALS, by J. L. Walsh. Oct. 1958, 7p. (AFOSR-TN-58-1001) (AF 18(600)1461) AD 206144; PB 137779 Unclassified

Also published in Jour. Math. and Mech., v. 9: 193-196, Mar. 1960.

A proof is presented of the theorem on the points of interpolation on the boundary of a given region D. In this case, D is the interior of an ellipse. Let the boundary B of a bounded region D in the (u, v)-plane be an ellipse and let the function $U(u, v)$ be defined and satisfy a Lipschitz condition of some positive order on

HAR. 05:020-033; HAR. 10:001

B with respect to arc length. Let the harmonic polynomial $p_n(u, v)$, of degree not greater than n , coincide with $U(u, v)$ in $2n + 1$ points equally spaced on B with respect to the conjugate of Green's function for the exterior of $D + B$ with pole at infinity. Then the sequence $p_n(u, v)$ converges to $U(u, v)$ uniformly on B, hence converges uniformly in $D + B$ to the corresponding solution of the Dirichlet problem.

THE METHOD OF ORTHOGONAL DECOMPOSITION FOR DIFFERENTIALS ON OPEN RIEMANN SURFACES, by L. V. Ahlfors. [1958] [15]p. (AF 18(600)1461) Unclassified

Published in Ann. Acad. Scient. Fenn., Series A. I., No. 249/7, 1958, 15p.

Let Γ be the space of square integrable differentials on an open Riemann surface W . Various orthogonal decompositions are considered in the space Γ which are useful in function theory. Some idea of the questions dealt with can be seen from the following list of relevant subspaces of Γ : the subspace Γ_c of closed differentials; the subspace $\Gamma_h = \Gamma_c \cap \Gamma_c^*$, the subspace of harmonic differentials; the subspace Γ_e of exact differentials; Γ_{co} , the closure of the subspace of closed differentials with compact carriers; Γ_{eo} , the closure of the subspace of differentials of functions with compact carriers; and the subspace Γ_{se} of semi-exact differentials, i.e., of differentials which are closed and have zero periods around all dividing cycles. The space Γ_{hm} is defined by the orthogonal decomposition $\Gamma_h = \Gamma_{hse} + \Gamma_{hm}^*$. It is shown that $\Gamma_{hm} \subset \Gamma_{he} \cap \Gamma_{ho}$ with equality for finite Riemann surfaces. It is also shown that each differential in Γ_{hm} is the limit in norm of a suitable sequence of harmonic measures on an exhaustion of W . Considerable use is made of Schottky differentials on a finite Riemann surface. The remainder of the paper deals with the application of the method of orthogonal decomposition to the case of differentials with prescribed singularities and periods, and with a generalization of Abel's theorem. THE PROBLEM OF MINIMAL MODELS IN THE THEORY OF ALGEBRAIC SURFACES, by O. Zariski. Oct. 1957 [39]p. incl. refs. (AFOSR-TN-57-691) (AF 18(600)1503) AD 136685 Unclassified

Also published in Amer. Jour. Math., v. 80: 146-184, Jan. 1958.

The two theorems listed below have been shown to hold in the abstract case ($p \neq 0$) for algebraic surfaces. By use of the properties of exceptional curves of the second kind, fundamental theorem A has been shown to be a consequence of fundamental theorem B. Fundamental theorem A: if a birational class C of non-singular surfaces contains no minimal model, then C contains a ruled surface. Fundamental theorem B: if a non-singular surface F carries an irreducible exceptional curve E of the second kind, then F is birationally equivalent to a ruled surface, and if, furthermore, the self-intersection number (E^2) of E is strictly positive, then F is a rational surface.

INTRODUCTION TO THE PROBLEM OF MINIMAL MODELS IN THE THEORY OF ALGEBRAIC SURFACES, by O. Zariski. July 25, 1957, 84p. incl. refs. (AFOSR-TN-57-517) (AF 18(600)1503) Unclassified

Also published as Publication of the Math. Soc. Japan, No. 4, Tokyo, Math. Soc. of Japan, 1958, 89p.

A modern approach to the classical problems of the theory of algebraic surfaces is presented and these problems are generalized to fields of characteristic p . The basic properties of rational transformations of algebraic varieties over an algebraically closed field are treated quite generally. A full proof of Bertini's theorem is given. Exceptional curves on an algebraic surface without singularities are discussed. The factorization theorem of anti-regular transformations into quadratic transformations is proved. The behavior of the canonical system of a surface with respect to birational transformations is discussed. It is found that the irreducible components of an exceptional curve of the first kind are non-singular curves. The theory of minimal models including the theorem of Néron and Severi concerning the behavior of the base number of algebraic divisors relative to birational transformations is used to prove that each birational class $\{F\}$ satisfies the minimum condition for the relation $<$. The approach used ultimately leads to a proof of Castelnuovo's theorem that a subfield of a rational function field $k(x,y)$ must be rational if k is algebraically closed and separable.

A FUNDAMENTAL INEQUALITY IN THE THEORY OF EXTENSIONS OF VALUATIONS, by I. S. Cohen and O. Zariski. [1957] [8]p. (AFOSR-TN-58-721) [AF 18(600)1503] AD 162256 Unclassified

Published in Illinois Jour. Math., v. 1: 1-8, Mar. 1957.

Let K be a field and let K^* be a finite algebraic extension of K , of degree n . Let v be a valuation of K , and let $v_1^*, v_2^*, \dots, v_g^*$ be the distinct extensions of v to K^* .

The following inequality is proven

$$\sum_{i=1}^g e_i f_i \leq n.$$

The value group and the residue field of v are denoted by Γ and Δ respectively, and the analogous entities for v_i^* are denoted by Γ_i^* and Δ_i^* . It is known that (a) the number g of distinct extensions v_i^* of v is finite, that

(b) Δ_i^* is a finite extension of Δ , and that (c) Γ is a subgroup of Γ_i^* of finite index. The integers $f_i = [\Delta_i^* : \Delta]$ and $e_i = \text{index of } \Gamma \text{ in } \Gamma_i^*$ are respectively the relative degree and the reduced ramification index of v_i^* with respect to v . To conclude the paper, some conditions are given under which the equality sign in the above equation is valid.

ON CASTELNUOVO'S CRITERION OF RATIONALITY $p_a = P_2 = 0$ OF AN ALGEBRAIC SURFACE, by O. Zariski. [1958] [13]p. [AF 18(600)1503] Unclassified

Published in Illinois Jour. Math., v. 2: 303-315, Sept. 1958.

Let F be a nonsingular (irreducible) algebraic surface over an algebraically closed ground field k . A theorem of Castelnuovo asserts that if the arithmetic genus p_a and the bigenus P_2 of F are both zero, then F is a rational surface. This theorem has been proved for fields k of arbitrary characteristic p , except in the case $(K^2) = 1$ where K is a canonical divisor on F . In the present paper proof is also given for the case $(K^2) = 1$. An immediate consequence of Castelnuovo's criterion of rationality is the well-known theorem of Castelnuovo on the rationality of plane involution. This theorem is stated as follows: Let $k(x, y)$ be a purely transcendental extension of an algebraically closed field k , of transcendence degree 2, and let Σ be a field between k and $k(x, y)$, also of transcendence degree 2 over k . If $k(x, y)$ is a separable extension of Σ , the Σ is a pure transcendental extension of k . It is shown in this paper by an example that the condition of separability of $k(x, y)/\Sigma$ is essential.

Presented at annual meeting of the Amer. Soc. of Biol. Chemists, Chicago, Ill., Apr. 15-19, 1957.

Published in Fed. Proc., v. 16: 264, Mar. 1957.

The detection of zinc in several enzymes had led to the proposition that this metal is functional in the reactions catalyzed by these enzymes. This has been inferred from data indicating the simultaneous aggregation of zinc and of enzymatic activity during isolation of these enzymes, accompanied by the disappearance of other metals. Chelating agents known to form complexes with ionic zinc in aqueous systems have been employed to inhibit enzymatic activity, and the kinetics of this inhibition have been examined, particularly with 1,10-phenanthroline. Such studies further imply an essential role for zinc. 1,10-phenanthroline forms mono, bis, and thermolecular complexes with zinc. Absorption maxima at 3275 and 3425A have been found for these systems. The extinction coefficients of the 3 molecular

species at these 2 wavelengths have been calculated. The addition of 1,10-phenanthroline to various zinc-containing enzymes and zinc-insulin has demonstrated changes in absorption at 3275 and 3425A. The direct interaction of 1,10-phenanthroline with the protein-bound zinc has thus been demonstrated, simultaneously permitting the quantitative determination of the metal. The stoichiometric relationships of zinc, and 1,10-phenanthroline have been studied in these enzymes and correlated with the inhibition data. Spectrophotometric studies of zinc enzymes with other chelating agents also demonstrate changes characteristic of their ionic zinc systems. (Contractor's abstract)

SULFHYDRYL GROUPS, ZINC CHELATING INHIBITORS AND THEIR RELATIONSHIP TO THE ACTION OF YEAST ALCOHOL DEHYDROGENASE (Abstract), by F. L. Hoen and B. Zotos. [1957] [1]p. [In cooperation with Peter Bent Brigham Hospital, Boston, Mass.] [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-186604] Unclassified

Presented at annual meeting of Amer. Soc. for Exper. Pathol., Chicago, Ill., Apr. 15-19, 1957.

Published in Fed. Proc., v. 16: 359-360, Mar. 1957.

The alcohol dehydrogenase of baker's yeast (YADH) has been shown to be a zinc metalloenzyme. A molecule of DPN and/or DPNH is bound to YADH at or near each of the 4 zinc atoms in the enzyme. Yeast ADH also contains sulfhydryl groups, and inhibition studies with specific reagents for -SH have been interpreted to indicate they are enzymatically active sites; no direct correlation between the analytical and the functional data is at hand. The significance of these findings for the explanation of the molecular basis of YADH action requires further study. YADH has been titrated with Ag⁺ alone and in the presence of metal binding agents. The number of -SH groups measured per molecule of enzyme is a critical function of the physical-chemical parameters of the system. The presence of a variety of chelating agents, however, does not change the number of titratable -SH groups at concentrations which inhibit enzyme activity. Similarly, the presence of DPN in a 10⁻⁵ molar excess does not alter titratable sulfhydryl content of the enzyme significantly. It may be concluded that the observed inhibition of YADH with metal binding agents is not due to their effects on -SH groups. (Contractor's abstract)

ZINC METABOLISM IN POST-ALCOHOLIC CIRRHOSIS (Abstract), by B. L. Vallee, W. E. C. Wacker, and J. H. R. Kaegi. [1957] [1]p. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) [Sponsored jointly by Office of Naval Research and Air Force Office of Scientific Research under Nonr-186604] Unclassified

Presented at annual meeting of the Amer. Soc. Clin. Invest., Atlantic City, N. J., May 6, 1957.

Published in Jour. Clin. Invest., v. 36: 933, June 1957.

Iron in hemochromatosis and copper in Wilson's disease are implicated in the pathogenesis of these diseases, both of which ultimately lead to cirrhosis. Zinc, another transition-element, participates in the dehydrogenation of ethanol. This led to studies of zinc in post-alcoholic cirrhosis. In normal individuals ~ 500 µg per 24 hr of directly reacting zinc is excreted. Elimination of zinc in the urine apparently varies with the functional capacity of the post-alcoholic liver. "Zincuria" from 750 to 2,500 µg per hr has been observed in individuals with cirrhosis and hepatomegaly; apparently the first authenticated instance of primary "zincuria" without albuminuria. One terminal, jaundiced individual, however, with a small liver, ascites, serum-zinc 49 µg per cent, and BSP 61 per cent, excreted ~ 50 µg of zinc in 24 hr. Oral zinc induced transient changes in zinc excretion, and after

HAR.11:006 - HAR.11:008

ten days the BSP was 53 per cent. Another patient with marked hepatomegaly presented a different pattern: Serum-zinc was 77 μg per cent, urinary zinc excretion was about 800 μg per 24 hrs and the BSP was 32 per cent during the control period. Oral zinc abruptly decreased urinary zinc concentration to ~ 400 μg per 24 hr. This level was maintained below the mean of the normal series throughout the experimental period. Serum-zinc rose to within normal limits. BSP was 10 per cent after ten days, remaining at this level. The participation of zinc in the dehydrogenation of ethanol, in the metabolism of post-alcoholic cirrhosis and the tendency of physiological quantities of zinc to restore normal biochemical patterns in the individuals studied emphasizes the unsuspected participation of this transition-element in another pathologic process, characterized by severe cicatrization in its terminal stages.

Published in Jour. Amer. Chem. Soc., v. 79: 4813-4814, Sept. 3, 1957.

Fractionation of horse-kidney cortex with EtOH and $(\text{NH}_4)_2\text{SO}_4$ gave a product containing 20-5 mg/g dry

weight of cadmium in $\text{Cl}_3\text{CCO}_2\text{H}$ -precipitable material in successive fractionations. Ultracentrifugation in a synthetic-boundary cell showed the final products of 4 successive fractionations to be undispersed with a sedimentation (uncorrected for viscosity of diffusion)

varying from 0.94 to 1.22×10^{-13} . Paper electrophoresis at pH 8.5 of the product of 1 fractionation showed 3 components moving toward the cathode; the slowest comprised about 70% of the material. The Cd content rose 30-fold throughout the fractionation from the first extract to the product. Cd was not removable by dialysis at pH 7, but was removed by treatment with hot $\text{Cl}_3\text{CCO}_2\text{H}$. With the exception of Zn, other metals initially present or introduced during fractionation were removed and occurred in concentration in the final material. The possibility of isomorphism with Zn is discussed. The product contains 14% N, and reacts positively to ninhydrin and biuret. Hydrolysis and paper chromatography showed serine, glycine, aspartic and glutamic acids among other non-identifiable amino acids. The last fraction contained about 1% hexosamine.

The Biophysics Research Lab. of the Harvard U. Medical School and the Peter Bent Brigham Hospital was dedicated on May 17, 1954. The laboratory, which comprises an area of about 7,500 sq ft was completely remodeled within the existing facilities of the hospital. It has been fully equipped with all the instruments necessary for investigations in emission and absorption spectroscopy, intermediary metabolism and physical chemistry. It was established with major grants from the Rockefeller Foundation and National Institutes of Health. The first application to the Office of Naval Research was submitted in Apr. 1952 and a contract went into effect in 1953. The present report constitutes a review of activities, under this joint grant from the Navy, Army and Air Force, which was administered by the Office of Naval Research. Results of the work accomplished in the past years have been published in the scientific literature and is included in the bibliography. A brief resume of the work is listed as follows: Spectroscopy: Porous cup electrode sparking method; Noble gases and the dc arc; The direct-reading flame spectrometer; The cyanogen-oxygen flame; The coenzometer. Enzymology: Metalloenzymes; Kinetics;

Mixed complexes; Other active groups; Cadmium protein; Electron transport in mitochondria; Metal content of subcellular fractions; Hibernation. Clinical Investigation: Copper in myocardial infarction; Lactic and malic dehydrogenase in myocardial infarction; Magnesium and acute renal failure; Zinc in cirrhosis. Mathematics: The sequential probability ratio test; Stochastic models. Analytical Chemistry: Determination of zinc (by means of methyl cellosolve and dithione); Zinc in urine; Concentration techniques; Contamination and separation.

ZINC METABOLISM IN HEPATIC DYSFUNCTION. II. CORRELATION OF METABOLIC PATTERNS WITH BIOCHEMICAL FINDINGS, by B. L. Vallee, W. E. C. Wacker, and A. F. Bartholomay. [1957] [11]p. incl. diagrs. tables, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research under Nonr-186604]) Unclassified

Published in *New England Jour. Med.*, v. 257: 1055-1065, Nov. 28, 1957.

Extension of previous studies demonstrated marked abnormalities of zinc metabolism in patients suffering from postalcoholic cirrhosis. In addition to markedly lowered concentrations of zinc in serum, this element is present in significantly lower concentrations in the liver tissue of such persons. Simultaneously, these patients excrete abnormally large quantities of zinc in their urine; a terminal patient, however, excreted subnormally low quantities of zinc. The administration of zinc sulfate in physiologic quantities tends to restore normal excretory patterns. The bromsulphalein retention in 5 patients with post-alcoholic cirrhosis tended toward normal in the course of these investigations on zinc metabolism. No attempts at specific therapy of the disease were undertaken. The data are interpreted in the light of the comparative biochemistry of zinc and ethanol metabolism. A conditioned zinc deficiency is conjectured to be consistent with the present data, and the known historical, pathophysiologic and pathobiochemical knowledge of this disease.

A STUDY OF MAGNESIUM METABOLISM IN ACUTE RENAL FAILURE EMPLOYING A MULTICHANNEL FLAME SPECTROMETER, by W. E. C. Wacker and B. L. Vallee. [1957] [9]p. incl. diagrs. tables, refs.

(In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research under Nonr-186604]) Unclassified

Published in *New England Jour. Med.*, v. 257: 1254-1262, Dec. 26, 1957.

The development of a simple, precise, and accurate flame spectrometric method for the determination of magnesium in serum made possible this study of magnesium metabolism in acute renal failure. The clinical pictures of magnesium intoxication and the uremic syndrome are similar. The severity of the potassium intoxication associated with acute renal failure does not always correlate with the serum concentration of this element. These facts led to an investigation of magnesium in the serum of patients with acute renal failure is significantly increased in all cases. In general, this elevation parallels that of potassium; in several patients, however, the elevation of magnesium is out of proportion to that of potassium. Owing to marked similarities of the electrocardiographic changes associated with hyperkalemia and hypermagnesemia, those due to hypermagnesemia are often mistaken for those of hyperkalemia. Changes in the electrocardiogram typical of hypermagnesemia were observed in these patients. One patient in this series had the signs of magnesium intoxication involving both the central nervous system and the heart. The electrocardiographic abnormalities disappear, and the serum magnesium concentration decreases with hemodialysis. These findings have an important bearing on the diagnosis and management of this syndrome which is accompanied by major disturbances in electrolyte metabolism. (Contractor's abstract)

SPECTROPHOTOMETRIC EVIDENCE FOR ENZYME INHIBITOR COMPLEXATION, by B. L. Vallee, T. L. Coombs, and R. J. P. Williams. [1958] [5]p. incl. diags. refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under Nonr-186604) Unclassified

Published in Jour. Amer. Chem. Soc., v. 80: 397-401, Jan. 20, 1958.

A mixture of ionic zinc and 1,10-phenanthroline demonstrates absorption maxima at 3125, 3275 and 3425A, in a special 5 cm absorption cell; these maxima have not been previously described. Addition of 1,10-phenanthroline or of 8-hydroxyquinoline-5-sulfonic acid to the zinc metalloenzymes, carboxypeptidase, yeast alcohol dehydrogenase or liver alcohol dehydrogenase, or to the zinc protein complex, insulin, produces ultraviolet absorption spectra, which are entirely analogous to those observed with the ionic zinc-1,10-phenanthroline or 8-hydroxyquinoline-5-sulfonic acid system. These spectra therefore demonstrate the existence of protein-zinc-chelate mixed complexes. Spectral evidence indicates these complexes to be completely dissociable upon dialysis. 1,10-phenanthroline and 8-hydroxyquinoline-5-sulfonic acid, previously shown to inhibit carboxypeptidase, yeast ADH and liver ADH, had been postulated to exert these inhibitory effects through interaction with the zinc atoms of the enzymes. The spectral data provide direct evidence for this proposed chemical interaction resulting in the formation of enzymatically inactive enzyme-zinc-chelator complexes. These findings offer additional evidence that zinc is an active site for these metalloenzymes and substantiate the previously proposed mechanisms for inhibition by metal chelators. THE ROLE OF ZINC IN ALCOHOL DEHYDROGENASES. II. THE KINETICS OF THE INSTANTANEOUS REVERSIBLE INHIBITION OF YEAST ALCOHOL DEHYDROGENASE BY 1,10-PHENANTHROLINE, by F. L. Hoch, R. J. P. Williams, and B. L. Vallee. [1958] [12]p. incl. diags. tables, refs. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under Nonr 186604) Unclassified

Published in Jour. Biol. Chem., v. 232: 453-464, May 1958.

The kinetics of the instantaneous, reversible inhibition of yeast alcohol dehydrogenase (YADH) activity by a metal-binding agent, 1,10-phenanthroline (OP), have been investigated. One molecule of diphosphopyridine nucleotide or of reduced diphosphopyridine nucleotide competes with one molecule of OP, indicating that the coenzyme is bound to [(YADH)Zn₄] at or near each of the zinc

atoms. Ethanol or acetaldehyde does not compete with OP, and the zinc atoms thus do not appear to be the chemical locus of a ternary complex. The inhibition data, together with a formulation of the reaction steps and a method for graphic solution, allow calculation of the velocity constants. The rate of dissociation of the enzyme-coenzyme complex appears to be a rate-limiting step. The formulation of YADH action in the light of these observed interactions with its zinc atoms is consistent with other data obtained without consideration of the metal as an active site. THE ROLE OF ZINC IN ALCOHOL DEHYDROGENASES. III. THE KINETICS OF A TIME-DEPENDENT INHIBITION OF YEAST ALCOHOL DEHYDROGENASE BY 1,10-PHENANTHROLINE, by R. J. P. Williams, F. L. Hoch, and B. L. Vallee. [1958] [10]p. incl. diags. (In cooperation with Peter Bent Brigham Hospital, Boston, Mass.) (Sponsored jointly by Office of Naval Research and [Air Force Office of Scientific Research] under Nonr-186604) Unclassified

Published in Jour. Biol. Chem., v. 232: 465-474, May 1958.

The kinetics of the time-dependent, irreversible inhibition of yeast alcohol dehydrogenase by a metal-binding agent, 1,10-phenanthroline (OP), have been investigated. Under the stated conditions, the rate of inactivation is first order initially, when enzyme and OP are preincubated. A reaction scheme and a mechanism of inhibition are presented which fit the data. The instantaneous formation of a dissociable enzyme-inhibitor complex which contains 1 molecule of OP per active site appears to be the primary event. The subsequent slow addition of a 2nd molecule of OP to each site of enzymatic activity, forming a second complex by a process that is irreversible in an enzymatic sense, seems to account for the time-dependent inhibition. This type of inhibition may occur in other enzyme systems as well. (Contractor's abstract)

Zinc is a constant constituent of crystalline beef liver glutamic dehydrogenase. Eight preparations contained between 2 and 4 gm atoms of zinc per mole of apoenzyme. The zinc concentration rises to a maximum value during the course of crystallization while the concentration of other metals fails to stoichiometrically negligible levels. The enzyme is inhibited by a number of reagents of differing chemical structure but capable of coordinating zinc. This inhibition is immediate and reversible by dilution or the addition of zinc ions to the reaction mixture. (Contractor's abstract)

SOME REMARKS ON TAUBERIAN THEOREMS, by A. Jakimovski. Jan. 1958, 27p. incl. refs. (Technical note no. 1) (AFOSR-TN-58-209) (AF 61(052)04) AD 154110 Unclassified

Also published in Quart. Jour. Math., v. 9: 114-131, June 1958.

Typical of the main results of this paper is the following theorem (stated here for sequences): Let $\{s_n\}$ be A -summable to s , and for some $\lambda < 1$, $M < 0$, and finite c ,

$$\liminf_n \min_{n < m \leq \lambda n} (s_m - Ms_n) > -c; \text{ then}$$

$$Ms - c \leq \liminf_n s_n \leq \frac{s+c}{M}, \text{ and } \{s_n\} \text{ is } (c, k)\text{-summable to } s \text{ for each } k > 0. \text{ If } (M-1)s < c, \text{ then } \lim_{n \rightarrow \infty} s_n = s.$$

The bounds on $\liminf_n s_n$ and $\limsup_n s_n$ are best possible. The result is a specialization of a theorem on (L, α) -summability. $s(x)$ is (L, α) -summable to s for some fixed $\alpha > -1$ if

$$L^\alpha(\tau) = \frac{\tau^{\alpha+1}}{\Gamma(\alpha+1)} \int_0^\infty s(t) t^\alpha e^{-\tau t} dt$$

exists for all $\tau > 0$ and approaches s as $\tau \downarrow 0$. The (L, α) method is regular, and it is shown that (L, β) -summability implies (L, α) -summability to the same sum for all α such that $\beta > \alpha > -1$. The use of non-absolutely convergent integrals here is a non-specious generalization. The iteration of the (L, α) method and the continuous Hausdorff transformation is also considered. (Math. EXTENSIONS, RETRACTIONS AND PROJECTIONS, by B. Grünbaum. Jan. 1958, 64p. incl. refs. (Technical note no. 2) (AFOSR-TN-58-210) (AF 61(052)04) AD 154111 Unclassified

An intermediate theory dealing with metric spaces and with operations restricted by conditions analogous to the boundedness of the norm of linear transformations is given. The concepts and quantitative aspects of Banach spaces theory, in combination with the generality and diversity of metric spaces develop a theory. By generalizing the results of Aronszajn-Panitchpakdi; the connection between "uniform" retractions and extensions of uniformly continuous functions with a subadditive modulus of continuity is established. Applicability to Banach spaces is shown and results and on the connection of projections with the extensions of linear operations are obtained. Also, a geometric property of the range-space is exhibited which characterizes the maximal increase of the norm or moduli of continuity for immediate extensions. This geometric property, the "expansion constant" of the space enables the investigation of extension properties (i.e. Banach spaces). Results are given and quantitative aspects of the extension problem for Minkowski spaces are discussed.

THE COERCIVENESS PROBLEM FOR INTEGRO-DIFFERENTIAL FORMS, by S. Agmon. May 1958, 72p. (Technical note no. 5) (AFOSR-TN-58-671) (AF 61(052)04) AD 162203; PB 136868 Unclassified

The solution of the problem of coerciveness for quadratic forms (not necessarily formally positive) over function classes defined by general boundary conditions is discussed. The general coerciveness theorem is given in which the bounded domains are considered for the sake of simplicity. A similar result holds for a wide class of unbounded domains. The general result depends on the corresponding coerciveness theorem in a half-space for forms with constant coefficients. This special case is further reduced, via the Fourier transform, to the problem of characterizing strongly coercive integro-differential forms with constant coefficients on the half-line. This method could be used to solve the general coerciveness problem for integro-differential quadratic forms over vector functions. (Contractor's abstract)

PROJECTION CONSTANTS, by B. Grünbaum. May 1958, 31p. incl. refs. (Technical note no. 6) (AFOSR-TN-58-672) (AF 61(052)04) AD 162204; PB 138978 Unclassified

Also published in Trans. Amer. Math. Soc., v. 95: 451-465, June 1960.

The projection constant P_X^* of a real Banach space X is defined as the greatest lower bound of all reals c having the property: for any normed space Y \subset X there exists a projection P: Y \rightarrow X such that $\|P\| \leq c$.

If $P_X^* = \min c$, P_X^* is called exact. Projection constants for a number of concrete spaces are determined. Bounds for other spaces are obtained as well as bounds of given concrete spaces for projections onto subspaces.

A GENERALIZATION OF THE LOTOTSKI METHOD OF SUMMABILITY, by A. Jaklmovski. June 1958, 29p. (Technical note no. 8) (AFOSR-TN-58-674) (AF 61(052)04) AD 162206; PB 136869 Unclassified

Also published in Mich. Math. Jour., v. 6: 277-290, 1959.

Many results proved for the Lototsky, or L, method of summability are valid for a general class of transformations to which the L transformation belongs. Given a sequence $\{d_n\}$, $n \geq 1$, d_n will denote the product

$d_1 d_2 \dots d_n$ and not as it sometimes denotes $\Gamma(d_n + 1)$.

$\{P_{nm}\}$, $m = 0, \pm 1, \pm 2, \dots$; $n = 0, 1, 2, \dots$, will denote the number defined by $P_{00} = 1$, $(x \cdot d_n) \Big| =$

$\prod_{n=1}^{\infty} (x \cdot d_n) = \sum_{m=0}^{\infty} P_{nm} x^m$, $P_{nm} = 0$ for $m > n$ and $n \neq 0$.
 $m=1$ $m=0$

THE PARAMAGNETIC RESONANCE SPECTRUM OF GADOLINIUM IN HYDRATED LANTHANUM TRICHLORIDE, by M. Weger and W. Low. May 1958 [14]p. incl. diagrs. (Technical note no. 2) (AFOSR-TN-58-543) (AF 61(052)59) AD 158360; PB 136996
Unclassified

Also published in *Phys. Rev.*, v. 111: 1526-1528, Sept. 15, 1958.

The paramagnetic resonance spectrum of Gd^{3+} in $LaCl_3 \cdot 7H_2O$ has been measured at a frequency of 9373 mc at both room temperature and liquid air temperature. The observed lines have been fitted to a spin Hamiltonian involving b_2^0 , b_2^2 and b_4 terms by means of 3rd order perturbation for the b_2 terms and 1st order perturbation for the b_4 terms. No specific mechanism has been obtained for the line splitting, and the complex temperature dependence of the splitting indicates the possible existence of a number of mechanisms.

THE OPTICAL SPECTRUM OF Co^{2+} IN THE CUBIC CRYSTALLINE FIELD OF CaF_2 , by R. Stahl-Brada and W. Low. July 1958 [23]p. incl. diagrs. tables, refs. (Technical note no. 4) (AFOSR-TN-58-1036) (AF 61-052)59) AD 206485 Unclassified

Also published in Phys. Rev., v. 113: 775-780, Feb. 1, 1959.

The optical spectrum of Co^{2+} in CaF_2 has been analyzed, and absorption bands are found at 3μ , 1.5μ and $550\text{m}\mu$ which show fine structure. In addition there are weak and narrower bands at 19,220, 19,580, 20,450, 21,750, 22,000, 25,750 and intense lines at 44,250, 48,200 cm^{-1} . The spectrum is interpreted to arise from transitions from the orbital singlet to various Stark levels split by spin-orbit interaction, and yields values of $Dq = 340 \pm 10 \text{ cm}^{-1}$, $E(P) = 14,000 \pm 100 \text{ cm}^{-1}$, $E(G) = 16,250 \pm 100 \text{ cm}^{-1}$. The spectrum of Co^{2+} in the eight coordinated cubic symmetry is compared with Co^{2+} in octahedral and tetrahedral symmetry as well as with Cr^{3+} in octahedral symmetry. [ANALYSIS OF RETICULAR AND CORTICAL POST-DISCHARGES FOLLOWING ELECTRICAL RETICULAR STIMULATION] Analyse des post-décharges réticulaires et corticales. Engendrées par des stimulations électriques réticulaires, by A. Hugelin and M. Bonvallet. [1957] [10]p. incl. diagrs. table. (AFOSR-TN-58-540) (AF 61(514)1100) AD 158356; PB 140329 Unclassified

Also published in Jour. Physiol. (Paris), v. 49: 1225-1234, 1957.

Effects of reticular post-discharges: In an animal with an anatomically intact cortex but with its inhibitory cortical system blocked by administration of a dose of chloralose, the reticular post-discharge lasted about 10 times more than in the diencephalic animal. In non-anesthetized animals, the cortical influence which enhances the reticular activity seemed to be concealed by the power of the corticifugal inhibition. The motor effects of the reticular post-discharge were about 100 times shorter in the "encéphale isolé" than in the chloralosed animal. Effects of cortical post-discharge: A cortical servomechanism theory is discussed which describes the reticular net as one functional unit which, when put into action, acts as a whole and produces an output of indifferential ascending and descending impulses. Experiments were conducted to demonstrate that (1) the diffuse inhibitory cortical system has normally a continuous tonic activity which is in opposition to that of the reticular facilitatory system; and (2) the variations of intensity of this inhibitory tonus are directly dependent on the fluctuations of the general excitatory state of the cortex. In spinalized unanesthetized preparations a prebulbar electrical reticular preparation elicited the classical motor facilitation which is controlled at once by an inhibition which brings back the motoneuron excitability to initial level or lower. This inhibition originated in the neocortex. The bilateral and diffuse origin of the inhibition was demonstrated by the unsuccessful attempts to block it by localized cortical coolings. The descending pathways of this inhibition are extrapyramidal. A supra-bulbar transection of the brain stem did not change the cortical inhibitory control of reticular motor facilitation. The simultaneous recording of EEG and the masseter reflex showed that the motor facilitation always coincided with a cortical arousal, and that the cortex-originated inhibition was always secondary to it. In the absence of reticular stimulation the diffuse cortical inhibitory system displayed a permanent activity, the intensity of which was conditioned by the cortical tonus. At sensory rest this corticofugal inhibitory tonus equalized the reticular facilitatory tonus. (ASTIA abstract)

FURTHER INVESTIGATIONS OF THE LAMINAR-TURBULENT TRANSITION IN A FREE JET (ANNULAR NOZZLE), by O. Wehrmann and H. Fabian. Final rept. Dec. 1956, 44p. incl. diagrs. tables, refs. (AFOSR-TR-57-31) (AF 61(514)915) AD 126494 Unclassified

The experimental results and theoretical considerations reported here are a continuation of earlier investigations devoted to the problem of laminar-turbulent transition in a free jet. The fact that consecutive ring vortices and their mutual interaction govern the local transition range in the free boundary of a circular jet, could be substantiated by improved hot-wire techniques. The law, governing the shedding frequency of the ring vortices as function of the Reynolds number, has been inspected closely, and an influence of the nozzle boundary layer had been found. Most emphasis has been laid on the detailed investigation of the vortex structure of the jet boundary. By application of a special calibration method it has been possible to measure the velocity distribution of the vortices numerically and to determine with rather good accuracy the value of a critical vortex Reynolds number which describes the final stage of a vortex before its three dimensional decay. In all these investigations three types of nozzles have been used: rounded nozzles of various diameters, a sharp-edged orifice, and an annular nozzle with a solid core at its center. In all three cases the frequency law and the

transition phenomena show the same characteristics. In the last chapter of this report first stages of a new series of experiments are described. The problem in question is the acoustic control of the transition phenomena. It could be proved that sound waves of low energy cannot only stabilize the vortex shedding but moreover can vary the shedding frequency in a limited range. Some analogies to the well known transition criteria of the first plate boundary layer are pointed out. (Contractor's abstract)

ANALYTICAL AND EXPERIMENTAL INVESTIGATION OF THE FEASIBILITY OF PRODUCING STATIC LIFT BY VORTEX MOTION, by R. M. Lockwood. Technical summary rept. Jan. 14, 1958, 1v. incl. illus. diagrs. refs. (Rept. no. 178) (AFOSR-TR-58-16) (AF 49(638)-171) AD 148115 Unclassified

A broad preliminary investigation has been conducted to determine if it is feasible to create static lift in air with small-scale cyclonic vortex motion. A survey of the literature and a variety of experiments with simple equipment were conducted. On the basis of this work a revised description of the fundamentals of cyclonic vortex motion is made, which also suggests some reasons why this motion occurs. The conclusions are as follows: (1) Cyclonic vortices have been formed between paired suction drains with counterrotating circular flow around them. (2) It should be possible to derive some lift from an arrangement like the preceding one, but magnitudes have not yet been determined. (3) It does not appear to be feasible to induce a cyclonic vortex in air over a single drain which is unenclosed (i.e., completely open to the atmosphere). (4) There is a possibility that half-ring vortices may be created by means of intermittent jets. (5) The passage of the ends of a half-ring vortex across a surface might induce a pressure differential on that surface. (Contractor's abstract)

INVESTIGATION OF THE CORROSIVE COMPONENT OF MECHANICAL WEAR, by R. H. Baskey. Final progress rept. May 1, 1958, 100p. incl. illus. diagrs. tables, refs. (AFOSR-TR-58-73) (AF 18(600)1589) AD 158313; PB 135624 Unclassified

Measurements were made of the corrosive wear on sliding steel surfaces as a function of load, distance of travel, and frequency of rotation past a given area in such a manner that the effects of adhesion and abrasion of the base metal were eliminated. The corrosive wear

HOR.04:001 - HOR.04:003

varied linearly with the distance of the travel. There were loads below 20,000 g/sq cm where the amount of corrosive wear was negligible. Above this figure, the wear varied linearly with the load until the mating surfaces broke completely through the oxide film to initiate a type of fretting corrosion. Up to 75 cm/sec the volume of wear products for steel running against steel, where an oxidized film is formed on each surface, varied closely with the equation $V = k WL \ln([1/f\tau] + 1)$, where k and τ are constants, W is the load, and L is the distance traveled. As the frequency increased, the wear volume increased. Oxidation depended on the time interval, temperature of asperities, oxygen present, and ambient temperatures. The amount of wear depending on corrosive wear decreased due to a decreasing time interval. When rubbing brass against an oxidized iron film frequency had an effect similar to that found for steel against steel. It was not possible to measure the oxidation of Al by knoop impressions because the Al_2O_3

oxide particles erode the soft base Al. Increasing the temperatures from 40° to 200°F gave an increase in the volume of wear up to 72°F, remained constant from 72° to 150°F, and increased up to 200°F.

CRYSTALLOGRAPHIC AND MAGNETOCHEMICAL STUDIES ON ABO_3 GROUP COMPOUNDS OF

LANTHANON AND MANGANESE OXIDES, by R. C. Vickery and A. Klann. Mar. 1, 1957, 7p. incl. tables. (Technical note no. 1) (AFOSR-TN-57-122) (AF 18-(603)96) AD 120477 Unclassified

Also published in Jour. Chem. Phys., v. 27: 1161-1163, Nov. 1957.

The three rare earths studied were Pr, Nd and Dy. A Gouy magnetic balance was used for all magnetic measurements. Samples were formed by firing at both 900°C and 1200°C. The observed susceptibilities were compared with the expected values by addition of the component values. All the products showed an enhanced susceptibility of 55 to 175% above additive component values. The firing of the samples had a greater effect on the Nd systems than the others. The Pr systems showed the greatest increase in susceptibility. From this it is concluded that there is alignment of the magnetic moments not only of the 3-d and 5-d shells but also hybridization of the 4-f electrons of the lanthanon ions. X-ray evidence showed little compound formation at 900°C; but, after two hours treatment at 1200°C, the perovskite pattern could be identified and was apparently stabilized after 20 hr firing.

MAGNETIC SUSCEPTIBILITIES OF ORTHO AND META VANADATES OF NEODYMIUM AND PRASEODYMIUM, by R. C. Vickery and A. Klann. Mar. 1, 1957, 4p. incl. table. (Technical note no. 2) (AFOSR-TN-57-123) (AF 18(603)96) AD 120478 Unclassified

Also published in Jour. Chem. Phys., v. 27: 1219-1220, Dec. 1957.

The ortho vanadates of Nd and Pr were found to have tetragonal unit-cells with $a_0 = 7.30$ A and $c_0 = 6.45$ A. The meta vanadates were found to have cubic perovskite structures with unit-cells of edge length 3.90 A. The Nd vanadates had observed susceptibilities which were the same as the additive values of their components. The Pr vanadates showed a marked increase in their observed susceptibilities. It was concluded that this increase was due to the multivalent character of both the metal ions. In these cases Heisenberg exchange effects are expected to be important.

PREPARATION AND MAGNETIC PROPERTIES OF PYROCHLORE-TYPE TITANATES OF NEODYMIUM AND PRASEODYMIUM, by R. C. Vickery and A. Klann. Mar. 1, 1957, 3p. incl. table. (Technical note no. 3) (AFOSR-TN-57-124) (AF 18(603)96) AD 120479; PB 126935 Unclassified

Also published in Jour. Chem. Phys., v. 27: 1220-1221, Dec. 1957.

The x-ray patterns of $Pr_2Ti_2O_7$ and $Nd_2Ti_2O_7$ confirm

Roth's theory that oxides of the largest A^{3+} ions with tetravalent ions give distorted pyrochlore structures, whereas slightly smaller A^{3+} ions form cubic pyrochlore compounds. X-ray diffraction shows that compounds formed at 900°C are simply oxide mixtures, but compounds formed at 1200°C are pyrochlore structures. Susceptibility measurements also confirm this statement. The ratio of Ti to the lanthanon has little effect on the x-ray properties of the products. However the perovskite lattice can be changed to a pyrochlore lattice by the addition of a lanthanon oxide. The magnetic susceptibility of this pyrochlore system is largest when the ratio is 1 to 2.3. The Pr systems exhibited larger observed susceptibilities than the additive values of their components.

MAGNETIC SUSCEPTIBILITIES OF PRASEODYMIUM AND TERBIUM OXIDES, by R. C. Vickery and A. Ruben. May 1, 1958, 11p. incl. diagrs. tables, refs. (Technical note no. 4) (AFOSR-TN-58-292) (AF 18(603)96) AD 154197; PB 135263 Unclassified

The x-ray powder diffraction patterns at room temperature and the magnetic susceptibilities in a temperature range from liquid nitrogen to 600°K have been measured for the three oxides of praseodymium - Pr_2O_3 ,

Pr_6O_{11} , and PrO_2 - and the three oxides of terbium - Tb_2O_3 , Tb_4O_7 , and Tb_6O_{11} . The measured values of the magnetic moments are in good agreement with theoretical expectations and the Curie-Weiss law up to 300°K. Above this temperature the temperature-susceptibility curve shows a sharp change in slope and would yield considerably lower magnetic moments if extrapolated.

AN UNUSUAL FORM OF NEODYMIUM SILICATE, by R. C. Vickery and R. Sedlacek. [July 1, 1957] 4p. incl. illus. [Technical note no. 1] (AFOSR-TN-57-317) (Also bound as Appendix I with its AFOSR-TR-57-86; AD 136676)(AF 49(638)5) AD 132388 Unclassified

Also published in Research, v. 10: 371-372, Sept. 1957.

An unusual form of neodymium silicate was observed in the preparation of a simple, Pb-based glass. Microscopic examination of undissolved residues of Nd_2O_3 showed that the blobs of oxide acted as foci for the development of rosettes of needle-like crystals. Attempts to isolate these crystals for analysis showed that they were unattacked by warm HF, H_2SO_4 , HCl, HNO_3 , and concentrated alkalis. The resistance to HF attack was such that the surrounding glass matrix could be etched away, leaving the crystals in relief above the etched background. Some spicules of these crystals were shown by qualitative microanalysis to contain only Nd and SiO_2 ; tests for Pb by the dithizone reaction gave negative results. It was not possible to determine crystal angles on the specimens obtained, but they were observed to be anisotropic, extinguishing at 90° under polarized light.

EFFECTS OF LOW CONCENTRATIONS OF RARE

EARTH OXIDES UPON REFRACTIVE INDEX AND DENSITY OF A LEAD GLASS, by R. C. Vickery and R. Sedlacek. July 1, 1957, 10p. incl. diag. tables. (Technical note no. 2) (AFOSR-TN-57-318) (AF 49(638)5) AD 132389 Unclassified

Density and refractive-index observations were made of PbSiO_3 glasses containing relatively low concentrations (0.1 to 2.0%) of rare-earth oxides. The base glass was equivalent to Corning 0120. In general, the density and refractive-index measurements reciprocated each other; a general form of graphical plot is shown. From the plot, a correlation of effect is noted with passage through the rare-earth series in that the inclusion of heavy earths, of ionic size smaller than the light group, produced an initial drop in density and refractive index before increasing values for these parameters. The lighter earths generally increased both density and refractive index. Where ionic size is appropriate, i.e., up to ca. 1.1 Å radius, the ion will insert within the PbSiO_3 lattice.

This, being already strongly polarized, will develop a further deformation and repulsion effect which leads to ionic repulsion and expansion of the lattice to the point of maximum stress before breaking down to form a 3-dimensional polyhedral network that involves the rare earths in silicate structures. The introduction of La into the glass produced density and refractivity data plots analogous to those of the heavy earths, i.e., an initial dip and then an increase; Sc adopted a data plot similar to that of the heavy earths. Within the heavy lanthanon group, a certain sequence in plot may be observed, the nadir shifting to lower concentrations of rare earths as ionic size increases.

RARE EARTHS IN GLASS SYSTEMS, by R. C. Vickery and R. Sedlacek. Technical rept. Oct. 1, 1956-Sept. 30, 1957. Oct. 30, 1957, 1v. incl. illus. diagrs. tables, refs. (AFOSR-TR-57-86) (AF 49(638)5) AD 136676 Unclassified

The effect upon density and refractive index has been studied of the inclusion of low concentrations of rare-earth ions in lead silicate, soda-lime, and phosphate glass matrices. Rare-earth concentrations of up to approximately 2 atomic % have no appreciable effect upon refractive indices, but a significant change is noted in density values. Such changes present particularly noticeable trends in phosphate glasses; these trends are observable also to a certain degree in soda-lime glasses, but less noticeable in lead glasses. It is considered that the variable function of the Pb^{2+} ion obscures the general effect of rare earths in lead silicate glasses; but in soda-lime, and more specifically in phosphate glasses, evidence is highly satisfactory that the lanthanons (La - Lu) function only as network

HOR. 05:004; HOR. 06:001-003

modifiers, but that scandium and yttrium in concentration > 0.2 and 1.0 atomic % function strongly as network formers. This is shown to be in accord with concepts associating glass function with cation electronegativity. Observations are also presented on the formation of a neodymium silicate, resistant to hydrofluoric acid; on shifts and dissection of neodymium and praseodymium absorption spectra in phosphate glasses; and on fluorescence of glasses containing samarium, europium, and ytterbium. ABSORPTION SPECTRA OF RARE EARTHS IN GLASSES, by R. C. Vickery and R. Sedlacek. [1957] 4p. incl. illus. (Bound as Appendix II with its AFOSR-TR-57-86; AD 136676) (AF 49(638)5) AD 136676(a)
Unclassified

Also published in *Nature*, v. 181: 39-40, Jan. 4, 1958.

In initiating research on the effect upon physical properties of rare earths in glasses, the absorption spectra of a phosphate glass (Corning 4600) containing varying concentrations of rare earths have been examined. Contrary to earlier data, dissection and wavelength shift occur for certain neodymium and praseodymium absorption bands while the Pr bands also decrease in intensity. This evidence strongly indicates the existence of complex ions of the type $[\text{Ln}(\text{PO}_4)_x]$ in phosphate environments.

Also published in *Jour. Chem. Soc. (London)*, No. 103: 498-503, Feb. 1959.

The synthesis and some properties of the higher carbides of some rare earths are reported. The reaction investigated is that between rare earth oxides and carbon at high temperatures and under low pressures of argon. Carbide formation proceeds via metal production, and interstitial compounds can exist of rare earth metal held in the carbide lattice. The higher carbides (LnC_2) adopt a tetragonal structure, but scandium differs

from the lanthanons and yttrium in forming only a hexagonal monocarbide (ScC); this is basically attributed to the small size of the scandium ion which sterically per-

mits its association with only one carbon atom. (Contractor's abstract, modified)

The intrinsic paramagnetism of trivalent rare earth ions is shown to be affected only to a minor degree upon carbide formation. Except for samarium and ytterbium carbides, the small negative difference noted between theoretical and observed magnetism is attributed to partial spin coupling or quenching of the orbital angular moments. As carbides, samarium and ytterbium are considered to adopt their bivalent states. Bohr magneton numbers and Curie-Weiss constants are presented for the carbides studied. (Contractor's abstract)

A STUDY OF A FAMILY OF LAVES-TYPE INTER-MEDIATE PHASES, by R. P. Elliott. Final rept. Mar. 15, 1955-May 14, 1956. Jan. 18, 1957, 18p. incl. diagrs. tables. (AFOSR-TR-57-12) (AF 18(600)1399; continued by AF 18(603)130) AD 120421 Unclassified

Paramagnetic susceptibility measurements were made on binary and ternary Laves-type phases of constant atomic proportions of titanium and zirconium. Comparison of the susceptibilities of the binary compounds with the susceptibilities of the component elements indicates that the free electrons of the components are contributed directly to the compound lattice. Measurements of the ternary alloy susceptibilities indicate a nonlinear function with composition. This is indicative of a complex density of states vs energy curve precluding direct calculation of the component valencies. Paramagnetic trends of binary and ternary Laves compounds offer further proof that the free electron valency of the elements of the first transition series decreases as atomic number increases. A NEW METHOD FOR MEASURING INTEGRATED INTENSITIES PHOTOGRAPHICALLY, by L. V. Azaroff. [1957] [5]p. incl. illus. diagrs. [AF 18(600)1168] Unclassified

Published in Acta Crystallographica, v. 10: 413-417, June 10, 1957.

A bent-crystal monochromator is used in conjunction with a conventional Buerger precession camera. Each reflection intensity is recorded on the film as a rectangular spot having nearly constant intensity across the long direction and a narrow plateau across the short direction. The integrated intensity is obtained by direct measurement of the height of this plateau with a densitometer. The use of crystal monochromatized x-radiation permits the recording of the direct beam on the same film and the determination of the absolute value of each intensity. The use of crystal monochromatized x-radiation also permits increased exposure times to detect weak intensities owing to the very low background intensity. The accuracy of this method has been tested with a CaF_2 crystal and the agreement between observed and measured structure factors was better than 2%. (Contractor's abstract)

X-RAY ABSORPTIMETRY IN SYSTEMS OF LIGHT ELEMENTS, by D. Greenberg. Final rept. Dec. 1, 1955-Nov. 30, 1956. Feb. 6, 1957, 30p. incl. illus. diagrs. tables. (AFOSR-TR-57-13) (AF 18(600)1563) AD 120423 Unclassified

A proposed non-destructive quantitative analytical technique for determining the per cent composition of compounds composed of light elements which utilized the properties of the x-ray absorption coefficients of these elements has been investigated. The method involves determining the absorption by the unknown of monochromatic x-rays at several different wavelengths, and the subsequent solution of a series of simultaneous linear equations which yields directly the densities of the elements under consideration in the unknown compound. Detailed descriptions are given of the apparatus used to obtain fairly intense collimated monochromatic x-ray beams by fluorescence excitation, as well as of the x-ray detection system. Data is presented to illustrate the stability and reproducibility of the apparatus, and experimental results are given that support the feasibility and applicability of the method. Suggestions are made whereby the precision of the instrument could be improved in subsequent laboratory prototypes. (Contractor's abstract)

INVESTIGATION OF ELECTROMAGNETIC LAUNCHERS FOR HIGH-SPEED PROJECTILES, by K. W. Miller, R. M. Bergslien and others. Quarterly rept. no. 3, Oct. 1, 1956-Dec. 31, 1956. Jan. 18, 1957, 38p. incl. diagrs. appendices. (AFOSR-TN-57-229) (AF 18(603)56) AD 119535 Unclassified

Work has continued during the past quarter on the phenomena which may be expected to occur in and near the crossbar and under the sliding electric contact type electromagnetic launchers. Skin effect and proximity effect are shown to be appreciable with important but not extremely undesirable results by: increasing resistance voltage drop and losses, decreasing inductance or bar driving force, increasing force of repulsion between rails, causing non-uniform pinch effect, and increasing heating under the sliding electrical contact. This last result is most serious, skin effect surface heat combining with probable local parasitic currents to increase temperature otherwise expected due to friction, contact voltage drop, arcing and other heat producing causes. A long slender crossbar is advantageous and perhaps a longitudinally laminated rail surface

IIT.09:002 - IIT.09:004

may be required to improve operation of the sliding contact. The following appendices are included: Appendix A - Transient Skin, Proximity, Pinch, Repulsion and Temperature Effects in Rails; Appendix B - Diffusion of Electric Current into Rods, Tubes, and Flat Surfaces; and Appendix C - Parasitic Currents at Sliding Contacts.

STUDY OF ELECTROMAGNETIC GUN, by K. W. Miller and R. M. Bergslien. July 1957, 43p. incl. diagrs. (Technical note no. 1) (AFOSR-TN-57-244) (AF 16-603)56) AD 126541 Unclassified

Also published in Proc. Second Hypervelocity and Impact Effect Symposium, Naval Research Lab., Washington, D. C. (May 22-24, 1957), Washington, Naval Research Lab., v. 1: 127-151, Dec. 1957.

A general review is presented of the field of electromagnetic accelerators for high speed projectiles. All three of the basic electromagnetic gun types - Induction solenoid, repulsion coil and parallel rail d-c gun - involve difficult problems which must be resolved. A major problem inherent to all types is that enormous amounts of electric energy are required to accelerate even relatively small masses to hypervelocities. Electromagnetic energy converters in the form of the homopolar generator and inverse electric gun and capacitive and inductive storage devices offer some promise. However, at the present time no conclusion can be made as to the best possible source. Other problems inherent in all gun types are mechanical and aerodynamic friction, skin and proximity effects, large magnetic forces, and definite thermal limitations. The induction and repulsion type guns involve very serious timing problems, while the parallel rail d-c gun involves a complex sliding contact problem. The comparative merits and limitations of the three types of guns require further theoretical and experimental analysis to choose among them. (Contractor's abstract)

ELECTROMAGNETIC ACCELERATION OF HIGH-SPEED PROJECTILES, Aug. 1957, 1p. (AFOSR-TN-57-547) (in its 1957 Annual rept., p. 28) (AF 16(603)56) Unclassified

To study ablation and impact problems associated with high-altitude aircraft and missiles, the Air Force requires means for accelerating pellets to extremely high velocities. The Air Force Office of Scientific Re-

search placed a project with the Foundation to study the application of electromagnetic principles to the design of a high-velocity accelerator. The goal is to achieve velocities in the order of 25,000 to 35,000 ft/sec with pellets of controlled shape, mass, and material. Part of this velocity range is higher than the escape velocity from the earth. Acceleration by electromagnetic means, such as is used in conventional electric motors, may not be subject to as low theoretical limitations as other methods presently used for obtaining high velocities. This project involves theoretical and experimental investigation of the phenomena and limitations associated with high-speed electromagnetic accelerators. A small-scale electromagnetic accelerator is currently being constructed. (Contractor's abstract)

INVESTIGATION OF ELECTROMAGNETIC LAUNCHER FOR HIGH-SPEED PROJECTILES, by J. L. Radnik and A. Bak. Final rept. May 1958, 67p. incl. illus. diagrs. tables. (AFOSR-TR-58-84) (AF 16(603)56) AD 158393; PB 135363 Unclassified

The design and performance characteristics of a parallel rail electromagnetic accelerator were studied to determine the feasibility of the linear motor accelerator as a research tool capable of accelerating small particles to velocities of 25,000 ft/sec and above. The program consisted of a study of the basic electro-mechanical relationships, a study of suitable energy sources, and the design, construction, and evaluation of an experimental accelerator system. More than 100 test projectiles were fired with a 10 ft, two turn experimental accelerator energized by a 12,500 j capacitor bank-transformer arrangement. A maximum muzzle velocity of 1990 ft/sec was attained with a 5.8 g steel-aluminum projectile at a conversion efficiency of 8.5%. The best results were obtained with projectiles having a hard metallic sleeve which partially confined the molten metal at the contact surfaces. From this work it was concluded that the most serious problem in achieving hypervelocities with the parallel rail electromagnetic accelerator is the contact problem. The use of multiple turns and a projectile design which minimizes the arcing losses appear to be the most promising approaches. Inductive and capacitive storage were concluded to be the most suitable energy sources for a parallel rail hypervelocity accelerator installation. (Contractor's abstract)

RADIATION SYNTHESIS OF FLUORINATED AROMATIC COMPOUNDS, by P. Y. Feng and L. Mamula. [1957] 5p. incl. diags. (AFOSR-TN-57-537) (AF 18-(603)121) AD 136523 Unclassified

A series of radiation induced cross-halogenations were observed which are exemplified by these overall reactions: (1) $C_6H_6 + CF_4 \rightarrow C_6H_5CF_3 + HF$ and (2) $C_6H_6 + CF_4 \rightarrow C_6H_5F + CHF$. Other systems studied included C_6H_6 or $C_6H_5CH_3$ irradiated together with γ rays; the liquid portions were then analyzed by means of an IR spectrophotometer. The data indicate the formation of $C_6H_5CF_3$, C_6H_5F , and CHF_3 . The formation of HF was indicated by the attack on the walls of the capsules. Under the conditions of the experiments CF_4 dissolved in benzene according to Henry's law, and the $G(\text{radical})$ values of CF_4 - benzene systems were of the order of 0.7 to 1.1 as determined by the diphenyl picryl hydrazyl method.

THE USE OF POLYMER DEGRADATION REACTIONS IN RADIATION DOSIMETRY (Abstract), by P. Y. Feng. [1957] [1]p. [AF 18(603)121] Unclassified

Presented at meeting of the Amer. Nuclear Soc.,
New York, Oct. 28-31, 1957.

Published in Second Winter meeting of the Amer.
Nuclear Soc. Program and Abstracts, Oct. 29, 1957,
p. 47.

Conventional dosimetry systems employing aqueous solutions of solid materials can be applied to organic systems only after corrections for absorption differences. Moreover, many of the dosimeter systems are applicable only to limited radiation dosage ranges because of their inherent limitations, such as the ferrous sulfate dosimeter, or their intended range, e.g., the ceric sulfate dosimeter. The radiation induced degradation of polymers in solution may be used as a dosimetry system with a wide dosage range and an easy method of measurement. It is shown that radiation dosages over four orders of magnitude can be measured readily with one dosimetry system. Experimental work was performed with polystyrene in halogen containing solvents. The effects of concentration, molecular weight and dosage were studied. The results and a detailed analysis of them are reported.

PREPARATION OF FLUORO-CHEMICALS BY RADIATION INDUCED CROSS-FLUORINATION. Technical rept. Sept. 16, 1956-Sept. 15, 1957. Dec. 2, 1957, 42p. incl. diags. tables, refs. (AFOSR-TN-58-20) [AF 16-(603)121] AD 148089; AD 150616 Unclassified

The radiation behavior of a number of fluorine compounds, including CF_4 , CHF_3 , CF_2Cl_2 , CFC_2Cl , $C_2F_4Cl_2$, C_6H_5F and $C_6H_5CF_3$ in the presence of benzene and other organic compounds was studied. Diphenyl picryl hydrazyl disappearance and polymer degradation experiments showed that the fluorine compounds studied have considerably lower radiation sensitivities than the corresponding chlorine or bromine compounds. Irradiation of solutions of the fluorocarbons in benzene produced aromatic fluorine compounds with a total G value up to approximately 3 in the more favorable cases in spite of the known stability of fluorocarbons toward attack by radicals. On the basis of the radical yield data, it was concluded that free radical reactions cannot be responsible for the formation of all of the fluorinated aromatic compounds. Ion-molecule reactions in the liquid state are suggested as a possible contributing factor to the observed reaction results. (Contractor's abstract)

RADIOLYSIS OF CF_4 - C_6H_6 SYSTEMS, by P. Y. Feng and L. Mamula. [1956] [2]p. incl. diags. (AF 18(603)-121) Unclassified

Published in Jour. Chem. Phys., v. 28: 507-508, Mar. 1958.

Infrared spectra of the radiation induced cross-halogenation in carbon tetrafluoride - benzene systems indicates the presence of $C_6H_5CF_3$, C_6H_5F , and CHF_3 , as well as HF. It is concluded that a free radical induced reaction is not responsible for these products, but perhaps rather an ionic reaction takes place.

RADIATION EFFECT IN ORGANIC FLUORINE COMPOUNDS (Abstract), by P. Y. Feng and L. Mamula. [1958] [2]p. incl. tables. [AF 18(603)121] Unclassified

IIT. 10:006; IIT. 11:001

Presented at Fourth annual meeting of the Amer. Nuclear Soc., Los Angeles, Calif., June 2-5, 1958.

Published in *Trans. Amer. Nuclear Soc.*, v. 1: 39-40, June 1958.

Irradiation of solutions of the simple fluorocarbons, e. g., carbon tetrafluoride in aromatic hydrocarbons, produces metathetical products as exemplified by the reaction $CF_4 + C_6H_6 \rightarrow C_6H_5F + CHF_3$ or

$CF_4 + C_6H_6 \rightarrow C_6H_5CF_3 + HF$. The yields of these metathetical products increase with the CF_4 to C_6H_6

ratio. The highest yield so far corresponds to a $G(C_6H_5CF_3 + C_6H_5F)$ of 3, and was obtained with the CF_4 - C_6H_6 system under approximately four atmospheres CF_4 pressure. Results are given of other systems studied. If the $C_6H_5CF_3$ and C_6H_5F from the irradiation of CF_4 and C_6H_6 was produced by a radical process, only radical combination processes can be responsible for the observed products because CF_4 is inert toward attack by C_6H_5 or H radicals whereas F or CF_3 form either addition or degraded products with C_6H_6 . Using the dpph method, the G (radical) values of a series of fluorine compounds have been determined and are shown in this report. A number of radical combination processes in addition to those leading to $C_6H_5CF_3$ and C_6H_5F formation are possible.

Furthermore, the diphenyl picryl hydraziyl technique gives as a rule the highest radical yields in the literature. On the basis of radical yield data alone, one would expect a maximum $G(C_6H_5F + C_6H_5CF_3)$ value of the order of $\frac{1}{2}PG_r$, where P is the probability of the radical combination reaction leading to the observed product and is of the order of 0.1 (the factor $\frac{1}{2}$ comes from the fact that 2 radicals are needed to form one molecule). Thus the $G(C_6H_5CF_3 + C_6H_5F)$ value

should be of the order of 0.1. The observed rather high value of G must therefore be due to mechanisms other than those of a radical nature, and reaction mechanisms involving ionic species are suggested. Irradiation of solutions of polystyrene in fluorinated liquids results in, among others, degradation of the polymeric material. Comparison of the polymer degradation data in such systems with data from the degradation of polystyrene in CCl_4 , C_6H_6 , etc., shows also that the radiation stability of the fluorine compounds approaches those of the corresponding hydrogen analogs and are much lower than those of the chlorine analogs. In addition, whereas energy transfer occurs readily from C_6H_6 to CCl_4 in CCl_4 - C_6H_6 systems, the transfer of absorbed radiation energy from C_6H_6 to compounds such as C_6H_5F is of only minor importance. Such

differences, as are expected on the basis of energy level consideration, are also confirmed in the experiments.

RADIATION CHEMISTRY OF ORGANIC HALOGEN COMPOUNDS (Abstract), by P. Y. Feng. [1958] [1]p. (AF 18(603)121) Unclassified

Presented at Internat'l. Congress of Radiation Research, Burlington, Vt., Aug. 11-15, 1958.

Published in *Radiation Research*, v. 9: 113, July 1958.

Radiation chemistry of organic halogen compounds is an interesting subject in view of the high radiation sensitivity of the organic chlorine, bromine, and iodine compounds and the relative radiation stability of organic fluorine compounds. In this paper, recent experimental results supplementing publications elsewhere which report work in progress at the Foundation will be described, including diphenylpicrylhydrazyl disappearance, gas yield, polymer degradation, and product analysis. As a rule, it has been found that the radiation stability of fluorinated organic compounds is far greater than that of the other halogenated compounds and compares with that of the corresponding hydrocarbons. The effect of the halogen groups on the radiation behavior of a molecule is found to be usually additive. For mixtures containing the halogenated organic compounds, energy transfer processes are generally feasible, but there are also processes which cannot be adequately explained by radical mechanisms. Such reactions will be described and the possibility of liquid phase ion-molecule reactions will be discussed.

A STUDY OF A FAMILY OF LAVES-TYPE INTERMEDIATE PHASES, by R. P. Elliott. Final technical rept. Feb. 21, 1958, 15p. incl. diagra. (AFOSR-TR-58-49) (AF 18(603)130; continuation of AF 18(600)1399) AD 154199 Unclassified

Ternary alloys between binary Laves-type phases of transition elements have been used to investigate the valencies of the transition elements. Systems containing constant atomic proportions of niobium, tantalum, and hafnium indicate, as had previous systems containing titanium and zirconium, that the valencies of the first transition series decrease continuously with increasing atomic number. On the basis of the previously calculated valencies, values between three and four were calculated

IIT.12:001 - IIT.12:004

for the valencies of niobium, molybdenum, hafnium, tantalum, and tungsten. Limited data indicate that the valencies of the second and third transition series increase and then decrease with increasing atomic number. Generalizations concerning the variation of valency for a given group could not be made. Unreconcilable data indicate that factors other than the free electronic valency are affecting the free energy and hence the miscibility ranges of the ternary Laves phases. (Contractor's abstract)

PHOTOELASTIC STUDY OF STRESS WAVE PROPAGATION IN LARGE PLATES, by J. W. Dally, A. J. Durelli, and W. F. Riley. Nov. 5, 1958, 28p. incl. illus. diags. table. (AFOSR-TN-58-748) (AF 18(603)144) AD 162271; PB 138061 Unclassified

Dynamic photoelastic methods with a low modulus urethane rubber compound as the model material were employed to study wave propagation in large plates. The loading was accomplished by using small package explosives in the form of electrical primers. The charges were placed at the corner and center of one long side of a large rectangular plate. It was found that the photoelastic fringe patterns could in certain cases be related to the dilatational and distortional waves produced by the explosion. The effect of the reflection of the dilatational wave at glancing incidence was to increase the boundary fringe order at the leading edge of the wave by about 50%. The maximum fringe order which moved along an interior line decayed as it propagated away from the point of load application as a function of $r^{-3/2}$. (Contractor's abstract)

A PHOTOELASTIC APPROACH TO TRANSIENT STRESS PROBLEMS EMPLOYING LOW MODULUS MATERIALS, by J. W. Dally, W. F. Riley, and A. J. Durelli. Oct. 1958, 36p. incl. illus. diags. refs. (AFOSR-TN-58-891) (AF 18(603)144) AD 204138; PB 139408 Unclassified

Also published in Jour. Appl. Mech., v. 26: 613-620, Dec. 1959.

An attempt was made to develop a method for studying dynamic stress distributions by using photoelasticity and low-modulus materials. Hysol 8705, a urethane rubber compound, was selected as the most promising low-modulus material. The mechanical and optical properties of Hysol 8705 were studied under static and

dynamic loadings. The modulus of elasticity and the strain fringe value were dependent on the rate of loading. Poisson's ratio and the stress fringe value were independent of the rate of loading for strain rates greater than 8 in./in./sec. The specific energy loss for the material was about 10% for the stress ranges associated with photoelastic determinations. Experimental observations of photoelastic fringe patterns in a rectangular strut subjected to axial impact were made to illustrate the potential of the method. Three different end conditions were imposed on the unloaded end of the strut; (1) a free end normal to the axis, (2) a fixed end normal to the axis, and (3) a free end inclined 45° to the axis. The fringes, in cases where ends were normal to the axis, followed the same law of reflection as the law for stresses given by elementary wave theory. (ASTIA abstract)

STRESS CONCENTRATION FACTORS UNDER DYNAMIC LOADING CONDITIONS, by A. J. Durelli, J. W. Dally, and W. F. Riley. Dec. 1958, 23p. incl. illus. diags. table. (AFOSR-TN-58-892) (AF 18(603)144) AD 204137; PB 139407 Unclassified

Dynamic photoelastic methods, with a low modulus urethane rubber as the model material, were employed to study stress concentrations resulting from geometric discontinuities in rectangular bars subjected to an axial impact. The impact was applied by dropping a weight on one end of the bar, and the dynamic fringe patterns were photographed with both a Fastax camera and a microflash-still camera combination. The results of the investigation showed that the maximum stress in a rectangular bar with a central circular hole occurs at the same minimum section for static or dynamic loading, and the stress concentration factors are the same. Whether the coincidence of the static and dynamic stress concentration factors is a general law remains to be established. It was also established in the investigation that the average velocity of fringe propagation through the region of the discontinuity is the same as the velocity of fringe propagation in a region of the bar far removed from the discontinuity. Thus, a fringe reaches a point after the discontinuity at the precise time it would have reached the point had the discontinuity not been present. (Contractor's abstract)

DEVELOPMENTS IN THE APPLICATION OF THE GRID METHOD TO DYNAMIC PROBLEMS by A. J. Durelli, J. W. Dally, and W. F. Riley. Dec. 1958, 26p.

IIT. 13:001, 002; IIT. 14:001, 002

incl. illus. diags. (AFOSR-TN-58-893) (AF 18(603)
144) AD 204136; PB 137783 Unclassified

Also published in Jour. Appl. Mech., v. 26: 629-634,
Dec. 1959.

The grid method for use in dynamic stress studies is discussed. A rubber-thread grid network in a low modulus model material (a urethane rubber known as Hysol 8705) was used in conjunction with a microflash light source to record grid distortions and photoelastic fringe patterns in a model subjected to dynamic loading conditions. By considering a strut subjected to axial impact it was possible to establish that the static and dynamic values of Poisson's ratio were identical, and the strain fringe value of the material varied with strain rate. In addition, stresses in the axial and transverse directions were determined along the centerline of the strut. Finally, the methods established were applied to the problem of a circular disk subjected to diametrical impact and both principal stresses were determined along a vertical diameter at one instant during impact.

A study has been carried out on the fabrication methods and electrical characteristics of a group of sulfides, selenides, and tellurides. Unsuccessful attempts have been made to fabricate semiconductors from either MoS_2 or NiS because of cracking or high reactivity.

Samples of Sb_2Se_3 , ZnTe , PbTe , and AgTe samples were prepared by melting the constituents in a fused quartz tube in a hydrogen atmosphere. The Sb_2Se_3 sample showed semiconducting properties with an activation energy of 0.82 ev. Hall measurements on a ZnTe sample indicated a carrier density in excess of $5 \times 10^{20}/\text{cc}$ and thus metallic conductivity.

THE RESPONSE OF CRYSTAL PHOSPHORS TO NUCLEAR RADIATION, by L. Reiffel. June 4, 1957, 52p. incl. illus. diags. tables. (Technical note no. 1) (AFOSR-TN-57-313) (AF 49(638)113) AD 132384
Unclassified

The utility of a parameter other than temperature is being investigated for its effect on luminescence behavior of the simple alkali halide phosphors. The effect of pressure on luminescent systems is examined with particular reference to the phosphorescent decay of long-lived traps in Tl-activated NaI. Important parameters of the trapping centers may be obtained by subjecting the phosphor to hydrostatic stress during phosphorescent decay. Increased pressure tends to favor configurational coordinate distances smaller than equilibrium values, while thermoluminescence experiments and other techniques which rest on variations in temperatures carry the system with equal probability to larger and smaller than equilibrium values of configurational coordinates. The critical displacement of I^- from their equilibrium position which allows thermal collapse of a specific trap in NaI (Tl) is +0.19A (an outward displacement). For another trap in the same material, thermal collapse sets in with the ions moved inward by -0.045A. The effect of these displacement values is observed as a change in phosphorescent lifetime under pressure. As a second illustration of the utility of pressure, a type of experiment, termed the pressure break, was devised which is essentially equivalent to experiments where the temperature of the phosphor is changed over large ranges, almost instantaneously. The ability of the phosphor to stand rapid pressure changes permits experiments to be conducted at essentially constant light sum in the crystal. The technique is still in the early stages of development.

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 137, Mar. 27, 1958.

Also published in Proc. Internat'l. Conf. on Solid State Physics in Electronics and Telecommunications, Brussels (Belgium) (June 2-7, 1958), N. Y., Academic Press, v. 4 (Part 2): 697-704, 1960.

Study is made of the effect of pressure on the isothermal phosphorescent decay of thallium-activated alkali halides. Data is included on so-called pressure break experiments which involve rapid changes in pressure such that the light sum in the crystal remains sensibly constant during the pressure change. This method has great advantage when dealing with very long-lived traps where isobaric runs of extraordinary duration would be required. It is shown that first order kinetics may be used to explain both the changes in brightness occasioned by pressure transients and the changes in lifetime produced by static pressurization. The activation volumes required for the one process also fit the data for the other process in the case of NaI(Tl). (Contractor's abstract, modified)

The photochemical and thermal decomposition reactions of methyl mercuric chloride are described. The principal products of the thermal decomposition were methane and benzene with smaller quantities of ethylene and butene. These products suggest that reactions of the type below occur:

- (1) $CH_3HgCl \rightarrow CH_3 + HgCl$
- (2) $CH_3 + CH_3HgCl \rightarrow CH_4 + CH_2HgCl$
- (3) $CH_2HgCl \rightarrow CH_2 + HgCl$

In contrast the photochemical decomposition yields hydrogen, methane, ethane, and propane as the principal products suggesting an entirely different mechanism than the above. Preliminary studies of the photolysis of Al_2Cl_6 vapor are also given.

OBSERVATIONS ON THE MECHANICAL BEHAVIOUR OF HEAT-TREATED STEEL AT HIGH HARDNESS LEVELS, by N. H. Polakowski. [1957] [8]p. incl. diagrs. refs. [AF 18(603)68] Unclassified

Published in Jour. Iron and Steel Inst., v. 185: 67-74, Jan. 1957.

Untempered martensite behaves in many respects like an annealed metal. It has a low elastic limit which can be raised by cyclic stressing; its Meyer index and strain-hardening exponent are high. Despite the high indentation hardness and the internal stresses it contains, fresh martensite work-hardens during plastic deformation although work-softening could have been expected to occur in these conditions. Tempering up to about 300°C causes the strain-hardening properties to decrease progressively and the elastic limit to rise. The impact fracture energy and ductility at sub-zero temperatures fall to a minimum but they can be improved or otherwise altered by prior cold-working at room temperature. Most of these facts cannot be explained or accounted for if the commonly held view of virgin martensite being inherently very hard is accepted as an axiom. However, they all find their natural place in an integrated picture if as-quenched steel is visualized as being relatively soft but capable

of rapid work-hardening when deformed. Tempering below 300°C is assumed to produce a hardening effect roughly similar to that of cold-working. A working hypothesis is developed in the paper based on the above premise and incorporating a Cottrell type mechanism involving locking of dislocations by migration of solute carbon atoms. This is then applied to account for various peculiar aspects of the mechanical behaviour of hardened and tempered steel. (Contractor's abstract)

LATTICE DEFECTS IN GERMANIUM AND SILICON AND THEIR EFFECT ON ELECTRICAL PROPERTIES, by P. L. Copeland, J. R. Madigan, and L. J. Fiegel. [Technical rept. no. 2, July 1, 1955- Oct. 1, 1956] Feb. 15, 1957. (AFOSR-TN-57-78) (AF 18(600)643) AD 120422 Unclassified

The equilibrium barrier height of a p-n junction rectifier was measured as a function of temperature from 77° to 373°K . The barrier height was determined by observing the saturation of the open circuit junction decay voltage with increasing forward bias. The height of the barrier at a given temperature is equal to the original difference in Fermi levels in the isolated n- and p-regions of the diode. At low temperatures it should, therefore, approach the energy gap and should tend to zero at high temperatures as both regions approach intrinsic material. Measurements on silicon alloy junction diodes are in general agreement with this predicted behavior and because of the heavy doping of the emitter essentially describe the behavior of the Fermi level in the base region.

FUNDAMENTAL PROCESSES OF FRICTIONAL WEAR IN ALKALI HALIDE CRYSTALS, by P. L. Copeland and E. Zwicker. Oct. 1957, 78p. incl. illu. diagrs. refs. (AFOSR-TR-57-85) (AF 18(600)643) AD 136675 Unclassified

Friction and wear between single crystals of lithium fluoride was extensively investigated. The mechanism proposed by Bowden and Tabor to explain the features of metallic friction was found to apply also to friction in lithium fluoride. This mechanism was particularly successful when applied to explain the characteristics of the special fractures of triangular shape named "deitas" which were formed in (100) surfaces. The presence or absence of a dislocation layer in the surface of lithium fluoride was found to affect the character of the deitas. The roughness of the surfaces also had an effect on the

IIT. 06:005; IIT. 07:002;
ISG. 01:002

deltas. The alkali halides LiF, NaCl, KCl and KBr were compared in friction and wear, and a significant trend was found in the wear features which appeared to show dependence on cohesive energies and ion sizes of the crystals. Electropolished copper single crystals in friction with silicon and brass displayed a peculiar dependence of coefficient of friction on load. No wear was detected in the case of copper on silicon. Electropolished single crystals of copper and nickel on polycrystalline zinc behaved as might be expected, showing a small but steady decrease in coefficient of friction with load which is often observed in a wearing in process. FRICITION AND WEAR IN LITHIUM FLUORIDE
(Abstract), by E. Zwicker and P. L. Copeland. [1958]
[1]p. [AF 18(600)643] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago
U., Ill., Nov. 28-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3:
359, Nov. 28, 1958.

The nature of friction and wear between single crystals of lithium fluoride was extensively investigated. The general mechanism proposed by Bowden and Tabor to explain metallic friction is equally applicable to lithium fluoride, and explains the unique triangular shaped "deltas" formed in the (100) surfaces by controlled sliding friction between single crystals. The previous treatment of the crystals, particularly the presence or absence of a layer of dislocations in the surface, affects the shape and depth of the deltas. Using the techniques of Gilman and Johnston to develop etch pits, it was possible to observe the array of dislocations produced by friction, especially in the region of a delta.

AROMATIC FLUORINE COMPOUNDS BY KF FLUORINATION (Abstract), by G. C. Finger, C. W. Kruse and others. [1957] [1]p. [AF 18(600)985] Unclassified

Presented at meeting of the Sixteenth Internat'l.
Congress of Pure and Appl. Chem., Paris (France),
July 18-24, 1957.

Published in Résumés des Communications, v. 2: 303,
July 1957.

Replacement of aromatic -Cl and -NO₂ groups by -F in activated aryl halides with KF was reported by Finger and Kruse. The present paper discusses recent research and conclusions. Examples of nitroaryl halides studied in dimethylformamide (DMF) and dimethyl sulfoxide (DMSO) are: 3-fluoro-4-chloro-, 2,3- and 2,5-dichloro-, 3-fluoro-2,4-dichloro-nitrobenzenes. All showed -Cl replacement in the 2 and 4 positions. The isolation of a small amount of 2,3-dichlorofluorobenzene in the second example indicated -NO₂ replacement by -F. 2,5-Dichloronitrobenzene gave both 2,5-dichlorofluorobenzene and 5-chloro-1,2-difluorobenzene as by-products. 1,3-Difluoro-4,6-dinitrobenzene was obtained quantitatively by heating at steam bath temperature the chloro analog with KF in DMF. Activation by the -CN group in 2-chlorobenzonitrile is very slight; a trace of 2-fluorobenzonitrile was formed and identified as 2-fluorobenzoic acid. The reactivity of polychlorobenzenes to KF was examined. Preliminary results indicate that

ILL.02:004 - ILL.02:007

the 1,2,3,5-tetrachloro-, pentachloro-, and hexachlorobenzenes show considerable lability of certain chlorine atoms. Hexachlorobenzene gave 2,4,6-trichloro-1,3,5-trifluorobenzene. As in the case of 1,2,3-trifluorobenzene, the KF method made possible the synthesis of 1,2,3,4-tetrafluorobenzene, b. p. $93.5-94^\circ$, n_D^{20} 1.4069.

Presented at Fifty-ninth annual meeting of the Amer. Ceram. Soc., Dallas, Tex., May 6, 1957.

Also published in Jour. Amer. Ceram. Soc., v. 42: 146-150, Mar. 1, 1959.

The resistance to thermal fracture exhibited by ceramic coatings applied to iron was studied in the unsteady state. Physical properties and residual stresses in the coated systems were related to thermal shock resistance. Coating failure was observed to occur when a critical shock temperature differential was exceeded and the stresses necessary to induce fracture were identified by the thermal and residual stresses developed. Theoretical analysis based on flat plate specimens and experimental results were in close agreement. (Contractor's abstract)

THE EFFECT OF PRE-STRESSING ON THE STRENGTH OF CERAMIC COATINGS, by J. H. Lauchner, D. G. Bennett and others. Sept. 1957, 30p. incl. diagrs. tables, refs. (Rept. no. 79) (AFOSR-TN-57-768) (AF 18(603)28) AD 136758
Unclassified

Abstract published in Jour. Amer. Ceram. Soc., v. 42: 4h, Jan. 1, 1959.

The brittle quality of ceramic coatings has been recognized for years, but only limited quantitative information is available on the maximum strain which coatings will withstand without fracture. This study was undertaken to evaluate the effect of residual coating strain on the fracture resistance of a coating under statically induced strains. Ceramic coatings were applied to sheet iron strips and the residual strains developed as a result of thermal treatment were calculated. The coated-metal strips were statically loaded to induce axial tension,

buckling or torsion. Coating strain was measured by means of SR-4 strain gages or calculated from optical measurements of the maximum deflection in buckling. Coating fracture was indicated by an electrified particle technique and the coating strength resolved into terms of residual and mechanically induced strains. Coatings were observed to fracture when strained approximately $1,000 \times 10^{-6}$ in./in. in tension. Compression failure occurred when strains of $10,000^{-6}$ in./in. were exceeded. The maximum strain which could be induced into the coating without fracture appeared to be the algebraic sum of residual strain and the critical strain at which fracture occurred. THE EFFECT OF SINGLE OXIDE ADDITIONS ON THE DEVITRIFICATION TENDENCIES OF A BARIUM-BORO-SILICATE CERAMIC COATING GLASS, by R. R. Reschetz, W. R. Bratschun and others. Sept. 1957, 27p. incl. illus. tables. (Rept. no. 80) (AFOSR-TN-58-251) (AF 18(603)28) AD 154154; PB 133961
Unclassified

The effect of single oxide additions of ceria, titania, ceria, bismuth oxide and zinc oxide on the devitrification tendencies of a barium-boro-silicate glass was investigated. Coated specimens on type 347 stainless steel were examined by x-ray diffraction after exposures at 871°C for times up to 150 hr. All of the additions studied delayed to some extent the initial appearance of the devitrification products as compared to the base glass. All coatings of the ceria and zinc oxide series plus those compositions with smaller molar additions of TiO_2 and Bi_2O_3 appeared to retain their continuity and dimensional stability after 150 hr of heating at 871°C . Of these, the coating with 1.50 mol of ceria appeared to be the best. This coating, as well as the coating with 2.00 mol of ZnO , exhibited the least crystalline change over the 150 hr of heat treatment at 871°C . Powder patterns on selected coating samples revealed the existence of preferred orientation and selective crystallization at or near the coating surfaces. Although certain coatings exhibited considerable crystalline activity, they still retained continuity and stability characteristics.

SOME STUDIES OF THE INTERACTION OF COBALT AND NICKEL WITH TITANIUM DIBORIDE, by T. A. Willmore and D. G. Bennett. Apr. 1958, 44p. incl. illus. tables. (Rept. no. 81) (AFOSR-TN-58-515) (AF 18(603)28) AD 158326
Unclassified

When combinations of cobalt and titanium diboride are heated in the temperature range of 1600° to 2750°F, chemical reaction occurs to produce titanium monoboride and cobalt boride. The observed tendency for cobalt and titanium diboride to persist is interpreted as a function of the ratios of these reacting constituents. Melting was detectable at temperatures as low as 2000°F and, for compacts containing 95 wt-% cobalt - 5 wt-% titanium diboride, melting was essentially complete at approximately 200°F below the melting point of cobalt. Due to the number of phases formed the mechanism of melting is probably not a simple process. It was established that boron is essential to produce low melting effects by substituting titanium for titanium diboride on a titanium-equivalent basis. Compacts of nickel and titanium diboride yielded results which closely paralleled those obtained with cobalt and titanium diboride. Their melting characteristics, however, indicated that the slope of the liquidus is probably less steep than in the cobalt system. In both systems, a prevalent tendency for melt and solid fractions to separate makes it difficult to maintain homogeneous samples. Hence, equilibrium is difficult to establish.

STUDIES OF THE STABILITY OF HIGH TEMPERATURE RESISTANT CERAMIC COATING GLASSES, by W. R. Bratschun, C. N. Williams, and D. G. Bennett. July 1958, 33p. incl. illus. diagrs. tables. (Rept. no. 82) (AFOSR-TN-58-828) (AF 18(603)28) AD 202913 Unclassified

X-ray diffraction analysis of a series of glass-metal composite specimens heat treated up to 200 hr at 870°C revealed 2 types of glass devitrification behavior: (1) the cyclic development, disappearance, and reappearance of various diffraction peaks, indicating considerable crystalline activity, and (2) for certain glasses the early development of diffraction peaks which persisted throughout the 200-hr heat treatment. An equilibrium between the devitrification products and the residual glass was indicated in the second type of behavior. A complex coating glass composed of a simple barium borosilicate with additions of 5 oxides, CaO, ZnO, TiO₂, Bi₂O₃ and CeO₂, was found to devitrify slower but to form the same crystalline products as the simple glass. Single additions of these oxides to the simple glass delayed the initial appearance of devitrification products. CaO, ZnO, Bi₂O₃, and TiO₂ additions went into solution during smelting and later apparently took part in the devitrification process by forming compounds with BaO, B₂O₃, and/or SiO₂. CeO₂ additions went into solution during smelting, but crystalline ceria precipitated during firing and remained as a separate phase during subsequent heat treatment.

FATIGUE AND INTERNAL STRESS ANALYSIS OF CERAMIC COATED METAL COMPOSITES, by J. H. Lauchner and D. G. Bennett. Sept. 1958, 32p. incl. diagrs. tables, refs. (Rept. no. 83) (AFOSR-TR-58-129) (AF 18(603)28) AD 203494 Unclassified

Ceramic coated metal composites were studied in regard to their behavior under mechanically and thermally induced stresses. Residual coated metal system stresses were measured as a function of temperature and integrated with analysis of thermal shock, static and repeated loadings. Coating metal interfacial structure considerations indicate a saturation of the glassy phase by oxides of the base metal accompanied by the presence of residual strain gradients essentially within the interfacial zone. Theoretical analysis of flat plate coated metal composites was found to be in close agreement with experimental results obtained from annealed coated metal specimens in the absence of viscous or plastic flow. Cobalt bearing vitreous ceramic coatings were observed to fracture when strained approximately 1,000 micro in./in. in tension or 10,000 micro in./in. in compression under room conditions and finite straining periods. The maximum induced strain (thermal or mechanical) which cobalt bearing ceramic coatings could withstand without fracture was found to be a function of residual stress.

SOME STRUCTURE AND PROPERTY STUDIES OF RADIATION REFLECTIVE CERAMIC COATINGS, by E. Johnson, H. G. Lefort, and D. G. Bennett. Sept. 1958, 46p. incl. illus. diagrs. tables. (Rept. no. 84) (AFOSR-TR-58-138) (AF 18(603)28) AD 204555 Unclassified

The objective of the work described was to study and record the chemical behavior of various radiation reflective crystallites in different types of matrix glass, all under controlled heat treatments. It was necessary to confine the scope of the investigation to a study of the behavior of crystalline CeO₂ in two types of matrix glass, one alkali and alumina rich and the other alkali and alumina free, plus a limited study of the chemical behavior of stabilized zirconia in matrix glasses of simple barium-boro-silicate type. The results obtained with zirconia are reported in the Appendix. After laboratory techniques had been suitably resolved, significant measurements were made by x-ray and radiant energy emissivity methods. It was found that the alkali and alumina bearing matrix glass showed a greater devitrification tendency than the alumina and

ILL. 02:011; ILL. 03:002-004

alkali free glass; increasing amounts of CeO_2 correspondingly tend to reduce the devitrification tendencies in the alumina and alkali bearing glass; cerium oxide is more stable in an environment free of alkali and alumina than in one containing them; increasing amounts of CeO_2 correspondingly tend to increase the suppression, or reflectance of radiant energy; and with increased heating time (at 76°C) the coatings consisting of CeO_2 in an alkali and alumina rich matrix glass lose their radiation suppressive properties much more rapidly than do the coatings consisting of CeO_2 in an alumina and alkali free matrix glass.

THE EFFECT OF RESIDUAL STRESS ON THE FATIGUE STRENGTH OF CERAMIC COATING-METAL COMPOSITES (Abstract), by J. H. Lauchner and D. G. Bennett. [1958] [1]p. [AF 18(603)28] Unclassified

Presented at Sixtieth annual meeting of the Amer. Ceram. Soc., Pittsburgh, Pa., Apr. 29, 1958.

Published in Bull. Amer. Ceram. Soc., v. 37: Program, p. 39, Apr. 29, 1958.

Flat plate fatigue studies of ceramic coating-metal composites were carried out in conjunction with elastic studies of the composites. Calculated residual system stresses were correlated with experimental fatigue data and theoretical analysis of internal strains produced by repeated loading. A relation between fatigue strength and residual stresses was observed for repeated loading below the elastic limit of the coatings.

Preparation is reported of $\text{NdCl}_3 \cdot 4\text{C}_2\text{H}_5\text{OH}$,

$\text{NdCl}_3 \cdot 3\text{C}_2\text{H}_5\text{OH}$, $\text{NdCl}_3 \cdot 3\text{n-C}_3\text{H}_7\text{OH}$, and $\text{NdCl}_3 \cdot 3\text{n-C}_4\text{H}_9\text{OH}$. The absorption spectrum of NdCl_3

in methanol, ethanol, n-propanol, and n-butanol alcohols was varied. Conductivity studies on NdCl_3 in these alcohols indicated that this salt is a weak electrolyte in methanol and ethanol and becomes progressively weaker in n-propanol and n-butanol. Attempts to electrodeposit Nd metal from these solutions were unsuccessful. Dimethylformamide (DMF) was unsatisfactory as a solvent from which to deposit rare earth metals. However, electrolyses of Sm (III), Eu (III), Gd, and Th chlorides gave nothing but intense red-brown solvent reduction products. $\text{ThCl}_4 \cdot 4\text{DMF}$, $\text{NdBr}_3 \cdot 8\text{DMF}$ and $\text{SrCl}_2 \cdot 3\text{DMF}$ were prepared. Conductance and electrolysis studies on SrCl_2 in DMF indicated that this salt is a weak electrolyte. Electrolyses using various metal electrodes resulted in deposition of an amorphous Sr-containing material; electrolysis using a Hg cathode gave Sr amalgam. Eu (II) chloride is only slightly soluble in DMF; almost insoluble in tetrahydrofuran, ethanol, and acetonitrile; and soluble in ethanolamine. Spectra of Sm (III) and Eu (II) chlorides in DMF and of Eu (II) chloride in acetonitrile were recorded.

The reaction La_2O_3 with HBr at elevated temperatures to produce anhydrous LaBr_3 was investigated as a

ILL.16:001 - ILL.16:003

method of preparing other rare-earth bromides. Br gas introduced into the reaction with the HBr flow was essential for complete reaction. The preparation of bromides by the reaction of HBr with anhydrous rare earth benzoates was also investigated. X-ray diffraction patterns of the bromides were of 3 types: La and Pr bromides were isomorphous, as were Nd and Sm bromides; GdBr₃ exhibited a third, unidentified structure type. The bromides are moderately soluble in pyridine and slightly soluble in acetonitrile. Crystalline solvated rare earth bromide phases were formed in both solvents during solubility studies. The acetonitrile addition compounds corresponded to the formula LnBr₃·xCH₃CN where x is 3 for La, Nd and Gd; 4 for Sm; and 5 for Pr. The rare earth bromides were found to be weak electrolytes in both acetonitrile and pyridine. The absorption spectra of Nd and Pr bromides in acetonitrile and pyridine, as compared with those in aqueous solutions, showed slight shifts in wavelengths of absorption bands, changes in intensities, and, in the case of Nd, resolution of various bands. Electrolyses of rare earth bromides in pyridine and acetonitrile indicated an increase of rare earth metal ion content of the anolyte.

DIRECT TITRATION OF HYDROCHLORIC-SULFURIC AND NITRIC-SULFURIC ACID MIXTURES IN ACETONE SOLVENT. AUTOMATIC DERIVATIVE POTENTIOMETRIC OR SPECTROPHOTOMETRIC END POINT DETECTION, by H. V. Malmstadt and D. A. Vassallo. [1959] [5]p. incl. diagrs. tables, refs. (AFOSR-TN-58-75) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)137 and Standard Oil of Indiana) AD 148123 Unclassified

Also published in *Anal. Chem.*, v. 31: 206-210, Feb. 1959.

Accurate automatic methods are described for direct titration of nitric-sulfuric and hydrochloric-sulfuric acid mixtures. Using tri-n-butylmethylammonium hydroxide as titrant and acetone as solvent the proton from either hydrochloric acid or nitric acid is titrated together with the first proton from sulfuric acid to give one end point. The second proton from sulfuric acid is titrated to another end point. Both endpoints are sharp and can be determined successively with equal precision by either automatic derivative potentiometric, automatic derivative spectrophotometric, or manual visual detection. The end point reproducibilities are about 0.01 ml and a relative precision of 0.2% is realized, if a total volume of about 5 ml is involved in each calculation. Solvent and titrant considerations and characteristics of the end point detection systems are discussed. (Contractor's abstract)

THE ABSORPTION OF DIETARY CHOLESTEROL IN MAN (Abstract), by T.-M. Lin, E. Karvinen, and A. C. Ivy. [1956] [1]p. [AF 18(606)1580] **Unclassified**

Presented at meeting of the Amer. Physiol. Soc., Atlantic City, N. J., Apr. 18-20, 1956.

Published in *Fed. Proc.*, v. 15: 120, Mar. 1956.

A study has been made of the extent of the fecal elimination of sterols by nine young healthy subjects when fed a basal relatively low fat and low cholesterol diet to which increasing amounts of cholesterol were added weekly following a control period. The basal diet for the period of one week provided approximately 20 g of fat, 120 g of protein and 490 g of carbohydrates daily. It was adequate in regard to vitamins, bulk, and minerals. The daily menu yielded approximately 2600 cal on the average. Feces were collected from the fourth to seventh day of each dietary period. The serum cholesterol was determined on the seventh day. The mean daily sterol elimination on the low fat and low cholesterol basal diet was 908 mg. The maximum individual cholesterol absorption amounted to 2.8 g. The blood cholesterol was slightly increased when more cholesterol was added in the diet, but the increase was not statistically significant (basal, 185 ± 60 mg% and the highest cholesterol diet, 222 ± 74 mg% of cholesterol).

CAPACITY OF HUMAN INTESTINE TO ABSORB EXOGENOUS CHOLESTEROL, by E. Karvinen, T.-M. Lin, and A. C. Ivy. [1957] [14]p. incl. tables, refs. (AFOSR-TN-57-213) (AF 18(600)1580) AD 126511 **Unclassified**

Also published in *Jour. Appl. Physiol.*, v. 11: 143-147, Sept. 1957.

The capacity of the human intestine to absorb cholesterol when added in increasing amounts to a basal diet containing approximately 10 g of animal and 10 g of vegetable fat, 380 mg of cholesterol, and 300 mg of phytosterols per day was studied in 16 healthy subjects. Cholesterol was added to this diet for a period of one week in the amounts of 1, 3, 6 and 9 g/day mixed with 17 g of margarine made from hydrogenated soya and cottonseed oil. The average intestinal capacity of the subjects to absorb cholesterol was 2.0 g/day. A maximum capacity of 2.9 g was observed in two different subjects during 19 tests on 16 subjects at the 6 g level of intake. The maximum observed on the 9 g level in 8 subjects was 2.5 g/day. An increase in the margarine intake from approximately 17 g to 40 g/day (total fat from 33 to 50 g/day) did not increase the amounts of cholesterol absorbed. Under the conditions of this study the average maximal intestinal capacity to absorb cholesterol is of the same order of magnitude as the estimated hepatic synthesis of cholesterol. SOME PARAMETERS OF STEROL METABOLISM IN MAN ON A STEROL- AND FAT-FREE DIET, by A. C. Ivy, E. Karvinen and others. [1957] [10]p. incl. tables, refs. (AFOSR-TN-57-214) (AF 18(600)1580) AD 126512 **Unclassified**

Also published in *Jour. Appl. Physiol.*, v. 11: 1-7, July 1957.

The average daily fecal elimination of digitonin precipitable sterol in 11 subjects on a fat- and sterol-free synthetic diet was 421 mg ± 222 mg/day (standard deviation) with 95% confidence limits of 272 mg and 570 mg/day. When expressed in relation to body weight the mean was 5.8 mg/kg/day with 95% confidence limits of 4.4 and 7.2 mg/kg/day. For the 7 males the figure was 6.4 mg/kg/day and for the 4 females 4.5 mg/kg/day. The difference between sexes was not statistically significant. On applying the depletion theory, the average total daily size of the intestinal endogenous sterol pool was calculated as 1400 ± 740 mg/day on zero lipid intake. Of the 1400 mg, 380 mg was reabsorbed or was

ILL. 17:004-006; ILL. 05:004

Involved in the enterohepatic circulation of sterol. The total capacity of the intestine to absorb cholesterol on a low fat diet was 2 g/day of dietary or exogenous cholesterol plus 0.98 g/day of endogenous sterol, or 2.98 g/day. The average total daily synthesis of cholesterol by the body was calculated to be 2100 mg, the amount catabolized being 1680 mg. Assuming that 87% of the cholesterol metabolized is converted to bile acid, then 1460 mg/day of cholesterol is converted to bile acid. The various parameters were calculated for a man weighing 70 kg and the confidence limits of the estimates are given. (Contractor's abstract)

Two new methods were used in the estimation of the endogenous intestinal sterol pool. A procedure called the "depletor method" which measures exclusively the quantity of cholesterol actually available for absorption yielded 17 mg/day/100 g rat for the size of the total intestinal pool of endogenous cholesterol. Another procedure called the "balance method" by which the entire amount of cholesterol excreted in the feces is measured gave a value of 15 mg/day/100 g rat. Both methods are discussed and compared with the radioactive cholesterol method.

CHOLESTEROL METABOLISM. THE EFFECT OF PALMITIC AND STEARIC ACID AND OF NICOTINIC ACID ON THE DEVELOPMENT OF EXPERIMENTAL ATHEROSCLEROSIS IN THE CHICK, by A. C. Ivy, E. Karvinen, and T.-M. Lin. Final rept. Oct. 1, 1955-Sept. 30, 1956. Apr. 1, 1957 [19]p. incl. tables. (AFOSR-TR-57-30) (AF 18(600)1580) AD 126468 Unclassified

Also published in Jour. Appl. Physiol., v. 11: 8-11, July 1957.

This study was undertaken because it had previously been found that palmitic and stearic acid, when fed as the sole source of lipid in the diet, markedly decreased the absorption of dietary cholesterol in the rat. This was apparently due to the poor utilization of these fatty acids by the rat. In the present experiment, it was observed that palmitic acid and nicotinic acid ameliorated experimental atherosclerosis in the chicken caused by the feeding of cholesterol. Stearic acid, however, had no significant effect on the atherosclerosis.

This study on human subjects was made because it had been found in rats that stearic and palmitic acid were poorly utilized and impaired the intestinal absorption of cholesterol. Fifteen young healthy adult humans were fed a basal diet containing 20 g of fat (10 g vegetable and 10 g of animal), 120 g of protein, and 490 g of carbohydrate daily. The fecal excretion of cholesterol and total lipid was determined during the last 3 days of eight 7-day dietary periods. Nine subjects consumed the basal diet (BD) for one week, then the BD plus 30 g/day of palmitic acid, then the BD plus one egg/day (300 mg of cholesterol), then the BD plus one egg plus 30 g of palmitic acid. Six subjects followed the same routine, except that 30 g of stearic acid replaced the palmitic acid and 3 g of cholesterol were fed instead of egg. The absorption of the endogenous and the dietary cholesterol was not influenced significantly by either fatty acid. The palmitic and the stearic acid were utilized by the human subjects to the extent of 55% and 21%, respectively. Comparison is made between the results of this study and similar observations made on the rat.

FIXED POINTS AND OTHER SPECIAL POINTS AND POINT SETS UNDER MAPPING, by D. G. Bourgin [1958], 49p. incl. refs. (AFOSR-TR-58-146) (AF 18(603)32) AD 205093; PB 139606 Unclassified

Discussions on a variety of problems connected with mappings are presented. A general theorem on a common image point for a special mapping of a space admitting 2 periodic homeomorphisms is discussed. Several considerable generalizations of the results of the theorem of Bagemihl (Fund. Math., v. 40: 3-12, 1953) are obtained, and a more direct argument is given pivoting on index theorems. Based on separation arguments for manifolds, it has been established that under deformation of circles, various special point pairs move along the continua. At some stage of the deformation of an n sphere, its intersection with a fixed sphere must contain n orthogonal n tuples of antipodal point pairs and the mapping of such an n tuple. Proof of a lemma on putative carriers of certain cycles on a torus, which is applicable to other types of manifolds, is presented and is used to give results on a

CONDITIONAL BROWNIAN MOTION AND THE BOUNDARY LIMITS OF HARMONIC FUNCTIONS, by J. L. Doob. Oct. 31, 1957, 40p. incl. refs. (AFOSR-TN-57-625) (AF 18(603)11) AD 136728 Unclassified

Also published in Bull. Soc. Math. de France, v. 85: 431-458, 1957.

Functions and stochastic processes on a Green space R are discussed as defined by Brelot and Choquet, except that the dimensionality 2 is not made exceptional (so that Riemann surfaces are excluded) and that points at infinity are excluded. A general situation is studied for a procedure of revitalizing generalized harmonic function which is discussed for its implications in the study of the Dirichlet problem by probability methods. Conditional Brownian motion processes are studied and the concept of Naim's fine limit at a point of R' is analyzed. A variation of Fatou's boundary value theorem is proved for a probabilistic interpretation.

PROBABILITY THEORY AND THE FIRST BOUNDARY VALUE PROBLEM, by J. L. Doob. Oct. 31, 1957, 29p. (AFOSR-TN-57-627) [AF 18(603)11] AD 136729 Unclassified

Also published in Illinois Jour. Math., v. 2: 19-36, Mar. 1958.

The place of the relativized first boundary problem for a class of regular functions, used in studies of harmonic functions on a Green space, is discussed. Boundary limit properties of extremal and minimal regular functions are obtained. A characterization in probability terms of upper and lower first boundary value problem solutions is obtained which makes possible the resolutive functions. The characterization implies that if the domain of the functions has a compact

closure in the defining space, every continuous boundary function is resolutive.

THE NONSATURABILITY OF THE STRAIN FIELD OF A DISLOCATION BY POINT IMPERFECTIONS, by R. Thomson. July 15, 1957, 18p. (Rept. no. MEDUI-19-AF) (AFOSR-TN-57-266) (AF 18(600)1311) AD 126565 Unclassified

Also published in Acta Metallurgica, v. 6: 23-28, Jan. 1958.

It is shown that a dislocation strain field is not saturated by point imperfections when the dislocation dilatation is exhausted. Elastic saturation effects are possible due to the direct elastic interaction between the point imperfections, but are probably rare. The saturation problem is equivalent to the problem of nucleation of precipitates, and thus should be discussed in terms of the short range non-linear and electronic forces between the imperfections.

THE MECHANICAL PROPERTIES OF METALS AT LOW TEMPERATURES, by H. M. Rosenberg. Oct. 15, 1957, 31p. incl. tables, refs. (Rept. no. MEDUI-20-AF) (AFOSR-TN-57-666) (AF 18(600)1311 and AF 18(603)22) AD 136655 Unclassified

Also published in Metallurgical Rev., v. 3: 357-379, 1958. (Title varies)

Results are presented of a review of the literature on the mechanical properties of metals at low temperatures. The strength is usually enhanced rather than impaired down to the temperature of liquid He, 4.2°K, and it is only in a few metals that brittleness sets in. Elasticity, creep, fatigue, and internal friction are also considered. Experiments show that there is usually a slight increase (about 10%) in the elastic constants between room temperature and 4.2°K, and most of this occurs above 90°K. Most low temperature experiments have utilized ultrasonic techniques; either the resonant frequency or the transit of high frequency pulses through the specimen are measured. With few exceptions the tensile strength of all face centered cubic and hexagonal metals increases quite considerably below room temperature and even below 20°K. The tensile strength of Al increases about 4 times between room temperature and 4.2°K and that of most of the other metals is doubled. For metals in which a decrease in temperature produced a large change in the tensile strength, there was a correspondingly large change in the fatigue strength.

Published in Jour. Appl. Phys., v. 28: 532-541, May 1957.

A simplified method of calculating the crystallographic features of a diffusionless (martensitic) phase change is described and applied to the gold-cadmium alloy cubic-

orthorhombic transformation. Use of the method requires a knowledge of the initial and final crystal structures and the specification of the crystallographic plane and direction of the inhomogeneous shear. It is based on the requirement that after partial transformation the interface between two phase be free from stress on a macroscopic scale. The method involves representing on a stereographic net (a) the loci of directions in the original phase unchanged in length by the structure per se and (b) the loci of directions unchanged in length by the inhomogeneous shear. The intersection of these loci determine possible undistorted interface planes. Excellent agreement with experimental observations is found when the method is applied to the cubic-orthorhombic transformation in gold-cadmium alloys. (Contractor's abstract)

Presented at meeting of the Fourth Congress of the Internat'l. Union of Crystallography, Montreal, Canada, July 1957. (Title varies)

Also published in Acta Metallurgica, v. 6: 680-693, Nov. 1958.

A simple graphical method is presented for determining directly from observations of the crystallographic features of a martensitic transformation, the inhomogeneous deformation which is part of the total transformation distortion. The method involves reversing the usual solution of the problem from the crystallographic data to a prediction of the transformation mechanism and determines uniquely that pattern of inhomogeneity which could produce that particular set of crystallographic features. The technique is a more elegant and much shorter version of the previous graphical formulation of the Wechsler-Lieberman-Read theory of martensitic transformations. The correctness and utility of the theory is substantiated, and the inverse method is applied to the f.c.c. to b.c.t. austenite-martensite transformation in an Fe-Ni-C alloy for which accurate data are available.

A theory of dislocation climb is presented for the case where the crystal possesses a supersaturation of vacancies (or interstitials). The equations governing the climb process describe the jog populations and the nucleation of new jogs by the vacancy supersaturation. The same equations can be used to derive the jog population on a dislocation network at equilibrium and yields a result which is not a simple Boltzmann factor solution. A model is constructed for the nucleation of jogs in dislocations which are split into partials. The model predicts the slow climb of split dislocations as compared with whole dislocations. The case of high supersaturation typical of a quenching experiment is compared to the low supersaturation of an annealing process, and the jog production process peculiar to high supersaturation is discussed. It is suggested that impurities should play only a minor role in jog nucleation, but should be concentrated at the nodal points of the network by the climb process. It is, however, possible under conditions of high supersaturation for the nodal points to act as jog sources and multipliers, and this possibility suggests one reason why a dislocation network wall can be a particularly good sink for vacancies if the supersaturation is high. Detailed numerical results are difficult to predict because of the lack of information concerning the basic parameters of the theory. One of these parameters is the mobility of a vacancy along the dislocation. An attempt is made to interpret the results of the pipe diffusion data to obtain the mobility of the vacancy. The discussion leads to some interesting constraints on the configuration of the core of the dislocation which require a net volume change in the crystal due to the presence of the dislocation. The estimated volume change in copper is approximately $1/2$ atomic volume per atom length of dislocation. Finally, in an appendix, a solution is obtained for the diffusion of vacancies in the presence of a dislocation sink where the solution includes the force terms between the vacancies and the dislocation. Experiments were performed to obtain fundamental information about the martensite transformation in steels. An x-y double micrometer positioning device was designed for locating a predetermined area in an x-ray beam. Orientation relationships were determined on an alloy containing 22% Ni-0.8% C which were in agreement with those reported in literature. Similar experiments with an Fe-30% Ni alloy failed to yield Laue patterns that could be used for orientation relationships.

The very few and diffuse spots indicated that the martensite plates in this alloy are imperfect, and that theories based on a homogeneous distortion are invalid. Attempts to produce large single crystals and a single interface transformation in the Fe-30% Ni alloy were unsuccessful. The habit planes of 12 martensite plates were determined by a 2-surface analysis in an alloy containing 2.8% Cr and 1.5% C. A stereographic plot of the poles of these habit planes revealed them to lie between (225) and (259), referred to the austenite axes. Electron microscope studies revealed striations in the martensite plates that could indicate slip or twinning. A graphical method was developed for analyzing the martensitic transformations. Essentially, the method is a stereographic representation of the theoretical mathematical analysis of the transformation.

Also published in *Acta Metallurgica*, v. 6: 130-132, Feb. 1958.

An investigation was initiated to determine whether damping might drop to zero in a MgCd system with 50% Mg and if so, the manner in which the damping falls from the high value reported by Lulay at 29% Mg to zero at 50% Mg (*Acta Metallurgica*, v. 4: 627, 1956). Specimens were prepared and analyzed with regard to the relative amounts of Mg and Cd by a double sulfate method described by Lulay in his thesis written at the University of Illinois in 1955. The internal friction rose from a minimum near zero at 25% Mg to a maximum of 0.13 at 29.3% Mg in an almost straight-line curve. The rise was followed by a sharp drop to a minimum at 31.6% and an equally sharp rise to another maximum of 0.146 at 33% Mg. From about 34 to 38.4% Mg there was a linear drop in the internal friction which is believed to be indicative of a 2-phase region, the phases being an ordered phase and a random solid solution. The variation of the peak temperature with composition was apparently oscillatory. It was concluded from the data that an ordered phase exists based on the MgCd superlattice extending from above 50 to 39% Mg. It was assumed that between 34 to 39% Mg a disordered phase exists. From 29 to 25% Mg, another 2-phase region exists consisting of the ordered compound $MgCd_3$ and the disordered phase. (ASTIA abstract)

Apr. 1959.

Measurements have been made of changes in some physical properties of quenched alloys of 70% Au-30% Ni when they were annealed at low temperatures. Changes in the electrical resistance, volume, and Young's modulus were observed to occur. They indicate that there is at least one metastable precipitate formed on low temperature annealing; it occurs about 10^4 times earlier than the main phase change which has been well studied previously. There is a critical temperature above which this low temperature phase is unstable; this is about 225°C. Exact description of the low temperature phase is not possible, but it does seem to be either (1) clusters of Au-rich or Ni-rich atoms or (2) regions of high geometrical order. Quenched-in vacancies are presumed to control the rate of the reaction but the precipitate is not thought to be simply clusters of vacancies. (Contractor's abstract)

June 1958.

Structural changes associated with Kirkendall diffusion in single crystal copper-alpha brass couples have been studied. Vapor-solid couples in which zinc was diffused into copper from the vapor were investigated using metallographic and x-ray techniques. The following effects were found under certain conditions in the diffusion zone: (1) dislocation formation; (2) arrangement of dislocations into sub-boundaries; (3) recrystallization and formation of new grains; and (4) twin formation. The dislocation density and fineness of sub-structure were greatest at the lowest diffusion temperatures. Recrystallization was found at low diffusion temperatures, and twin formation was always associated with recrystallization. An explanation of these phenomena is given in terms of the production and subsequent redistribution of dislocations by climb and slip mechanisms during diffusion. (Contractor's abstract)

DEFORMATION IN EXTENSION AND COMPRESSION,
by J. B. Darby, Jr., C. T. Tomizuka, and R. W. Balluffi.
July 1958 [33]p. incl. illus. diagrs. refs. (AFOSR-TN-
58-546) (AF 18(603)106) AD 158363 UnclassifiedAlso published in Jour. Appl. Phys., v. 30: 104-112,
Jan. 1959.

Self-diffusion of Ag^{110} in silver single crystals subjected to simultaneous deformation at 800 and 900°C was studied using the sectioning technique. The crystals were orientated for duplex slip and were deformed in extension and compression at constant strain rates from 1 to 28×10^{-5} per sec and total strains as large as 0.33 were attained. Recrystallization occurred in the initially single crystal specimens during diffusion-deformation under all conditions except tension at 800°C. The effect of straining on the rate of diffusion was found to be small in all cases. The straining changed the diffusivities by less than 50 percent, and it is concluded that the observed changes were probably within the experimental error. The results indicate that any increases in diffusion rate due to the generation of point defects or short circuiting paths during deformation were small. These conclusions are shown to be consistent with other experiments involving these phenomena. (Contractor's abstract)

Mar. 1959.

Vacancy diffusion models which predict parabolic diffusion-penetration kinetics implicitly assume that vacancy equilibrium is maintained everywhere. However, a non-equilibrium vacancy distribution is generally established by the pumping action of the chemical gradient in the Kirkendall effect. A more general diffusion model is, therefore, developed in which vacancies are not necessarily maintained in equilibrium. The behavior of the model is then investigated and non-parabolic kinetics are found. However, the kinetics approach those of the equilibrium model as either the vacancy lifetime approaches zero or as the diffusion time becomes very

ILL. 19:004-006; ILL. 08:008

long. The applicability of the equilibrium model, therefore, depends upon the particular system and diffusion time. Machine calculations using the equations of the non-equilibrium model are compared with experimental results and it is concluded that non-parabolic effects are probably of little importance in usual face-centered-cubic metallic systems by the time diffusion measurements are made by conventional sectioning methods; i.e., when $Dt > \sim 10^{-5} \text{ cm}^2$. ON THE KIRKENDALL EFFECT IN THE HEXAGONAL CLOSE-PACKED PHASE OF CADMIUM AND MERCURY, by D. H. Killpatrick and R. W. Balluffi. Dec. 1958, 1v. incl. diagr. table, refs. (AFOSR-TN-58-1135) (AF 18-(603)106) AD 208084 Unclassified

Also published in Jour. Appl. Phys., v. 30. 443-450, Mar. 1959.

Sandwich type and vapor-solid type diffusion couples have been used to study marker movements, polygonization, and void formation in the hexagonal close-packed phase of a cadmium-mercury system. A strong marker shift was found to occur towards the alloy side of the sandwich couple indicating faster diffusion of mercury than cadmium. Extensive polygonization was found in the diffusion zones of the vapor-solid couples by x-ray methods. A few large isolated voids were found in the vapor-solid couples from which mercury has diffused out. The observed Kirkendall effect phenomena are qualitatively similar to those found in cubic systems which have been previously studied, and the results are consistent with a vacancy diffusion mechanism in the present system. THE EFFECT OF SIMULTANEOUS PLASTIC FLOW ON SELF-DIFFUSION IN SILVER SINGLE CRYSTALS (Abstract), by J. B. Darby, [Jr.], C. T. Tomizuka, and R. W. Balluffi. [1958] 1p. [AF18(603)106] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 124, Mar. 27, 1958.

Buffington and Cohen found that self-diffusion in iron at 89°C was apparently increased by a factor of 15 applying a compressive strain rate of $\dot{\epsilon} = 0.27 \text{ hr}^{-1}$. This result

could conceivably be caused by the generation of point imperfections during deformation or by short circuiting along dislocations and interval cracks. We have carried out somewhat similar experiments on silver single crystals orientated for duplex slip. Ag^{110} was plated on (111) and $(\bar{1}10)$ faces of the bar shaped crystals and the penetration curves were obtained by sectioning. The Gaussian curves showed no effect resulting from the deformation within the expected experimental error (measurement of the diffusivity to $\pm 20\%$) for $\dot{\epsilon} < + 0.2 \text{ hr}^{-1}$ at 900°C and $\dot{\epsilon} < 0.03 \text{ hr}^{-1}$ at 800°C. The total strains were < 0.35 . Changes in structure were also investigated, and at 900°C recrystallization occurred during the runs. Further experiments in compression are in progress.

ANALYSIS OF DIFFUSION IN MEDIA UNDERGOING DEFORMATION, by H. Fara and R. W. Balluffi. Dec. 1957, 4p. (AF 18(603)106) Unclassified

Also published in Jour. Appl. Phys., v. 29: 1133-1134, July 1958.

An investigation of diffusion in media undergoing plastic deformation has been carried out for the case of a rectangular parallelepiped which is being continuously deformed at a constant rate and for which the specimen surfaces are the principal planes of deformation. The boundary conditions assumed are those in which there are instantaneous plane sources at one or more surfaces with no impingement at the center. A solution for the instantaneous concentration is given in terms of a power series in the term $A_n x^2/4tD$, where D is the diffusivity constant, $\dot{\epsilon}_1$ are the constant strain rates along the principal axes, and $A_n = \sum_{k=1}^n a_k (\dot{\epsilon}_1 t)^{n-k}$. The general power series solution is reduced in the special case, $\dot{\epsilon} = 0$, to the solution for the static diffusion problem.

EFFECT OF LOW TEMPERATURE PLASTIC DEFORMATION UPON THE OPTICAL PROPERTIES OF ALKALI HALIDES, by G. Chiarotti. Apr. 1957, 14p. diagr. refs. (AFOSR-TN-57-155) (AF 18(600)662) AD 126447 Unclassified

Also published in Phys. Rev., v. 107: 381-387, July 15, 1957.

The optical absorption spectrum of KBr and KI crystals, which have been plastically deformed at low temperature, has been observed in the region of the α band in order to detect single ion vacancies generated by moving dislocations. As a result of the present experiment no α band has been observed in KBr and KI crystals plastically deformed at several temperatures between -180°C and -125°C . The number of α centers is estimated to be less than 10^{18} cm^{-3} for KBr or KI crystals after 5% of plastic strain. A general broadening of the fundamental absorption band takes place after plastic deformation. On the other hand a yellow photoluminescence can be excited in the spectral region of the broadened fundamental absorption. A rough proportionality exists between the amount of luminescence and the number of photons absorbed in the region of the crystal responsible for the extra-absorption. Annealing at room temperature reduces both luminescence and extra-absorption. A qualitative explanation is given, which is based on the present knowledge of defects in alkali halides. IONIC CONDUCTIVITY AND DIFFUSION IN SILVER BROMIDE, by A. S. Miller. [1957] 1v. incl. diagrs. tables, refs. (AFOSR-TN-57-224) (AF 18(600)662) AD 126522 Unclassified

A study was made of the deviation between calculated and experimentally observed diffusion coefficients. Conductivity and self-diffusion measurements were made on single crystals of pure AgBr and on AgBr with added positive divalent Cd ions. The theory is developed and the experimental procedure is described. The results are tabulated and compared with other work in the field. An error analysis is also given. From a comparison of the data for the 2 cases of AgBr crystals, the deviation of the calculation from the observed diffusion coefficient can be separated from components caused by each defect type.

TRANSIENT PHOTOCONDUCTIVITY IN AgCl at ROOM TEMPERATURE, by F. C. Brown. July 1957 [38]p. incl. diagrs. tables, refs. (AFOSR-TN-57-366) (AF 18(600)-662) AD 132438 Unclassified

Presented at meeting of the Amer. Phys. Soc., Philadelphia, Pa., Mar. 21-23, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 120, Mar. 21, 1957.

Also published in Jour. Phys. Chem. Solids, v. 4: 206-216, 1958.

Consideration is given to transient rather than steady-state photoconductivity in the presence of mobile ionic defects. With fast-pulse techniques, it is possible to separate electronic from ionic currents and to observe primary photoresponse in essential agreement with a single trapping model. Polarization due to shift is discussed. Data are given on 20 Bridgman crystals. Pure AgCl grown in vacuum, chlorine, or an inert atmosphere, and from moisture-free material, and the products of hydrolysis (Ag and Ag_2O), showed relatively low photoresponse. Crystals grown in air, without filtering or in vacuum from a moist starting charge, showed larger photoconductivity and electron lifetimes on the order of microseconds. Electrical glow curve experiments on XVIII_3 crystals indicated that traps of thermal depth about 0.4 eV were present in highest concentration. The lifetime of an electron in a trap of this depth is about 1 msec at 300°K . Therefore, these states control the lifetime of electrons in the fast-pulse measurements as well as in experiments carried out at 77°K . Crystals which have a large range or lifetime at 300°K appeared to have similar properties when cooled slowly to liquid-N temperatures.

KBr crystals have been irradiated with monochromatic light of a wavelength of $190\text{m}\mu$ at liquid nitrogen temperature. When an electric field is applied to the crystal and its temperature subsequently raised, a burst of current is observed at -130°C , which corresponds to the destruction of V_1 centers. Evidence is presented that F centers and V_1 centers are created simultaneously by absorption of photons in the tail of the fundamental band of the crystal.

MOBILITY OF THE POLARON IN AgCl, by F. C. Brown and F. E. Dart. July 1957 [15]p. incl. diagrs. table, refs. (AFOSR-TN-57-368) (AF 18(600)662) AD 132440
Unclassified

Also published in Phys. Rev., v. 108: 281-284, Oct. 15, 1957. (Title varies)

Transit-time measurements of electron mobility in AgCl have been extended to very low temperatures. Results are presented for an air-grown Bridgman crystal and for a Kyropoulos crystal of high purity. A maximum mobility of about $250 \text{ cm}^2/\text{volt-sec}$ at 80°K was found for the former and a maximum of $480 \text{ cm}^2/\text{volt-sec}$ at 55°K for the latter. It appears that imperfections strongly influence the mobility at low temperatures. At intermediate temperatures the data are in best agreement with the theory of interaction with optical modes of vibration of the lattice from which it is found that $\mu_0 = 30(e^{280/T} - 1) \text{ cm}^2/\text{volt-sec}$. This corresponds to a polaron effective mass of $m^*/m_0 = 0.28$ where m_0 is the free electron mass.

PHOTOCONDUCTION IN KBr AND KI CONTAINING F CENTERS, by N. Inchauspé. [1957] [6]p. incl. diagrs. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)662] and Office of Naval Research) Unclassified

Published in Phys. Rev., v. 106: 898-903, June 1, 1957.

Photoconductivity in potassium bromide and potassium iodide containing F centers has been investigated at 80°K . The product of the quantum yield and unit range has been measured over the spectral range from 2.0 to 5.8 eV with F-center concentrations between 10^{15} and 10^{17} cm^{-3} . Evidence is presented to show that the mechanism for the production of photoelectrons depends upon the photon energy and the concentration of F centers. Two mechanisms for the production of photoelectrons are suggested by the data: the ionization of F centers by excitons and direct optical ionization of F centers.

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill. Mar. 27-29, 1958.

Abstract published in Bul. Amer. Phys. Soc., Series II, v. 3: 127, Mar. 27, 1958.

Also published in Phys. Rev., v. 111: 462-471, July 15, 1958.

Primary photoconductivity has been investigated down to 6.5°K in single crystals of pure AgCl using low intensity, monochromatic light pulses and a sensitive electrometer. Results are presented which are in agreement with a theory of the transient response taking into account light absorption and electron trapping. The electron yield per absorbed photon (quantum efficiency) is found to be high, somewhat less than one, in the long-wavelength tail and through the first peak of optical absorption for all crystals and temperatures down to 6.5°K . These results agree with the proposed band scheme if allowances are made for direct and indirect transitions. Electron trapping properties are strongly dependent on sample preparation, but certain features are believed characteristic of the silver halides. Whereas the density of deep (0.5 eV) traps may be very low in well-annealed AgCl, a high density of very shallow ($< 0.1 \text{ eV}$) traps exists in the crystals prepared so far. Prominent electrical glow peaks have been observed at 15°K , 35°K , and 178°K . No evidence for hole mobility has been found and upper limits on possible hole ranges are given.

HALL EFFECT FOR ELECTRONS IN SILVER CHLORIDE, by K. Kobayashi and F. C. Brown. Aug. 1958 [28]p. incl. diagra. tables, refs. (AFOSR-TN-58-743) (AF 18(800)882) AD 201509 Unclassified

Also published in Phys. Rev., v. 113: 507-513, Jan. 15, 1959.

Experiments were conducted to determine whether the drift mobility of electrons in single crystal AgCl at 60° to 100°K was due to scattering by imperfections or to multiple trapping effects, and to extend mobility data into the very low temperature range. A fast pulse technique was developed for making steady state dc measurements of the half voltage. A cryostat and 2 separate high-vacuum systems and manifolds were used for making the measurements. An analysis is given of the method of measurement. Three air-grown crystals of AgCl which contained heavy metal impurities of the order of parts in 10^7 were selected for the experiments. The magnitude of the Hall mobility computed from the change in the resistance was dependent upon the uniformity of the crystal with regard to trapping lifetime. The sign of the observed Hall effect in the crystals tested was negative. The results indicated that the Hall mobility for electrons released by light rises to very, very high values at low temperature indicating samples of high perfection. Holes apparently made little contribution, if any, to the Hall effect in crystals studied in agreement with separate experiments on transient photoconductivity. Electrons were scattered by both acoustical and optical vibrations depending upon the range of temperature. Magnetoresistance effects began to become important at the lower temperatures and higher magnetic fields. (ASTIA abstract)

DICHROISM OF THE F AND M BANDS IN KCl, by H. Kanzaki. Sept. 1958 [6]p. incl. diagra. tables. (AFOSR-TN-58-852) (AF 18(600)662) AD 203495 Unclassified

Also published in Phys. Rev., v. 110: 1063-1068, June 1, 1958.

The dichroism of the F and M absorption bands that can be produced by optical bleaching of the F band with polarized light at 87°K is critically dependent on the concentrations of F and M centers. The changes in half-widths and peak positions of the F and M bands that accompany the development of dichroism suggest that the F-band dichroism is due to a spatial association of F and M centers. It is probable that an excited F

center can transfer energy to a neighboring M center. Dichroism of the F and M bands can be produced at room temperature by optical bleaching of either band with polarized radiation. (Contractor's abstract)

DRIFT AND DIFFUSION OF PHOTOELECTRONS IN AgCl AT ROOM TEMPERATURE (Abstract), by F. C. Brown. [1958] [1]p. [AF 18(800)882] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 127, Mar. 27, 1958.

Although AgCl is an ionic conductor at 300°K it is possible to study transient photoconductivity by using short (0.2 μ sec) light pulses synchronized with pulses of applied voltage. Single crystals can be prepared in which electrons released into the conduction band by light remain free for times as long as 50 μ sec before being trapped in deep states. Holes appear to be immobile in AgCl and electron-hole recombination processes relatively unimportant. At low voltages photocurrent decay times are a direct measure of electron trapping times. These times are the same whether the crystal is illuminated in the volume or by strongly absorbed light near one surface (electrons separated from holes by electric field). At higher voltages a sheet of electrons can be injected at the cathode and collected at the anode. The transit times yield values of drift mobility about equal to Hall mobility. The spread in time of arrival at the anode is in agreement with the Einstein-Nernst relation relating diffusion constant and mobility only in the limit of low intensity. At high light intensity space charge effects increase the width of the observed collection pulse and cause it to be asymmetrical.

The ionic conductivity and the self-diffusion coefficient of silver have been measured in silver bromide and in silver bromide-cadmium bromide single crystals between 20 and 380°C. There exists a range of temperature

ILL. 09:005; ILL. 10:002;
ILL. 11:011-013

for crystals containing cadmium within which the ratio of the conductivity to the self-diffusion coefficient has the value of 1.25 which is predicted for the vacancy mechanism of diffusion by the Einstein relation as modified by the Bardeen-Herring correction. This result is in agreement with the assumption that divalent cadmium ions replace monovalent silver ions in the crystal lattice and introduce an equal number of silver-ion vacancies. These excess vacancies reduce the concentration of interstitial silver ions to a negligible quantity through the operation of the mass-action law. Under these conditions diffusion occurs only by the vacancy mechanism. Conductivity and diffusion data obtained with pure silver bromide crystals are in fair agreement with the more extensive data of Friauf. (Contractor's abstract)

ENERGY-BAND STRUCTURE OF A HYPOTHETICAL CARBON METAL, by R. C. Casella. [1958] [7p. incl. diagrs. tables, refs. (AF 18(600)689) Unclassified

Published in *Phys. Rev.*, v. 109: 54-60, Jan. 15, 1958.

Energy bands are derived for a hypothetical crystal composed of carbon atoms arrayed in a single face-centered-cubic lattice by the method of orthogonalized plane waves (OPW). The bands are compared with those of diamond which have been obtained by Herman. It is shown that the hypothetical crystal is an almost perfect metal. A potential for atomic carbon in the 3P ground-state is computed within the framework of Slater's free-electron-exchange approximation. An analytical approximation to this potential is provided. Results of a general symmetry analysis, appropriate for application of the OPW method to any f.c.c. lattice, are given. The cohesive energy of the metallic crystal relative to that of diamond is discussed within the approximation employed. (Contractor's abstract)

ABOUT THE EQUIVALENT CIRCUIT OF THERMISTORS, by E. K. Weise and B. P. Lathi. Nov. 1, 1957, 43p. incl. diagrs. tables. (Technical note no. 9) (AFOSR-TN-57-797) (AF 33(038)12644) AD 148029 Unclassified

An equivalent circuit for thermistors was developed and the elements were determined for a commercial bead type, both for alternating current and for direct current transients. The circuit contains an inductance for which values of several thousand henries were found. The dependence of the circuit elements upon the position of the operating point on the characteristic, upon frequency, and upon outside parameters, as voltage and series resistance, was determined. For a particular bead type thermistor critical frequencies of about 1 cps at an operating point with a current of 1 ma and of about 3.5 cps at 2 ma respectively were found. At these frequencies the thermistor displayed the behavior of a pure inductance in producing a phase shift of exactly 90° between voltage and current. Other investigators used the same equivalent circuit previously. Their considerations and data were compared with the findings of this work which shows progress over the earlier investigations especially in demonstrating the limits of the applicability of the equivalent circuit assumed. Investigations of electric and magnetic properties of reduced (IIa) group titanates are reported which were made at the University of Illinois from 1950 to 1957. Sintered samples of Mg_2TiO_4 , $MgTiO_3$, $MgTi_2O_5$, $CaTiO_3$, $SrTiO_3$, and $BaTiO_3$ were measured at temperatures between $-190^\circ C$ and $+1,500^\circ C$ in inert atmospheres. The electric conductivity was measured between $-190^\circ C$ and $+1,500^\circ C$. Between $+20^\circ C$ and $-190^\circ C$ the Hall effect was measured. The behavior of magnetic susceptibility was investigated over a wide range of temperature and composition. The n-type donors were produced in the titanate lattice by partial reduction in gas mixtures containing hydrogen. The donor concentration was determined by weighing before and after reoxidizing heat treatment where possible. The electron mobility was determined from both conductivity and Hall effect data; the results were compared. Investigations of the resistance-temperature characteristics, the voltage-current characteristics, and the equivalent circuit of thermistors are discussed. (Contractor's abstract)

TEMPERATURE-RESISTANCE STUDIES OF EVAPORATED BISMUTH FILMS, by J. M. Galligan. Jan. 25, 1957, 46p. incl. illus. diagrs. tables. (Technical note no. 1) (AFOSR-TN-57-38) (AF 33-038)21255) AD 115076 Unclassified

Metallic elements when in thin film "state" exhibit many anomalous and unusual properties. Among these might be mentioned the temperature dependence of resistance. It has been found that when the temperature of some thin films is increased the resistance decreases. This temperature dependence upon film thicknesses, i.e., resistance was investigated. The investigation was carried out on evaporated films of bismuth. This investigation thus might help to understand how the process of conduction occurs in thin films. It was found that the temperature coefficient of resistance, α , was negative for those films which had a resistance in the range from 12 to approximately 400 ohm. Above 400 ohm α was positive. Thermal activation energies were obtained. For fresh films, they ranged from $+0.27$ to -0.09 electron volt, with the maximum value at a resistance of about 50 ohm and a value of zero near 400 ohm. Aging in air for one month had the effect of increasing all values of activation energy by about 0.07 electron volt.

Some of the areas of solid state research for which thin film techniques are uniquely suited are outlined. Four main qualities which distinguish evaporated films from bulk material are discussed: (1) the surface area per unit volume is substantially greater in thin films; (2) the complex physical structure of metal films implies a greater amount of macroscopic disorder per unit volume than is found in bulk; (3) the crystallite units of thin films are granular in size and can be made of the same order as the mean free path of conduction electrons; and (4) the grain boundary area per unit volume is unusually large, and points within the grain boundaries are never far from the free surface. Relevant studies of certain basic solid state problems suggested by each of the latter are cited.

Infrared and electrical studies made on evaporated bismuth films suggest that the observed characteristics are largely determined by the film structure. The films were evaporated at 10^{-5} mm pressure onto cellulose nitrate substrates. Electron microscope examination shows that up to about 2000 Å thickness the films possess a single-layer polycrystalline structure. Thickness-resistance measurements and low frequency current noise studies indicate that the major contribution to the film resistance is from the grain boundaries. Temperature-resistance characteristics have been related to average crystallite size. The infrared studies indicate that there are two types of grain boundaries, namely, those which contribute to the conductivity and those which do not. This conclusion is also confirmed by electron diffraction effects. By taking into account the capacitance of the grain boundaries it is possible to explain the infrared characteristics. Calculations from the measurements give an initial grain boundary thickness of about 15 to 30 Å. (Contractor's abstract)

Presented at meeting of the Amer. Phys. Soc., Ithaca, N. Y., June 19-21, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 254, June 19, 1958.

Evaporated thin films of bismuth deposited on cellulose nitrate substrate have been studied. Measurement of the temperature dependence of resistance in films in the resistance range from 12-360 ohms showed that the resistance decreased with an increase in temperature. The maximum activation energy was about 0.027 electron volt in this resistance range. In the resistance range above 400 ohms the resistance increased with increasing temperature, with activation energies as low as 0.009 ev. The reason for this negative activation energy is not understood, but the measurements are reproducible and it is well outside experimental error. No simple model could be proposed to explain this negative activation energy in the absence of information about the density and type of electrical carriers. Aging the films in air, for one month, had the effect of increasing the activation energies.

The generation of light pulses as short as $69 \mu\text{sec}$ in duration at a repetition rate of six billion/sec has been achieved by the use of a specially designed electro-optic Kerr cell driven at microwave frequency. Since the operation of a Kerr cell at such frequencies involves electric fields which change so rapidly that the field cannot be considered constant even for the length of time required for light to travel the two or three in. length of a Kerr cell, a new theory of Kerr cell operation has been worked out which takes the transit line into account. The results of this analysis and the effect of the transit time upon Kerr cell behavior, including operation with combined ac and dc electric fields, are discussed. The properties of liquid dielectrics which are pertinent to an understanding of the Kerr effect are reviewed, with

ILL. 13:004; ILL. 14:005,006

particular attention to dipole orientation polarization and various theoretical and empirical methods of describing the behavior of liquid dielectrics in the region of molecular rotation dispersion. Measurements of the dielectric properties of nitrobenzene, a liquid exhibiting a very large Kerr effect, were carried out over a large frequency range, and the results of this work are reported, along with a comparison of the properties of nitrobenzene with those of carbon disulfide and an evaluation of their relative merits and limitations. The design of a microwave Kerr cell and the compromises inherent in the choice of geometry and dimensions, as well as the problems and techniques involved in the actual construction of a cell are described in detail. The optical and electrical system in which a Kerr cell functions, and the experimental procedures which were used in the investigation are summarized, including a method of using the electro-optic shutter to check its own operation and to prove the existence of microwave modulation of a light beam. Finally, the results of the measurements which were made concerning the operation of a Kerr cell driven at microwave frequency, and the variation of the instantaneous and average light transmitted by such a shutter are presented. THE TIME ELEMENT IN PHOTOELECTRIC EMISSION, by D. F. Holshouser and H. M. Von Foerster. Final technical rept. May 16, 1958, 90p. incl. illus. diagrs. tables, refs. (AFOSR-TR-58-67) (AF 18(600)018) AD 158274 Unclassified

Effort was made to measure the degree of photoelectric response of transmission-type cesium-antimonide photocathodes to light pulses of 100- μ sec duration. A measurement of the photoelectric response to light pulses of 170- μ sec duration was obtained by modulating the light from a FX12 type xenon flashtube with a specially designed Kerr cell shutter driven by pulsed 3 kmc/sec microwave power. The degree of modulation of the photoelectric emission produced in a 1P42 type phototube by the modulated light was obtained by using the photoelectron current to generate microwave power in a resonant cavity whose output can be measured. Results indicate that the photoelectric response time of cesium-antimonide photocathodes of the transmission type, under operating conditions of high peak illumination of short duration, was of the order of 1 μ sec. A useful and reliable modulated light source was realized which provided intense periodic 170- μ sec light pulses. Shorter pulses are attainable at the expense of brightness, and pulses as short as 10 μ sec could probably be achieved. A device for the detection of light modulated at microwave frequencies was developed. Its frequency limitation was the response

time of the photoelectric surface employed. (ASTIA abstract)

EFFECT OF HEAVY DOPING ON THE SELF-DIFFUSION OF GERMANIUM, by M. W. Valenta and C. Ramasastri. [1957] [12]p. Incl. diagrs. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18-(600)1310 and Motorola, Inc.) Unclassified

Presented at Symposium on Semiconductors of the A.I.M.E. Inst. of Metals Div., Feb. 20, 1956.

Also published in Phys. Rev., v. 106: 73-75, Apr. 1, 1957.

The germanium self-diffusion coefficients for intrinsic, heavily-doped n - and p-type germanium were measured at several temperatures. It was found that the self-diffusion coefficient is greater for heavily-doped n-type than for intrinsic germanium and that the self-diffusion coefficient for intrinsic germanium is greater than for heavily-doped p-type. If it is assumed that a vacancy acts as an acceptor and that germanium self-diffusion goes by the vacancy mechanism, the observed changes in the value of the self-diffusion coefficient with doping are in the direction and of the order of magnitude of changes calculated from the shift in the Fermi level alone. It is concluded that germanium self-diffusion probably proceeds by the vacancy mechanism. (Contractor's abstract)

OPTICAL PHONON CONTRIBUTION TO CARRIER ENERGY LOSSES IN SEMICONDUCTORS (Abstract), by T. N. Morgan. [1957] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(600)-1310] and Signal Corps) Unclassified

Presented at meeting of the Amer. Phys. Soc., Notre Dame U., South Bend, Ind., June 20-22, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 265-266, June 20, 1957.

Measurements of deviations from Ohm's law in semiconductors in high electric fields give information about energy loss processes for energetic electrons and holes. Microwave fields have been used to heat the carriers and the resulting changes in dc resistance in germanium and silicon specimens at temperatures between 77°K and 300°K have been observed. The results are in disagreement with the theory of Shockley and others based on the

MEASUREMENT OF GERMANIUM SURFACE STATES BY PULSED CHANNEL-EFFECT, by G. Rupprecht. [Jan. 1958] [27]p. incl. diagrs. refs. [AF 18(600)1310] Unclassified

Also published in Phys. Rev., v. 111: 75-82, July 1, 1958.

Densities, cross sections and activation energies of several fast germanium surface states are inferred from low temperature conductivity relaxations in a thin diffused surface layer. Relaxations are induced by application of a sudden reverse biasing pulse. The observed rate of change of channel conductance as a function of temperature is analyzed in terms of a model wherein the equilibrium surface Fermi level is presumed to remain in close proximity to a trap level. The results indicate the existence of an electron trap 0.24 ev from the conduction band and two hole traps 0.17 ev and 0.22 ev from the valence band. (Contractor's abstract)

EFFECT OF DOPING ON THE DIFFUSION OF IMPURITIES IN GERMANIUM (Abstract), by M. W. Valenta. [1958] [1]p. [AF 18(600)1310] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 102, Mar. 27, 1958.

The diffusion coefficients of indium, antimony, arsenic and tin were measured in As-doped, intrinsic and Ga-doped germanium over a temperature range from 760°C to 880°C. Donor diffusivities in the As-doped (about 10^{19} atoms/cm³) samples ranged from 1.3 to 2.7 times the corresponding ones in intrinsic germanium, and those in the Ga-doped (about 10^{19} atoms/cm³) ranged from 0.55 to 0.65 times those of the intrinsic samples. The acceptor diffusivity also changed with doping in the same direction (greater in n-type than p-type germanium), but the change was appreciably smaller than that observed for donors. Likewise, tin has a larger diffusion coefficient in n-type than p-type germanium. The observed changes are in the direction predicted by a vacancy mechanism in which *As* donors form complexes with negative vacancies, and acceptors form complexes with both neutral and negative vacancies.

EFFECT OF DOPING ON THE DIFFUSION OF IMPURITIES IN SILICON (Abstract), by M. F. Millea. [1958] [1]p. [AF 18(600)1310] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 102, Mar. 27, 1958.

The diffusivities of P, Sb, Sn and In in "intrinsic" ($\sim 10^{15}$ impurity atoms/cm³ or less), heavily doped n-type ($\sim 5 \times 10^{19}$ atoms/cm³), and heavily doped p-type ($\sim 2 \times 10^{20}$ atoms/cm³) silicon have been measured to obtain information on the way diffusion takes place. The measured diffusivities of p and Sb in n-type are twice their values in intrinsic silicon; their diffusivities in p-type are one half those in intrinsic silicon. These changes are in the direction expected for vacancy diffusion. The diffusivity of Sn in n-type is about 50% larger than in intrinsic, whereas in p-type it is about equal to that in intrinsic silicon. Opposite changes are found for the diffusivity of indium; it is about 6 times larger in p-type and about 50% lower in n-type than in intrinsic silicon. Possible diffusion mechanisms for substitutional impurities in silicon are discussed in the light of these and other data.

MICROWAVE CARRIER HEATING AND IMPACT IONIZATION OF IMPURITIES IN GERMANIUM (Abstract), by K. Seeger. [1953] [1]p. [AF 18(600)1310] Unclassified

Presented at meeting of the Amer. Phys. Soc., Chicago, Ill., Mar. 27-29, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 112, Mar. 27, 1958.

Deviations from Ohm's law have been measured in germanium between 80 and 300°K by extending the method used by Morgan to microwave field intensities of 10^4 v/cm. In agreement with dc measurements of Ryder and others on n-type germanium, the resistivity increases

ILL.20:001 - ILL.20:003

with field intensity E and the drift velocity saturates at high fields. No distinct E^2 region occurs, contrary to Ryder's results. In the low-field region the effects of various carrier concentrations have been investigated. With zinc-doped germanium at 80°K a resistivity decrease has been observed even at microwave fields down to the order of 1 v/cm. In this region the resistivity change is proportional to the square of the field and may be due to hole heating in the impurity scattering range. The large resistivity decrease at fields near 10^4 v/cm is considered to be caused partly by impact ionization of holes from the 0.097 ev Zn acceptor level.

THEORETICAL AND EXPERIMENTAL EVALUATION OF THE REBATRON - A RELATIVISTIC ELECTRON BUNCHING ACCELERATOR. by I. Kaufman. Dec. 1, 1956, 312p. incl. illus. diags. tables, refs. (Technical note no. 1) (AFOSR-TN-57-7) (AF 18(603)62) AD 115039 Unclassified

The development of sources of appreciable RF power in the 1 mm to 0.1 mm wavelength range of the electromagnetic spectrum has yet to be accomplished. A very promising approach to the problem is the coherent interaction with a circuit, or the direct radiation, of a tightly bunched, megavolt electron beam. Work on a device for producing such a beam has resulted in a compact relativistic electron bunching accelerator, designated the REBATRON. One form of rebatron consists of an electron gun followed by two 10 cm cavities that are powered by a megawatt source. Calculations have shown that it may be possible to achieve very short, high density electron bunches from this rebatron, corresponding to strong harmonic content of up to the two-thousandth harmonic of this 3000 mc/sec source. A direct measurement to verify the degree of bunching, involving the measurement to pulse times of 10^{-13} sec, has obvious complications. Fortunately, a change in one of the rebatron parameters that influences the bunching is accompanied by a change in the output electron momentum spectrum, so that the rebatron performance may be evaluated by correlation of computed with experimentally determined momentum spectra. Such a comparison between theoretical and experimental momentum spectra has yielded very satisfactory results and has resulted in the conclusion that, to a high degree, this rebatron operates as predicted. Beam coupling experiments at 72.2 kmc/sec (the 26th harmonic) has further confirmed this conclusion. This report describes the rebatron, calculations of its theoretical behavior and their results, the experimental methods used in the attempt to verify the computed results, and the experimental results obtained. MEGAVOLT ELECTRONICS MILLIMETER WAVE COUPLING STRUCTURE RESEARCH AT THE UNIVERSITY OF ILLINOIS, by P. D. Coleman. [1957] [15]p. incl. diags. refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)62 and Atomic Energy Commission under AT(11-1)392) Unclassified

Published in Proc. First Tri-Service Millimeter Wave Symposium, Army Signal Engineering Labs., Fort Monmouth, N. J., Sept. 10-11, 1957, p. 120-134.

The purpose of this research was to show that a bunched megavolt electron beam represents the highest power level, most non-linear element yet proposed for frequency multiplication. Pulsed powers of tens of kilowatts with a useable beam harmonic of 100 appear practical as demonstrated with S-band bunching accelerators. Further, it was shown that megavolt electronics makes possible at least three new types of coupling systems which can circumvent the frequency limitation problems encountered by conventional microwave tubes. The following topics are discussed: frequency multiplication with a non-linear element and with an electron beam; desirable beam characteristics; bunching characteristics of a practical S-band rebatron; types of megavolt electronics beam coupling structures; excitation of higher order modes; dielectric loading of a metal cavity; a dielectric harmonotron; Cerenkov coupling structures; and comparison of megavolt electronics beam coupling schemes.

SYNTHESIS OF VOLTAGE TRANSFER FUNCTIONS WITH RIGHT HALF PLANE ZEROS BY RC FEEDBACK NETWORKS, by J. J. Mikulski. Mar. 15, 1957, 17p. incl. diags. (Technical note no. 1) (AFOSR-TN-57-16E) (AF 49(638)63) AD 126461 Unclassified

Presented at the Third Midwest Symposium on Circuit Theory, Iowa State Coll., Ames, May 1958.

Also published in Proc. Third Midwest Symposium on Circuit Theory, Iowa State Coll., Ames, 1958, p. 9.1-9.23.

The synthesis of voltage transfer functions with complex poles and right half plane (RHP) zeros has been approached previously through the use of active feedback networks by Armstrong and Reza, and Sallen and Key. In their studies, zeros are realized by passive

RC networks and are thereby limited in their location in the s plane. Feedback was employed to realize complex poles. In no instance was a zero on the positive real axis realizable. In these previous studies, the configuration was limited to proportional or RC passive network feedback. By utilizing a more general feedback function, one with RHP poles resulting from an unstable minor loop, a zero of $W(s)$ is realized in the RHP. This problem is investigated and design equations are given for system parameters to realize any $W(s)$. A numerical example illustrates the method. System sensitivity to parameter variation is briefly investigated and optimum conditions chosen for design.

TRANSFER FUNCTION SYNTHESIS WITH ACTIVE ELEMENTS, by F. F. Kuo. Apr. 15, 1957, 19p. incl. diags. (Technical note no. 2) (AFOSR-TN-57-206) (AF 49(638)63) AD 126503 Unclassified

Presented at the National Electronics Conference, Chicago, Ill., Oct. 7-9, 1957.

Also published in Proc. National Electronics Conference, v. 13: 1049-1056, 1957.

A synthesis procedure is given for synthesizing both minimum and non-minimum phase transfer functions using canonical RC structures which realize complex zeros of transmission. The use of RC sections to produce complex zeros of transmission is based upon a method due to Dasher. However, Dasher's method is restricted to the synthesis of minimum phase networks only. With the aid of active networks and canonical RC sections, it is possible to realize transfer functions which are not possible by Dasher's method. The active network representation used is the controlled-source-RC network which is equivalent to a transistor-RC-network. The partitioning theorem is used to remove the canonical RC structure.

SYNTHESIS OF ACTIVE NETWORKS WITH NEGATIVE IMPEDANCE CONVERTERS, by R. T. Chien. May 5, 1953, 60p. incl. diags. refs. (Technical note no. 4) (AFOSR-TN-58-494) (AF 49(638)63) AD 158304; PB 137068 Unclassified

The Linvill configuration is used to synthesize second-order, non-positive-real, driving-point functions. Synthesis is accomplished by the use of a surplus factor. With the arbitrariness of the surplus factor, one

ILL.21:004 - ILL.21:005

is able to control the driving-point function. The existence of the solution in all cases is demonstrated and the minimum number of elements property of the solution is proved. It is shown that only five elements are required besides the negative impedance converters (NIC). RC networks are used in some cases and RL networks are used in the remaining cases. The synthesis of a transfer function together with the driving-point function is accomplished by application of Cauer's method of partial removal of poles. Useful results are obtained in synthesizing the transfer voltage ratios with different terminations, including the case of open output terminals. The conditions of realization are obtained and given in terms of coefficients. The method used is further extended to realize all three functions. Necessary and sufficient conditions are found for three functions to be a realizable set. The synthesis itself is carried out in the same manner as in the previous cases. For higher order functions, a procedure is outlined to find the desired pole positions by cut and try, for the synthesis of a driving-point function, or a driving-point function together with a transfer function. Also published in part in I.R.E. National Convention
Record, Pt. 2: 18-22, 1959. (Title varies)

If a network contains a variable parameter x (capacitance, or g_m of a vacuum tube, etc.), the polynomials of the driving-point and transfer functions describing the network have coefficients which are linear functions of x . The roots of the polynomials are also functions of x . Since the locations of the poles and zeros of these network functions are important in both analysis and synthesis of the network, it is desirable to know quantitatively the tendency for a root to vary with the parameter x . A measure of this tendency to vary is provided by the sensitivity function $S = dp/dx$, where p is a root of a polynomial. Properties and theorems pertaining to this sensitivity function are given in this work. Root sensitivity and the root locus of the polynomial are closely related topics. Sensitivity is shown to be the residue of a pole of a specialized form of the root locus equation whose poles are the roots of the given polynomial. From the properties of this special root locus form, it is shown that intersections of root loci have

infinite sensitivities. Other cases of infinite sensitivity figures are studied. The sum of the sensitivities of the roots of any polynomial is derived, and some properties are given as related to certain defined classes of polynomials. Numerical examples computed on ILLIAC are given to illustrate sensitivity properties of representative root loci. The sensitivity properties described above are applied to the analysis and synthesis of RC networks. In network analysis, several theorems pertaining to the sensitivity of double zeros of transmission and to a class of insensitive elements are given. The sensitivity factor is introduced in the synthesis of RC ladder networks by the Cauer procedure. Several sensitivity criteria are given for the synthesis of optimum RC ladder networks. Finally, a study is made of certain sensitivity properties of closed-loop feedback networks. A number of suggested problems for further study are given. (Contractor's abstract)

Presented at I.R.E. National Convention, New York,
Mar. 24-27, 1958.

Published in I.R.E. National Convention Record, Pt. 2:
70-75, 1958.

In a previous paper (W. Mayeda and M. E. Van Valkenburg, I.R.E. WESCON Convention Record, Pt. 2: 137-144, 1957) the advantages of the digital computer in the analysis and synthesis of passive networks were described. The present paper extends this work to include linear nonreciprocal networks in which the current of a branch depends not only on the voltage of that branch, but might also be unilaterally dependent upon the voltage of other branches in the network. The topological formulas are presented in a form convenient for digital computer programming. Features of the program are outlined, and the advantages of speed and accuracy are illustrated by several examples which include stability and sensitivity considerations.

A DIGITAL PULSE INTEGRATOR FOR FLASH MEASUREMENTS, by H. H. Kramer and E. J. Bair. Aug. 29, 1958 [12]p. incl. diags. (AFOSR-TN-58-777) (AF 18(603)93) AD 201925; PB 138173 Unclassified

Also published in Jour. Opt. Soc. Amer., v 50: 807-810, June 1960.

A digital pulse integrator is described for measuring the voltage-time area of electrical impulses such as the photocurrent resulting from the photoelectric observation of a xenon flash source. As the basis of its operation, the positive pulse to be integrated charges a capacitor. A decade scaler is used to count the number of smaller negative pulses from a crystal oscillator that are required to discharge the capacitor to its original voltage. A specific circuit was tested with square pulses having an adjustable amplitude and duration. The observed count is proportional to the pulse area with an accuracy and reproducibility greater than 0.3% for an individual pulse in the range 10- to 100-msec volts (with 45- to 100-v amplitudes). Limitations and applications of this type of integration are discussed briefly.

ORIENTATION BY AURAL CLUES, by I. Kohler. [1957] [16]p. incl. illus. diags. refs. (AFOSR-TR-57-54) (AF 61(514)889) AD 136462 Unclassified

Also published in Naturwissenschaftliche Monatschrift, no. 6/7: 1-16, May 1957.

Research has been performed to determine the possibilities and limits of orientation by means of sound. The ear is considered as a "receiver" and an "interpreter." Sound projectors are developed to facilitate controlled investigation as well as actually to improve conditions for orientation by sound. The so called 'obstacle sense' of blind persons is based on modifications of sound produced by reflection from nearby objects. Results show that the most effective guiding sounds are those emitted from the observer himself and that the obstacle sense can be awakened and developed to maximum efficiency by training.

A GENERALIZED FUNCTION-THEORY AND THE RELATED DIRICHLET PROBLEM. PART II, by J. Sanders. [1957] [14]p. (AF 18(600)791) Unclassified

Published in Ann. Math., v. 66: 141-154, July 1957.

In the first paper of this series (item no. IAS.04:001)

the author considered the equation $N^2(u) = 0$ and constructed a function theory related to this equation. The present paper is devoted to the solution of the Dirichlet problem for the equation $N^2(u) = 0$. The method used is patterned after the "double layer potential" method of solving the Dirichlet problem for Laplace's equation. G. Lauricella [Acta Math., v. 32: 201-256, 1909] and K. Schröder [Math. Z. v. 48: 553-675, 1943] employed a similar idea in dealing with the Dirichlet problem for the biharmonic equation. The author proceeds differently, using the function theory which he developed in his first

IAS.05:014 - IAS.05:017

paper. It is shown that the Dirichlet problem in question is equivalent to the determination of a certain Σ_2 -monogenic function from its values on the boundary. The main result concerns the Dirichlet problem which consists of finding a solution u of $N^2(u) = 0$, of class C^4 in a domain D , of class C^1 in the closure of D , which on the boundary C of D satisfies $u = f(s)$, $\partial u / \partial n = g(s)$, where f and g are given continuous functions of the arc length s on C . It is found that this problem possesses one and only one solution, under suitable differentiability assumptions relative to the boundary C and the functions σ and τ . (Math. Rev. abstract)

APPLICATION OF HILBERT SPACE METHODS TO LIE GROUPS ACTING ON A DIFFERENTIABLE MANIFOLD, by J. Lelong-Ferrand. Dec. 1956, 6p. (AFOSR-TN-57-14) (AF 18(600)1109) AD 115046

Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 43: 249-252, Feb. 1957.

Using Hilbert space methods, the author states five theorems on Lie groups acting on a differentiable manifold. Proofs are promised in a subsequent publication. Examples of the theorems are:

(1) If y is a compact ν -dimensional group and if X_α

($\alpha = 1, 2, \dots, \nu$) denotes a basis of its algebra, there exists a constant k such that $f \in \mathcal{H}$ (=Hilbert space of square integrable functions) and $\int f d\tau = 0$ imply

$$\int k \sum_{\alpha} X_{\alpha} f \|^2, \text{ where } d\tau \text{ is the invariant measure.}$$

(2) An element X of the Lie algebra of a Lie group y defines a one-parameter compact subgroup of y if, and only if, there exists a constant k such that every function $f \in \mathcal{H}$, orthogonal to the space $\mathcal{H}' = \{ \varphi; \varphi \in \mathcal{H}, X\varphi = 0 \}$, satisfies $\int f \leq k \|Xf\|$. INTEGRATION OF A DIFFERENTIAL FORM ON AN ANALYTIC COMPLEX SUBVARIETY, by P. Lelong. Dec. 1956, 6p. (AFOSR-TN-57-20) (AF 18(600)1109) AD 115054

Unclassified

Also published in Proc. Nat'l. Acad. Sciences, v. 43: 246-248, Feb. 1957.

The purpose of this note is to give a precise definition of the operator of integration:

$$t(\varphi) = \int_W \varphi$$

for an exterior differential form φ on an analytic complex subvariety W . The problem arises because an analytic complex subvariety in a domain D of C^n (or, more briefly, an analytic set in D) is not, in general, a manifold. We give (a) an existence theorem for $t(\varphi)$, (b) a proof that t is a closed current in D , that is $t(\varphi) = 0$ for the forms with compact support, which are homologous to zero in D . CONSTRUCTION OF THE ENVELOPES OF HOLOMORPHY OF ARBITRARY DOMAINS, by H. J. Bremermann. Feb. 1957, 31p. incl. refs. (AFOSR-TN-57-49) (AF 18(600)1109) AD 115088

Unclassified

Also published in Rev. Mat. Hisp.-Amer., v. 17: 175-200, 1957.

In the space of several complex variables C^n there is associated with every domain D its "envelope of holomorphy" $E(D)$ which is the largest domain (schlicht or locally schlicht) containing D such that all functions holomorphic in D can be continued holomorphically into $E(D)$. For a given domain D the envelope $E(D)$ thus is defined by "the set of all functions holomorphic in D ." The problem to construct D explicitly for any given domain D is solved completely for the case where both D and $E(D)$ are schlicht. The process can be carried out by a computer. If D or $E(D)$ or both are non-schlicht, then the process is still applicable and it is shown that it gives $E(D)$ if it converges to a pseudo-convex domain. (Contractor's abstract)

Let G be a Lie group with a finite number of connected components and let $R(\mathfrak{b})$ denote the ring of complex-valued continuous functions on G whose translates are finite dimensional. Investigation is undertaken of (1) the algebraic structure of $R(\mathfrak{b})$, (2) the group A of automorphisms of $R(\mathfrak{b})$ regarded as G -module, and (3) the relation between G and A . A case of central interest is the one in which $R(\mathfrak{b})$ is a finitely generated ring. Under this hypothesis, A turns out to be the "universal complexification" of G . This result can be regarded as a direct generalization of Tannaka's duality theorem for compact Lie groups and Harish-Chandra's analogue for connected semi-simple groups. The hypothesis that

$R(b)$ be finitely generated is equivalent to the condition that G modulo the topological closure of the commutator subgroup of the connected component of the identity be compact. Conversely, if A is the universal complexification of G , then $R(b)$ is finitely generated. Thus the class of Lie groups with $R(b)$ finitely generated is the precise class for which Tannaka's duality holds. (Contractor's abstract)

"plurisubharmonic solution" is closely connected with the envelope of holomorphy of a certain domain and can be computed explicitly. Finally extensions to noncontinuous boundary values, Banach spaces, and Stein manifolds are discussed. The plurisubharmonic solution together with the corresponding plurisuperharmonic solution gives an estimate for the variation of the harmonic solution (of $2n$ real variables) and solutions of similar differential operators under holomorphic transformations. GENERAL MINIMAX THEOREMS, by M. Sion. Apr. 1957 [10]p. incl. refs. (AFOSR-TN-57-204) (AF 18(600)-1109) AD 126501 Unclassified

Also published in Pacific Jour. Math., v. 8: 171-176, 1958.

The main result in this paper is the following generalization of von Neumann's minimax theorem: Let M, N be compact, convex spaces and f a function on $M \times N$ that is upper semicontinuous and quasi-concave in M and lower semi-continuous and quasi-convex in N ; then

$$\max_{\mu \in M} \min_{\nu \in N} f(\mu, \nu) = \min_{\nu \in N} \max_{\mu \in M} f(\mu, \nu).$$

From this we deduce other general minimax theorems including those of Kneser, Fan, and Nikaido. (Contractor's abstract)

ON A GENERALIZED DIRICHLET PROBLEM FOR PLURISUBHARMONIC FUNCTIONS AND PSEUDO-CONVEX DOMAINS. CHARACTERIZATION OF SILOV BOUNDARIES, by H. J. Bremermann. Apr. 1957, 49p. refs. (AFOSR-TN-57-178) (AF 18(600)1109) AD 126473 Unclassified

Also published in Trans. Amer. Math. Soc., v. 91: 246-276, May 1959.

The Perron-Caratheodory method to find a harmonic function assuming given values on the boundary of a domain is extended from one to several complex variables. The harmonic functions are replaced by the plurisubharmonic functions. The upper envelope of the plurisubharmonic functions smaller than or equal to the given boundary values (where these are prescribed) is a plurisubharmonic function, but it is in contrast to one variable, in general not pluriharmonic, which is a real part of a holomorphic function. It exists for pseudoconvex domains and assumes the (arbitrarily) given boundary values if and only if these are prescribed on the Silov boundary. Its properties are studied and the Silov boundaries are characterized. It is shown that this

FUNCTION RINGS AND RIEMANN SURFACES, by J. Wernier. May 1957, 42p. (AFOSR-TN-57-207) (AF 18(600)1109) AD 126504 Unclassified

Also published in Ann. Math., v. 67: 45-71, Jan. 1958.

The Banach algebra C of all continuous complex valued functions of the unit circle is studied. The closed subalgebras of C which contain the constant 1 and which separate points on the circle are classified as far as possible. Rings of analytic functions on certain Riemann surfaces play a central part in the classification. A restricted class of subalgebras of C is considered. The method used here however can be applied to a much wider class.

AND LIE ALGEBRAS. I, by G. Hochschild and G. D. Mostow. June 1957, 30p. (AFOSR-TN-57-308) (AF 18(600)1109) AD 132379 Unclassified

Also published in Amer. Jour. Math., v. 79: 924-942, Oct. 1957.

Let K be a group, G a subgroup of K , ρ a representation of G , and V the representation space of ρ . A representation σ of K is an extension of the representation ρ of G if the representation space W of σ contains V as a G -stable subspace and σ coincides with ρ on V . A standard construction is given yielding W for K such that W contains V as a G -stable subspace and is finite dimensional wherever such a representation space exists at all. If K is a connected Lie group, and for the category of finite dimensional continuous representations of K , this gives a complete solution of the extendibility problem. A construction is given which makes it possible to treat the more general case where $K = HG$ with $H \cap G$ compact. Some of the basic results on the existence of faithful representations for connected Lie groups are proved by means of the extension theorem. In particular, the use of Ado's theorem on the existence of a faithful representation for a Lie algebra is completely eliminated. Zassenhaus's extension theorem (Comment. Math. Helv., v. 26: 252-274, 1952) for Lie algebras is proved.

RINGS OF ANALYTIC FUNCTIONS, by J. Wermer. July 1957, 24p. (AFOSR-TN-57-421) (AF 18(600)1109) AD 132500 Unclassified

Also published in Ann. Math., v. 67: 497-516, May 1958.

Let E be the open unit disk in the z -plane and let \bar{E} be its closure. Let ϕ be an analytic function on E extendable to all of \bar{E} to be continuous and assume if z_1 and $z_2 \in \bar{E}$, $z_1 \neq z_2$, then $\phi(z_1) \neq \phi(z_2)$. Under this hypothesis, and by a well-known theorem of J. L. Walsh (Amer. Math. Soc. Colloquium Publications, v. 20: 36), every function analytic on E and continuous on \bar{E} is uniformly approximable on \bar{E} by polynomials in ϕ . Previous work by J. Wermer on function rings and Riemann surfaces (Ann. Math., v. 67: 45-71, 1958) is continued to include the analogous approximation problem when the single function ϕ is replaced by a pair of analytic functions ϕ and f , and the disk E is replaced by a finite region on a Riemann surface. The study is restricted to the case when ϕ and f are both analytic on the boundary of the region considered as well as on the region itself.

ON THE FUNDAMENTAL GROUP OF A HOMOGENEOUS SPACE, by G. D. Mostow. June 1957 [14]p. incl. refs. (AFOSR-TN-57-371) (AF 18(600)1109) AD 136556

Unclassified

Also published in Ann. Math., v. 66: 249-255, Sept. 1957.

Proof is presented that generally if the fundamental group of a homogeneous space M is solvable, then it is finitely generated and its rank cannot exceed the dimension of M (a homogeneous space is a connected space on which a Lie group operates transitively). The method of proof consists of reducing the problem to the case in which the group acting transitively on the homogeneous space is itself solvable and of applying the results of P. A. Smith (Ann. Math., v. 36: 210-229, 1935) on solvable Lie groups. Smith proved that the rank of the fundamental group F of a group manifold G cannot exceed the dimension of G .

Kaplansky has questioned whether every vector space with an alternate inner product is the sum of two subspaces such that the inner product of any two elements in the subspace equals zero. For the case of a vector space with countable dimension, the question has been answered by Kaplansky in the affirmative. The answer is negative when the vector space has uncountable dimension as is shown by the use of a counterexample.

Let X be a topological space, F a family of couples (x, σ) where x is a point of X and σ is a positive Radon measure on X having compact support and vanishing on the point x , and G a family of positive Radon measures on X with compact supports. Let E be the set of all continuous real-valued functions u on X such that

IAS.05:027 - IAS.05:030

$\int u d\sigma \leq u(x)$ for every (x, σ) in F and $\int u d\tau \leq 0$ for every τ in G . Then E is a convex cone which is closed in the topology of uniform convergence on compact sets and also is closed under taking the minimum of two functions (i.e., is a lower semi-lattice). The authors' principal result is the converse theorem that any such cone of functions can be characterized by a set of inequalities of the above type. If the cone E is compact around its vertex (i.e., if the functions of E , suitably normalized, form an equi-continuous family), then the compact supports of the above measures can be restricted to finite sets, and the above theorem becomes a direct generalization of the classical Harnack inequalities for positive harmonic functions. [INTEGRATION OVER A COMPLEX ANALYTICAL SET] Intégration sur un ensemble analytique complexe, by P. Lelong. [1957] [34]p. [AF 18(600)1109]

Unclassified

Published in *Bull. Soc. Math. de France*, v. 85: 239-262, 1957.

An attempt is required in the theory of functions of several variables, to form an exact definition of the integral $\int_A \omega$ stretched over an analytic set A . An obstacle is the fact that analytic sets do not demonstrate points which can be made uniform. The work defines $t(\omega) = \int_A \omega$ and shows that $t(\omega)$ is a closed, positive current of double degree (p,p) when $(p = \dim A)$. The result is gained with the aid of interesting continuity theorems for currents. A particular development is devoted to the surface content of analytical sets.

SOME GLOBAL PROPERTIES OF CONTACT STRUCTURES, by J. W. Gray. May 1958, 45p. incl. refs. (AFOSR-TN-58-431) (AF 18(600)1109) AD 158235; PB 135154 Unclassified

Also published in *Ann. Math.*, v. 69: 421-450, Mar. 1959.

A problem is investigated for determining if different contact structures exist on a given manifold. A manifold carries a contact structure if the coordinate transformations can be chosen to preserve the 1-form $dz - \sum y^i dx^i$ up to non-zero, multiplicative factor. If the manifold is orientable, then this property is equivalent to the existence of a globally defined 1-form α of maximal rank. Further equivalent conditions are discussed. The existence of the 1-form implies that the structure group of the tangent bundle can be reduced to the unitary group. The manifold is said to be an almost-contact manifold. The obstructions to the existence of such a structure are investigated. Global contact transformations, i.e., transformations which preserve α up to a non-zero, multiplicative factor τ , are discussed. Analysis occurs only in the definitions and the proofs consist of algebraic manipulations. The factors τ which occur in contact transformations are not arbitrary. Results are applied to the study of deformations of contact structures. Appropriate definitions are reviewed and the proof that all deformations are trivial is provided. The property that the strict deformation space consists of the entire appropriate first cohomology group is presented. (ASTIA abstract)

THE HULL OF A CURVE IN C^n , by J. Wermer. [1958] [12]p. (AF 18(600)1109) Unclassified

Published in Ann. Math., v. 68: 550-561, Nov. 1958.

If S is a compact subset of C^n , the space of n complex variables, its hull $h(S)$ is defined to be the set of all x in C^n with the following property: to every polynomial P in n variables there corresponds a point y in S such that $|P(x)| \leq |P(y)|$. Then $h(S)$ is compact (it is the maximal ideal space of the algebra which is the uniform closure of the polynomials on S) and contains S . The author studies the nature of $h(S)$ when S is an arc or a simple closed curve, with the aid of his recent work on function algebras [Ann. Math., v. 67: 45-71; 497-516. See also item nos. IAS.05:021; IAS.05:023]. If y_1, \dots, y_n are analytic functions in a disc $D: |\lambda| < r$ and if the map $\lambda \rightarrow Y(\lambda) = (y_1(\lambda), \dots, y_n(\lambda))$ is a homeomorphism of D , then the set $Y(D)$ is said to be an element through the point $Y(0)$. A set Σ in C^n is an analytic surface if each point p on Σ , except perhaps for points in a discrete subset Σ_0 (called multiple points), has a neighborhood U in C^n such that $U \cap \Sigma$ is an element through p , while each p in Σ_0 has a neighborhood U in C^n such that $U \cap \Sigma$ is the union of a finite set of elements through p . Suppose now that $\varphi_1, \dots, \varphi_n$ are analytic functions on the unit circle T which together separate points on T and suppose that the derivative of φ_1 has no zero on T . Let Γ be the simple closed curve consisting of the points

$$(\varphi_1(u), \dots, \varphi_n(u)) \quad (|u| = 1).$$

Theorem: Under these conditions, either $h(\Gamma) = \Gamma$, or $h(\Gamma) - \Gamma$ is an analytic surface with at most finitely many multiple points; the second alternative occurs if and only if

$$\int_{|u|=1} P(\varphi_1(u), \dots, \varphi_n(u)) \varphi_1'(u) du = 0$$

for every polynomial P in n variables. Next, suppose that ψ_1, \dots, ψ_n are analytic functions on the unit interval I which together separate points on I , and suppose that the derivative of ψ_1 has no zero on I . Let L be the arc consisting of the points $(\psi_1(t), \dots, \psi_n(t))$ ($0 \leq t \leq 1$).

Theorem: Under these conditions, $h(L) = L$; in fact, every continuous function on L is the uniform limit of polynomials on L . These theorems are complemented by the following examples: (a) It was previously known that there are arcs in C^n ($n \geq 2$) whose hulls are at least 2-dimensional; (b) the author now shows that there is

a simple closed curve in C^6 whose hull is at least 4-dimensional (it contains the cartesian product of two spheres). Thus, the analyticity of the parametrizations cannot be dropped from the hypotheses of the above theorems, although the possibility is open that it can be replaced by a weaker assumption. (Math. Rev. abstract)

[THE CHARACTERIZATION OF RUNGE AREAS BY PLURISUBHARMONIC FUNCTIONS] Die Charakterisierung Rungescher Gebiete durch pluri-subharmonische Funktionen, by H. J. Bremermann. [1958] [14]p. incl. refs. [AF 18(600)1109] Unclassified

Published in Math. Ann., v. 136: 173-186, 1958.

A pair (D, D') of domains of holomorphy in C^n is called a Runge pair if D is contained in D' and if the set of all holomorphic functions on D' is dense in the set of all holomorphic functions on D , equipped with the topology of compact convergence. The main result of this paper is: (D, D') is a Runge pair if and only if $D = \lim D_k$,

$D_1 \subseteq D_2 \subseteq \dots \subseteq D$, where $D_k = \{z: V_k(z) < 0\}$ and $V_k(z)$ is plurisubharmonic in D' . $W(z)$ is called plurisubharmonic in D' if for every relatively compact subset D_0 of D' there is a sequence W_1, W_2, \dots of C^∞ -functions on D_0

such that $W_1(z) \geq \dots \geq W(z)$, $W(z) = \lim W_k(z)$, and

$$\sum_1^n \frac{\partial^2 W_k(z)}{\partial z_1 \partial \bar{z}_j} dz_1 d\bar{z}_j$$

is positive semidefinite. Consequences: (i) if (D, D') is a Runge pair and E a (1-dimensional) complex line, then $D \cap E$ is relatively simply connected with respect to $D' \cap E$. (ii) If D is a domain of holomorphy which is convex (in the usual sense), then (D, C^n) is a Runge pair. (iii) Let $D = \{z: V(z) < 0\}$ where $V(z)$ is plurisubharmonic in some neighborhood of \bar{D} ; then the Banach algebra of all continuous functions on \bar{D} which are holomorphic in D is dense in the algebra of all holomorphic functions on D , equipped with the topology of uniform convergence. IAS. 05:034; IAS. 10:001-003;
IAS. 11:001

An introduction is given for a class of function spaces, for which a potential theory without a "nucleus" is developed. Linear transformations ("contractions") $T(z)$ in the complex plane C are of importance for any two numbers z_1 and z_2 in reducing the separation:

$$|T(z_1) - T(z_2)| \leq |z_1 - z_2| \text{ and are called normal, if the}$$

point O remains fixed. Basic characteristics of Dirichlet spaces are defined. A space X of n points x_i ($i = 1, 2, \dots, n$)

is studied. \mathcal{C} is the vector space of all complex valued functions u on X and Hermite forms $H(u)$ are used to develop a Hilbert space, which can be ordered to a function $\Delta(x, y)$ defined upon $X \times X$, with the aid of which a generalized Laplace operator is formed. If for every normal contraction $T(u): H(T(u)) \leq H(u)$, then $H(u)$ is called a

Dirichlet form. If $H(u)$ is positive definite, then $H(u)$ is a Dirichlet norm and \mathcal{C} , provided with this structure, is a Dirichlet space. Numerous potential theoretical characteristics are given for these Dirichlet forms, respective spaces. A theory for the Dirichlet problem is developed. Three instructive examples from electrodynamics, electrostatics and the theory of conformal mapping are given.

[ON THE NATURE OF SOME COMPLEX ANALYTICAL ENSEMBLES] Sur l'aire des ensembles analytiques complexes, by P. Lelong. [1958] [AF 18(600)1109]

Unclassified

Published in Ann. Acad. Scient. Fenn., Series A. I., No. 250/21, 1958, 10p.

Further results are announced upon positive currents and the surface contents of analytical sets. The positive distribution forms $e = i \sum_{pq} \epsilon_p - dz_p \wedge dz_q$, con-

sidered in the complex number space C^n , have a limited growth in a more exactly defined sense. A plurisubharmonic function V is constructed through an integral, so that one has $\partial \bar{\partial} V = \epsilon$. A decrease of the growth is indicated for V . A construction of holomorphic functions for previously given zero position areas $A \subset C^n$ results as a special case. The author states the consequent result varies somewhat from the older Kneser theorem.

For any compact convex set with interior points K in the Euclidean plane E^2 , $1(K)$ is taken as the greatest

INS. 02:001; IQS. 01:001;
INT. 02:001; INT. 01:005

natural number with the following property: there are translates K_n , $1 \leq n \leq i(K)$, of K such that $K \cap K_n \neq \emptyset$ for all n ; $\text{Int } K_n \cap \text{Int } K_m = \emptyset$ for $n \neq m$. It is known that $7 \leq i(K) \leq 9$ for any $K \in E^2$, and that the bounds are obtained ($i(K) = 7$ if K is a circle, $i(K) = 9$ if K is a parallelogram). A conjecture by Hadwiger is established in the following theorem: If K is not a parallelogram, then $i(K) = 7$. Moreover, if 7 translates of K satisfy the above conditions, then one of them coincides with K . The proof using centrally symmetric convex sets, and applications are presented.

REVIEW AND ANALYSIS OF AERONAUTICAL RESEARCH INFORMATION, by S. P. Johnston and others. Jan. 1957-Dec. 1958. (AF 49(638)185)
Unclassified

Contract funds maintain the preparation of technical aeronautical abstracts, approximately 50% of which are from foreign literature. The abstracts are disseminated monthly under the title International Aeronautical Abstracts, a special section of Aeronautical Engineering Review which became Aero/Space Engineering in 1958. The abstracts are distributed to the European scientific community as a separate publication entitled IAS Abstracts. They cover the following scientific fields: acoustics (sound and noise); aerodynamics and fluid mechanics (including aerothermodynamics, boundary layer, flow of fluids, internal flow, jet flaps and wings, stability and control, and wings and airfoils); aeroelasticity; electronics; fuels and lubricants; instruments; missiles and rockets; nuclear energy; power plants (including jet, turbine, ram-jet, pulse-jet and rocket); propellers; research and research facilities; rotating wing aircraft; space travel; structures (including beams and columns, cylinders and shells, sandwich construction and thermal stress), and thermodynamics.

KINETICS OF THE SULPHURATION OF METALLIC SURFACES, by J. Llopis, J. M. Gamboa, and L. Arizmendi. Annual rept. no. 1. May 1958, 52p. incl. illus. diagrs. tables, refs. (AFOSR-TN-58-639) (AF 61(514)1329) AD 162170; PB 136887
Unclassified

Radioactive S isotopes were used to follow the kinetics of the sulfuration processes. Metallic disks were introduced into the reacting solutions and moved in simultaneous translation and rotation by a small motor running at 60 rpm. The amount of deposited S can be calcu-

lated from the measurements of radioactivity on the surfaces of the disks. Aqueous solutions of thiourea labelled with S^{35} and C^{14} were reacted with Cu and Pt and the kinetics of the reaction were followed at varying times of contact of the reacting phases. The chemical reaction took place at the surface of Cu, forming a film of CuS. The kinetics of the reaction can be represented

by the equation: $\frac{\Delta^2}{k_d} + \frac{\Delta}{k_r} = t$, where Δ is the deposit

formed per unit area. This expression contains the quadratic law, governed by k_d , and the law for reactions on interfaces, governed by k_r . Reaction with Pt finishes

with only a few layers of molecular thicknesses. The kinetics of this surface reaction can be accounted for either by a chemisorption of S on the surface of the Pt or by the formation of very thin layers in accordance with Mott's theory. Surface reaction experiments on Cu were conducted with solutions of sodium polysulfide

labelled with S^{35} . Results showed that at temperatures from 25° to 60°C the form of the curves representing the amount of S deposited against time corresponds to the above equation and that the reaction rate increases with temperature. For temperatures from 17° to -0.5°C a change in the kinetic law was noted because the film was porous and the corrosion was greater. The reaction of Cu and S dissolved in C_6H_6 followed a linear kinetic law. (ASTIA abstract)

A few chapters of this report are based on lectures given by von Kármán to acquaint aeronautical engineers with the phenomenon of combustion occurring in flowing media. A systematic treatment is presented for the thermodynamics of gas mixtures, the theory of chemical equilibrium, the elements of chemical kinetics, and the theory of transfer phenomena in gases and gas mixtures. Analyses are made of problems in flame stabilization, combustion of liquid droplets, and diffusion flames.

THE COMBUSTION OF DROPLETS. INFLUENCE OF FORCED CONVECTION, by C. S. Tarifa and G. Millan.

INT. 01:006, 007; INT. 03:001, 002

Dec. 20, 1956 [58]p. incl. diags. tables. (AFOSR-TN-57-303) (AF 61(514)734-C) AD 132374 Unclassified

The description of the experimental installations is followed by the results of the research program carried out at the Combustion Laboratory of the INTA in order to determine the influence of forced convection on the characteristics of the combustion of fuel droplets suspended from quartz filaments in an air stream. The following fuels were tested: benzene, toluene, n-heptane, ethyl and methyl alcohols. Results confirmed Spalding's findings on the existence of envelope combustion and wake combustion. The zone where each type of combustion takes place as well as that where both occur indistinctly, are determined. Results also suggest the applicability of Frössling's law to the study of the activation of combustion due to forced convection, at least for large Reynolds numbers. As an application of these results an appendix is concluded giving a computation of the reduction in the life-time of a droplet shot through a still atmosphere at a given initial velocity, as a consequence of convection effects. It is concluded that this reduction depends essentially on the initial Reynolds number of motion and, to a minor extent, on the Schmidt number of the fuel vapours and air.

ANALYSIS OF THE COMBUSTION PROCESSES IN GAS TURBINES, by G. Millán and S. Sanz. Oct. 8, 1956, 26p. incl. diags. refs. (AFOSR-TN-57-801) (AF 61(514)-734-C) AD 154209 Unclassified

Presented at Fourth International Congress on Combustion Engines, Zürich, 1957.

Analysis is made of the problem of the combustion of liquid fuels, specially applied to those normally used in gas turbines. Prior consideration is given to the problem of the combustion of single droplets, including the theoretical study of the process as well as an experimental verification of the results through the data obtained from the research work carried out at the Combustion Laboratory here. The effect of free and forced convection under the preceding conditions are studied both theoretically and experimentally using the results obtained at this laboratory. Experimental study is made on the interaction effect of droplets as a preliminary step for a generalization of the method to more complex systems. Graphical information is included for the determination of the times of combustion under the preceding conditions. Consideration is given to the problems of the combustion of sprays including an analysis of the possibilities of generalizing the results obtained above with the purpose of determining the combustion efficiency for more practical cases as well as other characteristic parameters of the process. An extensive

bibliography on each subject is included. (Contractor's abstract, modified)

HYDRAZINE DECOMPOSITION FLAME, by G. Millán and J. M. de Sendagorta. Aug. 30, 1957 [17]p. incl. diagr. (AFOSR-TN-57-670) (AF 61(514)997) AD 136659
Unclassified

The complete kinetic model of G. K. Adams and G. W. Stocks (Fourth Symposium on Combustion, Boston, 1952) is applied to calculate the propagation velocity of the laminar decomposition flame of hydrazine vapors. The results give an acceptable approximation to the flame velocity when they are compared to experimental values. The over-all reaction rate corresponding to the complete model is similar to that obtained with a simplified kinetic model when, for both cases, the radical concentration is determined under the steady-state assumption. COMBUSTION OF MONOPROPELLANT DROPLETS. PART I. A THEORETICAL MODEL OF THE COMBUSTION OF A DROPLET, by C. S. Tarifa and J. M. Salas Larrazabal. July 27, 1957 [49]p. incl. diagrs. table. (AFOSR-TN-57-671) (AF 61(514)997) AD 136660
Unclassified

The present work is a theoretical study of the combustion of a single droplet of liquid monopropellant in an inert atmosphere taking into consideration the diffusion phenomena and the chemical kinetics of the process. This first part of the study contains the integration of the differential equations of the process performed through an approximate analytical method. The validity of this method is checked by comparing its results with those obtained through a numerical integration of the system. Formulas are obtained from which the laws of variation of the magnitudes characteristic of the process can be deduced such as combustion velocity, distance of the flame front to the droplet, maximum temperature, etc., as a function of the droplet radius and of the different parameters, i.e., activation energy and temperature at the infinite. (Contractor's abstract)

COMPARISON OF ANALYTICAL METHODS FOR THE CALCULATION OF LAMINAR FLAME VELOCITY, by G. Millán and I. Da Riva. June 1958 [20]p. incl. diagrs. table. (AFOSR-TN-58-770) (AF 61(514)997) AD 201867; PB 136875
Unclassified

An extension is presented of the comparison between analytical methods for the calculation of the velocity of laminar flames to the case of second-order reaction, and where the ratio of diffusion coefficient to thermal diffusivity of the mixture is different from unity. The values resulting from the application of such methods to some typical cases are compared with those derived from an extension of Karman's method and with the values obtained through a numerical integration of the flame equations. The paper is divided into two parts. Part I establishes the flame equations through the usual application of the following simplifications: the molecular weight and specific heat of the mixture are constant, and thermal conductivity is independent from the composition but it varies linearly with temperature. Part II is devoted to a study of the methods under consideration by applying them to a short number of particular cases.

COMBUSTION OF MONOPROPELLANT DROPLETS, by C. S. Tarifa and P. Pérez del Notario. [1958] [40]p. incl. diagrs. tables. (AFOSR-TN-58-1038) (AF 61(514)997) AD 206477
Unclassified

Also published in Proc. Third European Aeronautical Congress, Brussels (Belgium) (Sept. 22-27, 1958), v. 2. 635-652, 1958.

A simplified model is proposed for the combustion of monopropellant droplets. The solution of the problem lies on the integration of a non-linear system of three differential equations, where the burning rate is given as

IOW. 03:001; IOW. 04:001, 002;
IEN. 01:001

an eigenvalue of the system. The integration is performed through an approximate analytical method. Results are compared to those obtained through numerical integrations of the system for first and second order chemical kinetics. Dimensionless results are shown and discussed, and some of them are compared to those obtained by experiments. A practical application is performed for hydrazine. (Contractor's abstract)

and Rescia. Properties of the confluent hypergeometric function are utilized in establishing recurrence relations of the probabilities. Some limiting cases are discussed; in particular it is pointed out the limiting case $\beta = \infty$ of Beall and Rescia is a Polya-Aeppli distribution with a consequent simplification of the computation of probabilities. The question of estimation of parameters in multiparametric families of contagious distributions will be considered in a later paper.

ON STABILITY IN THE LARGE FOR PERIODIC SOLUTIONS OF DIFFERENTIAL SYSTEMS, by G. Seifert. Mar. 18, 1957, 9p. (AFOSR-TN-57-88) (AF 18(603)51) AD 120436 Unclassified

Also published in Ann. Math., v. 67: 83-89, Jan. 1958.

The author considers the equation (1) $\dot{x} = f(x,t)$, where x is a real two-dimensional vector and f is periodic in t . The bounded, simply-connected region R in the (x_1, x_2) plane is called a relative bound for (1) if it is the closure of a domain, and if, for arbitrary t_0 , every solution $x(t)$ such that $x(t_0) \in R$ remains in R for $t > t_0$. The existence

of a periodic solution of (1) is implied by the existence of a relative bound, and the author gives additional conditions (too lengthy to be presented here) which insure its uniqueness. The method is the consideration of the boundary of R , defined parametrically by $x = z(u)$, $0 \leq u \leq 2\pi$. Let $x(t,u)$ be the solution of (1) such that $x(t_0, u) = z(u)$ and let $\Gamma_{t_0}^{(i)}$ denote the simple closed curve defined for $t \leq t_0$ by the points $x(t,u)$, $0 \leq u \leq 2\pi$.

Under the conditions given, it is shown that the length of $\Gamma_{t_0}^{(i)}$ tends to zero as $t \rightarrow \infty$, thus implying the uniqueness

of the periodic solution. The result is applied to a system equivalent to the equation $\dot{x} + f(x)x = g(x) + p(t)$. (Math. Rev. abstract)

EFFECT OF NEUTRON BOMBARDMENT ON THE MAGNETIC PROPERTIES OF IRON, by G. Biorci, G. Bonfiglioli and others. Sept. 1958 [49]p. incl. illus. diags. tables, refs. (Technical note no. 1b) (AFOSR-TN-58-1096) (AF 61(514)1331) AD 207597; PB 138781 Unclassified

Several specimens of commercial iron have been irradiated with a 1 mev neutron flux of $10^{18}/\text{cm}^2$. Comparison of magnetic properties before and after irradiation shows that the coercive force, the area of the hysteresis loop and the initial permeability have not changed appreciably, and that the remanence and maximum permeability have decreased by about 10%. Since the magnetization curves and hysteresis loops are sensitive to defects having size at least of the order of the Bloch wall thickness (1000A in Fe), their variations are interesting in investigating the possible presence of large defects produced by irradiation. Magnetic measurements seem to be more sensitive to such defects than x-rays methods. The results on magnetic properties confirm that the internal strains produced by

IEN.01:002, 003; IEN.02:001, 002

the radiation are so small that only a negligible contribution is made to the variation of the mechanical properties and that the analogy between radiation damage and cold working is very poor. It is concluded that the increase in strength of irradiated metals is mainly due to some mechanism of anchoring of the dislocations by the point defects produced during the irradiation itself.

MAGNETIC RELAXATION AT HIGH TEMPERATURE DUE TO GRAIN BOUNDARY SLIP AND TO DISLOCATIONS, by G. Biorci, A. Ferro, and G. Montalenti. Mar. 1958, 1v. incl. illus. diagrs. tables, refs. (Technical note no. 1a) (AFOSR-TR-58-68) (AF 61(514)1331) AD 158275
Unclassified

Also published in Proc. Internat'l. Conf. on Solid State Physics in Electronics and Telecommunications, Brussels (Belgium) (June 2-7, 1958), N. Y., Academic Press, v. 3 (Part I): 235-244, 1960.

The internal mechanical friction and the magnetic relaxation (the relative decrease of initial permeability after demagnetization) as a function of temperature were experimentally determined on specimens of iron of different origin. Both polycrystals and very large (10 to 30 sq cm x 0.05 cm) single crystals were examined. The elastic and magnetic relaxations of single crystals differed among the various types of iron; the magnetic relaxation showed all the characteristics of the diffusion viscosity, but the nature of what diffuses (impurities, dislocations, or other defects) was not determined. The magnetic relaxation in all the polycrystalline specimens was maximum (about 4%) at about 450°C. It corresponded to the internal friction

peak usually attributed to grain boundary relaxation, and has characteristics different from those of the diffusion viscosity. A theoretical interpretation, which is in agreement with experimental results, is given to account for a viscosity effect of this type present in all polycrystalline ferro-magnetic materials at a suitable temperature provided the magnetostriction is not zero and there are 90° Bloch walls.

ELECTRON MICROSCOPY STUDY OF SURFACE STRUCTURES IN HIGH PURITY (99.996) Al AND IN Al/4% Cu ALLOY. PART I, by G. Bonfiglioli, A. Ferro, and A. Mojoni. [1958] [16]p. incl. illus. (Technical note no. 1c) (AFOSR-TN-56-47) (AF 61(514)1333) AD 148087
Unclassified

The present work is concerned with the surface structures (SST) observed on electron microscope replicas of electropolished Al and Al/4% Cu. The results reported in the literature on the subject are reviewed and discussed together with some results by the writers. At the present state of knowledge, it is not possible to establish that the SST represent the true subgrain structure of the metal, since it is certain that their aspect is at least partially controlled by the electropolishing conditions. However, it seems very probable that the SST bear some relation with the crystal perfection, and possibly with a non-random distribution of impurity (Cu) atoms. Some further experiments are proposed, to clarify at which extent, keeping the polishing conditions constant, the true subgrain structure of the metal is related to the SST pattern. THERMOLUMINESCENCE AND F-CENTERS, PART I, by G. Bonfiglioli, P. Brovotto, and C. Cortese. [12]p. incl. refs. (Technical note no. 1b) (AFOSR-TN-58-355) (AF 61(514)1333) AD 154260
Unclassified

Also published in Phys. Rev., v. 114: 951-955, May 15, 1959.

Current theories used to explain the experimental results of thermoluminescence from x-ray irradiated NaCl crystals have been found inconsistent. A model has been proposed in which F-centers are the only traps present and some capture centers, probably V-centers, are responsible for depopulating the conduction band of the electrons raised from the F-centers. Various probabilities are associated with the different recombination

centers, so that as a recombination level becomes saturated with electrons from the conduction band, another level begins to fill, even though its probability of doing so is less than the first level. In this way the problem inherent in the first-order process explanation of the multiple peaks in the glow curves can be explained without the introduction of multiple types of traps.

Electron microscopy was used to study the relationship between the surface substructure of Al and Al/4% Cu alloy as controlled by the degree of aging and the surface substructure which appear in replicas of electro-polished specimens. The observations indicated that

IEN. 02:008; IST. 01:014-016

the surface substructure pattern is formed because of a selective oxidation which takes place when electro-polishing is conducted under proper conditions. The surface substructure in pure Al fails to give a direct picture of the actual substructure of the metal. In case of the Al/Cu alloy, however, there is a dependence upon the distribution of Cu atoms, which is particularly noticeable when Cu-rich phase precipitates begin to appear.

When an irradiated NaCl crystal is heated according to $T = T_0 + \beta t$, where T_0 is the initial crystal temperature, the crystal emits many peaks of light successively. The proposed theory indicates that some kinds of luminescent centers, L_i , (as many as the number of peaks)

are present in the irradiated crystal beyond the F centers. The emission of the i -th peak is due to the recombination with L_i centers of the electrons which have been thermally activated from F centers. The equation which rules the kinetics of the process for the peak is $-dN/dt = p_i e^{-E/kT} N_i n$, where N and n are respectively the instantaneous concentrations of the L_i and F centers, p_i is the transition probability belonging to the i -th, and E is the activation energy required.

THE RELATION BETWEEN PUPIL EFFICIENCIES FOR SMALL AND EXTENDED PUPILS OF ENTRY, by A. M. Ercoles, L. Ronchi, and G. T. di Francia. [1956] [6]p. incl. diagrs. (AF 61(514)634-C)
Unclassified

Published in *Optica Acta*, v. 3: 84-89, June 1956.

The authors investigated the magnitude of the apparent brightness produced by rays impinging on the same retinal area (the fovea) at different inclinations. In the measurements the photometric matching fields were illuminated by the method of Maxwellian view. Pupil efficiencies were determined for effective pupils of entry (focussed images in the pupil plane) as follows: a single "pinhole", two pinholes placed either symmetrically or asymmetrically with respect to the

pupil center, full circles and rings centered in the pupil, and finally, semi-circles. The main object was to find if the observed pupil efficiency for the extended pupil of entry patterns could be derived from the observed pupil efficiencies of the parts by applying the additive law. The three observers showed different behavior but in no case was the derived efficiency for an extended pupil of entry pattern greater than the directly observed efficiency (over-additivity). On the other hand, under-additivity does occur. A tentative theoretical explanation of under-additivity is suggested in terms of inhibition and of possible differences of inclination of the axes of the foveal cones. But it is conceivable that a component of inhibition may depend on the color-differences which accompany the Stiles-Crawford effect. (Contractor's abstract)

BASIC RESEARCH IN THE FIELD OF VISION. ON THE INFLUENCE OF BOTH SHAPE AND COLOR OF THE LIGHT STIMULUS ON THE HUMAN ELECTRORETINOGRAM, by L. Ronchi and P. Strocchi. [1957] 14p. incl. diagrs. (Technical note no. 9) (AFOSR-TN-57-64) (AF 61(514)634-C) AD 120405
Unclassified

Also published in *Atti Della Fondazione G. Ronchi*, v. 12: 61-69, Jan.-Feb. 1957.

The authors resume and extend an earlier research devoted to the study of the relation between the electroretinogram and the shape of the light stimulus. The predominance of light stimulus showing a slow time gradient of illumination with respect to rectangular stimuli of equal energy has been investigated in white and green (5461A) light. Both types of stimuli turn to be equivalent when blue-violet light (below 4916A) is used. These facts led them to suggest the hypothesis that in the vision of a temporal gradient of illumination an important role is played by those rods which are intermediate between the ideal rods and the cones. Also published in *Atti Della Fondazione G. Ronchi*, v. 12: 173-179, Mar.-Apr. 1957.

The variation of the critical flicker frequency is investigated as a function of the shape of the light pulses in different retinal locations. The predominance of the saw-tooth stimuli with respect to rectangular stimuli of equal energy is tested in extrafoveal vision, while in foveal vision the critical conditions do not depend on the shape of the light stimuli, in agreement with the classical assumptions. The effect is remarkable when white or green stimuli are used, but disappears when red or blue-violet stimuli are used. The agreement between these results and those obtained taking as response index the b-wave of the electroretinogram elicited by a single flash is stressed. (Contractor's abstract)

A discussion is presented of the human electroretinogram (Erg). Existing literature is surveyed to determine factors which influence the variability of responses. The results are discussed under differences in responses of different subjects to a given light stimulus, and differences in responses of the same subject to a given light stimulus. A statistical analysis is made concerning the scotopic b-wave and the fine structure of the Erg from 2000 available records. Particular attention is given to the response to 2 stimuli with the same energy but different shapes. The statistical validity of the predominance of a saw-tooth stimulus over a rectangular stimulus is discussed. The small wavelet which sometimes appears at the beginning of the b-wave is studied. Evidence is given that this wavelet is caused by cone reaction; no correlation is found between the implicit time of the wavelet and that of the main b-wave, and the frequency of occurrence decreases with increased exposure time. A statistical examination is made of the fast and slow components of the b-wave obtained in response to stimuli of practically unlimited duration and the time of rise ranging between 1 and 60 μ sec.

Research has been performed under the contract on the behavior of the human eye to determine the best conditions for vision and for the interpretation of many types of light signals. General aspects investigated are: (1) the role of the relative motion of an image with respect to the retina; (2) vision of a field with a space gradient of luminance; (3) the influence of drugs such as mydriatics and miotics on vision; (4) the reaction of the dark-adapted retina to a time variation of luminance; and (5) foveal and extrafoveal vision. One important conclusion reached is that detection and recognition are greatly improved by the presence of Mach bands. Therefore, it is useful to make them appear at the edge of an object

Also published in *Atti Della Fondazione G. Ronchi*, v. 12: 180-186, Mar.-Apr. 1957.

The differential sensitivity of the eye was measured by 2 observers on 6 fields with different luminance gradients. Different slopes were obtained by varying the width of the graded zone while the luminance of the 2 uniform zones was kept constant. The visual angle subtended by the graded zone (angular distance between lines a and b) could take the following values: 7, 12, 18, 25, 33, and 51 min of arc. Three sessions of foveal measurements and 6 of extrafoveal measurements (fixation point at 6° from the test stimulus on the nasal side of the visual field) were made with each of the following fields: 7, 12, 25, 33, and 51 min. The greatest number of observations were carried out with the 18 min field, 15 sessions of foveal measurements and 10 sessions for each of the following conditions: fixation point at 3° from the test stimulus, both on nasal and temporal side, and 6° on nasal side. The results obtained under equal experimental conditions were averaged and plotted separately for the 2 observers. The hypothesis that outside the foveal the differential sensitivity is affected by the presence of the gradient of luminance and not only by its rapid variations appeared to be supported. The foveal mechanism of interaction in the presence of a field with a linear gradient of luminance acts in such a way as to enhance the visibility of the borders of the graded field; for this mechanism a spatial variation of the luminance gradient seems to be particularly effective. The perifoveal mechanism tends to enhance only the visibility of the graded field as a whole, perhaps because of its operating in a retinal area having lower visual acuity.

Published in Atti Della Fondazione G. Ronchi, v. 12: 187-195, Mar.-Apr. 1957.

The contrast effect due to a field with a saw-tooth luminance distribution has been investigated. It has been found that the subjective luminance does not differ from that due to a uniform field, when the luminance variations are less than the differential threshold. Further the brightness of the Mach bands due to fields having different luminance distributions have been compared. The Mach band brightness is discussed in terms of the local variation of the luminance gradient.

BINOCULAR MEASUREMENTS OF BRIGHTNESS ON A FIELD PRESENTING A LUMINANCE GRADIENT, by A. Fiorentini and T. Radici. [1957] [9]p. incl. illus. diags. tables. (AF 61(514)634-C)

Unclassified

Published in Atti Della Fondazione G. Ronchi, v. 12: 453-461, Sept.-Oct. 1957.

A measurement of the subjective brightness distribution on a field presenting a linear gradient of luminance has been obtained by the method of binocular comparison. The measurements were performed by 2 observers. The comparison field is presented to the left eye only and the test field to the right eye only, so that the comparison field is not affected by the test field. The results of the 2 observers agree qualitatively and the small dispersion of the single experimental points seems to attest the accuracy and soundness of the method used. (Contractor's abstract)

ON THE INTEGRATIVE PROPERTIES OF THE DARK ADAPTED RETINA: ELECTRORETINOGRAPHIC INVESTIGATION, by L. Ronchi and M. Bittini. [1957] [9]p. incl. diags. tables. (AF 61(514)634-C)

Unclassified

Published in Atti Della Fondazione G. Ronchi, v. 12: 477-485, Sept.-Oct. 1957.

When blue-violet stimuli are used, at mean luminance levels, the dark adapted retina is found to be able to integrate all the energy received within the latency time of the b-wave, independently of the distribution of the luminance as a function of time. For white (or green) stimuli, this property does not hold: the efficiency of a given amount of energy is greater, the greater is the time of variation of the luminance within the stimulus. ON THE ELECTRICAL RESPONSE OF THE DARK-ADAPTED HUMAN RETINA TO STIMULI PRESENTING DIFFERENT TIME-LUMINANCE DISTRIBUTIONS, by L. Ronchi. [1957] [9]p. incl. diags. refs. (AF 61(514)-634-C)

Unclassified

Published in Atti Della Fondazione G. Ronchi, v. 12: 560-568, Nov.-Dec. 1957.

A summary is given of a number of researches made during the past 3 yr by the Istituto Nazionale di Ottica, concerning the influence of the shape of the light stimulus on the human electroretinogram. The reaction of the dark-adapted retina to a time variation of luminance has been investigated by measuring the height of the b-wave as well as the latency time and the rate of rise. The scotopic b-wave seems to be due to at least two different types of receptors; one type is able to integrate all the energy received within the latency time (at mean luminance values); for the other type, a given amount of energy is the more effective, the greater is the time of variation of the luminance during the latency time. With slowly rising stimuli of practically unlimited duration it was noticed that, in spite of the large variability of the responses, the slow components of the retinal reaction tend to inhibit the rapid ones. In some cases, the response consists of a slowly rising potential, nearly parallel to the rising of the luminance.

The visual contrast effect known as Mach bands, has

been investigated using colored fields. It has been found that the Mach lines are produced only by a sharp variation of the gradient of luminance along a given direction, but not by a sharp variation of the gradient of color. The characteristics of a bright Mach band (width and position) visible in a colored field where the gradient of luminance presents a sharp variation, turn out to be independent of the color. The band appears less saturated than the other parts of the field, and the degree of the desaturation has been found to be of the same order of magnitude for green as for red. The hypothesis is advanced that the mechanism responsible for vision of the bright Mach band is achromatic. (Contractor's abstract)

The characteristics are investigated of the Mach bands perceived in a field where the luminance varies in one direction. Five fields, which differ as to the extent of the graded zone, are tested. The brightness, the width and the position of the Mach bands are measured. It is found that the bright band and the dark band do not have symmetrical positions with respect to the edges of the graded zone, that their brightnesses vary by different amounts when the width of the graded zone decreases, and that the bright band is generally narrower than the dark band perceived in the same field. The lack of symmetry of the two bands is discussed. (Contractor's abstract)

Presented at the Internat'l. Colloquium on Physical Problems of Color Television, Paris (France), July 2-6, 1957.

Published in *Optica Acta*, v. 5: 71-76, Jan. 1958.

The presence of blurry edges between two areas of

different luminance produces a particular phenomenon of visual contrast, i.e., two lines are perceived, a bright line and a dark line separating the blurry edge of each area respectively. This phenomenon improves contour perception. It is of importance for television where the transmission of high luminance gradients requires a large frequency band. Luminance measurements have been carried out at various points of a field comprising two areas of different luminance, separated by a linear luminance gradient. Areas luminance levels are within normal television luminance values. Measurements have been carried out by binocular balance. Vision of blurry edges has also been investigated in the case of moving objects. Areas of similar nature, but with vibratory motion in a direction perpendicular to the edges, have been displayed to the observer. It has been found that, as long as movement amplitude and rate remain below certain limit values, area motion actually improves the perception of contrast. (Contractor's abstract)

BASIC RESEARCH IN THE FIELD OF VISION. PART 1. ON THE ELECTRICAL RESPONSE OF THE HUMAN EYE TO RED STIMULI OF DIFFERENT SHAPE, by L. Ronchi. **PART 2. EFFECT OF PULSE SHAPE ON CRITICAL FLICKER FREQUENCY AT DIFFERENT LUMINANCE LEVELS**, by M. Bittini. Jan. 1958 [13]p. incl. illus. tables, refs. (Technical note no. 1) (AFOSR-TN-58-208) (AF 61(052)17) AD 152249 Unclassified

Part 2 also published in *Atti Della Fondazione G. Ronchi*, v. 13: 47-50, Jan.-Feb. 1958.

Part 1: The responses to red stimuli presenting different distributions of time-luminance are compared. The height of the x-wave seems to be independent of the shape of the light stimulus while the height of the b-wave is greater, the greater the time of variation of the luminance. The latencies to peak of both waves are greater with a slowly rising stimulus than with a steep stimulus. Part 2: The influence of the shape of equal energy light pulses on the critical luminance (L_c) is

investigated at different frequencies of interruption in extrafoveal vision and in dark adaptation (angular diameter of the test field 1°). At low frequencies, fusion with saw-tooth pulses, occurs at a critical luminance lower than with rectangular pulses. The reversal is tested at higher frequencies. The "inversion" point is found just at the frequency value at which the rod branch matches the cone branch in the frequency of interruption against the L_c curve. (Contractor's abstract)

Part 1 also published in *Atti Della Fondazione G. Ronchi*, v. 13: 129-134, Mar.-Apr. 1958.

Part 2 also published in *Atti Della Fondazione G. Ronchi*, v. 13: 123-128, Mar.-Apr. 1958.

Part 1: The variability of the electroretinographic response obtained from a dark-adapted eye with stimuli of different colors (blue, green, yellow, red) was investigated. Blue or green stimuli elicit in most cases responses which consist of a scotopic b-wave, while

the cone response is either inhibited or revealed only by a small positive wavelet. In the case of red or yellow stimuli the variability of the shape of the electroretinograms appears instead to be great. This effect may be attributed to the fact that, in spite of dark adaptation, rod reaction is impaired by the red stimulation. The responses of the various groups of rods showing different time constants are not synchronized, and multiple waves arise. Part 2: If the scotopic b-wave is taken as an index of the efficiency of a light stimulus at high luminance levels, the efficiency seems to depend on the following parameters: total energy, color, duration, and total time of variation of the luminance. The behavior of the derivative of the luminance does not seem to affect the height of the response, but has some influence on the implicit time in that the response elicited by a slowly rising stimulus is somewhat delayed in time with respect to that elicited by a stimulus containing rapid variations of the luminance. The fine structure of the electroretinogram represented by the ripples on the top of the b-wave appears to be delayed.

UnclassifiedPresented at meeting of the Amer. Phys. Soc.,
Cambridge, Mass., Mar. 30-Apr. 2, 1959.Abstract published in Bull. Amer. Phys. Soc., Series
II, v. 4: 198, Mar. 30, 1959.A hot-wire anemometer represents a nonlinear system
consisting of the flow-field, the wire, and the asso-
ciated instrumentation. The method of extracting in-
formation from a heated thin wire, cooled by an un-
steady compressible flow, based on the concept of local
linearization around each operating point of the system,
was extended to wires in yaw and to constant-tempera-
ture systems. An X probe was designed and used for
boundary-layer measurements from which the Reynolds
stress and the energy flux could be obtained. The re-sults appeared to be consistent with plausible extrapola-
tions of low-speed concepts. Procedures for measure-
ments with single normal wires were clarified and im-
proved. The satisfactory agreement between results of
measurements with sleeved and bare wires made both
of tungsten and platinum-10% rhodium, with a variety of
holders, provided further verification of the rather
complicated methods of measurement and interpretation.
The techniques were applied to the study of the fluctua-
tion structure of a thick fully-developed turbulent bound-
ary layer at $M_1 = 1.77$. (Contractor's abstract)

(600)765) AD 148122 UnclassifiedAlso published in Jour. Phys. Chem., v. 62: 559-565,
May 1958.An improved method has been developed for measuring
the temperature of equilibrium between the crystal and
solution phases of multicomponent systems using a con-
stant temperature differential to control rate of cooling
and automatic recording of temperature as a function
of time. This makes possible the determination of true
equilibrium temperature without corrections for under-
cooling. Where crystallization velocities and rate of
attainment of equilibrium are small, this enables one to
obtain the true equilibrium temperature from a study of
the effect of cooling rate on the temperature displace-
ment of the cooling curve. The method has been applied
to the system diphenylmethane-diphenyl ether and com-
pared with other methods. (Contractor's abstract)

Also published in Rev. Scient. Instruments, v. 30: 463-467, June 1959. (Title varies)

An automatic adiabatic shield control has been constructed for a calorimeter designed to measure heat capacities and heats of fusion, using a combination of partial on-off control coupled with an integrating device which keeps the on-cycle equal in length to the off-cycle. A difference thermocouple is the primary source of the control impulse. By calibrating the control with zero heat input, corrections can be made for variations from absolute adiabatic states. Measurements on test compounds indicate a reduction of error due to heat leak to less than 0.1% of the heat to the sample. (Contractor's abstract)

THE ENTROPY OF FUSION OF LONG CHAIN PARAFFINS (Abstract), by R. H. Aranow, D. H. Andrews, and L. Witten. [1957] [1]p. (AF 18(600)765) Unclassified

Presented at Twelfth Calorimetry Conf., Portsmouth, N. H., Sept. 3-6, 1957.

A number of entropies of fusion of straight chain hydrocarbons have been tabulated from data in the literature. Where entropies of transition have been observed these have been added to the entropies of fusion in the appropriate manner to get an effective total entropy of fusion. A theory has been worked out to account quantitatively for the increase of entropy of fusion with chain length, based on the idea that each CH_2 group has three positions of minimum potential energy and that it is the resulting geometric disorder which accounts for the entropy of fusion increase with chain length. The relation of this theory to other physical chemical properties is discussed.

SOME OBSERVATIONS ON THE MEASUREMENTS OF HEATS OF FUSION (Abstract), by R. H. Dettre and D. H. Andrews. [1957] [1]p. (AF 18(600)765) Unclassified

Presented at Twelfth Calorimetry Conf., Portsmouth, N. H., Sept. 3-6, 1957.

Using a newly developed automatic adiabatic control designed to take into account rapid variations in rate of heating, measurements have been made of the heat of fusion of diphenyl ether and diphenyl methane. These values have been checked against values obtained from freezing point studies using a new design of freezing point apparatus which permits improvement in the accuracy of observation of the freezing points of binary mixtures. If, as sometimes suggested, there is a loosening of the bonds in the crystal lattice in the range of 10 to 20° below the melting point, this should cause not only an abnormal rise in heat capacity but an abnormal increase in solubility. If, on the other hand, a rise in heat capacity is due to traces of impurity there should not be a correlated increase in solubility. In this particular system, no abnormal changes in solubility were observed in the region below the melting point. The heat of fusion as calculated from the thermodynamic equation for solubility agrees with the value of the heat of fusion obtained calorimetrically if the increase in the heat capacity immediately below the melting point is attributed to impurity. This emphasizes the need for accurate measurements of heat capacity in the region just below the melting point, if proper extrapolation is to be made to obtain correct values of the heat of fusion.

THE ENTROPY OF FUSION OF LONG CHAIN HYDROCARBONS, by R. H. Aranow, L. Witten, and D. H. Andrews. Nov. 1957 [18]p. inci. diagrs. refs. (Technical note no. 3) (AFOSR-TN-58-88) (AF 18(600)765) AD 148138; PB 131758
Unclassified

Also published in Jour. Phys. Chem., v. 62: 812-816, July 1958.

The entropy of fusion of long chain paraffins is attributed to the onset at melting of the freedom of the molecule to undergo hindered rotation about each carbon to carbon bond. The entropy of fusion increases by a factor close to $R \ln 3$ for each additional CH_2 group added to the chain. Experimental deviations can be used to obtain information concerning the rotational energy levels of the molecules. The melting temperature T_m of the paraffin has been related to the energy level of the first torsional vibrational state E by the empirical relation $T_m = E/3k$.

DIHYDROPENTABORANE, by T. E. Larson and W. S. Koski. June 1957 [16]p. incl. diagrs. table. (Technical note no. 6) (AFOSR-TN-57-324) (AF 18(600)1526) AD 132396
Unclassified

Presented at meeting of the Sixteenth Internat'l. Congress of Pure and Appl. Chem., Paris (France), July 18-24, 1957.

Published in Résumés des Communications, v. 1: 157, July 1957.

The kinetics of the exchange of deuterium and B^{10} between diborane (B_2H_6) and dihydropentaborane (B_5H_{11}) were investigated. The order of both exchanges was 0.5 with respect to B_5H_{11} and 1.0 with respect to B_2H_6 . The reaction was a homogeneous one. The ratio of the deuterium rate constant to the boron rate constant was approximately 2. All of the deuteriums and borons and both molecules participated in the exchange. A possible mechanism for the exchange is proposed and consists of a rapid equilibrium between dihydropentaborane and two fragments arising from the dissociation of B_5H_{11} . This is followed by a rate determining bimolecular collision between one of the fragments and diborane resulting in the isotopic exchange. (Contractor's abstract)

A MASS SPECTROMETRIC APPEARANCE POTENTIAL STUDY OF ISOTOPICALLY LABELED DIBORANES, by W. S. Koski, J. J. Kaufman and others. Feb. 1958, 23p. incl. tables, refs. (Technical note no. 7) (AFOSR-TN-58-157) (In cooperation with Knolls Atomic Power Lab., Schenectady, N. Y.) (AF 18(600)1526) AD 152183
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 80: 3202-3207, July 5, 1958.

The appearance potentials of the molecule ions formed by electron impact from B_2H_6 , $B_2^2H_6$, B_2D_6 , and $B_2^2D_6$ have been measured by means of a mass spectrometer, where B^2 indicates the B^{10} isotope. A set of apparently self-consistent ionization potentials for these molecule ions has been estimated from the appearance potentials of the B^{10} enriched compounds. The resulting calculated ionization potentials for the fragments from $B_2^2H_6$ are compared with the ionization potentials estimated for fragments from $B_2^2D_6$ and are also compared with the results obtained from C_2H_6 . The mass spectra of B_2H_6 , $B_2^2H_6$, B_2D_6 , and $B_2^2D_6$ were also run at 70 ev

ionizing voltage in order to obtain a set of fragmentation patterns of the isotopically labeled diboranes under identical conditions. The mass spectra were used to calculate the monoisotopic spectrum of each type of diborane. (Contractor's abstract, modified)

A MASS SPECTROSCOPIC APPEARANCE POTENTIAL STUDY OF SOME BORON TRIHALIDES, by W. S. Koski, J. J. Kaufman, and C. F. Pachucki. Oct. 1958 [23]p. incl. diagr. tables, refs. (Technical note no. 8) (AFOSR-TN-58-855) (AF 18(600)1526) AD 203497
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 1326-1331, Mar. 20, 1959.

The appearance potentials of the positive ion fragments from BCl_3 , BBr_3 and BI_3 were measured mass spectroscopically. These measurements permitted a determination of the average B-I bond dissociation energy in BI_3 . A set of apparently self-consistent ionization potentials for the boron trihalides and fragments formed from these molecules has been estimated and compared with ionization potentials of other BY_3 molecules as well as for BY_2 and BY fragments (where Y can be H, halogen or alkyl substituents). Comparison of the ionization potentials of BY_2 radicals indicates an interesting correlation between the ionization potentials and the nature of the group attached to the boron. CY_3 radicals exhibit a similar behavior. The mass spectra of the boron trihalides were also run at 70 ev ionizing voltage to obtain a set of fragmentation patterns under constant conditions. KINETICS OF THE EXCHANGE OF DEUTERIUM BETWEEN DIBORANE AND TETRABORANE, by J. E. Todd and W. S. Koski. Oct. 1958 [17]p. incl. diagrs. tables, refs. (Technical note no. 9) (AFOSR-TN-58-940) (AF 18(600)1526) AD 205086
Unclassified

Also published in Jour. Amer. Chem. Soc., v. 81: 2319-2324, May 20, 1959.

The kinetics of the exchange of deuterium between diborane and tetraborane were found to be complex. The results indicate that the exchange proceeds by 2 different paths—one involves 2 hydrogen positions in tetraborane, and the other involves the remaining 8 or all 10 hydrogen positions. The major reaction is interpreted in terms of a rate-determining reaction of BD_3 from diborane with

JHU.08:002 - JHU.08:006

B_4H_{10} , while the minor reaction is envisaged as a rate-determining activation of 2 sites in tetraborane followed by rapid deuterium exchange with B_2D_6 . Boron atoms also exchange in this system although detailed kinetics studies were not made. (Contractor's abstract)

EXTENSIONS OF REPRESENTATIONS OF LIE GROUPS II, by G. D. Mostow. Aug. 1957, 27p. (AFOSR-TN-57-439) (AF 18(600)1474) AD 136429 Unclassified

Also published in Amer. Jour. Math., v. 80: 331-347, Apr. 1958.

A discussion is presented of the general problem of extending a representation from a normal closed connected subgroup G to an analytic group L with $L \supset G$. The special case of extending from an ideal G to a semi-direct sum $Q + G$, of the subgroups G and Q is resolved, and a Lie algebra L is reconstructed from an ideal G by successive formation of semidirect sums. Besides the extension methods previously developed (Extension of Representations of Lie Groups and Lie Algebras I, by G. Hochschild and G. D. Mostow), a new technique is set down which relies on the theory of algebraic groups, particularly on fully reducible subgroups of algebraic groups.

[THEORY OF INVARIANTS], by G. D. Mostow. Final technical rept. Aug. 1, 1955-July 31, 1958, 4p. (AFOSR-TR-58-101) (AF 18(600)1474) AD 162219; PB 136866 Unclassified

Research performed under this contract dealt mainly with 2 facets of the theory of Lie groups which involve distinctively different methods of analysis. Problems were investigated relating to the representations of a Lie group by linear transformations of a linear space and relating to the operations of a Lie group as a group of topological transformations on a manifold. Good results were obtained with problems related to the ring of representative functions of a Lie group.

TOROID TRANSFORMATION GROUPS ON EUCLIDEAN SPACE, by D. Montgomery and G. D. Mostow. [1958] [23]p. incl. refs. [AF 18(600)1474] Unclassified

Published in Illinois Jour. Math., v. 2: 459-481, Dec. 1958.

This paper deals with the action of an r -dimensional toroid G on a space X . The intersection of the isotropy groups G_y , $y \in Y \subset X$, is called the fixer of Y . For

$H \subset G$, $H^+(G)$ is the intersection of all the fixers containing H . A point x of X is a weight point if G_x is $(r-1)$ -dimensional; the homomorphism $G \rightarrow G/G_x$ is the weight

associated with x . A fixed point of $H \subset G$ is a point which is fixed under each element of H . The fixed set $F(H)$ of H consists of its fixed points. A star circle subgroup of G is a circle subgroup whose fixed set is not the fixed set of any connected subgroup property containing it. It is shown that if X can be compactified to a cohomology n -sphere over the integers by adding a single point ∞ , and if G acts almost effectively, then G is spanned by its star circle subgroups, $0 < \dim F(G) \leq n-2r$ and $F(G) \cup \infty$ is a cohomology sphere. If G acts effectively and $n = 2r$ or $2r+1$, then G has exactly r star circle subgroups; all fixer subgroups are connected; $(ST)^+ = S^+T^+$ for any two subgroups S and T ; G

has exactly r weights, 2^r fixer subgroups and 2^r isotropy classes. In case X is HLC and $n \leq 2r+1$, it is shown that the set U of points with trivial isotropy subgroups decomposes as $B \times G$, where B is a euclidean-like cohomology manifold. (Math. Rev. abstract)

REPRESENTATIONS AND REPRESENTATIVE FUNCTIONS OF LIE GROUPS. II, by C. Hochschild and G. D. Mostow. [1958] [9]p. (AF 18(600)1474) Unclassified

Published in Ann. Math., v. 68: 295-313, 1958.

This paper is a continuation of part I, hereafter referred

JHU.09:004 - JHU.09:006

to as RFGI [Ann. Math., v. 66: 495-542, 1957]. We continue here with some of the notation of that review. Let G be a Lie group, $R(G)$ the algebra of representative functions on G , A the group of proper automorphisms of $R(G)$, G^+ the universal complexification of G , and let t, t^+ be, respectively, the natural homomorphisms of G and G^+ into A . Also let γ be the homomorphism of G into G^+ implicitly defined in RFGI. The main results of RFGI had to do with a type of group referred to as a Tannaka group in our review of RFGI.

Here G^+ and $R(G)$ are investigated under more general circumstances. An early result settles the question of the existence of a locally faithful representation of G in the following way. Let G' be the commutator subgroup of G , S a maximal semisimple analytic subgroup of G , and T the radical of G' . Then G has a locally faithful representation if and only if the following conditions are satisfied: (1) G' is closed in G , (2) T is simply connected, and (3) $S \cap T = (1)$. A corollary then asserts that if G is solvable, connected, the existence of a locally faithful representation implies the existence of a faithful representation. Observe that $\text{Hom}(G, C)$ and $\text{Hom}(G, C^*)$ are subsets of $R(G)$. Let \exp denote the map from $\text{Hom}(G, C)$ to $\text{Hom}(G, C^*)$ given by exponentiation. Also let Q denote the image of \exp . Now for any $\alpha \in A$ and any $h \in R(G)$ put $\alpha'(h) = \alpha(h)(1)$. The following

characterization of the subgroup $t^+(G^+)$ of A is then given. Let $\alpha \in A$. Then $\alpha \in t^+(G^+)$ if and only if $\alpha'(\exp h) = \exp(\alpha'(h))$ for all $h \in \text{Hom}(G, C)$. Under certain assumptions the following result on the structure of $R(G)$ is obtained. Let P be the kernel of t . Then the following conditions are equivalent. (1) The factor group of the radical of G/P modulo its maximal nilpotent normal analytic subgroup is compact. (2) There is a finitely-generated translation and complex conjugation stable subalgebra U of $R(G)$ such that $C + \text{Hom}(G, C) \subset U$, $R(G) = U[Q]$ and the elements of Q are free over U . (3) G^+ is isomorphic with an algebraic group of complex linear transformations of a space $C \otimes V$ where V is a real vector space stable under $\gamma(G)$. It is also proved that for a group satisfying any one of the (equivalent) conditions of the theorem above the structure of A is given by $A = W \times t^+(G^+)$ where W is isomorphic to $\text{Hom}(Q, C^*)$. ON A THEOREM OF FROBENIUS, by P. Hartman. Feb. 1957, 17p. (Technical rept. no. 4) (AFOSR-TN-57-66) (AF 18(603)41) AD 120408 Unclassified

Proof is given for Frobenius' theorem which states that if w_1, \dots, w_h denote h linearly independent linear forms

in dx^1, \dots, dx^n with continuous coefficients in $|x| < 1$

possessing continuous exterior derivatives w_1, \dots, w_h and satisfying the integrability conditions $w_1 \dots w_h w_j = 0$ for $j = 1, \dots, h$, then in a vicinity of $y = 0$ there exists a mapping $x_j = x_j(y^1, \dots, y^n)$ for $j = 1, \dots, n$, which satisfies $x(0) = 0$ of class C^1 with nonvanishing Jacobian, $\det \frac{\alpha x^j}{\alpha y^k} \neq 0$, and which transforms w_1, \dots, w_h into linear

forms in dy^1, \dots, dy^h (with coefficients which are continuous functions of y^1, \dots, y^n). The integrability conditions are necessary and sufficient for the assertion of the theorem. The proof is deduced from 3 lemmas on the local uniqueness of solutions of nonlinear systems of ordinary differential equations. The first depends only on the boundedness of the coefficients in the exterior derivative of w_j ; the second requires continuity, and the third proves that under certain of the given conditions, the resulting matrix is independent of a certain scalar.

ON HÖLDER CONTINUITY AND NON-LINEAR ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS, by P. Hartman. Apr. 1957, 13p. (Technical rept. no. 5) (AFOSR-TN-57-175) (AF 18(603)41) AD 126470 Unclassified

Also published in Duke Math. Jour., v. 25: 57-65, Mar. 1958.

A discussion is presented of the estimates for the degree of continuity of mappings $(x, y) \rightarrow (p, q)$ subject to inequalities of the form $p_x^2 + p_y^2 + q_x^2 + q_y^2 \leq \text{const}$. $\partial(p, q) / \partial(x, y) + \text{const}$. The results are applied to the question of the Hölder continuity of second order derivatives of a solution of a second-order, elliptic partial differential equation in 2 independent variables. In particular, a crude but useful form of E. Hopf's (Math. Zeltschr., v. 34: 194-233, 1932) interior estimates for the case of 2 independent variables result very simply, without the use of potential theory. (Contractor's abstract)

ON EXTERIOR DERIVATIVES AND SOLUTIONS OF ORDINARY DIFFERENTIAL EQUATIONS, by P. Hartman. July 1957, 14p. (Technical rept. no. 6) (AFOSR-TN-57-344) (AF 18(603)41) AD 132417 Unclassified

Also published in Trans. Amer. Math. Soc., v. 91: 277-293, May 1956.

JHU.09:007, 008; JHU.20:001

Some applications are made of lemmas on local uniqueness and smoothness of solutions of systems of ordinary nonlinear differential equations. These imply results dealing with the local uniqueness of geodesics and the introduction of parallel or polar geodesic coordinates for binary Riemannian metrics. The results are extended from 2 to n dimensions and from geodesics to solutions of more general Euler-Lagrange systems. The assertions established are generalized to become applicable to problems of extremals for more general parametric problems of the calculus of variation.

ON MAXIMUM PRINCIPLES FOR NON-HYPERBOLIC PARTIAL DIFFERENTIAL OPERATORS, by P. Hartman and R. Sacksteder. Aug. 1957, 20p. incl. refs. (Technical rept. no. 7) (AFOSR-TN-57-501) (AF 18-603)41 AD 136491
Unclassified

Also published in Rend. Circ. Matem. Palermo, Series II, v. 6: 218-232, May - Aug. 1957.

Let A, B, C, D, E be defined on an (x, y)-domain T with a boundary T'. The differential operator $Lz = Az_{xx} + Bz_{xy} + Cz_{yy} + Dz_x + Ez_y$ is said to have a weak maximum principle on T if $\max_{T \cup T'} z = \max_{T'} z$

holds for every function which is of class C² on T+T' and which is of class C² and satisfies $Lz \geq 0$ on T. The following conditions are assumed and referred to as hypothesis H: (1) T is a bounded domain; (2) A, B, C, D, E are continuous functions on T which satisfy the inequalities $AC - B^2 \geq 0$ and $A^2 + B^2 + C^2 > 0$ and $A > 0$, hence $C \geq 0$; z is of class C²; and (3) z is continuous on T+T' and m denotes its maximum, $m = \max_{T \cup T'} z(x, y)$ on T+T'. The main result states: let H hold and $z(x, y) \neq m$ on every open subset of T; let $z = m$ hold at a point (x_0, y_0) of T; then there exists a characteristic arc passing through (x_0, y_0) on which $z = m$. This theorem is proved and used to derive some weak maximum principles and strong maximum principles, and to study the behavior of z at a point of T' where $z = m$. (ASTIA abstract)

ON SOLUTIONS OF $\Delta V + V = 0$ IN AN EXTERIOR REGION, by P. Hartman. Nov. 1958, 12p. (Technical rept. no. 8) (AFOSR-TN-58-984) (AF 18(603)41) AD 205914; PB 139632
Unclassified

Also published in Math. Zeitschr., v. 71: 251-257, 1959.

Let $V = V(x)$ be a solution of $\Delta V + V = 0$ in the entire p-dimensional x-space subject to the boundedness condition: $R^{-1} \int_{|x| < R} |V|^2 dx \leq C$. For fixed r, let

$V(x) = V(ru)$, where $|x| = r$ and $u = x/|x|$, have the

Fourier development (1) $r^{\frac{1}{2}(p-1)} V(ru) \sim (2\pi r)^{\frac{1}{2}}$

$\sum_{n=0}^{\infty} |c_n|^2 J_{\mu}^2(r) K(u)$ in terms of normalized spherical

functions $K_n(u)$ and Bessel functions of order $\mu =$

$n + \frac{1}{2}(p-2)$. It is shown that if $(2\pi r)^{\frac{1}{2}} J_{\mu}(r)$ is replaced by its approximation $2 \cos(r - \frac{1}{2}\mu\pi - \pi/4)$, the right side becomes a function $W(ru)$ which is an approximation to $V(ru)$ for large r in the sense that (2)

$R^{-1} \int_{|x| < R} |V - W|^2 dx \rightarrow 0$ as $R \rightarrow \infty$. This leads to

an easy proof of Magnus's theorem [Abh. Math. Sem. Univ. Hamburg]. An analog of the asymptotic formula is also obtained for solutions $V(x)$ of $\Delta V + V = 0$ defined only for large $|x|$. (Contractor's abstract)

BOUNDARY LAYER ALONG ANNULAR WALLS IN A SWIRLING FLOW, by H. Yeh. Mar. 1957, 30p. diags. (AFOSR-TN-57-105) (AF 18(600)991) AD 120455
Unclassified

Presented at meeting of the Amer. Soc. Mech. Engineers, San Francisco, Calif., June 9-13, 1957.

Also published in Trans. Amer. Soc. Mech. Engineers, v. 80: 767-776, May 1958.

The development of incompressible boundary layers along concave and convex stationary annular walls are investigated analytically and experimentally for a swirling flow, i.e., flow with both tangential and axial mean velocities. It was found that the integral momentum equation describing this type of boundary layer contains three correction terms to the conventional equation. The combined influence of these corrections appears to promote the growth of the boundary layer next to a concave wall. Other differences between the boundary layers with swirl and those without swirl are pointed out and interpreted. Measurements on turbulence intensities appear to confirm such interpretations.

NOTE ON A THERMOELASTIC PROBLEM FOR A
TRANSVERSELY ISOTROPIC HOLLOW SPHERE EM-
BEDDED IN AN ELASTIC MEDIUM, by J. Nowinski.
[July 1958] [2]p. (AFOSR-TN-58-578) (AF 49(638)377)
AD 231592 Unclassified

Also published in Jour. Appl. Mech., v. 26: 649-650,
Dec. 1959.

This note generalizes the Galerkin problem to consider thermoelastic stresses in anisotropic bodies with an axis of symmetry. Stresses are obtained in a hollow sphere of 2 different transversely isotropic or Winkler material (i.e., isotropic in a plane perpendicular to the radius vector) layers when the sphere is subjected to an internal pressure and spherically symmetrical temperature field. The sphere is embedded in an elastic medium which is also considered to be transversely isotropic. In the limiting case, the form of the Winkler coefficient is indicated for an isotropic material.

Unclassified

It is the purpose of the present paper to generalize the analysis developed by Lekhnitsky, Eubanks, and Sternberg, for transversely isotropic problems, to cylindrically orthotropic medium. The fundamental differential equation is solved for the following particular cases: (a) when it may be represented as a product of two modified Laplace operators (this implies a higher elastic symmetry, restricted by an additional relation), then the Hankel transformation has been used; (b) when the solution may be represented in a form of a product of a sine, cosine or exponential function of the variable z , and a function of the variable r , only; and (c) when the solution may be represented in a form of a combination of homogeneous integer polynomials. Some general examples concerning a half-space and a thick circular plate have been solved for illustration.

PHYSICAL PRINCIPLES OF VECTOR BALLISTO-

CARDIOGRAPHIC MEASUREMENT, by S. A. Talbot.
Final rept. Mar. 22, 1954-Mar. 22, 1958. June 1958, 1v.
Incl. illus. diagrs. refs. (AFOSR-TR-58-72) (AF 18-
(600)1107) AD 158301; PB 135626 Unclassified

An attempt was made to establish better techniques as well as improved understanding of the relationship between ballistocardiography (BCG) records and hemodynamic events. Attention was directed toward developing a first-order theory and experimental method for analyzing cardiovascular vector ballistics. A clear statement is presented on the pros and cons of a physical model able not only to provide the necessary basis for quantitatively dealing with the vector mechanics involved, but also incorporating enough of the biological realities to be meaningful. The symmetry properties of a recumbent human and the location of the cardiovascular acceleration patterns focused interest on the separation of dynamical variables possible in the transverse plane. The problem is discussed of a physical structure which is sufficiently light and rigid in all deflections and torsions to transmit without vibrational artifact the high stresses associated with gimbaling the body axially. The theory of liquid suspensions for correct frontal-plane BCG recording was scrutinized. In addition, the importance of frequency analysis of the BCG on a clinical scale was explained. PHYSICAL BASIS OF CARDIOVASCULAR SOUND.
AN ANALYTICAL SURVEY, by H. K. Wiskind and S. A.
Talbot. Dec. 1958, 118p. Incl. illus. diagrs. table, refs.
(AFOSR-TR-58-160) (AF 18(600)1337) AD 207459;
PB 140955 Unclassified

Cardiovascular sound is analyzed by relating observed phenomena to the basic concepts of physics through quantitative theoretical and experimental analysis of models. An account of simple observations of the sounds of a cavitating water jet and of an underwater vortical sound generator is given. Detailed analyses of vibrations in the human anatomy are presented. Three idealized models were investigated: (1) Monopole radiation in a model of the heart and chest having spherical symmetry. The "musical" murmur produced by an aortic regurgitant jet might be an example of such monopole radiation and it is discussed in quantitative terms. (2) Axisymmetric waves at acoustic frequencies in the blood-aorta system (waves down a viscoelastic tube containing an incompressible fluid). (3) General properties of extended tissue as an extended acoustic medium (vibrations in an isotropic viscoelastic medium with calculations of the impedance to a dipole). The development work on two types of instruments designed to measure the dynamic dilations of compliant tubes is described. The possibility of noisy murmurs being generated by turbulent blood flow is explored, and the problem of the possible

JHU.12:002, 003;
JHU.13:002, 003

effect of compliant vessel walls on the turbulent flow is briefly analyzed. (Contractor's abstract)

ION BALANCE AND LIGHT EMISSION IN THE HELIUM AFTERGLOW (Abstract), by D. E. Kerr and M. N. Hirsh. [1958] [1]p. [AF 18(600)363]
Unclassified

Presented at meeting of the Amer. Phys. Soc., Ithaca, N. Y., June 19-21, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 258, June 19, 1958.

In the afterglow following a pulsed discharge at pressures from 3 to 20 mm Hg in helium, the time dependence of I/n , the ratio of intensity of emitted molecular bands to electron density, suggests: (1) the light results from recombination between an electron and a He_2^+ ion; (2) at late afterglow times the rate of loss of He_2^+ ions

by recombination is much smaller than that by the predominant mechanism of ambipolar diffusion which occurs at a measured rate expressed by a value of D_p of 794.

The light intensity is not, in general, proportional to the square of the electron density. The electron density variation at late times reveals simultaneous loss by ambipolar diffusion and creation by collisions between metastable molecules. The ion so created may be He_2^+ , or it may be He^+ , which is rapidly converted by three-body collisions to He_2^+ . The creation of these ions is not reflected in the time dependence of the I/n ratio. We suggest that these ions may be formed in high vibrational states which do not yield molecular light directly or participate in collisional de-excitation to the ionic ground state (which we assume does yield molecular light by recombination). Various possible types of recombination mechanisms will be discussed.

CHARGE REMOVAL IN LOW-ENERGY PLASMAS (Abstract), by D. E. Kerr. [1958] [1]p. (Bound with its AFOSR-TR-58-125; AD 162274) (AF 18(600)363)
Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

Measurements of electron density in, and light radiated from decaying plasmas have been interpreted by some observers as indicating values of volume recombination coefficients as high as $10^{-6} \text{ cm}^3/\text{sec}$. Such large values

cannot result from simple radiative recombination, and other processes, such as dissociative recombinations, have been invoked. Careful examination of details of experimental procedure and of analysis and interpretation of the data raise doubt as to whether the large apparent electron loss rates are the result of volume recombination. A detailed study of recombination between electrons and He_2^+ ions shows the recombination coefficient to be certainly much less than 10^{-8} , but not less than $10^{-10} \text{ cm}^3/\text{sec}$. A critical discussion will be given of the numerous factors involved in interpretation of data leading to the results above. Connections will be shown with such basic atomic processes as: formation of excited states of molecular and atomic neutral and ionic species, destruction of these states by radiation and collisional quenching and collisions between metastable atoms. A discussion is also given of the limitations of the methods of measurement.

RADIATIVE TRANSITION IN PROTONIUM, by T. Fulton. Feb. 27, 1957, 7p. (Rept. no. HER-1) (AFOSR-TN-57-93) (AF 18(603)143) AD 120441
Unclassified

On the basis of preliminary estimates made from presently available data, the possibility of observing the radiative $2P - 1S$ transition in the hydrogen-like bound state of a proton and antiproton is suggested. A significant correction to the energy of such a transition would be provided by the nuclear interaction. The measurement of the transition energy could therefore be used to obtain a value of the scattering length for proton-antiproton scattering. (Contractor's abstract)

ANGULAR DISTRIBUTION OF K^+ MESON DECAY PRODUCTS (Abstract), by E. B. Brucker and G. Fazio. [1957] [1]p. (Sponsored jointly by Air Force Office of Scientific Research under [AF 18(603)143], Office of Naval Research, and Atomic Energy Commission)
Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 236, Apr. 25, 1957.

On the chance that the K^+ meson has spin greater than zero and is polarized when it is brought to rest in a stack of nuclear emulsions, several hundred stopped K_L mesons have been analyzed to detect an asymmetry of

the charged particle decay. Preliminary analysis by octants shows no evidence for an asymmetry. However, detailed angular distributions are now being plotted and are presented. Several possible causes for the lack of asymmetry are discussed. In addition, the angular distribution for 50 events definitely established as $K_{\mu 2}$ are presented.

PHENOMENOLOGICAL NEUTRON-PROTON POTENTIALS, by R. G. Newton and T. Fulton. [1957] [9]p. incl. diagrs. refs. [AF 18(603)143] Unclassified

Published in Phys. Rev., v. 107: 1103-1111, Aug. 15, 1957.

Central, tensor, and spin-orbit potentials are calculated for the neutron-proton triplet state. They allow explicit solution of the Schrödinger equation and fit the low-energy data: effective range, scattering length, deuteron binding energy, quadrupole moment, and D-state probability. The deuteron wave function as well as scattering wave functions which result from these potentials are also computed. The potential and wave functions which fit the low-energy singlet state data are also obtained. (Contractor's abstract)

STRIPPING TYPE NUCLEAR REACTIONS, by T. Fulton and G. E. Owens. [1957] [8]p. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(603)143 and Atomic Energy Commission) Unclassified

Published in Phys. Rev., v. 108: 789-794, Nov. 1, 1957.

An exact formal expression is derived which treats the initial and final states of a nuclear reaction in a symmetric manner. The specific example treated is the (d,n) reaction. The Coulomb interaction is not taken into account. Estimates of some of the terms of the general expression which is obtained provide some indication of the reasons for the similarity of the final results of the various approaches to direct interaction. One of the terms of the development includes effects of compound-nucleus formation. Suggestions are made for a single-particle model of the intermediate state. The process of exchange and heavy-particle stripping is incorporated into the formalism in the Appendix. (Contractor's abstract)

POLARIZATION OF THE RECOIL NUCLEUS IN $\bar{\mu}$ -CAPTURE, by T. Fulton. Dec. 20, 1957, 5p. (AFOSR-TN-58-31) (AF 18(603)143) AD 148070 Unclassified

Also published in Nuclear Phys., v. 8: 319-322, Mar. 1958.

JHU.13:010 - JHU.13:013

The complete expression is calculated for the allowed nonrelativistic transition rate of μ -capture from the atomic K-shell. It is used to obtain the expression for the polarization of the recoil nucleus. As is well known, the polarization term governs the asymmetry in the subsequent beta decay. If the incident μ are unpolarized, the polarization of the recoil following μ -capture in a Gamow-Teller transition can in principle distinguish between the coupling constants suggested by Lee and Yang and by Feynman and Gell-Mann. KNOCK-ON SCATTERING OF POLARIZED μ MESONS ON ALIGNED ELECTRONS, by T. Fuiton and L. Madansky. Jan. 20, 1958, 4p. (AF 18(603)143)

Unclassified

The knock-on scattering of polarized μ mesons on aligned electrons is to be used to measure the helicity of the μ meson. The following experiment is proposed: μ mesons chosen from forward decays of π mesons are directed on a block of magnetized iron with electron spins parallel and antiparallel to the μ beam. The cross section for the knock-on electrons is then to be compared in the two cases. Thus far the μ meson beams obtained are not sufficiently energetic enough to provide significant spin contributions.

DETERMINATION OF THE RELATIVE $\Sigma - \Lambda$ PARITY, by G. Feldman and T. Fuiton. Apr. 28, 1958, 10p. (AF 18(603)143)

Unclassified

Also published in Nuclear Phys., v. 8: 106-112, Sept. 1958.

An investigation has been undertaken to determine whether there are definitive experiments which can determine, at least in principle, the relative $\Sigma - \Lambda$ parity. Two such methods are discussed. They are both based upon the parity-conserving electromagnetic decays of the Σ^0 . The first involves the process $\Sigma^0 \rightarrow \Lambda^0 + \gamma$. It is necessary to measure the decay asymmetries of the Λ^0 together with the direction of the photon polarization. The second method (also calculated recently by Feinberg) involves an accurate measurement of the branching ratio for the reactions $\Sigma^0 \rightarrow \Lambda^0 + e^+ + e^-$ and $\Sigma^0 \rightarrow \Lambda^0 + \gamma$. The appendix is concerned with some properties of a general vertex part. (Contractor's abstract)

HIGH-ENERGY ELECTRON BREMSSTRAHLUNG FROM AN EXTENDED PROTON (Abstract), by D. Moroi, M. Dresden, and T. Fuiton. [1958] [1]p. [AF 18(603)143]

Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 184, May 1, 1958.

A calculation has been made of the energy and angular distribution of electrons and photons arising from the bremsstrahlung of high-energy electrons on an extended proton. The form factors describing the charge and current distribution of the proton are the ones used in the interpretation of the Stanford experiments on the elastic scattering of electrons on protons. The calculation is patterned after the usual bremsstrahlung calculation, and uses the Born approximation. As might be anticipated, the main effect of the extended charge and current, as contrasted with the point charge, is to be found in the distribution of those electrons and photons which are scattered through an appreciable angle with respect to the initial momentum direction. From these distributions, it is in principle possible to obtain independently both the complete charge and the complete current form factors. It is believed that the use of the Born approximation is justified, particularly since the main effect is important for large angles only. The influence of processes such as electron-electron bremsstrahlung, exchange terms, and nuclear recoil, can be computed and must be taken into account to obtain information about the form factors from the bremsstrahlung spectrum.

THE POLARIZATION OF KNOCK-ON ELECTRONS ARISING FROM SCATTERING BY POLARIZED μ -MESONS, by D. Fivel and T. Fulton. [1958] [6]p. incl. table. [AF 18(603)143] Unclassified

Published in Nuovo Cimento, Series X, v. 10: 682-687, Nov. 16, 1956.

An experiment is proposed for the direct measurement of the helicity of μ -mesons arising from π decay by studying the polarization of the high energy electrons produced in the collision of the polarized μ -mesons with unpolarized electrons. Polarization effects become significant only for muon energy of the order of a few gev. The separation of a polarized beam of μ -mesons from the decays in flight of high energy π 's is in principle made easier by the fact that the laboratory momenta of μ -mesons which are emitted in the forward and backward directions in the π rest system differ by about 42% as a consequence of the relativistic transformation from the center of mass to the laboratory system. Expressions in the laboratory frame are also given of the cross section for scattering polarized electrons by polarized μ -mesons. In the center of mass frame, the results agree with those calculated by Bincer. (Contractor's abstract)

EFFECT OF DISLOCATIONS AND GRAIN BOUNDARIES UPON THE DYNAMIC FORMATION OF SLIP BANDS IN ALUMINUM, by D. F. Haskell and R. B. Pond. May 1957 [54]p. incl. illus. diagrs. tables, refs. (AFOSR-TN-57-223) (AF 18(600)1587) AD 126521 Unclassified

A free grain boundary is found to have no effect upon the velocity of propagation of slip bands in aluminum. The method is explained by which a free grain boundary may be obtained by means of a 180° rotation about the longitudinal axis of an aluminum single crystal. Also, it is determined that the average slip band velocity in a crystal is not affected by the average step-pit density of the crystal; but that the slip velocity of propagation of nearest neighbor slip bands occurring in sequence is proportional to the average step-pit density. The crystallography of the slip systems which activate in a bicrystal containing a free grain boundary is discussed, and a relation between crystallography and slip band velocity is proposed. Slip activation may occur at a free grain boundary. (Contractor's abstract)

CINEMOGRAPHIC RECORDING OF MULTIPLE BEAM INTERFEROMETRIC FRINGES DURING PLASTIC DEFORMATION OF SINGLE CRYSTALS, by R. B. Pond and E. [H.] Harrison. 1957 [2]p. incl. illus. (AF 18(600)1587) Unclassified

Published in Rev. Scient. Instruments, v. 28: 574-575, July 1957.

The two techniques of multiple beam interferometry of metal surfaces and cinemography of the plastic deformation of metals, heretofore used individually, have

JHU.17:004, 005; JHU.18:002, 003

been coordinated in an effort to obtain information concerning the resolved rates of gliding during the slip process as a function of crystallographic orientation, strain rate, temperature, etc. The device used to join the techniques was the hydrocarbon, dibutyl phthalate, with which a half-silvered mirror could be coated without contaminating the silvered surface, and which possesses sufficiently high surface tension to hold the mirror in position. Using this technique, observations were made of the interference fringes developed, as well as the glide displacement which occurs as a function of time for a single slip line. Approximately 20 slip lines were shown to form within one specimen.

SLIP VELOCITIES IN SEVERAL METALS AS MEASURED BY INTERFEROMETRIC CINEMOGRAPHY, by R. B. Pond and E. [H.] Harrison. Aug. 1958, 61p. incl. diagrs. tables. (AFOSR-TR-58-96) (AF 18(600)1587) AD 162153; PB 138988 Unclassified

Velocities of edge dislocations propagation are measured and presented for (a) aluminum single crystals of varying orientation which have been extended at a constant rate; (b) aluminum single crystals of relatively constant orientation which have been extended at varying rates; and (c) α brass and copper single crystals of varying orientation which have been extended at constant rates. The difficulties of using the technique with Au, Ag, and β brass are presented and discussed. It is found that the velocity of edge dislocation propagation can be influenced by the juxtaposition in time and space of the slip line among its neighbors as well as by the rate of straining. These relationships are discussed. A reactivation of the slip plane after its first motion is more apparent in Cu and α brass than in aluminum. It is found also when slip is occurring there is no acceleration or deceleration during most of the interval--but the velocity of propagation is constant. (Contractor's abstract)

GRAIN BOUNDARY MOVEMENT IN BICRYSTALLINE ALUMINUM, by R. B. Pond and E. [H.] Harrison. [1958] [12]p. incl. illus. diagrs. table, refs. (AF 18(600)1587) Unclassified

Presented at Thirty-ninth annual Convention of Amer. Soc. Metals, Chicago, Nov. 4-8, 1957.

Published in Trans. Amer. Soc. Metals, v. 50: 994-1005, 1958.

An investigation is reported of the plastic deformation of aluminum bicrystals having grain boundaries normal to the specimen axis. Data indicate that these "free" boundaries behave quite differently from boundaries which contain the specimen axis and are therefore influenced by a grip effect. A technique for producing transverse boundaries is described. Stress-strain diagrams for such specimens are given which show that the index of strain hardening for bicrystals whose boundaries are free to translate is lower in the plastic region than the index for single crystals of the parent orientation. Examination of both tension and compression specimens having the [121] pole in the slip plane and 90 degrees from the specimen axis shows that the boundary does translate during deformation causing the bicrystal to assume a "V" shape. In tension specimens this translation is away from the acute angle made by the intersection of the slip planes in the two grains; in compression specimens, toward it. There is no significant bending of the slip planes at the grain boundary in either. (Contractor's abstract)

INTERFEROMETRIC SPECTROSCOPY IN THE FAR INFRARED, by H. A. Gebbie and G. A. Vanasse. [1956] [1]p. incl. diagrs. (AF 18(600)1307) Unclassified

Published in Nature, v. 178: 432, Aug. 25, 1956.

Interferometric spectroscopy in the far infrared was used to study the resultant intensity from two interfering beams when the optical path-difference between them is

continuously changing. The spectrum observed was that from two caesium bromide crystal surfaces modified by the absorption spectrum of residual water vapor. The spectral data were interpreted in terms of the Fourier transform, which was obtained by numerical analysis, using a high-speed digital computer. The resolution shown was arbitrarily restricted by the numerical analysis and did not represent the limit imposed by the maximum path-difference between beams. The interferometer appeared to be readily adaptable to large construction to obtain greater light-grasp and resolving power. A larger instrument with aperture 30 cm has been made for study of atmospheric transmission in the submillimeter wave region.

ROTATION-VIBRATION CONSTANTS OF AMMONIA (Abstract), by W. S. Benedict and E. K. Plyler. [1957] [1]p. (AF 18(600)1557) Unclassified

Presented at Symposium on Molecular Structure and Spectroscopy, Ohio State U., Columbus, June 10-14, 1957.

Published in Symposium on Molecular Structure and Spectroscopy. Abstracts, 1957, p. 34.

We have observed under high resolution the spectra of NH₃ and ND₃ between 1800-7100 cm⁻¹, and have analyzed 14 bands of the former and 9 bands of the latter species in that interval. The strongest combinations and overtones of the E vibrations are in general the perpendicular bands. Effective values of the rotation-vibration interaction constants and of ζ_3 and ζ_4 can be obtained from each analyzed band; these however show small variations in different combinations, so that it is difficult to obtain their limiting value at infinitesimal amplitude with a precision comparable to that of the measurements. One of the interactions responsible for this situation is the Fermi resonance between $2\nu_4^0$ and ν_1 , which is particularly marked in ND₃; another is the presence of the low potential barrier inversion. A table is included giving the best available values for the rotational constants in the ground state, their variation with vibration, and the resulting equilibrium dimensions.

TRANSMISSION FUNCTIONS FOR ATMOSPHERIC WATER VAPOR (Abstract), by W. S. Benedict. [1957] [1]p. (AF 18(600)1557) Unclassified

Presented at Forty-second annual meeting of the Opt. Soc. Amer., Columbus, Ohio, Oct. 17-19, 1957.

Published in Jour. Opt. Soc. Amer., v. 47: 1056, Nov. 1957.

An absolute calculation of atmospheric water vapor transmission in the pure rotation band has been made by summation of each line. Theoretical values were used for line positions, including weak isotopic lines, for rigid-rotator line strengths, and for Lorentz line widths. The transmission functions show pressure dependence and vary with spectral region. Over wide intervals they approach statistically calculated forms. Correlation with experimental data, especially Palmer's results from 20 to 40 μ , shows excellent agreement in form. Agreement in magnitude requires small increases in theoretical parameters, most probably resulting from positive deviations from Lorentz shape in the line wings.

A general discussion is given of methods used in the analysis of NH₃ vibration-rotation spectra, including the derivation of molecular constants and the determination of line strengths and line widths. Results are given for the region 2.15 to 2.48 μ (4,060 to 4,700 cm⁻¹), in which more than 800 lines have been measured. These have been analyzed into the inversion-doubled perpendicular combination band $\nu_2 + \nu_3$ ($\nu_0 = 4416.908$ and 4434.610 cm⁻¹; band strength = 19.7 cm⁻² atm⁻¹) and the inversion-doubled parallel combination band $\nu_1 + \nu_2$ ($\nu_0 = 4293.716$ and 4320.060 cm⁻¹; band strength = 2.9 cm⁻² atm⁻¹). Complete energy levels for these bands have been found up to J = 12 and 10, respectively, permitting determinations of molecular constants, which

include numerous higher-order effects involving the interaction of rotation, vibration, and inversion. The line widths range from a maximum of $0.57 \text{ cm}^{-1} \text{ atm}^{-1}$, when $K = J$ to a minimum of $< 0.2 \text{ cm}^{-1} \text{ atm}^{-1}$, when $K \ll J$. (Contractor's abstract)

VIBRATION-ROTATION BANDS OF AMMONIA. III. THE REGION 3.2-4.3 MICRONS, by W. S. Benedict, E. K. Plyler, and E. D. Tidwell. [1958] [17]p. incl. diags. tables, refs. (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1557 and Atomic Energy Commission) Unclassified

Published in Jour. Chem. Phys., v. 29: 829-845, Oct. 1958.

The weak absorption of NH_3 between $2373\text{-}3080 \text{ cm}^{-1}$ has been studied under high resolution, and a complete analysis given for over 1000 lines, including studies of the intensity and line width. The strongest bands ($S_\nu^0 = 0.44$ and $0.20 \text{ cm}^{-2} \text{ atm}^{-1}$, respectively) are $3\nu_2^s - 0^a$; and $3\nu_2^a - 0^s$; $\nu_3 - \nu_2$ ($S_\nu^0 = 0.074$); $\nu_3 + \nu_2 - 2\nu_2$ ($S_\nu^0 = 0.06$) have also been located. $\nu_2 + \nu_4$ shows anomalous intensity behavior as well as large vibration-rotation-inversion- ζ -splitting interactions. The lines in $3\nu_2$ are 40-50% narrower than those in the microwave region, and appear symmetrical with no pressure shifts. (Contractor's abstract)

BIOPHYSICAL INVESTIGATIONS OF BONE TRANSPLANTS AND BONE IMPLANTS. AN EXPERIMENTAL STUDY, by K. Holmstrand. 1957, 1v. incl. illus. diags. tables, refs. (AFOSR-TN-57-396) (AF 61(514)861) AD 132471 Unclassified

Also published in Acta Orthopaedica Scandinavica, Suppl. No. 26, p. 1-[91], 1957.

Biophysical techniques, including contact microradiography, x-ray diffraction techniques, the use of the polarizing microscope, and autoradiography with Sr^{90} were utilized in the study of about 180 bone transplants and bone implants in a series of 56 rabbits and in two dogs. The bone transplants were fresh autogenous and homogenous cortical, fresh autogenous and homogenous cancellous. The implants were cooked bone, os purum, glycerol-ashed bone, and calcined bone. The biophysical methods are discussed from the standpoint of their application to (1) the study of the mineralization processes related to the healing and ultimate fate of different bone transplants; and (2) the study of the resorption rate of bone implants as influenced by their ultrastructural organization.

BIOPHYSICAL ANALYSES OF THE FORMATION AND STRUCTURE OF HUMAN FETAL BONE. A MICRORADIOGRAPHIC AND X-RAY CRYSTALLOGRAPHIC STUDY, by G. Wallgren. 1957, 80p. incl. illus. diags. tables, refs. (AFOSR-TN-57-397) (AF 61(514)861) AD 132472 Unclassified

Also published in Acta Paediatrica, Suppl. No. 113, p. 7-80, 1957.

Quantitative microradiography, x-ray diffraction, and polarization microscopy techniques were applied to human fetal bone in order to gain new information about mineral distribution and rate of mineral deposition as well as about the ultrastructure of rapidly growing bone and its relation to development. Observations revealed the following: (1) newly-formed bone possesses a very low degree of mineralization; (2) mineral content increases rapidly during the three weeks immediately following its first appearance, but thereafter maintains an almost constant level up to the time of birth; (3) parallel to the rapid increase in mineral content, there occurs a rapid increase in the long dimension of the apatite crystallites, which in newly-formed bone is very small; (4) between one and two weeks after the

crystallites form in fetal bone, they exhibit a distinct orientation in the long axis of the collagen fiber bundles; and (5) the rate of increase in mineral content appears to be a function of the rate of increase in crystallite size, while the ultimate level of mineralization attained in a given ultrastructural area of fetal bone is governed by those factors which cause crystallite growth to cease.

[RESEARCH ON THE PHYSIOLOGY OF BONE TISSUE], by A. Engström. Final rept. Mar. 25, 1958, 6p. (AFOSR-TR-57-96) (AF 61(514)861) AD 148009 Unclassified

The role of the skeleton in normal and diseased conditions has been investigated from the molecular to the anatomical level. To facilitate research several new analytical methods have been developed including x-ray crystallographic and x-ray microscopic techniques. The high biological reactivity of bone is partially clarified. It appears that areas of low mineralization found extensively in young bone have a high reactivity and thus are sites of ionic exchange. Bone salt is highly reactive due to a large surface area with specific charge patterns. This type of apatite structure is of great importance in the homeostasis of body ions. A careful recalculation of the permissible total body burden for

Sr^{90} has yielded a value of 0.1 μ c rather than 1 μ c. Procedures for preserving bone tissue in bone transplantation have also been devised.

CONTACT MICRORADIOGRAPHY. A GENERAL SURVEY, by A. Engström. [1957] [10]p. incl. illus. diagrs. refs. (AF 61(514)861) **Unclassified**

Published in Proc. First Internat'l. Symposium on X-ray Microscopy and Microradiography, Cavendish Lab., Cambridge (Gt. Brit.) (Aug. 16-21, 1956), New York, Academic Press, 1957, p. 24-33.

The present status of contact microradiography is such that the resolution possible is that of the optimal resolution of a light microscope, i.e., about 0.2μ . A histochemical weighing technique is available which allows the estimation of the wet and dry mass of cellular structures as small as 10^{-12} to 10^{-14} gm with an error of 5-10%. The use of soft x-ray permits the quantitative histochemical analysis of certain biochemical elements in the cell such as P, S, and Ca with relatively good accuracy, while the use of ultra-soft x-rays should allow the extension of this technique to successful estimates of C, N, and O. Qualitative microradiography has found wide uses in studies of capillary circulation, mineral salt distribution, metallurgical research, and other fields. (Contractor's abstract, modified)

CRYSTALLOGRAPHIC STUDIES OF CALCIUM AND

STRONTIUM HYDROXYAPATITES, by C. Lagergren and D. Carlström. [1957] [6]p. incl. diagrs. refs. (AF 61(514)861) **Unclassified**

Published in Acta Chemica Scandinavica, v. 11: 545-550, 1957.

From x-ray crystallographic investigations on apatites in the system $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2 - \text{Sr}_{10}(\text{PO}_4)_6(\text{OH})_2$ it was found that no solid solutions could be formed in the region $\text{Ca}_3\text{Sr}_7(\text{PO}_4)_6(\text{OH})_2$ to $\text{Ca}_7\text{Sr}_3(\text{PO}_4)_6(\text{OH})_2$. The mixed apatite $\text{Ca}_3\text{Sr}_3(\text{PO}_4)_6(\text{OH})_2$, however, was shown to have a very well ordered lattice. In the light of these experimental findings, it was concluded that Sr ions in the inorganic crystalline phase of bone are probably bound rather firmly to the surface of the extremely small apatite crystallites. SUMMARY OF RECENT ADVANCES IN X-RAY MICRO-CHEMICAL TECHNIQUES, by A. Engström. [1957] [3]p. incl. diagrs. refs. (Sponsored jointly by Air Force Office of Scientific Research under (AF 61(514)861), Swedish Medical Research Council, and Rockefeller Foundation) **Unclassified**

Published in [Metabolism of the Central Nervous System, London, Pergamon Press, 1957, p. 7-9].

Two types of x-ray microscopy are discussed. In contact microradiography the specimen is placed in close contact with a fine-grained photographic emulsion and exposed with soft x-rays. Mass resolution can be as small as $10^{14} - 10^{15}$ g/ μ^2 . Accuracy is independent of specimen thickness since voltage can be selected. Projection and reflection microscopy has been aided by the development of the point focus x-ray source. Two types of x-ray diffraction are also discussed. Soft radiation, i.e. Al K α or Cu L α radiation, yields good intensity of scattered radiation from thin samples. Microdiffraction cameras are being developed.

Recent work performed at Karolinska Institute on the physiology and structure of the skeleton is reviewed with special attention given to the accumulation of radioactive strontium. This survey begins with a summarized general introduction regarding the metabolism of strontium. Two chapters then follow on the distribution of mineral salts in the skeleton and the molecular structure of the inorganic phase in bone. Actual experiments performed with radioactive strontium in animals are reported in Chapter IV. On the basis of the biological data obtained, calculations regarding the dose rates from the captured radiostrontium are presented in Chapter V. A discussion summarizes the data in chapters II, III, IV, and V and deduces from them values for the permissible total body burden of radioactive strontium in human beings.

THE INFLUENCE OF HYPOTHALAMIC THERMOCEPTIVE STRUCTURES ON THE ELECTROENCEPHALOGRAPH AND GAMMA MOTOR ACTIVITY, by C. von Euler and U. Söderberg. [1957] [18]p. incl. diags. refs. (AF 61(514)1083)

Unclassified

Published in EEG Clin. Neurophysiol., v. 9: 391-408, Aug. 1957.

It is shown that the effects of hypothalamic heating are mediated by common relays influencing both gamma motor and cortical activity. Hypothalamic thermoreceptive structures may, thus like most peripheral receptors, project upon the activating relay system of the brain stem. The muscle spindle test has been found to be a useful index of that system. The significance of the results for homeostasis of body temperature is discussed.

THE RELATION BETWEEN ACTIVITY AND BLOOD FLOW IN THE THYROID GLAND, by U. Söderberg. [1958] [3]p. incl. diagrs. refs. (AFOSR-TN-58-319) (AF 61(514)1083) Unclassified

Also published in *Experientia*, v. 14: 229-231, 1958.

Experiments are presented of the relation between thyroid activity and thyroid blood flow. A better understanding of the regulation of the thyroid functions has been made possible by using the uptake of iodine in the gland. Experiments were performed on 18 cats and 66 rabbits under light to moderate anaesthesia, and the animals were completely heparinized. Results of the experiments showed the following: (1) the rate of uptake of iodine was largely proportional to the blood flow through the gland, (2) the uptake was somewhat augmented when the animals were breathing pure oxygen and decreased during inhalation of gas mixtures rich in CO₂ or poor in O₂, (3) the turnover rate of iodine

within the gland was generally reduced, probably by influence of the anesthetics, (4) the rate of secretion of thyroid hormone, in contrast to the rate of uptake of inorganic iodide, was found to follow what was believed to be the titre of endogenous thyrotropic hormones (TSH) or administered exogenous TSH regardless of the blood circulation through the gland, (5) adrenaline injected intravenously had inconstant effects, (6) the rate of uptake of iodine and rate of release of thyroid hormone may be widely independent of each other, (7) changes in thyroid activities may be more rapid than was expected and thyroid activities may be a useful index of vegetative changes both in physiological and pharmacological experiments even in animals subjected to small operations under anesthesia, (8) nervous and hormonal stimuli have been shown to have marked effects on thyroid hormone secretion, however, these effects are due to changes in the responsiveness to TSH and cannot be demonstrated in the absence of the pituitary hormone.

SHORT TERM REACTIONS IN THE THYROID GLAND, by U. Söderberg. [1958] [113]p. incl. illus. diagrs. refs. (AFOSR-TN-58-426) (AF 61(514)1083) AD 158229 Unclassified

Also published in *Acta Physiologica Scandinavica*, v. 42: Suppl. 147, 1958.

The purpose of the investigation was to devise a method which would permit a continuous measure of the arteriovenous concentration difference both of iodide and of thyroid hormones, and to study briefly some nervous and hormonal influences on thyroid activity. Flow rates and radioactive iodine (¹³¹I and ¹³²I) concentrations of blood entering and leaving the thyroid gland were measured. The technique was employed in 19 cats and 66 rabbits. The thyroid was dissected free of its surroundings, its largest vein was cannulated and the others ligated. Each drop of blood which issued from the cannula was counted and fell on a moving strip of filter paper. The interval between the appearance of successive drops was measured and recorded by an electric ordinate writer. The drops on the filter paper were dried and then individually analyzed for radiiodine. A similar analysis of arterial blood was made. This provided the simultaneous descriptions of blood flow and arteriovenous concentration differences, and these two factors then permitted the calculation of the rate of uptake of iodine and the rate of secretion of hormonal iodine. The validity of the technique and the physiological significance of the results are discussed. The results show that it is possible to record the thyroid arteriovenous iodine concentration difference and blood flow continuously for several hours with a high degree of accuracy and good temporal resolution. This technique has revealed, and permitted the measurement of changes in activity which are both rapid and frequent and so provides a useful index of vegetative activity in experimental animals.

CO-ORDINATED CHANGES IN TEMPERATURE THRESHOLDS FOR THERMOREGULATORY REFLEXES, by C. von Euler and U. Söderberg. [1958] [18]p. incl. illus. diagrs. refs. (AFOSR-TN-58-793) (Sponsored jointly by Air Force Office of Scientific Research under AF 61(514)1083 and Swedish Medical Research Council) AD 203226 Unclassified

Also published in *Acta Physiologica Scandinavica*, v. 42: 1:2-129, 1958.

KSU. 01:001-003; KEN. 01:001

Hypothalamic temperature levels have been studied to determine whether changes in body temperature are the result of some regulatory mechanism. At these levels several heat-dissipating, heat-preserving and heat-producing reflexes appear and they cause shifts to new temperatures. Co-ordinated changes in the threshold temperatures for these thermoregulatory reflexes have been elicited in response to different stimuli. Stimuli which activate the electroencephalogram and the gamma motor system tend to raise the temperatures. Stimuli which deactivate the gamma motor system and evoke synchronized cortical activity tend to lower threshold temperatures. Body temperature changes correspondingly. The results indicate that body temperature is set at different levels in different states of activity.

ON DAS' THEORY OF NUCLEAR MAGNETIC RESONANCE IN SOLIDS, by J. W. McGrath and A. A. Silvidi. Mar. 24, 1958 [3]p. incl. diags. (AFOSR-TN-58-245) (AF 49(638)168) AD 154147 Unclassified

Also published in Jour. Chem. Phys., v. 29: 103-105, July 1958.

Das' theory developed the effect of vibratory rotary motion of water molecules in crystalline hydrates on the resonance spectra of the protons. Limitations on applicability of his theory are discussed. The theory is extended to the general case and a further effect on spectra is obtained. This effect is dependent upon the orientation of the proton-proton axis within the crystal, the orientation of the crystal in the magnetic field, the temperature and the height of the twofold potential barrier containing the water molecule. Partial experimental support of the theory is cited. Two methods for measuring proton-proton separations that do not require Das' theory corrections are described. A method for measuring the height of the potential barrier is described.

PROTON MAGNETIC RESONANCE IN HYDRATED SINGLE CRYSTALS (Abstract), by J. W. McGrath, A. A. Silvidi, and J. C. Carroli. [1958] [1]p. [AF 49(638)-168] Unclassified

Presented at meeting of the Ohio Section of the Amer. Phys. Soc., Akron, Ohio, Apr. 11-12, 1958.

Published in Bul. Amer. Phys. Soc., Series II, v. 3: 349, Aug. 26, 1958.

The proton-proton separations in a series of hydrated crystals are being remeasured since reported values vary by more than experimental error. If this variation is real, an explanation will be sought. A slightly modified Pound-Watkins NMR spectrometer is being used. Parameters are: rf = 25 mc, H = 5870 gauss, modulation amplitude = 1 gauss, modulation frequency = 280 cps and sweep speed = 0.02 gauss/sec. Signal to noise ratios for crystals are about 30. The Pake technique is being used. For gypsum the measured value of the p-p separation is $1.58 \pm 0.02\text{A}$. The p-p axes lie in the ab plane ($\pm 10^\circ$) and they make angles of $36 \pm 4^\circ$ and $45 \pm 4^\circ$ with the axis. These values agree well with those of Pake. In lithium sulfate, an orientation-independent shift of +3 gauss appears in the Pake curve. This is essentially in agreement with Pake. The origin and effects of this shift are being studied.

SPIN-LATTICE RELAXATION TIMES IN LIQUIDS (Abstract), by F. D. Adams and A. A. Silvidi. [1958] [1]p. [AF 49(638)168] Unclassified

Presented at meeting of the Ohio Section of the Amer. Phys. Soc., Granville, Ohio, Oct. 17-18, 1958.

Published in Bul. Amer. Phys. Soc., Series II, v. 3: 427, Dec. 29, 1958.

Proton spin-lattice relaxation times T_1 are being measured in liquids using a NMR spectrometer. The direct method of measurement is being used. Parameters are: rf frequency - 25 mc, field H - 5870 gauss, modulation amplitude - 1 gauss, and modulation frequency - 260 cps. For water (dissolved oxygen - 0.0057 cc/g standard pressure and temperature 26°C) the measured value of T_1 is 2.8 ± 0.1 sec. For diethyl ether T_1 is 3.5 ± 0.3 sec. These measurements agree with those made by Bloembergen, Purcell, and Pound. Spin-lattice relaxation times are being measured for other liquids.

SELECTIVE CLEMMENSEN REDUCTION OF 1,2-DIKETONES (Abstract), by W. T. Smith, Jr. [1957] [1]p. [AF 49(638)49] Unclassified

Presented at meeting of the Sixteenth Internat'l. Congress of Pure and Appl. Chem., Paris (France), July 13-24, 1957.

Published in Résumés des Communications, v. 2: 151, July 1957.

KEN.01:002, 003; KEN.02:001

The Clemmensen reduction of 2,3-pentanedione, 2,5-octanedione, diosphenol, and camphorquinone has been studied. In the cases of the first three compounds mentioned, it is possible to reduce one carbonyl group without reduction of the other. The reduction of 2,3-pentanedione and diosphenol gives a mixture of the two possible isomeric monoketones. 2,3-octanedione is reduced selectively to 2-octanone. Camphorquinone is reduced to a mixture of hydroxycamphor and hydroxyepicamphor. This mixture is not reduced further to the monoketones. A mechanism is advanced to explain both the results with camphorquinone and the reduction of the apparently more hindered carbonyl group of 2,3-octanedione. This explanation is based on two considerations. The first of these is the probable conformations of 1,2-dicarbonyl systems in acyclic and in five and six-membered ring diketones. The second consideration is that when conjugation is possible between the 1,2-dicarbonyl groups, the point of attachment of the diketone to the zinc will be at the oxygen rather than at the carbon.

INFLUENCE OF STRUCTURE AND SOLVENT, by W. T. Smith, Jr., D. Trinnell, and L. L. Grinninger. Oct. 1958, 6p. (AFOSR-TN-58-899) (AF 49(638)49) AD 204231 Unclassified

Presented at meeting of the Amer. Chem. Soc., Chicago, Ill., Sept. 10, 1958.

Also published in Jour. Org. Chem., v. 24: 664-666, May 1959.

The UV absorption spectra of aliphatic and aromatic N-sulfinyl amines in ether and alcohol were investigated. The spectra of both 2,4- and 2,6-dimethyl-N-sulfinylaniline were compared to obtain evidence that the band at 314 to 330 m μ is due to the conjugation of the NSO group. Molecular models show that considerable interference will occur between the NSO group and the methyl groups in the ortho position. Comparing the spectral data showed that the interference caused by the 2-o-methyl groups has a pronounced effect on the spectra. The data indicated that the longer wavelength band is due to the over-all system consisting of the aromatic ring and the NSO group. The shift of the maxima to longer wavelengths appears to be related to the methyl substituents. Unsubstituted N-sulfinylaniline has a maximum at 314 m μ ; introducing a methyl group in the 4 position shifts the maximum to 328 m μ . A 2-methyl substituent shifts the maximum to 322 m μ . In 2,4-dimethyl N-sulfinylaniline, the shift is 23 m μ . A slight steric effect of a single o-methyl group was indicated by a decrease of log ϵ from 4.00 in N-sulfinylaniline to 3.98 in 2-methylaniline; the decrease is significant because a methyl group in the para position increased the log ϵ to 4.10. N-Sulfinylaniline showed no reaction with allyl alcohol, ethylene glycol, isopropyl alcohol, tert-butyl alcohol, benzyl alcohol, and triethyl carbinol; however, it reacted with the more acidic alcohols. p-Nitro-N-sulfinylaniline reacted with methyl, ethyl, propyl, isopropyl, butyl, and tert-butyl alcohols.

N-SULFINYL AMINES. REACTIONS WITH CARBOXYLIC ACIDS, by W. T. Smith, Jr. and G. G. King. Apr. 1958, 7p. (AFOSR-TN-58-258) (AF 49(638)49) AF 154162 Unclassified

Also published in Jour. Org. Chem., v. 24: 976-978, July 1959.

Refluxing a solution of N-sulfinylaniline in acetic acid showed no evolution of SO₂, and no acetanilide could be isolated from the solution; unsuccessful results were obtained with other acids. Tests were conducted to show the catalytic effect of both thionyl chloride and HCl on the N-sulfinylaniline-acetic acid reaction. The catalytic effect of thionyl chloride appears to be due to the fact that it does not yield HCl under the conditions used in the reaction. Anilides of the following acids were obtained by refluxing the acid with N-sulfinylaniline and a drop of thionyl chloride: formic acid, 44% yield; benzoic acid, 30% yield; chloroacetic acid, 65% yield; and glutaric acid, a trace of dianilide. These reactions are not peculiar to N-sulfinylaniline. The N-sulfinyl derivatives of p-nitroaniline and cyclohexylamine are converted to the corresponding N-acetyl derivatives by refluxing in acetic acid containing a trace of thionyl chloride. The reaction of p-nitro-N-sulfinylaniline with acetic acid gives a 92% yield of p-nitroacetanilide.

ELECTRICAL AND OTHER PHYSICAL PROPERTIES OF SOME VITREOUS SELENIDES (Abstract), by D. F. Clifton and L. Gildart. [1957] [1]p. [AF 49(638)90]
Unclassified

Presented at meeting of the Amer. Phys. Soc., Boulder, Colo., Sept. 5-7, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 301, Sept. 5, 1957.

Properties of the vitreous form of compounds of the Group Vb and Group VIb elements of the type A_2B_3 (mainly selenides) have been studied. The absence of small angle x-ray scattering shows the materials to be truly vitreous rather than microcrystalline. Structure semiconducting behavior, tendency toward crystallization, softening temperature, and density are the properties considered.

SELENIDES PROJECT, by L. Gildart and D. F. Clifton. Progress rept. no. 1, July 31, 1958 [86]p. incl. illus. diagrs. tables, refs. (AFOSR-TN-58-849) (AF 49(638)90) AD 203361; PB 138436 Unclassified

An investigation was initiated into the general field of the electrical, liquid-solid transformation properties of systems of the group Va and VIa elements As, Sb, Bi, O, S, Se, and Te. Vitreous films of Sb_2S_3 were prepared on glass substrates by evaporation in vacuo with compositions ranging from about 46.9 to 51.8 wt-% Se. These were readily devitrified (crystallized) by moderate heat treatment, permitting direct comparison between properties of the vitreous and crystalline forms of the same sample. Semiconductivity was exhibited by both vitreous and crystalline Sb_2Se_3 films. The

vitreous films had an activation energy of 1.83 ± 0.14 ev, and the crystalline films had an activation energy of 1.07 ± 0.08 ev. The equal power spectral response for the region 4500 to 7000 Å is essentially flat for both types of film. A new semiconductor resistivity phenomenon, a switching effect, is described as follows: when a slowly increasing electric field is applied to a sample of stibnite, containing excess Sb, there is a sudden large drop in resistance, or an electrical breakdown, at a critical value of the field. The new low value of resistance is retained indefinitely at room temperature, but the resistance can be restored to the original high value at any time the sample is momentarily heated to 100° to 300°C. The cycle can be repeated at will. The duration of the breakdown is about 2 μsec, and the re-

sistance recovery at about 205°C is also abrupt. Liquid-solid transformation and structure studies were made on As_2S_3 , As_2Se_3 , As_2Te_3 , Sb_2S_3 , Sb_2Se_3 , Sb_2Te_3 , Bi_2S_3 , Bi_2Se_3 , and Bi_2Te_3 . (ASTIA abstract)

REVERSIBLE LOW-VOLTAGE BREAKDOWN IN STIBNITE (Abstract), by J. R. Davis and L. Gildart. [1958] [1]p. [AF 49(638)90] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 218, May 1, 1958.

Electric breakdown has been found to occur in both single-crystal and polycrystalline rods of stibnite containing up to 2.5% excess antimony at field strengths from 50 to 1000 volts/cm. This compares with breakdown fields in most insulators of the order of 10^6 volts/cm. The breakdown in stibnite establishes an electrically traceable low-resistance path through the material which at room temperatures is essentially permanent but which is rapidly annealed out when the sample is heated to about 300°C. After the temperature cycle the sample is apparently restored to its original state. In these samples the breakdown time is less than one microsecond and the resistance decreases from about 10^{10} ohms to about 10^4 ohms. Prebreakdown pulses are observed like those reported by McKay in silicon p-n junctions. Breakdown has also been produced in devitrified thin films of stibnite, but the fields required are much greater and the resistance change less pronounced.

VITREOUS AND CRYSTALLINE SEMICONDUCTING FILMS OF Sb_2Se_3 (Abstract), by T. E. Johnson and L. Gildart. [1958] [1]p. [AF 49(638)90] Unclassified

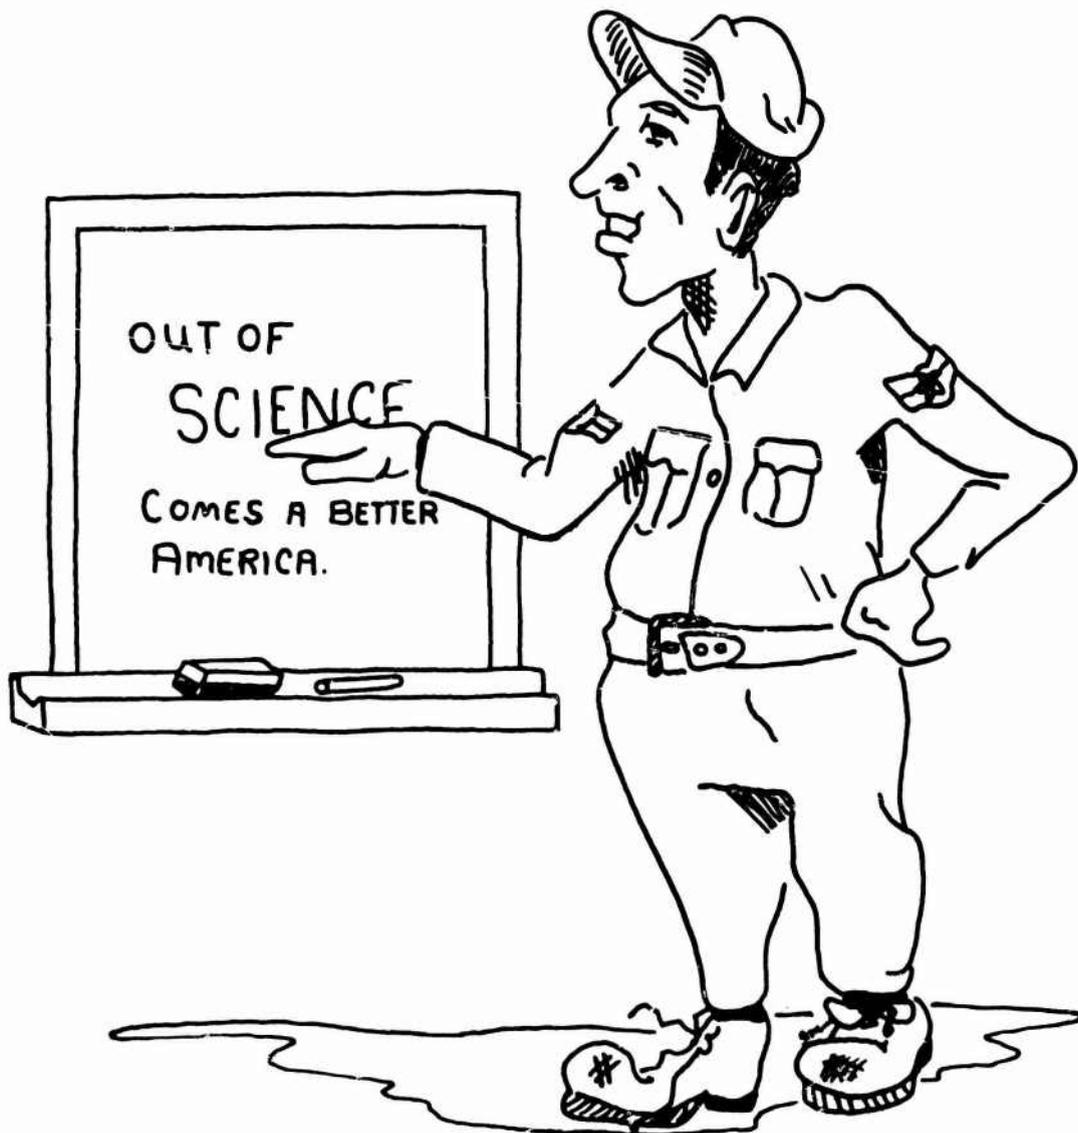

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 232, May 1, 1958.

Vitreous films of antimony triselenide, ordinarily a crystalline semiconductor in the bulk, have been prepared by vacuum evaporation on Pyrex. When heated from room temperature to about 250°C they show an initial (irreversible) activation energy of 1.8 ev, but

after a short while the films devitrify to a polycrystalline form with an activation energy of 1.1 eV (reversible). The large resistivity discontinuity produced in bulk Sb_2Se_3 by addition of 0.1% excess selenium was not found in the films, either in the vitreous or the crystalline form. The vitreous films had resistivities of the order of 10^7 ohm-cm at room temperature, and the

devitrified films of the order of 10^4 ohm-cm, and neither showed any appreciable variation of resistivity vs composition. Both forms showed moderate photoresponse in the visible, surprisingly flat from about 5000Å to beyond 7500Å. All films were of the order of $200 \mu\text{g}/\text{cm}^2$ in thickness; upon devitrification there was an apparent shrinkage revealed by fissuring in some cases, indicating a density increase of about 5%.

INHIBITION BY HYDROGEN PEROXIDE OF THE SECOND EXPLOSION LIMIT OF THE HYDROGEN-OXYGEN REACTION, by W. Forst and P. A. Giguère. Oct. 28, 1957 [16]p. incl. diagrs. refs. (AFOSR-TN-57-711) (AF 18(600)492) AD 136705 Unclassified

Also published in Jour. Phys. Chem., v. 62: 340-343, Mar. 1958.

The inhibiting action of hydrogen peroxide on the upper limit of the H-O reaction has been studied at 447°C by the withdrawal technique as a function of the composition of the mixtures. The pressure ratio of the inhibited limit to the normal 2nd limit showed a quadratic dependence on the peroxide concentration. The simplest scheme to account for the results is to add the two reactions $H_2O_2 + H \rightarrow H_2O + OH$ and $H_2O_2 + OH \rightarrow H_2O + HO_2$ to the generally accepted mechanism for the second limit.

The partially homogeneous character of the gas-phase decomposition of H_2O_2 above 400° was confirmed. When H, O, NO, and other gases were added to study their effect on the rate of decomposition, only H showed any effect; the reaction was markedly accelerated at 440-70° at total pressures in excess of 20 mm. At lower pressures the H reacted explosively with the O from the decomposition of the H_2O_2 , but the explosions occurred only after all or nearly all of the H_2O_2 had disappeared, although the mixtures were within the explosion range. H_2O_2 was found to be approximately 10 times as effective in inhibiting explosions as is H_2O .

SECOND-ORDER UNIMOLECULAR KINETICS IN THE THERMAL DECOMPOSITION OF HYDROGEN PEROXIDE VAPOR, by W. Forst and P. A. Giguère. June 27, 1958 [27]p. incl. diagrs. tables, refs. (AFOSR-TN-58-587) (AF 18(600)492) AD 162110 Unclassified

Also published in Canad. Jour. Chem., v. 36: 1308-1319, Sept. 1958.

The thermal decomposition of hydrogen peroxide vapor has been re-investigated by the static method as a function of initial pressure at pressures up to 22 mm Hg, and in the presence of inert gas (helium, oxygen and water) up to 100 mm Hg. In each case the apparent first-order rate constant increased linearly with pressure. It is demonstrated that under the present experimental conditions the pyrolysis of hydrogen peroxide shows behavior typical of an elementary unimolecular reaction in its low-pressure second-order region. The reaction was accompanied by a heterogeneous decomposition which in the presence of foreign gas became inhibited. Helium was used as inhibitor over the temperature range 430-470°C, which permitted calculating the activation energy for activation with peroxide and with helium. The results can be satisfactorily accounted for by assuming a critical energy of 47-50 kcal and 5 effective classical oscillators for activation with peroxide and 3 with helium, provided deactivation occurs on every collision. Kinetic evidence against this assumption is briefly discussed. (Contractor's abstract)

LIQUIDS, AND SOLIDS, by P. A. Giguère and J. A. Herman. [1958] [15]p. incl. diagr. refs. (AFOSR-TN-58-794) (AF 18(600)492) AD 202227 Unclassified

Presented at Internat'l. Congress of Radiation Research, Burlington, Vt., Aug. 11-15, 1958.

Also published in Radiation Research, Suppl. v. 1: 149-163, 1959.

A survey is presented of studies of oxygen intermediates based on direct physical evidence. The subject is narrowed down to the simplest intermediates, oxygen atoms, $\cdot\text{OH}$ and $\text{HO}_2\cdot$ radicals, and possibly a few others.

It is mentioned that the positive identification of a free radical in a given process may lead to elucidation of part or all of the mechanism involved. The difficulties, however, are considerable; of the various physical methods used so far to detect free radicals, only a few can yield detailed information on the nature of the species, their structure, etc.

KINETICS OF THE THERMAL REACTION OF HYDROGEN PEROXIDE WITH HYDROGEN, by W. Forst. Nov. 25, 1958 [21]p. incl. diagrs. refs. (AFOSR-TN-58-1070) (AF 18(600)492) AD 207230; PB 138351 Unclassified

Also published in Canad. Jour. Chem., v. 37: 1616-1620, Sept. 1959.

The reaction proceeds with a pressure increase at constant volume and is thus accessible to study by the static method. At the pressures used the rate of activation is rate-determining in the unimolecular decomposition of hydrogen peroxide. When experimental results are corrected for activation by hydrogen, the reaction is found to be first order in both hydrogen and peroxide. A simple mechanism consistent with experimental results consists of the reactions postulated in the decomposition of hydrogen peroxide, plus the reactions

Experimental evidence points to a low value for rate constant k_3 . The significance of these results is briefly discussed in connection with the kinetics of the nitric oxide-hydrogen reaction. (Contractor's abstract)

SOME GLOBAL THEOREMS ON HYPERSURFACES, by C.-C. Hsiung. [1957] [10]p. [AF 49(638)215] Unclassified

Published in Canad. Jour. Math., v. 9: 5-14, 1957.

The following theorem is established which Hopf and Voss obtained for $n = 2$ [Arch. Math., v. 3: 187-192]: Let V_n, V_n^* be two orientable hypersurfaces twice differentially imbedded in a Euclidean space E_{n+1} ($n + 1 = 3$). Suppose that there is a differentiable homeomorphism between V_n, V_n^* such that the orientations are preserved and the line joining every pair of corresponding points P, P^* is parallel to a fixed direction given by the unit vector I , and such that V_n, V_n^* have equal first mean curvatures M_1, M_1^* at every pair of the points P, P^* but no cylindrical elements whose generators are parallel to the fixed direction I . Then V_n, V_n^* can be transformed into each other by a translation. The proof is based on the integral formula

$$n \int v_n w (M_1^* - M_1) I \cdot N dA + \int v_n (1 - N \cdot N^*) (dA + dA^*) = 0,$$

where w is the distance PP^* ; N, N^* the unit normal vectors at P, P^* and dA, dA^* the area elements. From this theorem, other results of Hopf and Voss (paper quoted above) are also extended to $n > 2$. (Math. Rev. abstract)

THEORY OF FIELDS OF INTEGRAL SPIN GREATER THAN ONE (Abstract), by P. Havas. [1957] [1]p. [AF 18(600)1462] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 189-190, Apr. 25, 1957.

Equations describing wave fields for any integral spin have been established by Fierz. Although the general

form of the equation of motion of singularities of such fields was deduced by Harish-Chandra, this does not assure the existence of a self-consistent theory of arbitrary point singularities. A general theory of multi-pole singularities of spin zero fields was given recently, and the equations of motion of poles and dipoles of spin one fields are well known. For spins greater than one it has been found, however, that it is not possible to have simple poles whose fields satisfy all of Fierz' conditions. It appears that while higher poles are compatible with the field equations, no consistent equations of motion are possible for them. Due to this absence of interaction such fields are unobservable. Thus, at least within the framework of classical linear field theories, interaction of particles appears to be possible only through (neutral or charged) fields of spin zero or one.

DENSITY EXPANSIONS OF DISTRIBUTION FUNCTIONS. [Final] technical rept. Jan. 1958, 3p. (AFOSR-TR-58-42) (AF 61(514)961) AD 154137 Unclassified

The research performed under this contract in the field of statistical mechanics is summarized. Abstracts are presented describing the various aspects of the work. The studies have included: the development of new methods of obtaining density expansions for the partial distribution functions of fluid systems, with the help of integro-differential equations; the develop-

ment of a general statistical mechanical formalism on the theory of dielectric polarization; an investigation of some properties of the Wigner distribution function; an extension of the statistical mechanical theory of the ponderomotive force in polarizable systems to include systems with magnetic interactions; a survey of existing theories of relaxation phenomena; and clarification of the Curie principle on the influence of symmetry properties of matter on the coupling of irreversible process.

SOME RECENT APPLICATIONS OF NUCLEAR QUADRUPOLE RESONANCE IN STRUCTURAL AND RADIATION CHEMISTRY, by J. Duchesne. [1958] 13p. incl. tables, refs. (AFOSR-TN-58-350) (AF 61-514)1212) AD 154255 Unclassified

Also published in Chem. Soc. Symposia, Bristol (Gt. Brit.), 1958 (Special publication no. 12) London, The Chem. Soc., 1958, p. 235-244.

Applications of nuclear quadrupole resonance are restricted to a limited class of isotopes, since nuclei with 0 or half unit spins have no quadrupole moment. The detection of direct quadrupole spectra and the nature of chemical bonds are discussed. Quadrupole coupling constants upon condensation are found to vary from 2 to 12%. The changes observed vary according to the number of H₂ atoms in the molecule and follow the changes of the electric dipole moments. Fine structure and high energy radiation effects are also investigated.

NOTES ON NUCLEAR QUADRUPOLE RESONANCE IN SOLIDS, by J. Duchesne. [1958] 31p. incl. diag. table, refs. (Technical scientific note no. 1) (AFOSR-TN-58-815) (AF 61(514)1212) AD 202638 Unclassified

The study of the damage produced in solids by high energy radiation is based on a systematic analysis of the changes in the intensity of nuclear quadrupole resonance resulting from imperfections induced in a crystal lattice. The following results were obtained by using γ -rays: (1) among the halogenated organic compounds, the aromatics are more radiation resistant than the ionic and alicyclic compounds; (2) the accumulation of chlorines on an aromatic ring does not seriously affect radiation damage; (3) among the halogenated derivatives

LIE.04:001 - LIE.04:004

of benzene, p-dibromobenzene has a weak radiation resistance; (4) the presence of an OH radical in iodo-phenols seems to be responsible for the radiosensitivity of these compounds; (5) sulphur acts as a good protector in iodoform; (6) the molecular radiation resistance is approximately independent of the nature of the substituted halogen in the case of molecules composed of at least 2 benzene rings; (7) the degree of delocalization of the π -electrons seems to govern the radiation resistance among the aromatics; and (8) none of the post-effects characteristic as a sequel in vacuum occur from irradiation of $\text{CHI}_3 \cdot 3\text{S}_8$ in an oxygen atmosphere.

A special study was undertaken concerning the actions of fast neutrons in NaClO_3 and evidence was obtained that their efficiency in producing damage is about 10 times greater than that of γ -rays from Co^{60} . The problem of the slope of the resonance lines is discussed and suggestions are made in the distribution of the field gradients and in the part played by the induced impurities in the protective effects. Le calcium échangeable de la substance minérale de l'os étudié à l'aide du ^{45}Ca . III. Recrystallisation des sels osseux, by M. J. Dallemagne, P. Bodson, and J. Ueten. [1958] [13]p. incl. diagrs. tables, refs. (AF 61-(514)940) Unclassified

Published in Bull. Soc. Chim. Biol., v. 40: 232-245, Mar. 21, 1958.

Experiments were conducted which reveal the following:

- (1) Ca^{45} ions exchange with Ca^{40} ions on the surface of the microcrystals. There are two possible interpretations: (a) these calcium ions are located on the real surface of the microcrystals of a hydrated calcium phosphate with a Ca/P ratio of 2.26 and with the same lattice as hydroxyapatite; (b) these calcium ions are chemisorbed at the surface of microcrystals of a defect phosphate;
- (2) the surface exchanged Ca^{45} ions probably migrate into the lattice by diffusion and are entrapped between the crystalline particles which agglomerate; (3) these two phenomena are temperature dependent; (4) their occurrence does not require the presence of a water phase. However, the migration of the surface ions into the crystals occurs when 3 parts/100 of adsorbed water are still present in the solid phase; (5) these two phenomena correspond to the aging process of bone salts, their starting point is the mineralization of bone; and (6) apparently only a fraction of bone salts CO_2 is located at the surface of the microcrystals. As the Ca/P ratio of bone salts is high, the phenomenon of exchange with radioactive phosphorus is accompanied by fixation of PO_4^- ions. First the values of

this fixation, its influence on calculated rates of exchange were examined and the exchange itself was studied. On the mineralized bone, figures obtained for percentage of phosphorus exchange were close to those mentioned for calcium in the literature. Fractionated dissolution shows that heating modifies identically accessibility of PO_4^- or Ca^{++} ions previously exchanged.

Lastly, exchanges carried out on total bone give higher figures than for mineralized bone, but again for a single sample of total bone, results obtained for PO_4^- ions are

similar to those obtained for Ca^{++} . For each of the two ions, exchange rate is lower at the beginning of the experiment, this being apparently due to diffusion restricted by the presence of organic matter. These results therefore show that amounts of Ca^{++} and PO_4^-

situated on the surface of microcrystals or microcrystalline aggregates, represent the same percentage of the total amount of each of these ions. Heating ($300^\circ C$), while modifying the general structure of the mineral bone substance, does not bring about the appearance of a molecule of different structure. (Contractor's abstract)

EVIDENCE OF RECRUITING RESPONSES IN THE CAT'S MESENCEPHALIC RETICULAR FORMATION, by J. Schlag. [1958] [2]p. (AF 61(052)22) Unclassified

Published in Experientia, v. 14: 297-298, 1958.

Since it is apparent that an ascending influence exists between the rostral and caudal parts of the so-called centrecephalic structures, it seemed interesting to test the reverse possibility, namely a feedback action of the thalamus upon the brain stem reticular formation. This was done by looking for recruiting responses in the mesencephalic region. The results of the experiments conducted demonstrate the back action of the diffusely projecting system of the thalamus on mesencephalic regions which are physiologically considered as belonging to the reticular system.

If a 1-1/2-cm length of 2-mil tungsten wire is heated in a period of about 100 μsec , such as by the discharge of a condenser, at the end of the heating period, the temperature distribution along the wire is essentially flat. This fact is used in an investigation of the ignition of gases by electrically heated wires. Since the temperature distribution is flat, the current to maintain the center of the wire at a constant temperature is a measure of the heat flux from the wire to the gas. A theoretical analysis of the heat flow shows that the temperature of the center of the wire is independent of end losses for about 100 μsec . A general formulation of the problem is applicable to wires of any length and diameter. (Contractor's abstract)

Experiments were conducted on the ignition of gases with constant temperature wire ignition sources. The ignition

LIT.01:002, 003; LIT.02:001

of stoichiometric methane-air and stoichiometric hydrogen-air mixtures is characterized by an ignition delay where no visible flame appears. The nature of the ignition delay differs between the two mixtures. In the case of the methane-air system an exothermic reaction occurs during the preignition period. This preignition reaction propagates at a velocity and for a period of time that depend upon the temperature of the wire. Near the end of this period, the reaction accelerates to a more rapidly propagating flame front. In the hydrogen-air mixture no measurable reaction occurs during the preignition period. These observations suggest that the methane-air reaction is at least partially thermal in character while the hydrogen-air reaction is essentially due to a chain carrier mechanism. Some effects of wire size, wire composition, and gas pressure on the ignition delay have been investigated for the case of the hydrogen-air mixture. For a given wire temperature, the ignition delay increases when either the diameter of the wire or the gas pressure are reduced. The magnitude of this reduction in ignition delay agrees, at least to a first approximation, with theoretical considerations of the effect of wire size and gas pressure on ignition delay. A prototype laboratory chamber is described which provides the means of human occupancy, observations, and manual operations in an environment maintained at an absolute pressure of the order of one billionth of an atmosphere. The chamber is 8 ft in diameter and 15 ft long. The occupant is provided with a unique pressure suit which is supplied with oxygen for breathing and ventilation and allows for manual manipulations requiring considerable dexterity. The instrumentation, controls, and auxiliaries which supplement this laboratory chamber make the laboratory a complete facility for experimentation and study under conditions which closely simulate outer space. Several problems were associated with solutions adequate to the existing boundary conditions. These included the design, fabrication, and test (1) of constant volume enclosures for the human arm, wrist, and hand which allow free and low effort manipulation at an internal pressure of 5 psi (above outside ambient); (2) of a recirculating breathing and ventilating system designed to maintain human comfort in absolute vacuum; and (3) of a unique lead detection device used by the occupant to pinpoint leaks from the inside of the laboratory chamber. The preliminary design was completed of an airlock to permit entrance and egress of the inhabitant and equipment without materially disturbing the vacuum in the inner chamber.

[HIGH VACUUM TEST FACILITIES] by S. Hansen and R. A. Roche. Monthly progress rept. July 18, 1957 [16]p. incl. illus. refs. (AFOSR-TN-58-239) (AF 18-(600)1498) AD 154141 Unclassified

Continued trouble has been experienced with the mechanical pumps since substitution of Tri-Cresyl-Phosphate for pump oil. It appears that passing dry air through the pumps may result in sufficient improvement in pumping characteristics to allow for continuing the use of T.C.P. The medical instrumentation is now working satisfactorily; however, considerable difficulty was experienced in eliminating noise from the medical signal leads. Eight trial inhabited runs were undertaken during this month. Two runs were aborted due to difficulty with medical instrumentation and one was aborted due to a decrease in partial oxygen pressure as a result of an air leak in the CO₂ analyzer. The other runs were considered successful. On one run an equivalent altitude of 85 miles was reached during the test. A series of tests were run to evaluate the transient conditions resulting from operation of the emergency air system. Results indicate that the noise levels and temperatures experienced following operation of the emergency system are higher than desirable but are acceptable on an interim basis until system modifications can be made. The research study of past work relating to the proposed thermal equilibrium experiment has been completed. It has been determined that much of the data regarding specific characteristics of materials (reflectivity, emissivity vs. wavelength) is already available. There

LITTON RESEARCH ON PLASMA ACCELERATION

(Abstract), by G. Fonda-Bonard. [1958] [1]p. (Bound with its AFOSR-TR-58-125; AD 162274) [AF 49(638)-345] Unclassified

Presented at Conf. on Ion and Plasma Research, Maryland U., College Park, Sept. 30-Oct. 2, 1958.

The magnetohydrodynamics of accelerating gas plasmas is being studied. The magnetic field employed may be considered to be a radial field which is swept linearly with constant acceleration. That portion of the field which is of interest is produced within a long evacuated glass tube coincident with the axis of travel of the magnetic field. A small quantity of pre-ionized gas is admitted at the end of the tube coincident with the start of

LOC. 01:003-005; LON. 01:001

the field's acceleration down the tube. The action of the moving field is to fully ionize the gas and pinch it into a conducting toroid. The reaction between the toroid current and the radial field results in the toroid of plasma being accelerated down the tube at a velocity slightly less than that of the magnetic field. The method of achieving the desired field makes use of a series of single turn coils wound concentric with the evacuated tube and appropriately spaced along its length. These are excited in sequence to develop the moving field. Electric energy is provided by individual high voltage capacitors of appropriate energy which are discharged through the coils in sequence.

FREE OSCILLATIONS OF A GAS IN AN ELASTIC CYLINDRICAL SHELL, by H. V. Hahne. Aug. 30, 1957, 28p. incl. diagrs. (Technical note no. 2; rept. no. LMSD-2160) (AFOSR-TN-57-348) (AF 18(603)146) AD 132421 Unclassified

Acoustic oscillations of a compressible gas contained in an elastic cylindrical shell are investigated. The mass and the elastic properties of the shell, as well as the coupling between the gas and the shell, are taken into consideration. First, the general case which includes all possible modes is considered, and the frequency equation is derived. Then the two special cases of purely tangential and of purely longitudinal modes are considered. For the tangential modes numerical results for an assumed configuration are obtained and compared to those for an elastic shell in vacuum and for a rigid shell of analogous dimensions. It is found that, for the tangential modes, certain natural frequencies of the elastic gas-filled shell resemble closely the natural frequencies of a gas in a rigid shell, while the remaining natural frequencies are quite similar to the frequencies of an elastic shell in vacuum.

A SANDWICH BURNER MODEL FOR THE COMPOSITE SOLID PROPELLANT, by W. Nachbar and J. M. Park. Sept. 25, 1957, 30p. incl. diagrs. (Rept. no. LMSD-2181) (AFOSR-TN-57-418) (AF 18(603)146) AD 132497 Unclassified

An idealized solid propellant sandwich burner, composed of alternating flat slabs of fuel and oxidizer which are ignited edgewise, is proposed for theoretical study of the functional relationship of the regression rate, pressure, and surface temperature in the combustion of composite solid propellants, and the dependence of this

relationship on geometry and on physical and chemical material properties. The work of H. N. Powell on the gaseous sandwich burner is reviewed in detail to clarify the assumptions and certain mathematical procedures used there. An eigenvalue problem for the solid propellant sandwich is formulated in two ways: one, by an extension of Powell's analysis, and, two, by an application of the Shvab-Zeldovitch approach. (Contractor's abstract)

OSCILLATIONS OF A GAS IN AN ELASTIC CYLINDRICAL SHELL, by H. V. Hahne. [1958] [8p. incl. diagrs. (AF 18(603)146) Unclassified

Published in Proc. Third U. S. Nat'l. Congress of Appl. Mech., Brown U., Providence, R. I. (June 11-14, 1958), N. Y., Amer. Soc. Mech. Engineers, 1958, p. 753-760.

An analysis is made of the natural frequencies and modes of oscillation of a compressible gas contained in an elastic cylindrical shell. The mass and the elastic properties of the shell, as well as the coupling between the gas and the shell are taken into consideration. First, the general case which includes all possible modes and their combinations is considered, and the corresponding frequency equation is derived. This general frequency equation is then reduced to two special cases, that of purely circumferential and that of purely longitudinal modes. Numerical solutions of the frequency equation are obtained for the circumferential modes of a gas-filled steel shell of given dimensions. (Contractor's abstract)

THE ANALOGUE SOLUTION OF TEMPERATURE DISTRIBUTION AND EXTINCTION IN AN IDEALIZED CYLINDRICAL FLAME, by D. B. Spalding and M. D. Samain. Jan. 1958 [17]p. incl. diagrs. (AFOSR-TN-58-216) (AF 61(514)1014) AD 154117 Unclassified

To assist the theoretical study of combustion problems a resistance network analogue has been built. The analogue solves one dimensional nonlinear heat conduction and generation problems with two point boundary conditions. The particular problem studied is the extinction of a pepper pot combustion chamber as influenced by turbulence level. The analogue consists of a line of resistances. The voltages at the network points are analogous to temperature. Currents injected into the network points are analogous to heat released at those points. The network points are scanned automatically by a rotating switch and a function generator is used to

LON. 01:002; LON. 02:001;
LSU. 01:002, 003

adjust the currents at each point. The analogue produces a solution in a few seconds and the resulting temperature distribution and reaction distribution is displayed on a cathode ray tube along with the function generator input/output curve. (Contractor's abstract)

APPROXIMATE SOLUTIONS OF TRANSIENT AND TWO-DIMENSIONAL FLAME PHENOMENA: CONSTANT-ENTHALPY FLAMES, by D. B. Spalding. [1958] [21]p. incl. diagrs. tables. (AFOSR-TN-58-807) (AF 61(514)1014) AD 202362 Unclassified

Also published in Proc. Royal Soc. (London), v. 245A: 352-372, 1958.

The 'profile' methods of boundary-layer theory are adapted to predict the behavior of the transient flames resulting from contact of semi-infinite burnt and unburnt gas masses, contact of unburnt gas with an adiabatic catalyst, immersion of a finite slab of unburnt gas in a large mass of hot gas, and immersion of a finite slab of burnt gas in a large mass of unburnt. Comparison with some exact solutions suggests that the accuracy is normally better than 20%. The method is simple to use. The results are also relevant to two-dimensional steady-state flames.

RESEARCH ON THE CREEP OF METALS, by E. N. da C. Andrade. Annual rept. no. 1, Feb. 15, 1957-Jan. 15, 1958 [24]p. incl. illus. diagrs. (AFOSR-TN-58-227) (AF 61(514)1177) AD 154129 Unclassified

A study was made of the mechanism of creep in metals and the manner in which the process is governed by the behavior of the crystal grains. The method of simple shear, which uses an apparatus described by Andrade and Jolliffe (Proc. Royal Soc., v. 213: 3, 1952), was used. The specimen was in the form of a flat disk about 16 cm in diam and 1.1 cm thick with a circular groove cut into one face leaving an annulus of metal about 1 mm thick and 12 mm wide which was the section subjected to shear stress by either clockwise or counterclockwise torquing. The temperature of the specimen was carefully controlled, strain was automatically recorded, and the surface of the test section was microphotographed during creep. Observations included the effect of stress and temperature on the linear rate of creep, the effects of periods of off-load, and the effects of reversal of stress on a lead containing 0.0045% Ag and 0.0038% Cu. Other experiments were performed on a commercial lead during which the behavior of the crystal grains was observed for short periods of strain (6 hr, 15%)

followed by reversal of creep (5 hr) and for increased temperatures, stress, and time. A full interpretation of the results is dependent on further observations and study, but a preliminary discussion is presented.

CLANS WITH ZERO ON AN INTERVAL, by H. Cohen and L. I. Wade. Jan. 14, 1957, 21p. (AFOSR-TN-57-34) (AF 18(603)89) AD 115072 Unclassified

Also published in Trans. Amer. Math. Soc., v. 88: 523-535, July 1958.

The object of the paper is to characterize clans with zero on an interval. Partial results in this connection have been found by Faucett and Clifford. In addition the case when 0 (the zero) is an end point has been studied by Mostert and Shields. Finally, a forthcoming paper by Clifford on linear mobs with idempotent end points will contain many pertinent results. S is always a clan on an interval with zero. It is well known (e.g., Wallace) that the unit u is an end point. It can be assumed that it is the right hand end point (the other case, of course, can be handled by a dual argument). Call the other end point δ . Let L be the interval $[\delta, 0]$ and R the interval $[0, u]$ so that the following diagram for S is:

One may define a partial order $<$ on S as follows: $x < y$ if and only if x separates y and 0, (i.e., $x < y$ if both x and y are on the same side of 0 and x is closer to 0 than y is). The notation $\lambda, \lambda_1 \in L$ and $r, r_1 \in R$ is used.

NOTE ON WEAK CUT-POINTS IN CLANS, by R. J. Koch. May 15, 1957 [9]p. incl. refs. (AFOSR-TN-57-241) (AF 18(603)89) AD 126538 Unclassified

Also published in Duke Math. Jour., v. 24: 611-616, Dec. 1957.

A clan is a compact connected semigroup with unit. Since a clan need not be a homogeneous space, one may inquire as to the topological position of algebraically distinguished points, with some hope of a useful answer. Theorem 1 is of a somewhat technical nature, identifying a topologically defined subset as a normal subgroup of

LSU.01:004 - LSU.01:008

H_u , the maximal subgroup of the clan which contains the unit, u . This leads to results germane to the conjecture that the unit of a clan which is not a group cannot be a weak cutpoint. The reviewer has conjectured that finite-dimensional homogeneous clans are necessarily groups. Theorem 4 states that the unit of a homogeneous clan which is not a group (though perhaps infinite-dimensional) cannot be a weak cutpoint, and that there must be small open sets about u with connected complements. Theorem 5 is the result that, in a one-dimensional clan which is not a group, the unit cannot cut any subcontinuum. (Math. Rev. abstract)

ARCS IN PARTIALLY ORDERED SPACES, by R. J. Koch. May 22, 1958 [8]p. incl. refs. (AFOSR-TN-58-397) (AF 18(603)89) AD 154908 Unclassified

Also published in Pacific Jour. Math., v. 9: 723-728, 1959.

A theorem is presented on the existence of arcs in partially ordered spaces, and several applications are made to topological semigroups. The hypotheses are motivated by the structure of the partially ordered set of principal ideals of a compact connected topological semigroup with unit element. Among the applications are the following: (1) a compact, connected topological semigroup with a unit element contains an arc; and (2) a locally compact, connected topological semigroup with zero element, each of whose elements is idempotent, is arc-wise connected. The word arc is used in the sense of continuum irreducibly connected between two points. All spaces are assumed to be Hausdorff, but not necessarily metric. Simple non-metric examples of the theorems are furnished by the long line, i.e., the ordinals up to and including Ω , filled in with intervals, the operation being $a \cdot b = \min(a, b)$.

AFFINE SEMIGROUPS I, by H. Cohen and H. S. Collins. Aug. 20, 1958, 26p. (AFOSR-TN-58-709) (AF 18(603)89) AD 162243; PB 137432 Unclassified

Also published in Trans. Amer. Math. Soc., v. 93: 97-113, Oct. 1959.

Consideration is given to some properties of general affine semigroups. A complete characterization of all one and two dimensional compact affine topological semigroups and of all one dimensional affine semigroups and of all possible multiplications is listed in each of these cases. Proofs are included which show that the minimal ideal of each one or two dimensional compact affine topological semigroup is complex. A similar statement can be made for three dimensional semigroups with unit, and examples are given which show the theorem is false for dimension three without unit and in general for all semigroups of dimensions greater than four.

DUOMORPHISMS AND CLANS ON AN INTERVAL, by R. C. Phillips. Aug. 20, 1958, 8p. (AFOSR-TN-58-710) (AF 18(603)89) AD 162244 Unclassified

The paper characterizes the clans (compact connected Hausdorff topological semigroups with an identity element) which are homeomorphic to a unit interval and which have a nondegenerate kernel (minimal two-sided ideal). X is a topological space with a C considered to be irreducibly connected between two points x and y in X . If C is connected, x and $y \in C \subset X$ and there is no connected proper subset of C which contains both x and y . If for any two points x and y of X there exists exactly one continuum C such that C is irreducibly connected between x and y , one says X is uniquely arcwise connected. If X is uniquely arcwise connected and if a and b are elements of X , $[a, b]$ denotes the continuum in X which is irreducibly connected between a and b . Definitions and proofs are given for the theorems presented.

ORDERED SEMIGROUPS IN PARTIALLY ORDERED SEMIGROUPS, by R. J. Koch. Sept. 11, 1958, 6p. (AFOSR-TN-58-739) (AF 18(603)89) AD 201505; PB 136852 Unclassified

Also published in Pacific Jour. Math., v. 10: 1333-1336, 1960.

A locally compact connected partially ordered local semigroup with unit is shown to contain a compact connected linearly ordered local subsemigroup (containing the unit). This is an extension of a theorem of Gleason (Proc. Nat'l. Acad. Sciences, v. 36: 636-667, 1950). It follows that a compact connected partially ordered semigroup with unit and zero contains a standard thread joining the zero to the unit. (Contractor's abstract)

ON THE SEMIGROUP STRUCTURE OF CONTINUA, by R. P. Hunter. Sept. 11, 1958, 21p. incl. refs. (AFOSR-TN-58-740) (AF 18(603)89) AD 201506; PB 136853
Unclassified

Also published in Trans. Amer. Math. Soc., v. 93: 356-368, Nov. 1959.

This paper contains an investigation of the structure of topological semigroups defined on continua. The first part of the paper deals with a semigroup S irreducible between two points with $S^2 = S$. The author shows that if S has a zero, then S is an arc. The latter part is devoted to semigroups on hereditarily unicoherent continua. As a corollary the author obtains the result that a 1-dimensional clan with zero is arcwise connected. The proofs given, however, are somewhat hard to follow due to typographical errors and careless statements by the author. It is sometimes questionable if the author actually means what his statements imply. For example, in Definition 1.3, the author obviously means, though he does not state it, for the sets A , B , and C to be pairwise disjoint; for without this restriction Theorem 1.5 is false. Also the proof of Theorem 1.11 is inadequate; for the claim made that, if V is an open set containing A , the complement of a maximal prime ideal, then $\bar{S}V$ must have finitely many components, is clearly false. INTERPRETATION OF SOME FLAME SPECTRA IN TERMS OF REACTION KINETICS, by G. Nenquin, P. Thomas, and A. Van Tiggelen. [1956] [10]p. incl. tables. (AF 61(514)814)
Unclassified

Published in Bull. Soc. Chim. Belg., v. 65: 1072-1081, Nov.-Dec. 1956.

The spectral intensity emitted by different radicals in some flames sustained by some different combustibles and supporters of combustion (NH_3 , H_2 , C_2H_4 and $\text{C}_2\text{H}_3\text{Cl}$ vinyl chloride) on one hand and N_2O , O_2 , on the other, has been measured. The activation energy of production reactions for radicals can be calculated apart from the measured intensities of various dilution degrees, on the condition of knowing the temperatures in the front of the flame. It is proved that for certain radicals at least, the intensity variation for an increasing dilution by an inert gas is narrowly connected to the variation of the flame propagation velocity. For these radicals, the activation energies are close to those in the chain forming reactions.

FLAME PROPAGATION IN MIXTURES OF LESS USUAL FUELS WITH OXYGEN, by A. Van Tiggelen, J. Van Wonerghem, and P. J. Sloopmaekers. [1957] [18]p. incl. diagrs. table. (AFOSR-TN-57-276) (Bound with its AFOSR-TR-57-27, Feb. 1957; AD 126445) (AF 61(514)814) AD 126578
Unclassified

Also published in Bull. Soc. Chim. Belg., v. 65: 899-917, Sept.-Oct. 1956.

During this study, measurements were made of the flame-propagation velocities, flame temperatures, and distances between Schlieren and luminous flame cones for mixtures of O_2 and H_2S , CS_2 (H_2 -free), and a chlorinated hydrocarbon (vinylchloride), respectively, all being diluted with N_2 . Results obtained by using a mixture of $\text{Et}_2\text{O} + \text{O}_2 + \text{N}_2$ are presented for comparison.

It is concluded that the flames of the mixtures investigated here do not differ much from the usual hydrocarbon flames. Any differences result mainly from variation of the branching activation energy and from variation of the molecular weights of the chain carriers, which in the case of I are 17 or higher.

In this volume, the importance of the branching condition in flame propagation is considered. A general, but simple, theory for flame propagation is derived on the basis of the kinetics of chain reactions. This theory provides a good correlation between different flame properties and even between flames propagating in mixtures of different fuels and oxidants. Measurements are reported of flame temperature, burning velocity, and flame-front thickness for mixtures of the following fuels and oxidants: CO, H₂, NH₃, C₂H₂, (C₂H₅)₂O, C₂H₃Cl, H₂S, N₂H₄, CS₂, O₂, N₂O, Cl₂, and F₂. Overall activation energies, assumed to be approximately equal to the activation energy of the branching process, are derived from the experimental data. In addition, the intensities of the different bands emitted in the spectra are determined for the following flames: NH₃/O₂, C₂H₂/O₂, C₂H₂/N₂O, C₂H₄/O₂, and C₂H₃Cl/O₂. An attempt is made to give a kinetic

interpretation of these intensities, assuming chemiluminescent excitation of the emitting radicals. The results of the above work, accomplished on AFOSR-sponsored tasks at Louvain U. (Belgium), are reported in the following chapters:

Flame propagation velocities have been measured in H₂/Cl₂, H₂/F₂, CH₄/F₂ and CO/F₂ mixtures at different fuel/oxidant ratios and different dilutions. Corresponding flame temperatures have been calculated. Activation energies are deduced for the following mixtures: 10 kcal (H₂/Cl₂ flames); 11 kcal (H₂/F₂ flames); 18 kcal (CO/F₂ flames) and 9.5 kcal (CH₄/F₂ flames). It is assumed that these values are the activation energies of the branching processes involved in the reaction mechanism. (Contractor's abstract)

It is generally believed that in crystals like ZnS, the absorption of photons brings an electron from the valency band to the conducting band, if the speed of photon absorption is greater than the velocity of electron necessary to make the electron jump the forbidden band. In electroluminescence the field accelerates electrons

which reach the conducting band. If they do not fall into electron traps, they collide with luminescent centers. In condensers a loss angle (δ) results from displacement polarizability. It is believed that in electroluminescence δ is the consequence of the collisions of electrons and luminescent centers. An important part of the energy of these collisions is transformed into light. The purpose of this research is to study the relation between δ and light emitted. Results show that δ increases with light emitted and reaches values as high as 73. For condensers without EL powder and for condensers constructed with fluorescent or phosphorescent powders with the same dielectric binder, δ does not increase. It is felt that at least with ZnS phosphors, luminescence is related with photocurrent, and that electrons move through the crystal, but that these electrons do not meet EL centers. Condensers prepared with CuO give constant values in spite of the fact that CuO is a semiconductor. To date all of these experiments have shown that δ increases only in EL condensers. Oscillograms, which appear as a second method to study δ , particularly in EL of single crystals, have been taken, and the results obtained appear to be comparable to those obtained by other researchers in the field of single crystal electroluminescence.

STUDIES ON THE MECHANISM OF ELECTROLUMINESCENCE, by A. Luyckx, J. Vandewauwer, and S. Ries. Annual technical rept. Nov. 15, 1956-Nov. 15, 1957, 1v. incl. diagrs. tables. (AFOSR-TN-58-153) (AF 61(514)-1118) AD 152179; PB 142162 Unclassified

The present research is the first systematic work about electrical and dielectrical measurements concerning electroluminescent powders. Dielectric loss, resistivity and capacity were studied in function of ac voltage applied at the industrial frequency of 50 Hz; analogous measurements were made with phosphorescent powders and compared to electroluminescent ones.

ZnS single crystals prepared by sublimation were electroluminescent only after activation. The threshold of electroluminescence in ac field equals 500 volts/cm. Electrode zones give more intense glows. The brightness waves excited by half-wave fields show a peak in phase with the field. This peak is mostly due to anodic zone. It is attributed to injected charges. Our experiments were done on nine crystals prepared by the same method. Two types of crystals were identified. The first type shows a reverse current at the end of a half-wave field excitation. There is coincidence between the peak of this current and the out-of-phase light peak. This light is attributed to electrons under the influence of the space-charge field. With the second type of crystals there was no reverse current. The current wave and brightness wave are in phase with the field. With dc applied fields, some crystals show glows in the anodic region. Inversion of polarity provokes migration of the glowing zone towards the new anode. This was attributed to the migration of ions. Brightness waves obtained with half-wave excitation fields are not the same after dc field has been applied. The in-phase peak is less important; the dc field modifies the crystal. Published in Ann. Soc. Scientifique Bruxelles, Series I, v. 72: 58-74, June 18, 1953.

Dielectric loss, resistivity and capacity of electroluminescent (EL) condensers were studied in function of ac voltage applied, at the industrial frequency of 50 Hz; analogous measurements were made with phosphorescent powders and compared to EL. For EL condensers the loss angle ($\text{tg } \delta$) increases in function of applied voltage in some experiments from 0.05 to 1.91; no increase of $\text{tg } \delta$ was found for phosphorescent condensers. Resistance, R_p , of equivalent circuit for EL condensers decreases with increasing applied ac voltage; it does not do so for phosphorescent powders. Capacity, C_p , increases slightly for EL; it does not for phosphorescent powders. In dc fields, EL powders are more conductive than phosphorescent ones. The increase of $\text{tg } \delta$ for EL condensers has the same shape as the curve luminescence versus voltage. These results are inconsistent with a previous assumption that an essential difference between EL and phosphorescent powders lies in the presence of electron traps in the phosphorescent powders. Experiments showed that $\text{tg } \delta$ variation is partially due to internal processes in EL microcrystals and partially to the potential barrier cathode-crystals. A physical

LOV. 01:001; LOV. 02:001, 002

meaning of tg δ increase is proposed: It is due partly to an increase in the number of donor centers and partly to the possibility for electrons to jump potential barriers more easily. (Contractor's abstract)

QUANTITATIVE EMISSION SPECTROSCOPY AS A MEANS OF ANALYZING RESPIRATORY GASES, by C. S. White, W. H. Lockyear and others. [1958] [13]p. Incl. diagrs. table, refs. (AFOSR-TN-58-480) [AF 18(603)80] Unclassified

Presented at 25th annual meeting of the Aero. Med. Assoc., Washington, D. C., Mar. 31, 1954.

Also published in Jour. Aviation Med., v. 26: 104-116, Apr. 1955.

A Beckman DU spectrophotometer was modified to study the emission spectra of dry N_2 , O_2 , and CO_2 when the gases were energized electrically in an evacuated quartz

discharge tube. The spectra were determined from 2000-5000A at a tube pressure of 1000 μ and from 2000-5800A at pressures of 200 μ . In eight spectral regions emission phenomena were such that determination of CO_2 by the emission method might be possible, e.g., near 5840, 5580, 5180, 4820, 2880, 2820, 2658A, and between 2000 and 2200A. Exploration of the 4820A region from 4810-4840A indicated that emission at 4815A was of potential use for CO_2 analysis, but that with the technique employed the results were only consistent if the N_2 - O_2 ratio in the CO_2 containing gas was fairly constant. The resolution available with the method used was insufficient to allow practical determination of CO_2 in expired air under circumstances in which the O_2 - N_2 ratio varied widely, such as in O_2 breathing. The utility of the 4815A spectral region in CO_2 analysis could be increased if a spectrometric method of greater resolution were available. It was felt that the use of a grating spectrograph should be investigated, as should the use of a metal-free discharge tube energized by high frequency rather than dc voltage. EMISSION SPECTROSCOPY IN ANALYSIS OF RESPIRATORY GASES. II. CARBON DIOXIDE ANALYSIS USING THE CARBON DIOXIDE DOUBLETS NEAR 2896A, by C. S. White, L. C. Watkins, Jr., and E. E. Fletcher. [1958] [13]p. Incl. illus. diagrs. table, refs. (AFOSR-TN-58-481) [AF 18(603)80] Unclassified

Presented at 27th annual meeting of the Aero Med. Assoc., Chicago, Ill., Apr. 17, 1956.

Also published in Jour. Aviation Med., v. 27: 332-334, Aug. 1956.

A small-volume rf energized light source suitable for activation of the CO_2 emission doublets located near 2883 and 2895A is described. The discharge tube proved an adequate emission source for either the Beckman DU spectrophotometer or the Applied Research Laboratories quantograph and the instruments were utilized independently to study the emission characteristics of "dry" respiratory gases, particularly near the 2900A region of the spectrum. A simple modification of the spectrophotometer allowed the instrument to be used as a monochromator, and under appropriate operating conditions, satisfactory performance as a continuous CO_2 analyzer was achieved using the emission attributed to CO_2^+ at 2896A. At this wavelength, the relation between emission intensity and CO_2 concentration proved linear whether

the gas was present in air or in O_2 . However, the CO_2 in air curve was parallel to, but consistently above, that for CO_2 in O_2 . The relative youth of the emission method as a technique for continuous quantitative gas analysis is pointed out, some of the pertinent literature is summarized and a general discussion of the data is presented. Presented at 27th annual meeting of the Aero Med. Assoc., Chicago, Ill., Apr. 17, 1956.

Also published in Jour. Aviation Med., v. 27: 414-423, Oct. 1956.

Emission spectra of "dry" gas mixtures containing O_2 , N_2 , and CO_2 were studied using small-volume light sources in conjunction with monochromators employing a quartz prism (Beckman DU spectrophotometer) and a grating (Applied Research Laboratories quantograph) for light dispersion. Exploration of the calibration characteristics of the N_2 emission spectra produced with an rf excited quartz discharge tube revealed activity near 2372A which exhibited a near-linear relation between emission intensity and N_2 concentration. Photographic spectrograms were obtained between 5000-9000A using two light sources; namely, the positive column of a dc activated discharge tube and a rectangular quartz tube with external electrodes energized with rf. With both the dc and rf discharge tubes, O_2 emission was noted as a triplet near 7772, 7774 and 7775A and as a singlet near 8446A. However, N_2 activity present with the dc light source operated at lower pressures was markedly suppressed at higher pressures when the rf emission tube was employed. The preliminary nature of the data is emphasized and the potential significance of the results are briefly discussed. (Contractor's abstract)

Presented at 28th annual meeting of the Aero Med. Assoc., Denver, Colo., May 7, 1957.

Also published in Jour. Aviation Med., v. 28: 406-416, Aug. 1957.

A small volume, circular quartz discharge tube fitted with external metal electrodes is described which was adequate for energizing the O_2 triplet near 7772-75A and the O_2 singlet near 8446A. The operating characteristics of the discharge tube in terms of pressure, rf voltage, slit width and the relative emission noted with "dry" tank O_2 , CO_2 , N_2 and air in various combinations are presented. Calibration data are given for O_2 in N_2 which showed a curvilinear relation between emission intensity (at 7772-75A) and the higher concentrations of O_2 (100 to 20%), but the relation was linear at the lower O_2 concentrations (3 to 30%). Under similar conditions calibration figures for O_2 in CO_2 were linear up to 21% O_2 , but the curve fell below and was less steep than that for O_2 in N_2 . O_2 calibration in the presence of varying ratios of N_2 and CO_2 —obtained by diluting compressed air with CO_2 —was complex in that O_2 emission was apparently less than equal to and more than that for O_2 in N_2 when the O_2 concentrations were between 2-14, 14.5-16.5 and 17-20% respectively. metal electrodes and energized with an rf oscillator at 3.0 mc stabilized to minimize harmonics was employed as a light source on a Beckman DU spectrophotometer to explore the calibration characteristics of O₂ emission near 7772-7775A. Calibration curves for up to almost 100% dry O₂ in N₂ were curvilinear; up to about 20% O₂, the relation between emission output and O₂ concentration was essentially linear. The presence of dry CO₂ in dry O₂-N₂ mixtures yielded complex calibration curves for O₂ whereby O₂ activity was enhanced and depressed by small and large amounts of CO₂, respectively. A small rectangular quartz tube fitted with recessed flat rectangular external metal electrodes and energized with an rf oscillator at 3.0 mc was employed with the Beckman DU spectrophotometer to analyze CO₂ near 2896A. Near this wavelength, the analyzer yielded linear curves for CO₂ mixtures in air, but was not specific for CO₂ in that N₂ effects were also noted. The analyzer was not judged adequate for routine use in respiratory physiology.

The chronic electrical activity of the sub-cortical meso-diencephalic formations and of the cortex for animals with an intact head, carriers of a section of the cerebral trunk and finally for cats with the cortex removed was studied. Observations are made for periods of one wk to three mos. Cortical and sub-cortical electrodes are implanted at the level of several cortical regions and meso-diencephalic formations, under barbital anaesthesia. A section of the cerebral column is tested for certain animals before the implantation by means of a blade oriented stereotaxically. These relatively poikilothermal animals have their rectal temperature maintained at 38° by heating. The animals with the cortex removed are operated on for a time by the aspiration and coagulation of the neocortex. An acrylic resin prosthetic is located, from the frontal sinus to the occipital crest and the sub-cortical electrodes are fixed at its level. All the animals are tested in sound-proof cages. Histological controls verify the electrode situation, the extent of the cortical and cerebral trunk lesions.

MASSSES OF ATOMS $A > 40$, H. E. Duckworth. July 1, 1957 [24]p. incl. tables, refs. (AFOSR-TN-57-322) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)484 and National Research Council of Canada) AD 132393 Unclassified

Also published in *Progress in Nuclear Phys.*, v. 6: 138-161, 1957.

Sources of atomic mass information which are discussed are: the mass spectroscopic atomic mass difference, the determination of the energy balance in nuclear reactions, total β -disintegration energies, determination of atomic masses by microwave spectroscopy, and α -disintegration energies. Discussions are included on the need for heavier standards, the requirements of heavier standards, suggested heavy secondary standards, and permanence of O^{16} as a primary standard. Atomic masses for $A > 40$ are tabulated.

THE LUMINESCENCE RESPONSE OF PHOSPHORS TO LOW ENERGY ION BOMBARDMENT, by C. F. Eve and H. E. Duckworth. [1958] [13]p. incl. diagrs. tables, refs. (AFOSR-TN-57-701) (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)-

247, Ontario Research Foundation, and National Research Council of Canada) AD 136694 Unclassified

Also published in *Canad. Jour. Phys.*, v. 36: 104-116, Jan. 1958.

The luminescence response of samples of $ZnS:Ag$ and $Zn_2SiO_4:Mn$ to bombardment with various ions was determined as a function of the ion energy E . For $ZnS:Ag$, within the range of ion energies studied ($E < 25$ kev), the luminescence response L is proportional to $(E - E_0)^m$ where E_0 is the threshold energy which is not a very sensitive function of the ion mass. For $Zn_2SiO_4:Mn$ no threshold energy was observed except in the case of Li^{7+} ions, the lightest ions used with this phosphor. The experimental results for $ZnS:Ag$ appear to be consistent with a theory in which it is assumed that the bombarding particles penetrate the phosphor as neutral atoms and produce luminescence by electronic excitation of the lattice atoms due to small impact parameter collisions.

Also published in *Proc. Conf. on Nuclear Masses and Their Determination*, Max-Planck Institut für Chemie, Mainz (Germany) (July 10-12, 1956), London, Pergamon Press, 1957, p. 75-80.

The atomic masses of Ni^{58} and Ni^{60} have been determined by employing a double-focusing mass spectrometer using a doublet method. The values are larger than the previously accepted values but the Ni^{38} value agrees with a new measurement elsewhere. The effect of residual gas pressure in the spectrometer on the doublet spacing has been investigated and the results suggest that not all doublet spacings are pressure dependent.

THERMAL VIBRATIONS IN DICARBOXYLIC ACIDS (Abstract), by J. L. Amorós and M. L. Canut. [1957] [2]p. [AF 61(514)1146] Unclassified

Presented at Internat'l. Union of Crystallography, Montreal (Canada), July 10-19, 1957.

Published in Acta Cryst., v. 10: 794-795, Dec. 10, 1957.

Diffuse scattering of succinic, adipic and pimelic acids has been studied to get information about motion of waves traveling along a chain-like structure. A complete recording of such diffuse scattering at room temperature was necessary and Lauegrams in a Unicam camera of 6 cm diameter were taken by steps 3° apart in a range of 180° since the recording was taken with [010] as the vertical axis. The diffuse domains have two main features: (a) broad, round, definite domains, corresponding to a zone in the reciprocal space of about 30° having a as medium axis; (b) fine, long, extended domains (streaks) corresponding to directions in the reciprocal space normal to c chain direction. Diffuse scattering was plotted in reciprocal space using Bernal and Martin charts. Two aspects of diffuse scattering domains are discussed in detail: (1) wave analysis of chain-like structures; and (2) thermal motion and symmetry. (Contractor's abstract, modified)

Published in P. Dep. Crist. Min., v. 3: 5-13, 1957.

In order to get more information about thermal motion in crystals a systematic survey of the reciprocal space is developed, giving as a result an anisotropic $\langle f^2 \rangle$ normal and parallel to the chain direction. From this systematic survey it is possible to infer the nature of the thermal motion in a chain-like crystal. Making use of the Fourier transform

$$\rho_1 = \int_0^1 \langle f^2 \rangle e^{-2\pi i (hx)} dx$$

> 361 <

ρ_{\perp} and ρ_{\parallel} are readily calculated. Supposing an harmonic movement of the chain normal to the chain direction a new way has been developed by means of which it is possible to calculate u_{\perp} and u_{\parallel} . Values calculated by this method are consistent with the observed, giving a straightforward method for calculating thermal motion in crystals. (Contractor's abstract)

STUDIES OF THERMAL MOTION IN CRYSTALS, by J. L. Amorós, M. L. Canut and A. Bujosa. Annual rept. no. 1, Dec. 15, 1956 - Dec. 15, 1957, 1v. incl. illus. diagrs. tables, refs. (AFOSR-TN-58-154) (AF 61(514)-1146) AD 152180 Unclassified

Thermal motion of atoms in the dicarboxylic acids series was studied. A new method was developed for making a direct determination of molecular movement from a systematic analysis of the reciprocal lattice. Methods employing the electron density of a crystal were investigated, especially those based on $(F_o - F_c)$ Fourier synthesis. Several features relating densities and amplitudes were discovered. Diffuse scattering of a chain-like crystal was studied in β -succinic, adipic, sebacic, glutaric, and pimelic acids. Continuous diffuse scattering domains were characteristic of such diffuse scattering. Symmetry requirements for both atomic and wave motion in crystals were examined, and differences between static and dynamical space groups were emphasized. A comparison was made between diffuse scattering and both crystal expansion and polymorphism in an effort to evaluate the influence of atom motion in crystal motion (ASTIA abstract)

INTERPRETATION OF THE EXTENDED CONTINUOUS REGIONS OF X-RAY THERMAL DIFFUSE SCATTERING OF MOLECULAR CRYSTALS, by J. L. Amorós, M. L. Canut and others. [1958] 70p. incl. illus. diagrs. refs. (Bound with its AFOSR-TR-59-47; AD 215061) (AF 61(514)1146) Unclassified

Presented at meeting of the Amer. Cryst. Assoc., Cornell U., Ithaca, N. Y., 1959.

Also published in P. Dep. Crist. Min., v. 5, 1958.

Also published in Zeitschr. Krist., v. 114: 39-65, June 1960.

The weak extended continuous regions of x-ray thermal diffuse scattering of molecular crystals of different structural types are interpreted in terms of a new function, the difference Fourier transform (DFT) of the molecules. The experimental thermal diffuse scattering of adipic acid, succinic acid, hexamine, naphthalene and anthracene is compared with the isodiffusion lines computed with the DFT. The good agreement between theoretical and experimental values shows that DFT is a good approach to the interpretation of such continuous diffuse regions in molecular crystals and that independent (or antiphase) movement of the molecules as rigid bodies accounts for the morphology of such continuous regions of diffuse scattering. Also published in P. Dep. Crist. Min., v. 4: 23-29, 1958.

The structure is reviewed of forms IV and III. Experimental results of an x-ray diffuse scattering study are presented with Laue photographs and distributions of the diffuse scattering domains. In form IV high frequency vibrations are very clear, that is, optical frequencies characteristic of atomic groups vibrating as rigid bodies. But in form III the thermal diffuse scattering indicates that acoustical frequencies contribute

mainly to the vibrational spectrum. The apparent paradoxical diminution of thermal diffuse scattering at higher temperature is seen as a consequence of the structural change from form IV to form III.

65-75, 1958.

Also published in P. Dep. Crist. Min., v. 4: 30-37, 1958.

Laue photographs were taken at room and successively lower temperatures down to -85°C as the basis of this x-ray analysis study of the transition. No further transition from form V occurred at -80°C as had been suggested by specific heat studies. Diffuse scattering decreased very much in the low temperature form V while Laue spots increased both in number and intensity. Form V is found to belong to the tetragonal class, while modification IV has orthorhombic symmetry. Rotation photographs at low temperature show superstructure lines midway between levels of the corresponding room temperature photographs. The unit cell volume of V is 8 times that of IV. The transformation IV - V is reversible. In principle the mechanism of the transition can be explained on the basis of the superstructure formation but certain details fall outside of this formation phenomenon.

[POLYMORPHIC TRANSITIONS IN SINGLE CRYSTALS. II. IV - II-AMMONIUM NITRATE (84°C) TRANSITION AND II' (55°C) METASTABLE FORM] Transformaciones polimórficas en monocristales. II. Transición IV-II (84°C) del nitrato amónico y forma metaestable II' (55°C), by J. L. Amorós, P. Alonso, and M. L. Canut. [1958] [15]p. incl. illus. diags. [AF 81(514)1148] Unclassified

Published in Bol. R. Soc. Esp. Hist. Nat. (G), v. 58:
77-91, 1958.

Also published in P. Dep. Crist. Min., v. 4: 38-45, 1958.

Form II is obtained by heating form IV suddenly over the transition point 84°C , but by heating IV directly to 55°C the metastable II' results. Experimental results are given for an x-ray analysis of these transitions. Lattice constants are the same for both forms, II and II', $a = 5.68\text{A}$ and $c = 4.92\text{A}$. The space group for II is $P4_{2m}$ and for II' seems to be $P4$. The conclusion is reached that the production of disorder inherent in the jump from form IV to II can be obtained only by very quick heating. Less heating results in the metastable II' phase, but if the crystal receives enough energy, the transition to II is definitive.

QUASI INTERIOR POINTS OF CONES IN A LINEAR SPACE, by R. E. Fullerton. Feb. 1957, 16p. incl. diags. (AFOSR-TN-57-65) (AF 18(603)78) AD 120406

Unclassified

A topological definition of a quasi interior point of a cone in a linear topological space is given. If the cone has a non-void interior it is shown that all quasi interior points are interior points and that furthermore in L spaces and other commonly considered function and sequence spaces the notion of a quasi interior point coincides with the notion of a strictly-positive element of the space. Various geometric properties of quasi interior points of cones are proved to hold and in particular in section 5 certain separation and support properties of such sets are proved.

GEOMETRICAL CHARACTERIZATIONS OF BIORTHOGONAL BASIS SYSTEMS IN A BANACH SPACE, by R. E. Fullerton. July 1957, 17p. (AFOSR-TN-57-426) (AF 18(603)78) AD 136415

Unclassified

Proof is given that the existence of a certain type of cone in a Banach space is a necessary and sufficient condition for the existence of a biorthogonal basis system. The cone is named a biorthogonal basis cone and its properties are investigated. Most of the properties enumerated hold for bases in convex linear topological spaces and do not have to be formulated in terms of a norm topology. These considerations can be applied to the investigations of properties and characterizations of generalized biorthogonal basis systems by removing countability restrictions in certain of the assumptions.

An investigation of secondary flow effects, near the walls and through the blade passages of an axial compressor, and depiction of the mean flow have been made by means of smoke visualization. Vorticity distribution is analyzed both theoretically and experimentally. Analyses of the rotating stall flow pattern on a single stage axial compressor are made by means of dynamic stagnation, static pressure measurements, and smoke surveys. The results of both techniques are in good agreement. Smoke surveys appear to be of great assistance in the explanation of the rotating stall mechanism. They give clear evidence of the three-dimensional pattern of the phenomenon which might be a determinant factor for the different characteristics of rotating stall.

FLUTTER OF THIN PANELS AT SUBSONIC AND SUPERSONIC SPEEDS, by J. E. Greenspan and R. L. Goldman. July 1957, 1v. incl. illus. tables, refs. (Engineering rept. no. 9934) (AFOSR-TR-57-65) (AF 18(603)76) AD 136560; PB 132506

Unclassified

The flutter behavior of thin-skin panels was investigated in subsonic and supersonic flow. Experiments indicated that subsonic skin-flutter is possible. The subsonic and, to some extent, the supersonic flutter of finite skin panels is a periodical interchange between quasistatic shapes of the skin and is more complex than was assumed. A simple phenomenological analysis was developed on the basis of possible static shapes (for the membrane case) and yields qualitative agreement with the experimental results for the subsonic case. Flutter is self-limited in amplitude and is not necessarily destructive. A speech is included which was given by P. F. Jordan and E. Widmayer on Some Experiments On Panel Flutter at the Second Technical Symposium on Ballistic Missiles at the Ramo-Wooldridge Corp. (ASTIA abstract)

\mathcal{L} such that if $R \in \mathcal{L}$ and R^* is a translate of R , then $R^* \in \mathcal{L}$. A half ring \mathcal{L} which generates the class of all Borel sets in E^2 is called a non-degenerate half ring (n-d t.h.r.). The following theorems have been demonstrated: (1) the set P of all convex polygons forms a planar half ring; (2) a n-d t.h.r. P of convex polygons has a finite number of directions if and only if there exists a number m such that each $p \in P$ has less than m sides; (3) if P is a n-d t.h.r. of convex polygons, then for every pair of distinct directions of P , P contains a non-degenerate rhombus oriented with respect to these directions; (4) if H is a n-d t.h.r. of bounded convex sets in the plane, then each $h \in H$ is a convex polygon; and (5) if P is a n-d t.h.r., then I (a real valued set function defined on P) is proportional to the Lebesgue measure on P and the extension I' of I is proportional to the Lebesgue measure on the Borel sets in E^2 .

AN INTERSECTION PROPERTY FOR CONES IN A LINEAR SPACE, by R. E. Fullerton. Nov. 1957, 6p. (AFOSR-TN-57-765) (AF 18(603)78) AD 136755
Unclassified

Also published in Proc. Amer. Math. Soc., v. 9: 558-561, Aug. 1958.

It has previously been shown that if X is a real linear space with a very rudimentary topology, and if F is the family of all translates of a set C with an extreme point such that the intersection of any two set in F is another set in F , then C is a convex cone. A partial converse of the above is given in this paper. It is shown that if C is a cone and if $x, y \in X$ exist such that $(x+C) \cap (y+C)$ is a cone K , then there exists a $z \in X$ such that $K = z+C$. Examples of cones C having this property are discussed.

ON A CLASS OF TOPOLOGIES FOR FIELDS, by E. Correl. Feb. 1958, 10p. (AFOSR-TN-58-198) (AF 18(603)78) AD 152231
Unclassified

Locally compact topological fields are systematically studied and determined. A class of field topologies is examined which arises from l.c. topologies. A key definition says that a topology t for a field F is called l.c. if F together with t is a dense subfield of a non-discrete, non-indiscrete, locally compact topological field. The collection of all l.c. topologies for a field F generates a set J of field topologies for F , the set of all join topologies. The relation between an element of J and an arbitrary field topology for F is considered. Various definitions and lemmas are given and proved.

TOPOLOGICAL STRUCTURES FOR A SPACE OF CONTINUOUS FUNCTIONS, by R. E. McGill. June 1958, 25p. incl. diagrs. table. (AFOSR-TN-58-548) (AF 18(603)78) AD 158365
Unclassified

A discussion is presented of the properties and relationships of 7 topologies on the linear space of real valued continuous functions defined on the closed unit interval. The theory of quasi-convergence classes is developed in order to have a unified method for defining many of the topologies. Along with such properties as the relative strength, linearity, and semi-linearity of the topologies, topologies are given which coincide with the original topologies on either the weakly compact, uniformly bounded, or equi-continuous subsets of the function space. ALMOST UNIFORM CONVERGENCE VERSUS POINTWISE CONVERGENCE, by J. W. Brace. Aug. 1958, 6p. (AFOSR-TN-58-799) (AF 18(603)78) AD 202232; PB 138063
Unclassified

Also published in Proc. Amer. Math. Soc., v. 11: 986-987, Dec. 1960.

It has been established that the topology of almost uniform convergence on the collection of all bounded continuous real valued functions over a completely regular Hausdorff space is equivalent to the topology of pointwise convergence of the extended functions over the Stone Cech compactification (MDU.01:001). This raises the question as to when almost uniform convergence of a net of functions is equivalent to pointwise convergence of a net of extended functions over an enlargement of the original domain. This paper answers the question within certain restrictions.

The operator $1-\lambda T$, with λ a complex number, 1 the identity mapping, T a closed linear operator taking a Banach space X into itself, is taken. The purpose is a solution $x - \lambda T x = y$ for x , for a given y in X . A set of complex numbers called the generalized Fredholm domain for T is presented along with appropriate generalizations of the definition of the Fredholm radius. A

general class of operators having the spectral properties of compact operators is given, and a method analogous to the Fredholm method for integral equations is given applicable to the Fredholm domain of type I. A reverse method for determining information on eigenvalues is discussed. Further work is commented upon.

LATTICE VIBRATIONS IN SODIUM CHLORIDE TYPE STRUCTURES, by P. Mazur. [1957] 121p. incl. diagrs. refs. (Technical rept. no. 65) (AFOSR-TN-57-149) (AF 18(600)1015) AD 126438 Unclassified

Three problems in the theory of lattice vibrations in sodium chloride type lattices are investigated and quantitative treatments are carried out in detail. Firstly, assuming only nearest neighbor interactions with central and noncentral forces, the frequency spectrum (i.e., the number of normal modes of vibration between ω^2 and $\omega^2 + \Delta\omega^2$) is obtained exactly. The effect of 2nd nearest neighbor interactions on the spectrum is then treated as a small perturbation. Secondly, assuming only nearest neighbor interactions, the distribution function of the position of a typical atom around its equilibrium position is worked out. Analytic expressions for the dispersion are obtained as a function of temperature, central and non-central force constants, M (the heavier mass component), and m (the lighter mass component). Thirdly, the effect of defects on the lattice vibration is investigated. Depending on the type of defect introduced one finds localized modes emerging from either the acoustical band or the optical band or both. The self-energy of one isotope defect and the interaction energy between two isotope defects is obtained only for a one dimensional diatomic chain. The localized modes arising in the case of a three dimensional diatomic lattice (sodium chloride type) are examined only qualitatively from the Green's Function for the problem. EFFECT OF DEFECTS ON THE VIBRATION OF CRYSTAL LATTICES, by E. W. Montroll, A. A. Maradudin, and G. H. Weiss. June 1957, 26p. diagrs. refs. (Technical rept. no. 76) (AFOSR-TN-57-364) (AF 18(600)-1015 and AF 18(600)1315) AD 132436 Unclassified

Presented at Many Body Conf., Hoboken, N. J., Feb. 1957.

The effect of defects on the vibrational properties of crystal lattices is discussed qualitatively and quantitatively. A general method is presented for calculating the change in additive functions of the normal mode frequencies due to the presence of defects in the lattice. By an extension of this method one can calculate the frequencies of the localized modes of vibration associated with the defects. The theory is applied to the calculation of the frequencies of the localized modes due to impurity atoms in a linear chain, and also to the calculation of frequency splitting due to the presence of defect pairs. The change in the Helmholtz free energy and specific heat of a lattice due to the presence of a single defect is evaluated in the high temperature limit. An expression for the interaction energy between two isotope defects as a function of their separation at high temperatures is also given. Finally a method is presented for evaluating the effect of a large number of defects on additive functions of the normal mode frequencies. The method is illustrated by a calculation of the zero point energy of a disordered binary linear chain. (Contractor's abstract)

THEORY OF THE VIBRATIONS OF DISORDERED CRYSTAL LATTICES, by A. [A.] Maradudin and G. H. Weiss. [1958] [55]p. incl. diagrs. table, refs. (Technical rept. no. 79) (AFOSR-TN-57-365) (AF 18(600)1015 and AF 18(600)1315) AD 132437 Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Abstract published in Bull. Amer. Phys. Soc., Series 11, v. 3: 233, May 1, 1958. (Title varies)

A new method is presented for evaluating various additive functions of the normal mode frequencies for a lattice made up of different kinds of atoms which are randomly distributed over the lattice sites. This method, which is based on an expansion of the additive function expressed as a contour integral, is applied to the case where the lattice is made up of atoms with two different masses M_1 and M_2 which are present with probabilities p and $(1-p)$ respectively. Conditions under which the expansion converges are given for this case. The method is illustrated by some simple examples, and its generalization to more general disordered lattices is discussed. Presented at Internat'l. Convention on Condensed States in Simple Systems, Varenna (Italy), Sept. 11-15, 1957.

Abstract published in Nuovo Cimento, Series X, Suppl., v. 9: 235-236, 1958.

Also published in Phys. Fluids, v. 1: 55-72, Jan-Feb. 1958.

A systematic generalization of the Mayer cluster integral theory has been developed to deal with the quantum statistics of interacting particles. The grand partition function appears in a natural way and the cluster integrals are integrals over propagators which are derived from the Green's function solution of the Bloch equation. Every cluster integral can be represented by a hybrid of a Mayer graph and a Feynman diagram. The indistinguishability of particles causes each particle in a Mayer cluster integral to be replaced by a toron which can be described in the following manner through a Feynman diagram. Consider an (r, β) space in the form of a torus of tubal circumference β . A toron of order n is represented by a closed path which loops the torus n times so that a cut at constant β' (with $0 < \beta' < \beta = 1/kT$) on the torus identifies the position of n particles at β' . In the absence of a cut there is no indication of where one particle ends and another begins. The grand partition function is a sum over all graphs in which torons are connected by interaction lines which represent quanta of energy and momentum exchanged through collisions. The cluster integrals associated with rings of torons have been analyzed. In the case of electron gas the classical limit of the contribution of these integrals to the grand partition function yields the Debye-Hückel theory, while the low temperature limit leads to the Gell-Mann Brueckner equation for the correlation energy of the grand state. The construction of the cluster integral associated with any given diagram is explained. (Contractor's abstract)

Also published in Prog. Theoret. Phys., v. 20: 369-394, Sept. 1958.

Several methods of analyzing vibrational properties of crystal lattices with defects are developed. Integral expressions for additive functions of normal mode frequencies are derived following the work of Montroll and his collaborators. It is shown that the Helmholtz free energy can be evaluated at high and low temperatures without performing the integrations. The methods presented are valid for lattices of all dimensions, although specific results are presented here for one-dimensional monatomic and diatomic lattices. Using a method similar to that developed by Lifshitz, it is shown that the properties of a lattice with defects can be expanded in a series of powers of the concentration of defects. The coefficient of the n^{th} power depends on the properties of a lattice with no defects. Examples of such expansions are given. An exact expression for the frequency distribution function of a monatomic linear chain with an isotope defect is given. (Contractor's abstract)

Also published in Phys. Rev., v. 115: 18-24, July 1, 1959. (Title varies)

The Moment-Trace method has been used to compute the vibrational frequency spectrum of a randomly disordered, two-component, isotopic linear chain in terms of a wide range for the concentrations of the two kinds of particles and for the ratio of the masses of the particles. With the aid of the theory of random walks on lattices a combinatorial expression for the even moments of the spectrum has been obtained and has been used to calculate the moments up to $n = 20$. In addition, it has been possible to treat exactly the particular case of a chain in which the mass of one of the isotopic constituents becomes infinite, and the results of this calculation have shed light on the form of the spectra for lattices with large but finite mass ratios for the two constituents. The spectra are characterized by the disappearance of the square-root singularity at the maximum frequency which is found in ordered one-dimensional lattices, and by the appearance of impurity bands. The nature of these impurity bands is discussed. (Contractor's abstract, modified)

The problem of the propagation of waves in periodic media was studied. Details of the distribution functions of normal mode frequencies were investigated for several models of monatomic lattices and diatomic lattices. The effects of impurities on lattice vibrations and how these influence the thermodynamic properties are described. The use of Green's functions was explored. The exploitation of the relationship between the moments of a frequency distribution and random walks has been developed. The local behavior of atoms in a vibrating lattice has been examined and expressions found for the displacement of a given atom from its equilibrium position and for the cancellation of displacements of neighboring atoms. The method of spin waves has been applied to the problem of low temperature ferromagnetism of binary alloys. Anharmonicity was investigated in the simple case of a triatomic molecule

and the results are given. Detailed numerical calculations were started on ferroelectricity and also a collective electron treatment of ferro and anti-ferromagnetism in a two dimensional lattice. The Van der Waal forces and their influence on solid state structure of the rare gases was investigated. Research was started in an effort to generalize the Bohm-Pines method to take into account the lattice. In order to get some insight into the correlation problem, a rather simple two electron problem was solved. Montroll and Ward applied field theoretical techniques to the interacting electron gas and were able to obtain formulas for the cancellation energy. The theory of polymer solutions, the Boltzmann equation, transport problems, dislocations, Lancaster-like equations, latent heat of the antiferromagnetic transition in chromium, and lattice sums were also investigated.

ROLE OF BAND-BAND TRANSITIONS IN CHARACTERISTIC ENERGY LOSSES OF ELECTRONS PASSING THROUGH METAL FILMS (Abstract), by W. H. Lupton, R. A. Ferrell, and R. D. Myers. [1958] [1]p. [AF 18(600)1015]

Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 191-192, May 1, 1958.

Various investigators of the characteristic energy losses in aluminum have found a small peak at approximately 7 ev in addition to the predominant peak at 15 ev due to plasmon production, and have speculated whether it is due to band-band transitions. According to Hubbard the energy loss probability is proportional to $|ImK^{-1}|$, where K is the complex dielectric constant, and hence ImK would have a peak at 7 ev. But if $ReK \approx \omega_p^2/\omega^2$ and $|ImK^{-1}|$ has its maximum possible value, the calculated 7-ev energy loss probability is still only 0.7% of the probability of plasmon production. Furthermore, optical data do not exhibit such a peak at 7 ev. Hence we conclude that band-band transitions are not responsible for the 7-ev peak, which can instead be possibly ascribed to carbon contamination on the target foils. Calculations of the indirect effect of band-band excitation on the plasmon dispersion relation are in progress.

ON THE LOW ENERGY CUTOFF OF THE COSMIC RADIATION, by S. F. Singer. July 25, 1956, rev. June 10, 1957 [9]p. incl. diagrs. refs. (Technical rept. no. 51) (AFOSR-TN-57-411) (AF 18(600)1038) AD 132490; AD 210188 Unclassified

Presented at Internat'l. Convention on Cosmic Rays, Varenna (Italy), June 21-26, 1957.

Also published in Nuovo Cimento, Series X, Suppl., v. 8: 342-348, 1958.

The low energy cutoff knee in the primary cosmic radiation incident on the earth apparently depends on the solar cycle. It is unlikely that it is caused by a solar magnetic dipole field and it may not even be quite sharp. A model is developed to explain the absence of low energy nonrelativistic primaries based on diffusion deceleration coupled with ionization loss. Particles which have been decelerated by decreasing magnetic fields into the nonrelativistic range are likely to be trapped in a high field region and will disappear there by ionization loss. The position of the low energy cutoff and its change with time can be used as a tool to study the turbulence in interplanetary space. Various experimental approaches are indicated.

COSMIC RAY TIME VARIATIONS PRODUCED BY DECELERATION IN INTERPLANETARY SPACE, by S. F. Singer. July 25, 1956, rev. June 10, 1957 [13]p. incl. diagrs. refs. (Technical rept. no. 50) (AFOSR-TN-57-412) (AF 18(600)1038) AD 132491; AD 210187 Unclassified

Presented at Internat'l. Convention on Cosmic Rays, Varenna (Italy), June 21-26, 1957.

Also published in Nuovo Cimento, Series X, Suppl., v. 8: 334-341, 1958.

It is suggested that Forbush cosmic ray decreases as well as the 27 day decreases of cosmic ray intensity are modulation effects produced primarily by the deceleration of cosmic rays in interplanetary space due to the expansion of turbulent gas clouds from the sun. The detailed mechanism is one of diffusive deceleration and can therefore be considered as an inverse to the Fermi acceleration mechanism. The cosmic ray intensity variation during the solar cycle is accounted for as the cumulative effect of this mechanism which operates in connection with emission of solar gas. In this way it is possible also to account for the decrease in Feb. 1946 which lasted 6 mo. Some experimental tests are suggested to discriminate between different theories for the origin of cosmic ray time variations.

ON THE ORIGIN OF THE CHARGE SPECTRUM OF THE PRIMARY COSMIC RADIATION, by S. F. Singer. June 1957 [10]p. incl. tables, refs. (Technical rept. no. 73) (AFOSR-TN-57-413) (AF 18(600)1038) AD 132492; AD 210190 Unclassified

Presented at Internat'l. Convention on Cosmic Rays, Varenna (Italy), June 21-26, 1957.

Also published in Nuovo Cimento, Series X, Suppl., v. 8: 549-555, 1958.

The observed charge distribution of the primary cosmic radiation resembles the cosmic abundances of elements, but this resemblance is superficial. Severe discrepancies exist for Li, Be, and B, as well as for the ratio of heavy to medium nuclei. Much better agreement is obtained under the assumption that the original radiation consists mainly of heavy elements, principally Fe, and that nearly all of the lighter elements, including protons and alphas are produced by fragmentation. In the calculation new empirical data are used.

Also published in *Nuovo Cimento, Series X, Suppl.*, v. 8: 326-333, 1958.

Cosmic ray decreases of the Forbush type were observed in the immediate vicinity of the geomagnetic North pole during the summer of 1951. Their occurrence at the pole immediately rules out an equatorial ring current as their cause. A phenomenological picture is suggested for explaining some observed cases of cosmic ray storms without magnetic storms. The larger size of the polar decreases is explained on the basis of the focusing effect of the earth's magnetic field on primaries of different energies. The Forbush decreases are explained by a mechanism of diffusive deceleration which results from multiple reflection of the cosmic rays from receding centers of magnetic turbulence. This mechanism can be considered to be an inverse to the Fermi acceleration mechanism for cosmic rays.

A MODEL FOR SOLAR FLARE INCREASES OF COSMIC RAYS, by S. F. Singer. June 1957 [6]p. incl. diags. (Technical rept. no. 78) (AFOSR-TN-57-417) (AF 18(600)1038) AD 132496; AD 210189 Unclassified

Presented at Internat'l. Convention on Cosmic Rays, Varenna (Italy), June 21-26, 1957.

Also published in *Nuovo Cimento, Series X, Suppl.*, v. 8: 197-201, 1958. (Title varies)

A model is presented for the acceleration of cosmic ray flares in which only a small number of particles are given high energies and in which the geometry of the acceleration region determines the steepness of the energy spectrum. The statistical acceleration which occurs for the particles in the conducting gas in which turbulence is increasing is in part due to induction and in part to elastic collisions.

STUDIES OF A MINIMUM ORBITAL UNMANNED SATELLITE OF THE EARTH (MOUSE). PART III. RADIATION EQUILIBRIUM AND TEMPERATURE, by D. T. Goldman and S. F. Singer. [1957] [20]p. incl. diags. tables, refs. [AF 18(600)1038] Unclassified

Presented at Seventh Internat'l. Astronautical Congress, Rome (Italy), Sept. 1956.

Published in *Astronautica Acta*, v. 3: 110-129, 1957.

This paper deals with the problem of predicting the equilibrium temperature of an artificial earth satellite and of giving methods for designing and controlling its temperature under all types of conditions. The major

MDU.03:033 - MDU.03:036

heat sources are: (1) the sun; (2) sunlight reflected from the earth; and (3) long-wave radiation from the earth. Further, the additional production of heat by internal sources, such as nuclear power supplies, is considered. For a satellite traveling above the atmosphere the energy it receives is primarily transferred by radiation, infrared and visible. Therefore the equilibrium temperature of the satellite is determined by the properties of the satellite skin, i.e., its radiation characteristics (emissivity and albedo) in the visible and in the infrared regions of the spectrum. If we are dealing with a variable input of heat and are interested in the variation from the equilibrium temperature, then the thermal properties of the satellite body itself become of importance; the heat capacity of the satellite for example determines how rapidly it can follow the variation in heat input. We generally assume that the heat conductivity within the satellite is perfect so that all portions are at the same temperature, or at least that the skin is at an even temperature. Deviations from this ideal situation are considered separately. After we determine the sources of heat input in detail and after we discuss the small heat input effects (collision with the molecules, radicals, meteors, excited atoms, cosmic rays), we calculate the equilibrium temperature based on the equality of heat input and heat output, that is, a zero net flow of energy. The results for the equilibrium temperature are presented in the form of convenient nomograms to aid in preliminary design. (Contractor's abstract)

ENERGY SPECTRA OF THE COMPONENTS OF THE PRIMARY COSMIC RADIATION (Abstract), by S. F. Singer. [1957] [1]p. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 53, Jan 30, 1957.

A detailed analysis has been performed of balloon and rocket experiments including albedo and geomagnetic corrections. The analysis reveals that various primary components do not have the same velocity spectrum. In the relativistic portion of the latitude sensitive region expressions of the form aE^{-n} have been given for the particle flux density with energy greater than E . Values of the constants a and n have been found for protons, alpha particles, the group of elements C, N, O, and F, and for particles with Z greater than 10. An interpretation is given in terms of nuclear collisions and the resulting fragmentations of heavy primaries. However any clearcut experiments which demonstrate the absence of Li, Be, and B, or of H^2 , H^3 , and He^3 above the atmosphere would invalidate this interpretation. (Contractor's abstract, modified)

COSMIC RAY DECREASES DURING MAGNETIC STORMS (Abstract), by S. F. Singer. [1957] [1]p. [AF 18(600)-1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 192, Apr. 25, 1957.

Worldwide decreases of cosmic-ray intensity often occur during the main phase of magnetic storms. These Forbush-type events have been ascribed to the Störmer ring current (Chapman), or to a solar corpuscular beam (Alfven). Morrison, and more recently Parker, have postulated a highly turbulent magnetic field structure which partially screens the earth from cosmic rays by reflecting many particles without, however, changing their energy. In contradistinction, we consider here that the Forbush events result from a deceleration of cosmic rays; the energy decrease is produced in an inverse Fermi process which is set up as turbulent centers caused by a solar eruption expand outward and decay. Numerical estimates support this view. Crucial experimental tests will be discussed: (1) a possible shift in the position of the knee of the energy spectrum; (2) the spectrum of heavies compared to protons; and (3) the cosmic ray intensity at extremely large distances from the earth.

PROJECT FAR SIDE: MAN'S FIRST STRIDE INTO SPACE USES OFF-THE-SHELF HARDWARE, by S. F. Singer. [1957] [9]p. incl. illus. diags. [AF 18(600)-1038] Unclassified

Published in Missiles and Rockets, v. 2: 120-128, Oct. 1957.

A new dimension has been added to high altitude research: Far Side, which will explore space out to one earth radius (4000 miles) and possibly higher. Conceived by scientists of the Air Force Office of Scientific Research and developed by Aeronutronic Systems, Inc., the Far Side vehicle is a low-cost solution for reaching the highest altitudes yet attained by man. It is a multi-stage rocket launched at high altitude to overcome the atmospheric drag; specifically it is a four-stage combination of ten solid rocket motors lifted by a Skyhook balloon to an altitude of over 100,000 ft. The 1900-lb vehicle carries only a three-and-a-half-lb payload. In this paper on Project Far Side, the following topics are discussed: high altitude vehicles, the team behind Far Side, technical aspects, propulsion, dynamics and trajectories, scientific applications, the outer ionosphere, earth's magnetic field, cosmic rays, auroral particles, interplanetary dust, significance of experiments, long time exposures and recovery.

A METHOD FOR THE DETERMINATION OF THE VERTICAL OZONE DISTRIBUTION FROM A SATELLITE, by S. F. Singer and R. C. Wentworth. [1957] [10]p. incl. diags. refs. (AF 18(600)1038) Unclassified

Published in Jour. Geophys. Research, v. 62: 299-308, June 1957.

Because of its long lifetime below 45 km, ozone can deviate markedly from the concentration given by photochemical equilibrium considerations. Hence the ozone concentration can be used as an indicator of the motion of air masses, particularly in the stratosphere. The meteorological implications can be fully realized only by synoptic measurements, for which an artificial earth satellite is ideally suited. The method described employs the optical absorption properties of ozone in the ultraviolet region around 2900A. A detector looking down towards the earth will receive solar ultraviolet scattered by the atmosphere which has been attenuated both by scattering out and by ozone absorption. Calculations are presented to illustrate the effective depth in the atmosphere to which the detector "sees" the effective depth being defined as the point above which

ARTIFICIAL MODIFICATION OF THE EARTH'S RADIATION BELT, by S. F. Singer. [1958] [20]p. incl. diagrs. table, refs. (AFOSR-TN-58-952) (AF 18(600)-1036) AD 205345 Unclassified

Presented at meeting of the Amer. Astronaut. Soc., Washington, D. C., Dec. 27-31, 1958.

Published in Advances in Astronaut. Sciences, v. 4: 335-354, 1958.

The trapping properties of the earth's magnetic field have been investigated. It appears that high-energy protons and electrons can "live" for long periods of time, so that a small injection rate can build up large intensities. Natural injection mechanisms exist in the form of solar corpuscular radiation and in the form of cosmic ray albedo, leading to a "soft" and a "hard" radiation belt around the earth. A discussion is given of a proposal for artificial injection of electrons from a rocket-borne accelerator, as well as some of the consequences and applications of this technique. NEW ACCELERATION MECHANISM FOR AURORAL PARTICLES (Abstract), by S. F. Singer. [1958] [1]p. [AF 18(600)1038] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 40, Jan. 29, 1958.

Acceleration of solar protons (mean energy ~20 kev) to auroral energies (~1 mev as deduced from atmospheric penetration) is a longstanding problem. The acceleration mechanism operates near the earth on "trapped" protons, these oscillate back and forth along magnetic force lines while drifting azimuthally to produce the magnetic storm ring current. Two basic processes are described. (1) "Fermi collisions" with hydromagnetic waves which are excited by solar protons and guided by lines of force; their existence also explains observations of geomagnetic micropulsations. (2) Induction acceleration via the earth's field by bunched protons; this also explains observations of vlf radio emissions. The two processes in "push-pull" keep the proton's pitch angle from becoming too small too soon. Thus the proton gains much energy before it breaks out of the trap and into the atmosphere. This statistical acceleration process leads to an energy spectrum as suggested observationally. The push-pull scheme may also be important for galactic cosmic ray acceleration.

A NEW THEORY OF THE AURORA (Abstract), by S. F. Singer. [1958] [1]p. (AF 18(600)1038) Unclassified

Presented at IRE-URSI Symposium, Washington, D. C., Apr. 23-26, 1958.

Published in I.R.E. Trans. of Professional Group on Antennas and Propagation, v. AP-6: 312, July 1958.

A long-standing problem is to explain the energy of auroral protons. The author shows here that solar

protons trapped in the earth's magnetic field can be accelerated up to auroral energies. The mechanism does not use electric fields (e.g., Martyn or Alfvén). Instead some of the protons are accelerated by magneto-hydrodynamic waves which are in turn produced by the bulk of the solar protons. In this acceleration process the earth's magnetic field acts as the energy transfer agent. There is additional empirical evidence supporting the proposed mechanism, namely geomagnetic micropulsations, the VHF emissions from the upper atmosphere, and the evidence that the auroral protons have a distribution of energies.

THE DETECTION AND IDENTIFICATION BY ELECTRON SPIN RESONANCE TECHNIQUES OF TRAPPED FREE RADICALS (Abstract), by R. S. Anderson. [1957] [2]p. (AF 18(600)1582) Unclassified

Published in Program for Symposium of The Formation and Stabilization of Free Radicals, Nat'l. Bur. Standards, Washington, D. C. (Sept. 18-20, 1957), Washington, Nat'l. Bur. Standards, 1957, p. M1-M2.

Free radicals have been produced by ultraviolet irradiation of materials maintained at liquid nitrogen temperature. The irradiated material is examined for free radicals by subsequent observation, at liquid nitrogen temperature, in an electron spin resonance spectrometer. Approximately 125 compounds, mostly organic, have been examined by this method. Of this number about 100 have exhibited electron spin resonances indicative of the presence of free radicals trapped at the low temperatures. Identification of the resulting radicals, where possible, has been based upon the hyperfine structure exhibited by the resonances, both through the number of hyperfine components and their relative intensities. Observations have been made at both 3 and 1.2 cm

MDU.04:003 - MDU.04:005

wavelengths and it is significant that all resonances have been observed at a g-factor of 2, in spite of search over a wide range of magnetic fields. The following classes of compounds have been examined: saturated and unsaturated hydrocarbons, alcohols, acids and their anhydrides, aldehydes, ketones, esters, ethers, alkyl and aryl halides, and nitro-compounds. In general, no resonances have been observed in materials having melting points below 137°K, that is, less than 60° above the temperature of the irradiated material. While free radicals may generally be stabilized for long periods at low temperatures, some irradiated substances were observed to have different resonances after storage for a few days. Where two different resonance patterns appear superimposed, one, presumably the more reactive, may disappear. In other cases, the original resonance may decay and be replaced by a totally different resonance, indicating secondary reactions.

ELECTRON SPIN RESONANCE LINE SHAPES FOR SOLIDS HAVING NONISOTROPIC g FACTORS (Abstract), by R. P. Kohin and C. P. Poole, Jr. [1958] [1]p. [AF 18(600)1582] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 8-9, Jan. 29, 1958.

The line shape for a paramagnetic substance having three unequal g tensor components $g_1 > g_2 > g_3$ and a spin of $\frac{1}{2}$ is derived assuming that the molecules have a random distribution of orientations. If the component line shape for a particular orientation is assumed to have zero width, the line shape, normalized to unit area, is

$$I(g) = \begin{cases} 2gK(b/a)/\pi a & g_3 \leq g \leq g_2 \\ 2gK(a/b)/\pi b & g_2 \leq g \leq g_1 \\ 0 & \text{otherwise,} \end{cases}$$

where

$$a = \left\{ (g_2^2 - g_3^2)(g_1 - g_2^2) \right\}^{\frac{1}{2}}$$

$$b = \left\{ (g_1^2 - g_2^2)(g_2 - g_3^2) \right\}^{\frac{1}{2}}$$

and K(k) is a complete elliptic integral of the first kind. This line shape is characterized by an infinite peak at $g = g_2$ and shoulders at $g = g_1$ and g_3 . Integrations performed over nonzero component line widths are discussed.

ELECTRON SPIN RESONANCE OF ULTRAVIOLET IRRADIATED COMPOUNDS (Abstract), by C. P. Poole, Jr. and R. S. Anderson. [1958] [1]p. [AF 18(600)1582] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 8, Jan. 29, 1958.

The 9000 mc electron spin resonance spectra of over 100 ultraviolet irradiated organic compounds maintained at 77°K have been recorded at a g factor of two. The mechanism of radical production entails the absorption of the photon by a pi electron and the subsequent rupture of a nearby bond. Unsaturated hydrocarbons show well-resolved, symmetric, evenly spaced hyperfine structure of three to six lines. Aldehydes are characterized by a strong singlet attributed to the formyl radical on which there is superposed weaker time decaying multicomponent structure attributed to alkyl radicals. Nitrogen-containing compounds exhibit triplet structure resulting from the nuclear spin of nitrogen. Other classes of compounds will be discussed, including ketones, esters, acids, anhydrides, and halides. In general the resonances obtained are characteristic of the class of compound irradiated, and in many cases the radicals may be identified by the spacing and intensity ratios of the hyperfine structure components. Line widths and component separations are about two milliwobers per square meter. Line widths calculated from dipole-dipole interaction with surrounding protons agree with the observed widths. While most radicals are stable for weeks at 77°K, some change or decay with time indicating secondary reactions.

ELECTRON SPIN RESONANCE OF FREE RADICALS IN ULTRAVIOLET IRRADIATED HYDROCARBONS, ALDEHYDES, AND KETONES (Abstract), by C. P. Poole, Jr. and R. S. Anderson. [1958] [1]p. [AF 18(600)1582] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 179, May 1, 1958.

Unsaturated hydrocarbons, aldehydes, and ketones, maintained at 77°K, have been exposed for approximately 6 hr to the ultraviolet radiation from a high-pressure mercury arc. Electron spin resonance spectra, observed at a g factor of 2 with a 9000-mc spectrometer, are

MDU.16:001 - MDU.16:004

characteristic of the substances irradiated. Interpretation of specific hydrocarbon cases will be used to show that the characteristic hyperfine structure may be attributed both to hyperconjugation and the $\sigma - \pi$ interaction between the unpaired electron and neighboring hydrogen atoms in the radical. Aldehydes and ketones produce singlets attributed to formyl (CHO) and alkanoyl (RCO) radicals. The strong electronegativity of the oxygen on the carbonyl group (CO) suppresses the contact hyperfine interaction between the free electron and neighboring hydrogen atoms. Alkyl radicals formed simultaneously with the alkanoyl radicals appear similar to the photolysis products of unsaturated hydrocarbons.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 177, Apr. 25, 1957.

Also published in Phys. Rev., v. 107: 302-306, July 1, 1957.

If the wave function of a non-relativistic particle satisfies the Schrödinger equation with a velocity independent potential, then its scattering amplitudes (and the S-matrix in general) satisfy the same dispersion formulas as those derived for the scattering of light. In the present derivation, the validity of a perturbation expansion and certain integrability of the potential are assumed, and the requirement of the outgoing wave Green's function replaces the condition of strict causality for the scattering of light. The scattering amplitude for fixed momentum transfer is also shown to satisfy the dispersion relations. If the potential possesses bound states, then all the dispersion formulas are modified to include residue terms corresponding to singularities on the positive imaginary axis of the momentum plane. The necessity of these modifications are related to the divergence of the perturbation series for small wave numbers. Essential singularities of the S-matrix due to exponential-type potentials give no additional contribution to the dispersion formulas. (Contractor's abstract)

CAUSALITY AND THE DISPERSION RELATION: LOGICAL FOUNDATIONS, by J. S. Toll. [1956] [11]p. incl. diagr. refs. [Technical rept. no. 27] [AF 49(638)-24] Unclassified

Published in Phys. Rev., v. 104: 1760-1770, Dec. 15, 1956.

"Strict causality" is the assumption that no signal whatsoever can be transmitted over a space-like interval in space-time, or that no signal can travel faster than the velocity of light in vacuo. In this paper a rigorous proof is given of the logical equivalence of strict causality ("no output before the input") and the validity of a dispersion relation, e.g., the relation expressing the real part of a generalized scattering amplitude as an integral involving the imaginary part. This proof applies to a general linear system with a time-dependent connection between the output and a freely variable input and has the advantage over previous work that no tacit assumptions are made about the analytic behavior or single-valuedness of the amplitude, but, on the contrary, strict causality is shown to imply that the generalized scattering amplitude is analytic in the upper half of the complex frequency plane. The dispersion relations are given first as a relation between the real and imaginary parts of the generalized scattering amplitude and then in terms of the complex phase shift. REMARKS ON THE IMPLICATION OF "CAUSALITY CONDITION IN NON-INTERACTION REGION" AND THE UNITARITY OF THE S-MATRIX, by D. Y. Wong. July 1957, 6p. (Technical rept. no. 82) (AFOSR-TN-57-351) (AF 49(638)24) AD 132424 Unclassified

For the scattering of light by a spherically symmetric scatterer of finite range, the requirement of causality in the non-interaction region plus the unitarity of the S-matrix is shown to be sufficient for the determination of the imaginary part of the S-matrix element from its real part. This holds for each matrix element with a given angular momentum quantum number l . Ambiguity occurs only for the case when the S-matrix element is a pure exponential function of the frequency. Presented at Internat'l. Conf. on Mathematical Problems of Quantum Field Theory, Lille (France), June 1957.

By the theory of functions of more than one complex variable, the dispersion formulas of quantum field theory can be proved with essentially only Wightman's axioms and the known properties of the spectrum. Certain assumptions are made on the Fourier transforms, and a rigorous proof of the basic theorem is described briefly. For simplicity, the elastic scattering of neutral scalar bosons of equal mass is considered. A question is posed concerning the development of a method for determining the envelope of holomorphy of a domain which is invariant under the homogeneous Lorentz group, or invariant under other similar transformation groups. A special method of solution for the envelope is used which introduces certain restrictions. For pion-nucleon scattering the semi-tube method of proof presented for the theorem is satisfactory; however, it is not sufficient for the nucleon-nucleon, K-meson-nucleon and photon-nucleon scattering processes.

For a given set of low energy limits of the S-matrix, the solution of the dispersion relation for the scattering of light is shown to be non-unique even if one fixes all but the s-wave phase shift. Here the unitarity condition is also implied. It is known (D. Y. Wong and J. S. Toll, Ann. Phys., v. 1: 91, 1957) that if one further assumes the convergence of the usual perturbation method, then the low energy limits do determine the physical solution uniquely. An alternative iterative scheme is suggested

without recourse to the expansion in powers of a coupling parameter. The procedure is illustrated by the example of the scattering by a hard sphere.

Also published in Ann. Phys., v. 3: 49-66, Jan. 1958.

The causality condition is used to derive analytic properties and dispersion relations for the S-matrix $S(\omega)$ for the case of unquantized Klein-Gordon and Dirac fields interacting with a fixed spherically symmetric scatterer of finite radius. It is shown that $S(\omega)e^{2i\omega a}$ as a function of the energy ω is analytic and bounded in the upper half ω -plane, where a is the radius of the scatterer. An infinite sequence of scattering amplitudes which satisfy a dispersion relation are given in terms of the elements of the S-matrix. The real part of the S-matrix is expressed in terms of its imaginary part and a set of constants by means of the dispersion relation. (Contractor's abstract)

DISPERSION RELATIONS FOR THE S-MATRIX (Abstract), by J. S. Toll, D. Y. Wong, and J. M. Knight. [1957] [1]p. [AF 49(638)24]

Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 13, Jan. 30, 1957.

Dispersion relations for the S-matrix for fixed spherically symmetric scatterers of finite extent are derived to illustrate restrictions implied by strict causality on scattering through nonzero angles. The forward scattering of appropriate combinations of point sources and plane waves yields an infinite sequence of causal amplitudes which satisfy conventional dispersion relations. Inverting the relation for these causal amplitudes in terms of the S-matrix, one obtains dispersion formulas which give $\text{Im} S_m(\omega)$ for each m , in terms of combinations of the $\text{Re} S_\ell(\omega)$'s plus low energy limits of $\{S_\ell(\omega)/\omega^{2\ell+1}\}$ for all $\ell \geq m$. Hence the real part of the scattering amplitude is determined by its imaginary

part plus low-energy limits of $[S_\ell(\omega)/\omega^{2\ell+1}]$. If a perturbation expansion method is valid, then low-energy limits determine all phase shifts, or the s wave determines all other phase shifts. The massless scalar field, Maxwell field, Klein-Gordon field, and Dirac field are treated. The equivalent formulation of dispersion relations for the S-matrix in terms of the vanishing of commutators is derived and is being applied to Delbruck scattering.

BOUND STATE CONTRIBUTION TO DISPERSION RELATIONS FOR THE SCATTERING MATRIX (Abstract), by J. M. Knight and J. S. Toll. [1957] [1]p. [AF 49(638)-24] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., Apr. 25-27, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 177, Apr. 25, 1957.

Previous derivations by Toll, Wong, and Knight of the dispersion relations for the scattering matrix for a relativistic particle scattered by a fixed, finite, spherically symmetric scatterer can be modified to include interactions which permit bound states. A typical bound state of energy $\hbar\omega_B$ introduces a simple pole at $\omega = \omega_B$ in the corresponding element of the scattering matrix. For the ground state, this pole lies on the real frequency axis; to eliminate this singularity, a factor $(\omega - \omega_B)$ is introduced, which adds one arbitrary constant to the resulting dispersion relations. Metastable states correspond to singularities in the lower half of the complex frequency plane, which cause no alteration in the derivation or final form of the dispersion relations. Examples and applications are discussed.

CAUSALITY AND THE DISPERSION RELATION: S-MATRIX FOR THE MAXWELL FIELD, by D. Y. Wong and J. S. Toll. [1957] [2]p. incl. refs. [AF 49(638)24] Unclassified

Published in Ann. Phys., v. 1: 91-111, Apr. 1957.

The scattering of a classical Maxwell field by a fixed spherically symmetric scatterer of finite range is considered. This problem is easily related to the scattering of a scalar field which is considered first. The condition of strict causality is imposed on the forward scattering of a sequence of primary scalar wave packets

$\{\psi_p^{(n)}\}$, $n = 0, 1, 2, \dots$, in which the nth primary wave contains only partial waves for $\ell \geq n$. This implies that the dispersion relation is satisfied by each member of an infinite set of causal amplitudes which are expressed as combinations of the elements of the S-matrix $\{S^\ell(\omega)\}$. Inverting the relation for the causal amplitudes in terms of the S-matrix, one obtains a set of dispersion formulas which give $\text{Im}S_m(\omega)$, for each m, in terms of combinations of the $\text{Re}S_\ell(\omega)$'s plus the low energy limits of $[S_\ell(\omega)/\omega^{2\ell+1}]$ for all $\ell \geq m$. Hence the real part of the scattering amplitude, for all angles and frequencies, is determined by the knowledge of its imaginary part plus the low energy limits of $[S_\ell(\omega)/\omega^{2\ell+1}]$. Corresponding formulas exist for $\text{Re}S_m(\omega)$ and the imaginary part of the scattering amplitude. If a perturbation expansion method is valid, then the restriction is much stronger, namely, low energy limits determine all phase shifts, or, equivalently, the s-wave phase shift determines the phase shift for all higher angular momenta. The scattering of the Maxwell field is described by three matrices, corresponding to the two transverse modes and one longitudinal mode; each of these matrices is shown to satisfy the same set of dispersion relations as that for scalar waves, except for the omission of the s-wave equation in the case of transverse modes. The equivalent formulation of the derivation of the dispersion relations for the S-matrix in terms of the vanishing of commutators is given in an Appendix for the case of the scattering of scalar wave by a static potential. NOTE ON THE FORMULATION OF THE CAUSALITY REQUIREMENT, by J. G. Taylor and J. S. Toll. [1958] 13p. incl. diagr. (Technical rept. no. 110) (AFOSR-TN-58-631) (AF 49(838)24) AD 162161 Unclassified

Segal's recent formulation of the causality requirement (*Phys. Rev.*, v. 109: 2191, 1958) is considered. This formulation is shown to differ in important respects from the usual requirement of "no output before input" and certain difficulties of physical interpretation are discussed. Segal's formulation is shown to be more restrictive than the usual strict causality and to exclude bound states and certain types of resonances that occur in theories of physical interest. The discussion of the Klein-Gordon wave in terms of the characteristic momentum variable is analyzed further and the way in which Segal's formulation extends the domain of analyticity is described. THE FORMATION OF DISCONTINUITIES IN NON-LINEAR ELECTRODYNAMICS, by M. Lutzky. [1958] [30]p. incl. diagr. table. (Technical rept. no. 111) (AFOSR-TN-58-633) (AF 49(838)24) AD 162163; PB 136400 Unclassified

Also published in *Phys. Rev.*, v. 113: 1649-1652, Mar. 15, 1959.

Discontinuities can develop in the propagation of initially smooth waves governed by a classical non-linear theory of electrodynamics. The type of theory considered includes as a special case that of Heisenberg and Euler, up to second order in the invariants of the field. This theory describes the modifications that must be made in the Maxwell equations to include the classical limit of the non-linear vacuum effects of quantum electrodynamics. A particular solution of the equations is constructed by the method of characteristics. This solution illustrates how, with the appropriate well-behaved initial conditions, the characteristics can be made to intersect at later times, thus forming discontinuities. It is pointed out that the classical approximation fails when the gradient of the field strength becomes large, so that no definite conclusion can be drawn as to the actual physical creation of singularities. A more refined theory must be used to decide what occurs in the singular region. (Contractor's abstract)

CONNECTION OF PHASE SHIFT AND POTENTIAL FOR THE DIRAC EQUATION (Abstract), by F. Prats and J. S. Toll. [1958] [1]p. [AF 49(638)24] Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 36, Jan. 29, 1958.

Using a method of Gel'fand and Levitan, Jost and Kohn have shown how, for a Schrödinger equation with central potential, the potential can be determined (through the spectral function) by the phase shift, plus the energy and another arbitrary parameter for each bound state. A similar procedure is presented here, appropriately generalized to matrices, for the Dirac equation with a central potential with $\int_0^\infty r^m V(r) dr$ finite, ($m = 0, 1, 2$). From the analytic properties in the k-plane of the radial wave functions, a spectral function is introduced. The relation between eigenfunctions for two different potentials involves a kernel, from which the potential difference is obtained. The equation (analogous to the Gel'fand-Levitan integral equation) for this kernel can be constructed from the spectral function and eigenfunctions of the "comparison" potential and the spectral function for the unknown potential.

FARADAY EFFECT IN METALS (Abstract), by E. A. Stern and R. D. Mvers. [1958] [1]p. [AF 49(638)399]
Unclassified

Presented at meeting of the Amer. Phys. Soc., California U., Los Angeles, Dec. 29-31, 1958.

Published in Bull. Amer. Phys. Soc., Series II, v. 3: 416, Dec. 29, 1958.

The rotation of the plane of polarization of light reflected normally from a nonferromagnetic metallic surface that has a magnetic field perpendicular to it is shown to be expected from theoretical grounds. This effect in a ten thousand gauss field is about one thousand times smaller than the corresponding magneto-optic-Kerr effect in ferromagnetic materials. From symmetry arguments this Faraday effect for cubic metals is independent of the orientation of the crystal axes to the surface normal. However, it does depend on an average effective mass of the valence band electrons and thus can be used to measure this effective mass. Experimental values of this effective mass will be given for a few metals whose Faraday effect has been measured. Since only an average effective mass is measured by the Faraday effect, no detailed information on the shape of the Fermi surface can be directly obtained by this means. However the technique can be used at practically any temperature and with alloys and thus can give information on those metals whose band structure can't be easily studied by other techniques.

TWO DIMENSIONAL JET MIXING OF SUPERSONIC FLOW, by S. I. Pai. [1954] [9]p. incl. illus. diagrs. refs. (AF 18(600)86)
Unclassified

Published in Sonderdruck aus 50 Jahre Grenzschichtforschung, Festschrift, Braunschweig (Germany), Friedr. Vieweg and Sohn, 1954, p. 71-79.

Two-dimensional supersonic jet flows of air have been investigated by optical methods and the density functions measured and found to be error functions. In the cases of full expansion and over-pressure no interaction between the boundary layer flow and the core flow has been observed. The divergence of the jet mixing region decreases with increase of Mach number. In the case of an under-pressure distribution there is interaction between the boundary layer and the shock. The shock is curved and the flow field behind the shock is non-uniform. It has been shown experimentally that a two-

dimensional jet tends to be stable with respect to small disturbances at high Mach numbers.

A NEW GOVERNING EQUATION OF SHOCK ANALYSIS WITH HEAT TRANSFER IN POLYATOMIC GASES (Abstract), by P. J. Theodorides. [1956] [1]p. [AF 18-(600)428]
Unclassified

Presented at meeting of the Amer. Phys. Soc., California Inst. of Tech., Pasadena, Mar. 19-21, 1956.

Published in Bull. Amer. Phys. Soc., Series II, v. 1: 361, Nov. 23, 1956.

In shock analysis, steep gradients of temperature and high divergence of the velocity vector seem to invite a widening of the viscosity concept for polyatomic gases by dropping the Stokes' hypothesis, and including nonlinear friction. Symmetrical stress matrices are developed with three independent physical parameters of gas friction, viz., one of linear bulk viscosity and one each of linear and nonlinear shear viscosity. The conservation equations for mass, momentum, and energy are set for triaxial, laminar supersonic flow of an isotropic, compressible, viscous, and heat-conducting gas. These relations are combined with the state equation, transformed, and specialized for uniaxial, steady flow. Thus a new governing equation of shock analysis is derived. The integration is discussed for temperature effects upon all three viscosity parameters, the heat conductivity, and specific heat. Though explicitly continuous, the present theory is implicitly linked to kinetic theory in expressing accordingly most of the physical parameters. Then, quantum dynamics hold, for $T > 600^\circ\text{K}$, as to energies in vibrational modes with proper frequencies and overtones from spectrometry. For nonlinear damping, no empirical data of separation are so far available. But the expediency is open to fill up, after Gilbarg and Paolucci, with molecular Burnett numbers of third approximation as based on Sonine polynomials.

STRUCTURAL ANALYSIS OF HIGH SPEED WINGS FOR A QUASI TRI-AXIAL ELASTIC STATE IN THE SKIN, BIAXIAL IN THE LONGITUDINALS, by P. J. Theodorides. Feb. 1957, 19p. incl. diagr. refs. (Technical note no. BN-92) (AFOSR-TN-57-67) (AF 18(600)-428) AD 120409 Unclassified

Also published in Proc. Ninth Internat'l. Congress of Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956) v. 8: 71-85, 1957.

For aeroelastic efficiency, fast flight favors thin wings of low aspect ratio and utmost rigidity - either delta-shaped, or swept, or straight. This and economy in air mass are met by a composite class of wing design. Then, stiffened skin plates resist mainly normal strain from flexure, while thin webs and ribs, densely spaced, take most of the shear. For wings of such form and texture, an improved plate theory may be a sound basis of structural analysis. Elastic interplay of skin and stiffeners is accounted for, in present work, with care of avoiding both intricacies of thick skin theory and defects in Kirchhoff's way.

TRANSONIC FLOW AFTER SLIGHT MODIFICATION OF SMOOTH CONTOUR, by C.-C. Chang and W.-H. Chu. [1957] [11]p. [In cooperation with Minnesota U. Dept. of Aeronaut. Engineering under AF 18(600)1456] [AF 18(600)428] Unclassified

Published in Proc. Ninth Internat'l. Congress Appl. Mech., Brussels (Belgium) (Sept. 5-13, 1956), v. 2: 80, 1957.

The non-existence of transonic potential flow after slight smooth modification of contour was recently treated by Guderley (Advances in Appl. Mech., Academic Press, v. 3, 1953, p. 145-184). With both linearized hodograph differential equation and boundary conditions, it is difficult to make a convincing argument with his approximate approach. The present paper is an example of the resultant transonic flow after slight, smooth modification is made. The original channel flow is a portion of Temple-Yarwood flow, in which local supersonic flow symmetrically with respect to y-axis occurs along the central portion of convex curved wall. Then, the convex curved wall is slightly modified to maintain the following features: (a) the resultant curved wall has all continuous derivatives; (b) only the central portion is modified slightly; and (c) the resultant channel wall is still symmetrical with respect to y-axis. The resultant flow is calculated by means of relaxation method. To the accuracy of 1/100 of Mach number, the new transonic flow is still potential, and symmetrical with respect to y-axis. No shock is found. (Contractor's paper)

THE SHOCK WAVE IN A NON-MONATOMIC FLUID, by P. J. Theodorides. Feb. 1958, 20p. incl. diagrs. tables, refs. (Technical note no. BN-123) (AFOSR-TN-58-156) (AF 18(600)428) AD 152182 Unclassified

MDU.08:013, 014; MDU.09:054, 055

Also published in *Helvetica Physica Acta*, v. 31: 33-42, Nov. 15, 1958.

Analysis of the structure of shock profiles using conservation equations of mass, momentum, and energy which are specialized for a uni-axial steady flow taken initially as supersonic under stratospheric conditions. Boundary conditions for normal shock of varied strength are calculated for variable enthalpy. The shock waves in molecular nitrogen are given in tabular form. A graphical representation of shock transition and of shock wave profiles in molecular nitrogen is made. Results indicate that the temperature effects increase considerably the shock thickness in the velocity profile, and that a broadening of about 43% is added on account of bulk viscosity from ultrasonic measurements.

INVESTIGATION OF FACTORS AFFECTING THE CONTROL AND STABILITY OF HIGH SPEED AIRCRAFT AND MISSILES, by P. J. Theodorides. Final rept. Sept. 1, 1952-Feb. 28, 1958. Apr. 1958 [12]p. incl. refs. (Technical rept. no. BN-129) (AFOSR-TR-58-52) (AF 18(600)428) AD 154215 Unclassified

Work conducted for the contract was reviewed under the headings of (1) basic theory in fluid dynamics; (2) aerodynamics of unsteady flow; (3) elasticity of high-speed wings; and (4) shock analysis in nonmonatomic media. An annotated bibliography arranged in chronological order, by year, is presented for 14 reports and publications which are related to the contract investigation. Significant findings are detailed on the width of shock transition in N_2 for several intensities of normal shock,

high enough to unfreeze quantized vibration with negligible dissociation and ionization. Separation was made of the effects of the viscosities (linear shear friction, bulk viscosity) on the profiles (velocity, temperature) by alternate use of either Stokes' hypothesis or bulk viscosity data from ultrasonics. Numerical values for the shock width in the speed profile of N_2 were revealed as of the order of $d_u = (1.68) \cdot 10^{-6}$ m for $M_1 \sim 2.18$ and $d_u = (1.00) \cdot 10^{-6}$ m for $M \sim 4.99$ (accounting for bulk viscosity), while Stokes hypothesis ($K = 0$) yielded $(1.18) \cdot 10^{-6}$ m and $(0.69) \cdot 10^{-6}$, respectively. PARALLEL EFFECTS OF BULK VISCOSITY AND

TIME LAG IN KINETICS OF NON-MONATOMIC FLUIDS, by P. J. Theodorides. [1958] [19]p. incl. refs. (AF 18-(600)428) Unclassified

Published in *Zeitschr. Angew. Math. Phys.*, v. 9B: 668-686, Mar. 25, 1958.

The author considers the bulk viscosity and time lag in the kinetics of non-monatomic fluids involving one inner process such as a single mode of vibration within molecules. For a triaxial flow with trimolecular viscosity, equations of motion, continuity, and energy have been derived, and effects of bulk viscosity and quadratic shear viscosity on the Navier-Stokes equations are discussed. Utilizing the data on bulk viscosity for molecular nitrogen from ultrasonic measurements, the end state characteristics of shock waves have been calculated.

REFLECTION PRINCIPLES FOR SOLUTIONS OF EQUATIONS IN ELASTICITY, by J. H. Bramble. Aug. 1957, 58p. refs. (Technical note no. BN-106) (AFOSR-TN-57-499) (AF 18(600)573) AD 136489 Unclassified

Certain reflection principles are established for bi-harmonic functions which arise as solutions of equations in elasticity. The most general region D for which the principles are valid are not given; however, it should be noted that all results remain valid if D is chosen to be the intersection of D^* (the 2(3)-dimensional region which excludes the origin but contains a portion of a circle (sphere) of radius a with center at the origin) with $r \geq a$ and required to be finite; r is the distance from a point to the origin of the coordinate system. Certain theorems are proved which are applicable in presenting the formulas which establish the reflection principles; the sliding clamp condition is also considered. The continuations for the solutions of the elasticity equations are given in the case where the displacements

vanish on a circular arc or spherical surface in 2 or 3 dimensions, respectively. In the case where the normal stresses vanish on a circular arc, a continuation formula for stresses is obtained.

NEW BOUNDS FOR SOLUTIONS OF SECOND ORDER ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS, by L. E. Payne and H. F. Weinberger. Sept. 1957 [41]p. incl. diagr. refs. (Technical note no. BN-108) (AFOSR-TN-57-651) (AF 18(600)573) AD 136636 Unclassified

Also published in Pacific Jour. Math., v. 8: 551-573, 1958.

A generalization of Rellich's (Math. Zeltschr., v. 46: 635-646, 1940) identity to a large class of elliptic systems of second-order differential operators is employed to extend the results obtained previously (Jour. Math. and Phys., v. 4: 291-307, 1955) to equations involving such operators and rather general domains. Only the case of a single self-adjoint second-order operator without zero order term is treated in detail, but the results are extended to a class of nonself-adjoint second-order equations as well as a large class of elliptic systems of second-order differential equations. The identity is discussed and used to estimate several quadratic functions including the generalized Dirichlet Integral in terms of Dirichlet data for a general nonhomogeneous boundary value problem in N dimensions. An approximation to the generalized Dirichlet Integral is obtained by means of a functional of an arbitrary function. The error estimate is a quadratic functional in the deviation of the Dirichlet data of the arbitrary function from the given data. A general differential equation is considered with a provision made for an error of the arbitrary function both in the differential equation and in the boundary values, and the error estimate is a quadratic functional in both. The value of the solution of a Dirichlet problem at an arbitrary interior point is also given, and estimates are derived for the exterior Neumann problem in 3 or more dimensions.

ORDERING AND UNIQUENESS OF SOLUTIONS OF BOUNDARY PROBLEMS FOR ELLIPTIC EQUATIONS, by C. Pucci. Oct. 1957, 13p. (Technical note no. BN-112) (AFOSR-TN-57-690) (AF 18(600)573) AD 136684 Unclassified

Dirichlet, Neuman third and mixed problems are considered for the second order elliptic partial differential

equation of a general type. Ordering and uniqueness theorems are obtained as consequences of the maximum-minimum properties of the solutions of elliptic equations in the interior of the set T in which they are defined and on the boundary of T . An elliptic partial differential equation, $f(x, u, u_1, u_{11}) = 0$ is considered, which can

have singularities on the boundary of T and also at interior points of T . This means that in a neighborhood of some points x the first derivatives of f with respect to u and u_1 can be unbounded and, at these points x , u can

be without second derivatives and can have discontinuous first derivatives. Furthermore it is supposed that the equation can be of parabolic type on some hypersurfaces belonging to T . The hypotheses considered in this paper with regard to the equation and the class of solutions are in some way essential as is shown by four examples (C. Pucci, Atti. Accad. Naz. Lincei, 1957); in this generality the results are new even with regard to the Dirichlet problem.

REMARK ON A PAPER OF O. G. Owens, by L. E. Payne and H. F. Weinberger. [1957] [1]p. [AF 18(600)-573] Unclassified

Published in Duke Math. Jour., v. 24: 233, June 1957.

O. G. Owens (Duke Math. Jour., v. 23: 371-383, 1956) showed that if $u(x, y, t)$ is the solution of the wave equation $u_{tt} = u_{xx} + u_{yy}$ taking the values of a homogeneous

polynomial $\Psi(x, y)$ on the characteristic cone $(t^2 - x^2 - y^2 = 0)$, then u is a homogeneous polynomial in (x, y, t) of the same degree as Ψ . A simpler proof is given in this note by exhibiting $u(x, y, t)$ explicitly.

The problem is solved for the value $\Psi = x^p y^q$.

NOTE ON A LEMMA OF FINN AND GILBARG, by L. E. Payne and H. F. Weinberger. [1957] [3]p. (AF 18(600)-573) Unclassified

Published in Acta Math., v. 98: 297-299, 1957.

This paper has the same context as a prior paper of Finn and Gilbarg, "Three-dimensional Subsonic Flows, and Asymptotic Estimates for Elliptic Partial Differential Equations" (Acta Math., v. 98: 265-296, 1957).

It is shown that if u satisfies $(a^{ij})_{u,1}$, $j = 0$, and is such that a^{ij} (which depends on u) approaches the unit matrix of order n at infinity, then $\int a^{ij}_{u,1} dV$, over the region outside a sphere of radius r , is for large r of order $r^{2-n} + O(1)$. This is essentially a sharp result because for Laplace's equation the order is r^{2-n} .

ON A CAUCHY PROBLEM WITH SUBHARMONIC INITIAL VALUES, by A. Weinstein. [1957] [16]p. (AF 18(600)573) Unclassified

Published in Ann. Mat. Pura Appl., v. 43: 325-340, 1957.

This paper deals with the singular Cauchy problem for a Euler-Poisson-Darboux equation with non-negative index. The first part of this paper consists of an investigation of the properties of solutions of our Cauchy problem under the assumption that the initial data satisfy a differential equation of the Helmholtz type. In the second part the EPD equation is transformed into a generalized Tricomi equation in several variables. This could be used in the theory of subharmonic functions. Finally, classical theorems of Riesz and Montel on mean values of subharmonic functions are extended.

[ON THE ISOPERIMETRIC INEQUALITY OF CURVED AREAS] Zur isoperimetrischen Ungleichung auf gekrümmten Flächen, by A. Huber. [1957] [7]p. incl. refs. (AF 18(600)573) Unclassified

Published in Acta Math., v. 97: 95-101, 1957.

The author gives a simple proof of the following result, which he has previously [Ann. Math., v. 60: 237-247, (1954); v. 63: 572-587, (1956)] presented in somewhat less general form. Let a conformal metric $ds = e^{u(z)} |dz|$ be defined on a Riemann surface R , and suppose that $u(z)$ can be represented locally as the difference of two subharmonic functions $u(z) = u_1(z) - u_2(z)$. Let

γ be a locally rectifiable Jordan curve on R , enclosing a simply connected domain ω . Let $\mu_2(e)$ be the measure associated with $u_2(z)$, and write $\mu_2(\omega) = \alpha$. Then the following inequality holds:

$$\left(\int_{\gamma} e^u |dz| \right)^2 \geq 4\pi(1 - \alpha) \iint_{\omega} e^{2u} dx dy,$$

where $z = x + iy$; the sign of equality is valid if and only if $\alpha < 1$ and $u(z) = \log |\Phi(z)(\Phi(z))^{-\alpha}| + c$, where $w = \Phi(z)$ is an arbitrary conformal map of ω on $|w| < 1$ and c is an arbitrary real constant. (Math. Rev. abstract)

ON DISCONTINUOUS INITIAL VALUE PROBLEMS FOR CERTAIN NON-LINEAR PARTIAL DIFFERENTIAL EQUATIONS, by A. Douglis. Feb. 1958, 25p. incl. refs. (Technical note no. BN-112) (AFOSR-TN-58-165) (AF 18(600)573) AD 152192 Unclassified

The partial differential equations discussed are of the form $\frac{\partial u}{\partial t} + \frac{\partial F(u)}{\partial x} = 0$, where $F(u)$ is a continuously differentiable and convex function. Even though non-linear equations of the above type have discontinuities in the Cauchy solution, a meaningful solution can be obtained by accepting a condition of an integral type. The initial data admitted are bounded, measurable functions on the x -axis vanishing for $x < 0$. The integral type solutions have been found previously but are presently obtained by a method involving differencing in one direction which, it is hoped, may lend itself to a generalization. A difference quotient is obtained for the integral condition which leads to a recursive system of ordinary differential equations replacing the original equation. The difference quotients are shown to be bounded and to

satisfy a form of the "entropy condition". The proof is completed from general theorems on the class of bounded functions subject to such an entropy condition.

AN ORDERING PRINCIPLE AND GENERALIZED SOLUTIONS OF CERTAIN QUASI-LINEAR PARTIAL DIFFERENTIAL EQUATIONS, by A. Douglis. May 1958, 39p. incl. refs. (Technical note no. BN-136) (AFOSR-TN-58-456) (AF 18(600)573) AD 158263; PB 135160
Unclassified

Also published in Commun. on Pure and Appl. Math., v. 12: 87-112, Feb. 1959.

Let $F(u)$ be continuously differentiable and convex. By a "generalized" solution in the half plane $t \geq 0$ of the partial differential equation (1) $u_t + (F(u))_x = 0$ is meant a solution in an appropriate integral sense which satisfies the "entropy" condition (2) $u(x-0, t) \geq u(x+0, t)$ for $t > 0$. Under the additional hypothesis that F'' is integrable and is restricted by an inequality of the form (3) $a \leq F''(u) \leq b$, where $a = \text{const.} > 0$, $b = \text{const.}$, generalized solutions of (1) are constructed with arbitrary, bounded, measurable initial data which actually satisfy a sharper form, namely, (4) $u(x+h) - u(x) \leq h/at$ for $h > 0$, $t > 0$, of (2). Such solutions, moreover, are governed by the following ordering principle: If $u_1(x, t)$ and $u_2(x, t)$ are any two such solutions, and if $u_1(x, 0) \leq u_2(x, 0)$ for almost every value of x , then $u_1(x, t) \leq u_2(x, t)$ for every $t > 0$ and every x .

This principle is made the basis of existence and uniqueness theorems, when (3) is presumed, and, in a more restrictive form, of existence theorems alone, when (3) is not presumed.

[PROPERTIES OF THE MAXIMA AND MINIMA OF THE SOLUTIONS OF ELLIPTIC AND PARABOLIC SECOND ORDER PARTIAL DIFFERENTIAL EQUATIONS, PARTS I AND II] Proprietà di massimo e minimo delle soluzioni di equazioni a derivate parziali del secondo ordine di tipo ellittico e parabolico, Nota I, II, by C. Pucci. [1957 and 1958] 10p. incl. refs. (AF 18-(600)573) Unclassified

Published in Atti Accad. Naz. Lincei. Rend. Cl. Sci. Fis. Mat. Nat., Series VIII, v. 23: 1-6, Dec. 1957; v. 24: 3-6, Jan. 1958.

The general second order partial differential equation $L(u) = 0$ is discussed. A theorem is given, which is a generalization of a result given by E. Hopf for elliptic equations and L. Nirenberg for parabolic equations, and is essentially the following. Let u be a real function of class C^2 in S , an open sphere in R^m , with center at η and radius r_0 for which $L(u) \leq 0$ in S and u is continuous in \bar{S} . Let x^0 be a point of the boundary of S where $u(x^0) \leq 0$ such that, for all $x \in S$, $u(x) < u(x^0)$. If the coefficients satisfy certain conditions, then the lower limit of the ratio $[u(x) - u(x^0)]/\sqrt{xx^0}$, for $x \in$ a segment in S terminating at x^0 , is positive. A second theorem concerns conditions under which u can attain a maximum or minimum in the region. From these two theorems, various corollaries are given, such as the fact that when $c = 0$, u has no maximum or minimum in the interior of T .

CONTINUATION OF BIHARMONIC FUNCTIONS ACROSS CIRCULAR ARCS, by J. H. Bramble. [1958] [20]p. incl. refs. (AF 18(600)573) Unclassified

Published in Jour. Math. and Mech., v. 7: 905-924, Nov. 1958.

This paper establishes certain reflection principles (analogous to the classical Schwarz reflection principle for harmonic functions) for biharmonic functions subject to various boundary conditions. Explicit formulae are given for the continuation of a biharmonic function w across a circular arc Q when the following conditions are satisfied:

- (A) $w = M(w) = 0$ on Q ,
- (B) $M(w) = V(w) = 0$ on Q ,
- (C) $w_r = V(w) = 0$ on Q ,

where

$$M(w) = \Delta w + \frac{1-\sigma}{\sigma} w_{rr}$$

$$\text{and } V(w) = \frac{\partial}{\partial r} (\Delta w) + (1-\sigma) \frac{1}{2} [w_{\theta\theta} + \frac{1}{r} w_{\theta\theta}]$$

Δ being the Laplace operator and a the radius of the circle. If σ is taken to be Poisson's ratio, then (A) and (B) correspond physically to the cases where Q is the edge of an elastic plate which is "simply supported" and "free" respectively. Condition (C) corresponds to the so called "sliding clamped" case. (Contractor's abstract)

Maryland U. Inst. for Fluid Dynamics and Applied Mathematics, College Park.

CALCULATION OF THE CROSS-STREAM WAVE LENGTH OF THE THREE-DIMENSIONAL TRANSITION PATTERN AND CORRELATION WITH THE GORTLER INSTABILITY THEORY, by J. R. Weske and Y. Y. Chen. Oct. 1957 [31]p. incl. illus. diags. (Technical note no. BN-111) (AFOSR-TN-57-637) (AF 18(600)893) AD 138625 Unclassified

A theory is explained concerning the mechanism which, at an early stage of transition in the boundary layer, produces a regular 3-dimensional pattern. A discussion is presented of the cross-stream wave length with consideration given to (1) the generation of secondary vorticity along a curved streamline in the boundary layer, (2) the structure of the vortex sheet of secondary vorticity (3) computation of the field of induced velocities produced by the vortex sheet, (4) establishment of relationships for the cross-stream wave length, (5) the influence of the static pressure gradient in the direction of the mean flow and of variation of the Reynolds number, and (6) the relation between the sheet of secondary vorticity and the formation of longitudinal vortices. The secondary-vorticity relations for the case of rotational yet nonviscous flow are used to derive quantitative relationships for the cross-stream wave length of this pattern for uniform and for retarded free flow. Certain of the results are correlated with boundary layer and instability theory along curved walls by Taylor and Gortler. Comparison is made with available experimental results. (ASTIA abstract)

CHANGE OF THE LAMINAR BOUNDARY LAYER PROFILE THROUGH A PRESSURE DECREASE, by Y. Y. Chen. [1957] 3p. diags. (Bound with its AFOSR-TN-57-62; AD 120403 as Appendix II) [AF 18(600)893] AD 120403(b) Unclassified

A laminar boundary layer profile approximated by the relation is given

$$u_1 = U_1 \left(\frac{z_1}{\delta_1} \right)^{\frac{1}{2}}$$

where δ_1 = boundary layer thickness

U_1 = free stream velocity

Let there be a pressure drop between Station 1 and 2,

$$p_1 - p_2 > 0$$

Because of this pressure drop the flow will be accelerated both in the boundary layer and the free stream. As a result, the boundary layer will decrease in thickness and the streamlines will draw closer to the wall. The changes of the velocity profile brought about by the decrease of static pressure and in particular the ratio of distance from the wall of the streamlines $z_2/z_1 < 1$ will

be calculated. Disregard fluid friction in the process, also assume incompressibility. Since viscous action is disregarded, Bernoulli's equation holds along streamlines.

ON STEADY FLOW PATTERNS APPEARING WHEN A SINK IS COMBINED WITH BOUNDARY LAYER FLOW, by J. M. Burgers. [1957] 14p. diags. (Bound with its AFOSR-TN-57-62; AD 120403 as Appendix I) [AF 18(600)893] AD 120403(a) Unclassified

The description of steady flow patterns appearing when a sink is combined with boundary layer flow is compared to a two dimensional case justified by a case where fluid motion is slow relative to the speed of rotation of the system. Sheets of discontinuity in the field of flow (implemented by neglect of the viscosity effects) are studied with the assumption, that in the case of the boundary layer along a wall, the vorticity already present in the original undisturbed flow might act in a way comparable to the effect of the rotation in Taylor's experiments, and also that in the boundary layer case sheets of discontinuity might make their appearance. The observed tendency of dye streamers in a shear layer to spread out in the plane of principal shear is discussed.

ON THE ORIGIN AND MECHANISM OF VORTEX MOTION AT THE INLET OF INTAKES PLACED NEAR A FLAT SURFACE, by J. R. Weske. Nov. 1958 [24]p. incl. illus. diagrs. (Technical note no. BN-152) (AFOSR-TN-58-863) (AF 18(600)893) AD 203672
Unclassified

The mechanism by which a vortex is formed in the field of a sink which is located close to a solid surface is investigated and it is shown that the various forms which the vortex assumes can be related to the same pattern. Secondary vorticity has been found to be the link between the vorticity of the undisturbed boundary layer and the vorticity of the observed vortices. The optimum stream velocity for the generation of a vortex sink is investigated both theoretically and experimentally.

CALCULATION OF THE CROSS-STREAM WAVE LENGTH OF THE THREE-DIMENSIONAL TRANSITION PATTERN IN THE BOUNDARY LAYER ALONG A FLAT PLATE, by J. R. Weske. Nov. 1958, 16p. incl. illus. diagrs. refs. (Technical note no. BN-150) (AFOSR-TN-58-864) (AF 18(600)893) AD 203671
Unclassified

Observed three-dimensional transition motions in the boundary layer showing a pronounced pattern recurring periodically across the stream are analyzed under the assumption that secondary vorticity is a controlling factor and that viscous effects are of minor consequence. An optimum cross-stream wave length was computed which is numerically in agreement with experimental observations. The results of the computation point to the emergence of composite periodic vortex configurations. (Contractor's abstract)

TRANSITION FLOW PATTERNS, by J. R. Weske. Final technical rept. Nov. 1958, 4p. (AFOSR-TR-58-130) (AF 18(600)893) AD 203685
Unclassified

Flow patterns were investigated in horseshoe vortex patterns, periodic stable longitudinal vortices and cross-stream vortices. Experiments were made in the boundary layer along a flat plate over which in a deep stream of water laminar boundary layers were maintained at

Reynolds numbers up to $Re = 800,000$. Investigation was also made of flow patterns in the boundary layer leading to transition brought about by roughness elements placed on the plate. The horseshoe pattern by manipulation of adverse pressure gradients, was transmuted into one of longitudinal vortices on one hand and of cross-stream vortices on the other. A theoretical method of calculation of the cross-stream wave length was devised by which the optimum wave length was computed, its order of magnitude agreeing with experimental observations. Observations of strong secondary flows within the vortices stimulated the theoretical investigation of the process of stretching of vortices. (ASTIA abstract)

This third part considers problems of gas flow in which account is taken of diffusion. Attention is given to the production or disappearance of molecules in consequence of chemical reactions. The diffusion has been treated on the basis of a method developed by M. Krook (Phys. Rev., v. 99: 1896-1897, 1955), leading to equations of a relatively simple structure. The method operates with certain mean values for the collision frequency in which no account is taken of the variations in speed of the molecules. An extension is indicated which brings a partial correction for effect of the speed. (Contractor's abstract) (See also item nos. MDU.11:011 and MDU.11:013 for Parts I and II)

Also published in Proc. Fourth Midwestern Conf. on Fluid Mechanics, Purdue U., Lafayette, Ind. (Sept. 8-9, 1955), Lafayette, Purdue U. Engineering Experiment Station (Research Series no. 128), [1956] p. 259-272.

A general discussion of the problem of hypersonic viscous flow over an inclined wedge with heat transfer is given, in which the flow over an insulated flat plate is a special case. The skin friction, heat transfer coefficient as well as induced pressure distribution due to interaction of boundary layer flow and outside inviscid fluid flow, shock wave or expansion wave, are calculated by a generalized von Karman integral method for the boundary layer equations of a compressible fluid. A brief comparison of the present method with several other theoretical methods as well as some experimental data for special cases is given. The interaction phenomenon has profound effects on the skin friction, induced pressure distribution and heat transfer coefficients.

Consideration is given to a number of problems which present themselves when a plane shock wave moving in a gas of high electric conductivity approaches a magnetic dipole field. The subject is treated in a number of steps: first the conductivity is considered to be infinite and the reaction of the magnetic field upon the motion of the gas is neglected; in this way a provisional picture of the distortion of the magnetic field by the shock wave can be obtained. In the next part of the paper the conductivity is treated as finite, although large; in the third part the effect of the magnetic field upon the motion of the gas in the immediate neighborhood of the shock front is investigated. In part IV some considerations are developed concerning the reaction of the magnetic field upon the propagation of the wave; while part V brings a tentative discussion of the possibility of a steady field of flow. THE EFFECT OF MOLECULAR VIBRATION ON RECOVERY TEMPERATURE IN PLANE COUETTE

FLOW, by H.-T. Yang. May 9, 1957, 12p. incl. diagr. (AF 18(600)993) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 911-912, Dec. 1957.

A study has been made of the effect of molecular vibration on the recovery temperature in plane Couette flow at a temperature range between 600° and 3000°K. The plane Couette flow consists of the fluid flow between two infinite, parallel plates at a distance δ apart with the lower plate stationary at a temperature T_w and the upper plate moving with a velocity U in its own plane at a temperature T_w^* . It is assumed that sufficient time (larger than relaxation time), has elapsed since the start of motion of the upper plate so that the inert degrees of freedom are already in equilibrium; therefore the only independent variable is the ordinate y normal to the plates. The continuity equation and the boundary conditions on both plates require the normal component of flow velocity to vanish, i.e., $v = 0$. It is assumed further that the flow may be considered as continuum. The recovery temperatures, with molecular vibration taken into consideration, are presented gradually for oxygen and nitrogen at Pr (Prandtl number) = 0.70 and $T_w = 300^\circ K$. It is seen that the decrease of recovery temperature owing to absorption of internal energy by the molecular vibration is quite appreciable.

CYLINDRICAL SHOCK WAVES PRODUCED BY INSTANTANEOUS ENERGY RELEASE IN MAGNETOGAS DYNAMICS, by S. I. Pai. Feb. 1958 [27]p. incl. diagrs. tables. (Technical note no. BN-120) (AFOSR-TN-58-215) (AF 18(600)993) AD 154116; PB 147454

Unclassified

Analysis has been made of the behavior of a cylindrical shock wave produced by instantaneous energy release along a straight line of infinite extent in a conducting gas subjected to a magnetic field with circular lines of force. Initially the gas is at rest and has constant temperature. Both the initial density and the initial magnetic field H_0 are assumed to be inversely proportional

to some power of the radial distance r . It was found that similar solutions exist only if H_0 is proportional to $1/r$.

Similar solutions for various initial density distributions have been obtained. Numerical examples are given for constant initial density. The magnetic field has great influence on the pressure distribution but little influence on the density distribution within the shock. The pressure near the shock front is increased by the magnetic field while that near the center of the region is decreased. In

general, the magnetic field increases the flow velocity within the cylindrical shock. (Contractor's abstract)

FURTHER INVESTIGATIONS ON THE TRIANGULAR-PATCH STIMULATOR, by J. C. Hegarty and F. R. Hama. June 1957, 10p. incl. illus. diags. (Technical note no. BN-107) (AFOSR-TN-57-616) (AF 18(600)1014) AD 136605 Unclassified

This section deals with specific applications of transfer equations. The topics treated are: (1) coefficients of diffusion, heat conduction and viscosity, (2) diffusion and heat conduction in a binary mixture, (3) collision cross sections, (4) cross sections for molecules repelling each other according to a potential function $E(r)$, (5) Coulomb forces, (6) electric conductivity in fully ionized and in partially ionized gases, (7) magnetic field influences upon viscosity, (8) temperature exchange between various molecules, and (9) cases with very strong magnetic fields.

Systematic investigations were made of the triangular-patch turbulence stimulator which was proved to be very efficient. Results show that variations in shape and size of the plan form of the triangles do not affect the transition Reynolds number appreciably. The effectiveness, however, is rather sensitive to the flow direction to the stimulator. (Contractor's abstract)

REDUCTION OF SUPERSONIC JET NOISE BY MEANS OF TRIANGULAR-PATCH STIMULATOR, by F. R. Hama. Informal rept. Feb. 8, 1957 [5]p. incl. diags. [AF 18(600)1014] Unclassified

Small-scale tests were conducted with and without the

MDU.12:008 - MDU.12:011

triangular-patch stimulator, and the results were plotted to show total pressure in lb/sq in. vs sound level in db. Without the stimulator, it is shown that the noise level increases as the total pressure increases and a hump appears on the noise-level curve. In this hump region, screeching noise results. With the stimulator, the noise level increases when the total pressure is not very high, because the nozzle is overexpanded and the stimulator is not quite effective; however, the hump is eliminated completely and as a result the screeching noise is suppressed entirely. At higher total pressures, the noise level plateaus-off, i.e., the effectiveness of the stimulator increases as the total pressure increases.

REDUCTION OF UNDESIRABLE SHOCK-WAVE EFFECTS BY MEANS OF TRIANGULAR-PATCH STIMULATOR, by F. R. Hama. Informal rept. Mar. 6, 1957 [6]p. incl. illus. diagr. [AF18(600)1014]

Unclassified

An attempt was made to determine if an integral interference device, e.g., a triangular-patch stimulator, could be utilized to reduce shock waves, which are otherwise 2-dimensional (or conical), by shifting the direction of the oncoming flow to give weaker 3-dimensional configurations. In a simple experiment, a test was conducted in a straight diverging nozzle in which a thin brass stimulator, 1/32 in. thick, was attached on both the top and bottom sides of the nozzle. The results of this preliminary test indicate that the triangular-patch stimulator tends to reduce shock wave effects. It is suggested that stimulators of this type might find applications in: (1) preventing shock-induced separation; (2) reducing wave drag of a supersonic body; (3) improving the efficiency of a supersonic diffuser; (4) reducing boattail drag resulting from the jet effect; and (5) replacing the adjustable throat in an afterburner.

NOTE ON THE BOUNDARY-LAYER INSTABILITY ON A FLAT PLATE STOPPED SUDDENLY, by F. R. Hama. Mar. 15, 1957, 1p. (AF 18(600)1014) Unclassified

Published in Jour. Aeronaut. Sciences, v. 24: 471, June 1957.

It is theorized that in shear flow, a 2-dimensional vortex line with a positive vorticity, i.e., having the same direction as the background vorticity, is unstable under 3-dimensional disturbances, whereas that with a negative vorticity is stable. Examination of the validity of

the second part of this theorem is the objective of this study, with special emphasis being focussed on the stability problem on a decelerated flat plate. First, the case when a smooth plate moving at a constant speed through a still fluid comes to a sudden stop is considered briefly. Then the case when the plate encounters a sudden stop, followed by a sudden start is studied. Experimental results indicate that the second part of the theorem is correct. Therefore, when a flat plate experiences deceleration and acceleration, the boundary layer is unstable in the deceleration stage, but the instability is harmless and will not result in transition. It is noted that if the plate is kept still for a long time after the sudden stop the 3-dimensional waviness is sufficiently intensified so that the stabilizing effect of the shear flow on a negative vortex will become no longer applicable. In addition, the succeeding acceleration even promotes a sudden appearance of a turbulent spot by stretching the 3-dimensional vortex loop, even though the vorticity of the loop is negative. It is pointed out that the present case, in which a plate itself is decelerated and accelerated, should be distinguished from the case when the vorticity of oncoming flow to the plate fluctuates so as to create pressure gradients in the stream direction. In the latter instance, the boundary layer may separate and produce dangerous positive discrete vortices, whereas the flow does not separate on an oscillating plate.

THICK AXISYMMETRIC LAMINAR BOUNDARY LAYERS, by F. R. Hama. [1957] 12p. incl. refs. (AF 18(600)1014) Unclassified

Theories of thick axisymmetric laminar boundary layers along a thin circular cylinder are first reviewed briefly. The Mark-Glauert-Lighthill-Pohlhausen method is described in detail as it appears most attractive to practical purposes. In order to study experimentally the effect of large transverse curvature on boundary-layer

problems, avoiding technical difficulties inherent to wind-tunnel experiments on such problems, the free-convection temperature field along a vertically-suspended thin cylinder is investigated. Experimental results are in excellent agreement with a theory developed analogous to the Mark-Glauert-Lighthill-Pohlhausen solution. Transition location is found far behind that in the two-dimensional case. (Contractor's abstract)

MDU.12:012

Maryland U. Inst. for Fluid Dynamics and Applied Mathematics, College Park.

THE AXISYMMETRIC FREE-CONVECTION TEMPERATURE FIELD ALONG A VERTICAL THIN CYLINDER, by F. R. Hama and J. V. Recesso. Jan. 1958, 35p. diagrs. tables, refs. (Technical note no. BN-118) (AFOSR-TN-58-25) (AF 18(600)1014) AD 148064

Unclassified

The axisymmetric free-convection problem along a vertical thin cylinder is investigated theoretically as well as experimentally with a view to studying the effect of strong transverse curvature on boundary-layer problems. A theory is developed as an extension of the Glauert-Lighthill-Pohlhausen solution for any value of the x-parameter. Temperature profiles are measured at several sections along an electrically-heated brass cylinder of 10 ft height and 1/4 in. diameter. Experimental results of the local-heat-transfer coefficient agree well with the theory. This, in turn, justifies the theories of laminar boundary layer along a thin cylinder developed by Glauert and Lighthill and by others, at least indirectly. The location of laminar-turbulent transition is estimated from the temperature profiles and by a hot-wire observation. Transition is found to be delayed considerably compared with that in the two-dimensional case.

INVESTIGATION OF TRANSITION CAUSED BY THE STOPPING OF A FLAT PLATE, by J. C. Hegarty. June 1958 [33]p. incl. illus. diagrs. (Technical note no. BN-141) (AFOSR-TN-58-627) (AF 18(600)1014) AD 162157; PB 138871

Unclassified

The present paper investigates the amplification of the small perturbation due to boundary-layer instability into discrete vortex lines and their subsequent distortion into a three-dimensional pattern. The intensification of the vortices and the three-dimensional distortion is believed to be a necessary step of the phenomena of transition from laminar to turbulent flow. The investigation was initiated because of criticism against the use of a trip wire as a means of promoting the process of amplification of the small perturbation. The results in many respects are in accord with those obtained from the trip wire. In addition to the study of the three-dimensionality present in the vortex line, the mechanics of the rotation of the distorted line is also discussed. The rotation is due to the interaction of the mean flow with the induction effect. Relations between the parameters $\alpha \delta^*$, c_r and R_{δ} are plotted at the rear, R_{δ} being

limited to a small range of values. (Contractor's abstract)

Abstract published in *Bull. Amer. Phys. Soc.*, Series II, v. 2: 239, Apr. 25, 1957.

Also published in *Phys. Rev.*, v. 108: 619-629, Nov. 1, 1957.

Effects of lattice defects such as foreign atoms or holes on spin-spin interactions in a simple cubic lattice are calculated by using the so-called spherical model developed by Montroll, Berlin and Kac, and others. In the case when the concentration of defects is low and the distance between any pair of defects is large, the exact positions of defects are not important and the excess free energy and other thermodynamical functions are determined by the concentration and the nature of defects. The Langevin - Curie law of magnetic susceptibility is modified because of the presence of defects. The ferromagnetic Curie point is also determined by defects and it is a linear function of defects when the concentration is not large. In the case when defect atoms have stronger exchange interactions with their neighbors than the rest of nearest neighbors, the Curie point is raised and the specific heat vs temperature curve is enhanced. The reverse is true when defect atoms have weaker exchange interactions. (Contractor's abstract)

THE MEAN FIRST PASSAGE TIME FOR A RANDOM WALKER AND ITS APPLICATION TO CHEMICAL KINETICS, by S. K. Kim. June 1957, 31p. (Technical note no. BN-100) (AFOSR-TN-57-326) (AF 18(600)1315) AD 132398 Unclassified

Also published in *Jour. Chem. Phys.*, v. 28: 1057-1067, June 1958.

The mean first passage time for a random walk with reflecting and absorbing barriers is computed by assuming Onsager's reciprocal relation for the transition probabilities. The result, which is valid for an arbitrary dimensional random walk, appears as a quotient of determinants whose elements are the transition probabilities and the initial distribution. For the one dimensional case, this result is written as a series which converges rapidly when nearest neighbor transitions predominate; in fact, the series reduces to a closed form for the case when only nearest neighbor transitions are allowed, and always converges for the case when only nearest and next-nearest transitions are allowed. Montroll and Shuler's computation of the mean first passage time for the case of the truncated harmonic oscillator model of a diatomic molecule is simplified and extended to an arbitrary initial distribution. In addition, the mean first passage time for the case of anharmonic oscillator model is computed by using the transition probability obtained by Shuler, Bazley and Montroll. In terms of the mean first passage time, the range of validity of the equilibrium theory in chemical kinetics is discussed. (Contractor's abstract)

DEFECTS ON A DIPOLE LATTICE, by A. Isihara. June 1957, 17p. (Technical rept. no. 76) (AFOSR-TN-57-387) (AF 18(600)1315) AD 132462 Unclassified

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 29-Feb. 1, 1956.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 3: 42, Jan. 29, 1958.

Also published in Jour. Chem. Phys., v. 27: 1174-1179, Nov. 1957.

Effects of defects on dipole interactions in a simple cubic lattice are calculated using the spherical model developed by Berlin and Thomsen, Lax, and others. When the concentration of defects is small, thermodynamical functions are linearly dependent on the concentration. The Curie temperature in the three-dimensional lattice is raised or lowered linearly with the concentration according to whether the defects have stronger or weaker dipole interactions with their neighbors than the interactions which the rest of atoms have. Lattice vacancies also reduce the Curie temperature. The specific heat and electric susceptibility of defect lattice are calculated. In the presence of an homogeneous electric field, there exists a critical field which is influenced by defects. (Contractor's abstract)

Tensor Formalism for Coulomb Interactions and Asymptotic Properties of Multipole Expansions, by L. Jansen. Oct. 1957, 38p. incl. tables. (Technical note no. BN-113) (AFOSR-TN-57-698) (AF 18(600)1315) AD 136691 Unclassified

Also published in Phys. Rev., v. 110: 661-669, May 1, 1958.

A tensor notation for electric multipole interactions between molecular charge distributions is developed and applied to the evaluation of first and second order interaction energies. An equivalence theorem between cylindrically symmetric and linear assemblies of charge is established. The mathematical implications of using a multipole Taylor expansion in regions of configuration space where the series has no validity is discussed for the first and second orders of perturbation theory. A Study of the Restricted Random Walk, by R. S. Lehman and G. H. Weiss. Nov. 1957, 23p. incl. tables, refs. (Technical note no. BN-115) (AFOSR-TN-57-735) (AF 18(600)1315) AD 136722 Unclassified

Also published in Jour. Soc. Indust. Appl. Math., v. 6: 257-278, Sept. 1956.

This paper treats several aspects of the restricted random walk, both theoretically and numerically. It presents, for the first time, a study of the phenomenon of "trapping" in such random walks. A proof is given that such trapping must occur with probability one in most lattices. An ORDVAC study of this phenomenon shows that the number of survivors is very nearly an exponentially decreasing function of the number of steps. A further ORDVAC study of the mean square end-to-end distance of the restricted random walk is made, but sampling difficulties prevent definitive conclusions from being drawn. Remarks on the Vibrations of Diatomic Lattices, by A. A. Maradudin, P. Mazur and others. [1958] [22]p. incl. diagrs. table, refs. (Technical note no. BN-114) (AFOSR-TN-57-737) (AF 18(600)1315) AD 136723 Unclassified

Also published in Rev. Modern Phys., v. 30: 175-196, Jan. 1958.

This is mainly a review of selected topics in the theory of crystal vibrations, restricted primarily to aspects which the authors themselves have helped develop. The first section contains an interesting review of the history of the analysis of vibration spectra, beginning with related work of Lord Kelvin and Lord Rayleigh and ending with recent attempts to analyze singularities. This is followed by a derivation of the exact spectrum for an ordered diatomic cubic lattice with nearest neighbor forces only. The largest part of the paper, however, deals with various methods for approximating the spectrum of disordered binary alloys forming a cubic lattice and includes a discussion of (1) dilute mixtures, (2) slightly disordered structures, and (3) completely disordered arrangements. INTERMOLECULAR POTENTIAL BETWEEN LARGE MOLECULES, by A. Ishara and R. Koyama. [1957] [8]p. incl. diagrs. table, refs. [AF 18(600)1315]

Unclassified

Published in Jour. Phys. Soc. Japan, v. 12: 32-39, Jan. 1957.

The intermolecular potential between spherical polyatomic molecules is calculated, assuming the Lennard-Jones potential between atoms of polyatomic molecules. Owing to the distribution of atoms in polyatomic molecules the degree of infinite of potential is lowered when two polyatomic molecules approach each other. In the case of uniform distribution of atoms in polyatomic molecules, the degree is lowered by 5 orders and the minimum value of the potential is proportional to the radius of polyatomic molecule and to the square of the density of the atoms. At large intermolecular distance, the result of calculation of this case coincides with the results of Atoji and Lipscomb and of Hamaker. Calculation for a parabolic distribution of atoms is also given. The temperature and molecular weight dependence of the second virial coefficient of high polymer solutions are explained with the aid of calculated potential function.

Also published in Jour. Chem. Phys., v. 28: 700-705, Apr. 1958.

The previous work on vibrational relaxation of a system of harmonic oscillators has been extended to a system of anharmonic (Morse) oscillators. Numerical solutions of the relevant relaxation equations have been obtained on the ILLIAC (University of Illinois electronic digital computer) for some particular cases of initial δ -function and Boltzmann distributions. The results of these calculations show that the deviations of the fractional level population from the harmonic oscillator values are very small, being of the order of the anharmonicity in the case of relaxation of the initial Boltzmann distribution, and about five times the anharmonicity for the relaxation of the δ -function distribution. A general analytical perturbation procedure for the solution of the relaxation equations has been outlined and analytical solutions for several special cases are discussed briefly.

FREE RADICAL STATISTICS, by J. L. Jackson and E. W. Montroll. Feb. 1958, 1v. incl. diagrs. tables. (Technical note no. BN-121) (In cooperation with National Bureau of Standards, Washington, D. C.) (AFOSR-TN-58-186) (AF 18(600)1315) AD 152219 Unclassified

Also published in Jour. Chem. Phys., v. 28: 1101-1109, June 1958.

On the basis of a simplified statistical model, average concentrations of trapped free radicals condensed from a gaseous mixture are calculated. The trapped free radical concentration is obtained as a function of the free radical concentration in the gas and of the number of nearest neighbors in the solid. The mathematical problem presented by the model is solved rigorously in the one dimensional case (two nearest neighbors) and approximately for arbitrary numbers of nearest neighbors. Typical calculated percentages of trapped free radicals range from 14% for a simple cubic lattice to 10% for a face-centered cubic lattice, when the solid is condensed from a completely dissociated gaseous mixture. (Contractor's abstract)

eralized for the zero-point energy of a one-dimensional lattice and higher-order terms are obtained in the expansion. In two dimensions the agreement between the more accurate calculation here and that of Prigogine et al., indicates that their use of the Debye frequency spectrum as a zeroth approximation does not lead to appreciable error. In addition to a calculation of additive functions of the normal mode frequencies, a discussion is presented of the low-frequency end of the frequency-distribution function. (Contractor's abstract)

SCREW DISLOCATION CORE STRUCTURES IN SODIUM CHLORIDE. I (Abstract), by A. A. Maradudin. [1958] [1]p. [AF 18(600)1315] Unclassified

Presented at meeting of the Amer. Phys. Soc., Washington, D. C., May 1-3, 1958.

Published in *Bull. Amer. Phys. Soc., Series II*, v. 3: 233, May 1, 1958.

The positions of the ion rows at the core of a screw dislocation in sodium chloride have been calculated by minimizing semi-analytically the energy of interaction of these rows with themselves and the rest of the lattice. A Born-Mayer expression is used for the interionic potential function, and during the relaxation of the positions of the central ion rows all rows outside these are held fixed in the positions calculated by elastic theory. The numerical results indicate that this last restriction can lead to physically unrealistic results. Values for the relaxation displacements and energy changes will be presented.

A NEW EXPERIMENTAL APPROACH TO THE ANALYSIS OF COMPRESSOR PERFORMANCE. APPLICATION OF THE BOMELBURG SPARK METHOD TO THE MEASUREMENT OF DIRECTIONAL VELOCITY TRAVERSES AT THE OUTLET OF AN IMPELLER, by J. Herzog. Jan. 1957, 9p. illus. diagrs. (Technical note no. BN-90) (AFOSR-TN-57-3) (AF 18(603)92) AD 115035 Unclassified

Transverse measurements were made of the direction and magnitude of the instantaneous absolute velocity extending across the blade channel at the outlet of a rotating aircraft supercharger impeller by means of a spark technique. The impeller was operated at open throttle condition. It was rotated at a speed greatly reduced below normal because of limitation of drive power. The measured data were analyzed and related to the design constants of the impeller. Results give an insight into the qualitative nature of the flow, and indicate that further experience is necessary to determine the attainable accuracy of the method.

CHARACTERISTICS OF THE TECHNIQUE OF AERODYNAMIC INVESTIGATION BY MEANS OF SERIES OF ELECTRIC SPARKS, by J. Herzog, J. R. Weske and others. July 1957 [66]p. incl. illus. diagrs. (Technical note no. BN-105) (AFOSR-TN-57-359) (AF 18(603)92; continuation of AF 18(600)893) AD 132432 Unclassified

The investigations of Bomelburg (See MDU.10:005) on the technique of generating series of electric sparks at high frequencies for use in aerodynamic investigations were supplemented to establish the characteristics of this method of measurement and to determine its accuracy and limits of applicability. Single electric sparks of widely varying energy were produced across a spark gap placed into a Schlieren bench. The motion of the air heated by the spark was studied by photographing the momentary Schlieren image produced by a flash of light triggered at brief systematically varied periods after the termination of the spark. A condenser was used to apply 30,000 v across a 1-cm spark gap. The duration of the spark was varied from 3.5 to 200 μ sec, and the time delay between the termination of the spark and the beginning of the light flash varied from 0 to 1000 μ sec. Results indicated that the body of hot gas produced by the spark retains its initial shape for about 30 μ sec but disintegration begins within 100 μ sec. Theory and experiment led to the conclusions that (1) the deviation of parabolic spark traces is less than 10% for spark traces,

the height of which does not exceed 30% of their base length, and (2) deviations for sinusoidal displacement curves are 25 times larger than for parabolas. The spark wake in colder air rose at a nearly constant rate (0.4 fps). At supersonic speeds the electric discharge tended to follow the shock waves. Theoretical relations are appended for the observed deviation of spark paths from curved displacement profiles of an air stream. These served as a basis for the experimental calibration in Poiseuille flow. The following appendices are attached: I. Analysis of the Deviation of Spark Paths from the Curved Displacement Profile of the Fluid; II. The Temperature Field of Two Instantaneous Semi-Infinite Straight Line Sources Joining at Right Angles in a Homogeneous Three-Dimensional Heat Conducting Medium; and III. On the Measurement of Wind (Tunnel) Velocity Distributions by the Electric Spark Method.

A NEW EXPERIMENTAL METHOD FOR THE INVESTIGATION OF FLOW IN TURBOMACHINES, by J. Herzog and J. R. Weske. [1957] 11p. illus. [AF 18(603)92] Unclassified

Presented at annual meeting of the Aeronaut. Research Organization (DVL) and Soc. for Aeronaut. Research (WGL), Essen (Germany), Apr. 9-12, 1957.

Presentation is made of an electric spark technique for the experimental investigation of instantaneous local conditions of flow, for which in present practice hot wire anemometry of piezoelectric pressure and similar techniques of measurements are applied. This technique, devised for general aerodynamic measurements by H. Bomelburg and adapted to the investigation of flow in turbomachines by J. Herzog makes use of series of high frequency electric sparks. It permits the visual observation and the measurement of magnitude and direction of local velocity vectors, averaged over a few μ sec, in non-steady three-dimensional fields of flow. The method should be useful especially in the investigation of steady or non-steady transonic flow past fixed or moving blade rows. Merits, as well as limitations, of the spark technique are discussed in connection with the presentation of results of tests. Possibilities of application to the solution of problems of research and development are illustrated by examples of measurements carried out on centrifugal and axial flow compressor rotors.

THREE-DIMENSIONAL FLOW IN AXIAL TURBO-MACHINES, by J. R. Weske. Final rept. Apr. 1, 1958, 4p. (AFOSR-TR-58-53) (AF 18(603)92) AD 154244

Unclassified

Experimental work was carried out on rotating blade rows of both the axial flow and the radial flow type, and on fixed airfoil grids. The technique of electric sparks in the improved form developed by Bomelburg was used in order to cope with the three-dimensional and non-steady features of the flows encountered. To meet the requirements posed by the given task for qualitative survey as well as for quantitative measurements of the flow, the electric spark method was calibrated and adopted. It was shown that the accuracy of the electric spark method increases with air speed and that this method is especially suitable as a technique of measurement at transonic and supersonic speeds. Investigations of a rotating axial flow blade row were conducted with a rotating system of mirrors. Systematic measurements at the discharge of a rotating turbo-supercharger impeller were carried out. Further investigations with the electric spark technique were made in a suction wind tunnel of transonic flows past individual airfoils in grid arrangement.

SONIC LIMIT SINGULARITIES. PART II. EXAMPLES, by G. S. S. Ludford and S. H. Schot. May 1958 [30]p. incl. diags. (Technical note no. BN-135) (AFOSR-TN-58-419) (Sponsored jointly by Air Force Office of Scientific Research under AF 49(638)154 and Office of Ordnance Research under DA 36-034-ord-1486) AD 158222

Unclassified

Also published in Arch. Rational Mech. Anal., v. 2: 173-190, 1958.

Previously developed theory (item no. MDU.19:001) is extended to an investigation of the case of a general separation constant $n > 0$ to show that the corresponding class of flows has certain well defined geometrical features. For n less than a certain value n_0 , a typical sonic limit line flow in the physical plane represents a compressible analog of the incompressible flow about a corner with a certain corner angle and must be envisaged as taking place on a quadruply sheeted surface. The sheets are joined at a supersonic limit line which has the shape of a portion of a hypocycloid ($n > 1$) or epicycloid ($n < 1$). For $n < 1$, portions of the same sheet overlap in the large. The shape of the sonic limit line is discussed when solutions corresponding to different n are superposed. In this case the supersonic limit line can be eliminated and an isolated sonic limit line is obtained.

RAYLEIGH'S PROBLEM IN HYDROMAGNETICS: IMPULSIVE MOTION OF A POLE-PIECE, by G. S. S. Ludford. Nov. 1958, 21p. (Technical note no. BN-151) (AFOSR-TN-58-1073) (AF 49(638)154) AD 207242 Unclassified

Also published in Arch. Rational Mech. Anal., v. 3: 14-27, 1959.

Consideration was given to the motion of an incompressible, viscous, electrically conducting fluid contained between the parallel, plane, pole-pieces $y = 0, h$, of a permanent magnet which provides a uniform external field in the y - direction. Starting at time $t = 0$, with fluid at rest, the magnet is made to move uniformly in the negative x - direction. (Contractor's abstract)

THE SOLUTION AND HUYGENS' PRINCIPLE FOR A SINGULAR CAUCHY PROBLEM, by D. W. Fox. July 1958, 37p. incl. illus. (Technical note no. BN-137) (AFOSR-TN-58-568) (AF 49(638)228) AD 158387; PB 135570 Unclassified

Also published in Jour. Math. and Mech., v. 8: 197-219, Mar. 1959.

This paper gives an explicit solution in the large of the singular Cauchy problem for the hyperbolic equation $U_{tt} + (k/t)U_t = \sum_1^m (U_{x_1 x_1} + (\lambda_1/x_1^2)U)$ with the initial data $U(x, 0) = f(x)$ and $U_t(x, 0) = 0$, for all $i = 1, 2, \dots, m$.

The exact range of the parameter k for which the solution is given by an integral operator is determined. For all other non-exceptional values of k the solution is obtained by a recursive procedure which yields the analytic continuation of the integral in terms of k . The question of uniqueness is extensively treated. A main part of the investigation is devoted to the formulation of a necessary and sufficient criterion for Huygens' principle and the comparison of it to the corresponding results for the regular Cauchy problem and for the singular Cauchy problem for the Euler-Poisson-Darboux equation. ON THE GENERALIZED RADIATION PROBLEM OF WEINSTEIN, by J. L. Lions. Nov. 1958, 28p. (Technical note no. BN-149) (AFOSR-TN-58-1039) (AF 49(638)228) AD 206575 Unclassified

Also published in Jour. Math. and Mech., v. 8: 873-888, Nov. 1959.

The generalized radiation problem of Weinstein (item no. MDU.09:013) is to find a distribution $u(x, y)$ in the half plane $y \geq 0$ which satisfies $u_{xx} - u_{yy} - (k/y)u_y = 0$ with: (1) $u(x, y) \rightarrow 0$ for $x \rightarrow y$, and (2) $u(x, 0) = F(x)$ where k is a complex number. Weinstein has proved the existence of a solution u for $-\infty < k < 1$ and for functions F that are smooth enough. The existence and uniqueness of u has now been extended to the case in which (1) $-\infty < \text{Re } k < 1$ and without any condition on F , and (2) the most general

MDU.20:004; MDU.21:001, 002
MDU.15:002, 003

hypothesis on u is used. The impossibility of solving the problem for $Re\ k > 1$ has been demonstrated.

ON THE MECHANISM OF THERMAL IONIZATION BEHIND STRONG SHOCK WAVES, by H. D. Weymann. July 1958 [40]p. incl. illus. diagrs. refs. (Technical note no. BN-144) (AFOSR-TN-58-788) (AF 49(638)-401) AD 203113 Unclassified

The ionization process behind shock waves in noble gases has been investigated. It was found that in the initial stage, ionization follows a two step process in which a given atom is raised to the first excited elec-

tronic state by collision with another atom. Ionization is achieved after a second collision with an atom having sufficient relative translational energy to complete the process. It was not necessary to postulate that impurities influence the ionization rate of the noble gas. The theoretically derived temperature and density dependence of the ionization relaxation time is in agreement with the experimental results obtained by a number of different methods. A comparison of the absolute values of the relaxation times obtained theoretically and experimentally permits an evaluation of the cross sections for excitation and ionization by atom-atom collisions. MOLECULAR SCATTERING BY AN EXPONENTIAL POTENTIAL, by E. A. Mason. Feb. 1, 1957, 11p. incl. diagr. refs. (Rept. no. IMP-OSR-2) (AFOSR-TN-57-44) (AF 18(600)1562) AD 115082 Unclassified

A method is given for analyzing the results of small angle scattering measurements in terms of an intermolecular potential energy which can be represented as a decreasing exponential. A small angle approximation is used throughout, which permits the calculations to be performed analytically. As an example, the scattering of H_3^+ by He is considered, and the present method shown to be a considerable improvement over the previous interpretation in terms of an inverse power potential energy function. The same method can also be applied to other algebraic forms of potential energy functions. (Contractor's abstract)

CALCULATION OF SECOND VIRIAL AND JOULE-THOMSON COEFFICIENTS OF GASES AT VERY HIGH TEMPERATURES, by E. A. Mason. Feb. 18, 1957, 9p. incl. diagrs. (AFOSR-TN-57-81) (AF 18(600)1562) AD 120427 Unclassified

Also published in *Indus. Engineering Chem.*, v. 50: 1033-1035, July 1958.

Formulas are given for the second virial coefficients and zero-pressure Joule-Thomson coefficients of a gas at a temperature high enough that all molecular encounters can be assumed to be controlled only by forces of repulsion. Two forms of molecular interaction energy are considered: inverse powers and exponentials. The results for the inverse power potential are not new, but are for the physically more realistic exponential, for which an asymptotic series is given of which just the first term is almost always sufficient. As an example, the second virial coefficient of helium is calculated at

MDU.15:004 - MDU.15:007

high temperatures from an exponential potential given by Amdur and Harkness, and based primarily on beam scattering experiments. The agreement with experiment is satisfactory. The asymptotic formula also enables a check to be made on a semi-empirical calculation scheme proposed by Hirschfelder and Eliason. The accuracy of the semi-empirical scheme is somewhat disappointing, and a modification is proposed.

INTERACTION ENERGIES AND SCATTERING CROSS SECTIONS OF HYDROGEN IONS IN HELIUM, by E. A. Mason and J. T. Vanderslice. Apr. 11, 1957, 40p. incl. diagrs. tables, refs. (AFOSR-TN-57-152) (AF 18(600)-1524) AD 126442 Unclassified

Also published in Jour. Chem. Phys., v. 27: 917-927, Oct. 1957.

The interaction energies for the $H^+ - He$ and $H_2^+ - He$ system have been calculated for a range of internuclear distances and, in the $H_2^+ - He$ case, for two different configurations. The results are used to analyze the ion-scattering measurements of Simons and co-workers. It has been found that the predicted scattering cross sections are in remarkable agreement with the measured ones, provided allowance is made for a finite width of the ion beam. This agreement implies that the method of interpreting measured cross sections in terms of molecular forces is correct, and that specific apparatus effects have been correctly analyzed. The present calculations suggest, in contrast to previous assumptions, that the important forces are ones of repulsion rather than attraction, with the exception of those cases where chemical binding is clearly involved. It also appears that to obtain precise force information of physical significance from such scattering measurements, it is necessary to make allowance for the finite width of the ion beam. This has been illustrated for the scattering of H_3^+ ions in helium. Finally, the cross-section equations have been integrated for the case of scattering by an exponential potential and by a Lennard-Jones (8-4) potential.

SCATTERING CROSS SECTIONS AND INTERACTION ENERGIES OF LOW-VELOCITY He^+ IONS IN HELIUM, by E. A. Mason and J. T. Vanderslice. July 10, 1957 [7]p. incl. diagrs. (AFOSR-TN-57-575) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1562 and National Advisory Committee for Aeronautics) AD 136563 Unclassified

Also published in Phys. Rev., v. 108: 293-294, Oct. 15, 1957.

It is pointed out that the determination of ion-molecule forces from results of measurements of scattering of low-velocity ion beams in gases can be seriously in error unless some a priori knowledge of the nature of the forces is available. The scattering of He^+ in He is chosen as an illustration. The elastic and charge exchange cross sections calculated from Moisewitschs' theoretical force laws are shown to be in good agreement with the experimental values of Cramer and Simons. The force law determined by the latter authors directly from their measurements is in error because of the assumption of an incorrect form and the failure to consider the two interaction states involved.

INTERACTION ENERGY AND SCATTERING CROSS SECTIONS OF H^- IONS IN HELIUM, by E. A. Mason and J. T. Vanderslice. Sept. 20, 1957, 17p. incl. diagrs. table, refs. (AFOSR-TN-57-793) (Sponsored jointly by Air Force Office of Scientific Research under AF 18(600)1562 and National Advisory Committee for Aeronautics) AD 148025 Unclassified

Also published in Jour. Chem. Phys., v. 28: 253-257, Feb. 1958.

An approximate quantum mechanical calculation is made of the energy of interaction of H^- and He. The results are not of high accuracy, but serve to indicate the general nature of the interaction. This knowledge makes it possible to calculate more accurate values of the interaction from measured elastic scattering cross sections. The resultant interaction is combined with the previously known interaction of H and He to give an approximation to the inelastic (electron detachment) cross section, which is shown to be in reasonable agreement with the experiment. The calculations emphasize the importance of the repulsion forces rather than the attraction forces. The accuracy of a correction for the finite width of the ion is also examined in some detail.

Kihara's (Rev. Modern Phys., v. 25: 844, 1953) extension

MDU.15:008 - MDU.15:010

of the Chapman-Enskog theory of transport phenomena has been used (1) to obtain second- and third-order approximations to the mobility of gaseous ions in a weak electric field as a function of temperature and field strength and (2) to calculate the required collision integrals for a more realistic potential energy function than was used previously. This method assumed that there is no charge exchange between ions and molecules, no clustering occurs, and the quantum effects can be neglected. The mobility was expressed as a series in ascending powers of the square of the field strength with coefficients which were complicated functions of the temperature, the mass ratio of the ions and molecules, and the force law between the ions and molecules. The collision integrals were evaluated by numerical integration for a force law which considers the charge-induced dipole and quadrupole, the London dispersion forces, and an inverse twelfth power repulsion potential. In the potential energy function, 3 disposable parameters specified the depth and position of the minimum and the relative magnitudes of the various terms. Results of present calculations were used to analyze mobility data to obtain the disposable parameters which determined the ion-molecule force law. Good agreement existed between theory and experiment except for cases in which clustering was expected. (Contractor's abstract)

INTERACTION ENERGY AND MOBILITY OF Li^+ IONS IN HELIUM, by E. A. Mason, H. W. Schamp, Jr., and J. T. Vanderslice. Apr. 1, 1958 [16]p. incl. diagrs. table, refs. (Rept. no. IMP-OSR-9) (AFOSR-TN-58-271) (AF 18(600)1562) AD 154172 Unclassified

Also published in Phys. Rev., v. 112: 445-448, Oct. 15, 1958.

The interaction energy of Li^+ and He has been calculated for a range of internuclear separations. The results are not in very good agreement with a similar calculation by Meyerott (Phys. Rev., v. 66: 242, 1944), who used the same wave functions but approximated many of the molecular integrals. Considerable uncertainty is caused by lack of knowledge of the second-order exchange energy. The results are used to calculate the mobility of Li^+ ions in He gas as a function of temperature for comparison with experiment. It is concluded that the theoretical interaction energy is not inconsistent with the experimental mobility data, within the uncertainty caused by the second-order exchange energy. Presented at Convention on Condensed States of Simple Systems, Varenna (Italy), Sept. 11-15, 1957.

Also published in Phys. Fluids, v. 1: 370-383, Sept.-Oct. 1958.

Known intermolecular force laws are used to calculate virial coefficients of the equation of state and the transport properties at very high temperatures for the rare gases and for molecular nitrogen. The crucial force laws which enable the calculations to be carried to high temperatures are those derived from molecular beam scattering measurements, which are valid at close distances of molecular approach. The calculations cover the temperature range from 1000° to $15,000^\circ\text{K}$, but take into account only the translational degrees of freedom and neglect the effects of excitation, dissociation, and ionization. The treatment of mixtures is outlined, and illustrated by calculations for the binary system helium-argon. The methods which are used offer an approach to the problem of obtaining reasonably accurate estimates of gas properties at temperatures so high that direct experiments would be extremely difficult, if not impossible. MOBILITY OF HYDROGEN IONS (H^+ , H_2^+ , H_3^+) IN HYDROGEN, by E. A. Mason and J. T. Vanderslice. Nov. 14, 1958, 14p. diagrs. table, refs. (Rept. no. IMP-OSR-11) (AFOSR-TN-58-1005) (AF 18(600)1562) AD 206148 Unclassified

Also published in Phys. Rev., v. 114: 497-502, Apr. 15, 1959.

Force laws for H^+ , H_2^+ , and H_3^+ in H_2 have been calculated from theory and also from results on the scattering of low-velocity ion beams in H_2 gas. These results have been used to calculate the mobilities of the hydrogen ions in H_2 gas as a function of temperature. It has been found that the mobilities of H^+ and H_2^+ decrease slightly with increasing temperature, but the mobility of H_3^+ increases strongly. The agreement with experiment indicates that the unidentified hydrogen ion whose mobility has been measured is probably H_2^+ , rather than the usually assumed H_3^+ . (Contractor's abstract)

NOTE ON THE ABSORPTION OF RADIATION BY A
CYLINDRICAL SAMPLE OF A STRONG ABSORBER,
by E. A. Mason. [1958] [1]p. [AF 18(600)1562]

Unclassified

Published in Jour. Chem. Phys., v. 29: 1184, Nov. 1958.

The calculation of the absorption of radiation by a cylindrical sample of a strong absorber has been reduced by W. H. Clingman (Jour. Chem. Phys., v. 27: 322, 1957) to the evaluation of the integral,

$$J(\alpha) = (4/\pi\alpha) \int_0^{\pi/2} [1 - \exp(-\alpha \sin\theta)] \sin\theta \, d\theta,$$

where α is a dimensionless parameter involving the radius, density, and mass absorption coefficient of the sample. It is assumed that the incident light is parallel and that end effects are negligible. Clingman evaluated this integral by expanding the exponential in the integrand by the usual power series and integrating term by term. The very slow convergence for large α of the resulting series was overcome by the use of an IBM 650 calculator, and values of $J(\alpha)$ were tabulated up to $\alpha = 9.9$. It is possible to develop another series for $J(\alpha)$ which converges rapidly for large values of α , and which is useful for the evaluation of $J(\alpha)$ with a desk calculator. A further advantage of a simple series over a set of tables is that problems involving integrals of $J(\alpha)$ are more easily handled. Such problems arise, for instance, in connection with the Raman spectra of strongly absorbing substances. If the integration variable is changed to $x = \sin\theta$, the above equation can be written as

$$J(\alpha) = (4/\pi\alpha) \left[1 - \int_0^1 e^{-\alpha x} (1-x^2)^{-\frac{1}{2}} x \, dx \right].$$

The term $(1-x^2)^{-\frac{1}{2}}$ is expanded by the binomial theorem and the integration carried out term by term to give

$$J(\alpha) = (4/\pi\alpha) (1 - \alpha^{-2} - 3\alpha^{-4} \dots),$$

in which a number of exponentially decreasing terms have been dropped as negligible for large α . This simple formula is surprisingly accurate; for $\alpha = 4$, it is in error by only 0.14%, and the accuracy improves as α increases. The series is only asymptotically convergent, but the accuracy obtainable is obviously more than adequate.

The effects of lesions on functional activity of the visual cortex of cats are being studied. The lateral geniculate body and associated fibers were irradiated with ultrasound, and the activity of the visual cortex of the experimental half of the treated cat brain was compared with that of the untreated control half. Correlation analysis is being used to study the differences in response between irradiated and unirradiated sides. A typical correlogram indicated the diminution of activity of the visual cortex on the irradiated side. Results indicated that the right geniculate body is normal and that the left geniculate body shows impairment in the middle layer (i.e., to ipsilateral flash) and in the lowest layer (i.e., to contralateral flash). No function remained in the lateral geniculate on the left at F_7, L_{10}, H_3 . The results appeared to

indicate a lesion in the lower half or even the lower one-third of the left geniculate body. The upper one-third is probably unimpaired. The predictions were confirmed by gross histological examination. A distinct lesion was observed in the lateral lower one-third of the lateral geniculate body as well as in subjacent fibers. It will be possible to distinguish clearly between the contributions of the 3 respective layers of the lateral geniculate body to cortical activity. The action of ultrasound, both reversible and irreversible, is being studied on fibers of the optic tract to observe changes in conduction during and following irradiation with ultrasound, to determine the dose of ultrasound which alters conduction reversibility, and to determine the recovery time for restoration of normal functions. The maximum dose of ultrasound is being determined to which white matter can be subjected without irreversible alteration of its ability to function.

THE DEVELOPMENT OF CONCEPTS RELATING TO THE ELECTRICAL ACTIVITY OF THE BRAIN, by M. A. B. Brazier. [1958] 21p. refs. (Bound with its Progress rept., July 1958) (AF 49(638)98)

Unclassified

Also published in Jour. Nervous and Mental Disease, v. 126: 303-321, Apr. 1958.

The development of concepts relating to the electrical activity of the brain is presented historically, covering the period from Galvani (1791) to the present. From the information given, an attempt is made to lead up to a current hypothesis of the basic mechanisms responsible for EEG (electroencephalogram) potentials. It is stated that in the resting but awake brain the typical α rhythm is compounded of the massed synaptic potentials of the apical dendrites of pyramidal cells, synchronization resulting from the electrical field of maximal amplitude present in the total activity. The constant influx of stimuli from the external and internal environment of the organism reaches the pyramidal cells through the specific afferents (probably with an intercalary Golgi type-2 cell), and the resultant post-synaptic depolarization moves toward the cortical surface by electrotonic spread in the apical dendrites. The degree of depolarization of the dendritic tree (the substratum of the EEG) is controlled by the arrival via nonspecific afferents of facilitatory and inhibitory impulses from the brain stem modifying the level of excitability. This type of afferent plays onto the dendrites by axo-dendritic dynapsis in the superficial layers of the cortex, adding algebraically to the summing level of polarization. At the same time, any excessive development of discharge by the pyramidal cells is checked by their hyperpolarizing action of the small inhibitory cells activated by recurrent collaterals of these same pyramidal cells. The relative courses of these 3 events with their different rates of recovery set the rhythm of the waking brain. Variations from this homeostatic condition are discussed for the following: (1) sleep or coma; (2) vigilance; (3) selective attention; (4) efferent output; (5) photic driving; (6) conditioned reflexes; (7) barbiturate anesthesia; (8) cortical spiking in epilepsy; (9) petit mal absences; (10) brain tumors; and (11) destructive lesions. A bibliography of 108 references, ranging in time from 1791 to 1956 is also included.

EEG STUDIES OF FLICKER IN NORMAL MAN, by M. A. B. Brazier. [1958] 5p. diagrs. (Bound with its Progress rept. July 1958) [AF 49(638)98] Unclassified

Also published in ERDL-Tulane Symposium on Flicker, Tulane, 1957, p. 199-224.

Two methods of analysis were employed in these studies involving photic stimulation during EEG (electroencephalogram) recording, one being in the frequency domain, the other being in the time domain. The equipment and procedures are briefly described. Results of the analyses are discussed. It is pointed out that the frequency-domain analysis reports the activity/unit time whose oscillations resonate with the tuned circuits of the instrument. Lost in this type of analysis is all information as to phase of the waves, and therefore of trains of waves of the same frequency. Bursts of α with interposed waves of different frequencies are not differentiated by this type of analyzer from continuous trains of waves locked in phase with each other. In the time-domain analysis, information is presented about the voltage-time graph of the EEG throughout the whole length of the sample, indicating whether amplitude fluctuations in the EEG are related patternwise to those that have come before.

THE EFFECT OF THYROID HORMONES AND TEMPERATURE ON THE KINETICS OF CONTRACTION AND RELAXATION OF VENTRICULAR HEART MUSCLE, by W. R. Brewster, Jr., J. P. Isaacs and others. [1958] 30p. incl. diagrs. refs. (Bound with its Progress rept., July 1958) (AF 49(638)98) and AF 18(600)1258)

Unclassified

Also published in Bull. Johns Hopkins Hospital, v. 103: 157-182, Oct. 1958.

The kinetics of isometric contraction and relaxation have been observed in intact athyroid, euthyroid, and thyroid-fed dogs utilizing Walton strain gauge arches sutured to segments of both right and left ventricular heart muscle. The animal's heart and body temperatures were varied from 42°C to 17°C. Isometric contraction and relaxation of muscle displayed 4 distinct phases for analysis: (1) initial contraction characterized by a rapid and near maximal increase in tension; (2) contracted state during which a further slow increase in tension may occur; (3) relaxation; and (4) relaxed state. The temperature coefficients (Q₁₀) and Arrhenius activation energy (u) values were calculated for the duration of the above states, for the tensions developed, and for the oxygen consumption/ml/sq m/min. The Q₁₀ values for the duration of the phase of initial contraction and for the tension developed varied from 1.09 to 1.38, with (u) values of 2,600 calories to 6,040 calories. In contrast, the duration of the contracted state and the time required for isometric relaxation had Q₁₀ values varying from 2.7 to 3.4, and (u) values of 18,390 to 22,100 cal/mol. A linear, inverse, exponential relationship existed between the metabolic rate and either the duration

MGH.02:005, 006; MIT.02:002

of the contracted state or the time required for relaxation. Contraction possesses the characteristic of a physical process involving ionic interaction, diffusion, or viscous flow. Relaxation has the kinetic characteristics of an enzymatic reaction associated with and dependent upon chemical bond energy or electron transfer. Relaxation of ventricular heart muscle thus has the characteristics of an active metabolic process, its rate being related directly to thyroid hormone activity and temperature. RHYTHMIC ACTIVITY INDUCED BY PHOTIC STIMULATION IN RELATION TO INTRINSIC ALPHA ACTIVITY OF THE BRAIN IN MAN, by J. S. Barlow. [1958] 6p. diags. (Bound with its Progress rept., July 1958) [AF 49(638)98] Unclassified

Presented at annual meeting of the Biophys. Soc., Cambridge, Mass., Feb. 1958.

Also published in EEG Clin. Neurophysiol., v. 12: 317-326, 1960.

The relationship between intrinsic rhythmic activity and the response to slow rates of repeated light flashing has been studied in man, using recordings made from scalp electrodes on the occiput. As a measure of rhythmic activity, and in particular, its frequency, autocorrelations were made from magnetic tape recordings of the original data. For study of responses evoked by stroboscopic stimulation, a great number of individual responses were averaged electronically by means of a modification of the same computer used to obtain the autocorrelations. The results obtained indicate a close relationship between intrinsic activity or α activity of the occipital cortex, and the activity which is induced by photic stimulation, at least so far as their respective frequencies are concerned. These results are in agreement with earlier research by others conducted on experimental animals, in which a similarly strong relationship was found in many instances, suggesting that the generators of these 2 types of electrical activity have similar properties. A great deal more information is necessary, however, in order to state whether or not the 2 generators are identical. (Contractor's abstract)

A method is presented for estimating adrenalin and noradrenalin in urine. It employs an ion exchange resin, Amberlite XE-64, for purification. The subsequent chemical analysis is based on the well-known fluorimetric method. The simultaneous estimation of the 2 hormones is accomplished by a multiple-filter technique of fluorimetry. The selection of appropriate sets of filters is based on careful study of the fluorescence spectra of the compounds concerned. Evidence indicates that a high degree of specificity has been attained. The method has been extensively employed in the diagnosis of pheochromocytoma. In 150 control patients, the highest 24-hr excretion values were 17 μ g. of adrenalin and 100 μ g. of noradrenalin. Seven cases of pheochromocytoma have been studied. The importance of small excesses of adrenalin is apparent in one of these cases. The possible significance of low noradrenalin excretion is discussed. (Contractor's abstract, modified)

CYCLES ON ABELIAN VARIETIES, by A. Mattuck. [1958] [11]p. (AF 18(603)91) Unclassified

Published in Proc. Amer. Math. Soc., v. 9: 88-98, Feb. 1958.

Algebraic homology with rational coefficients of the general complex Abelian variety are studied. It is found that in each complex dimension the only homology classes represented by algebraic subvarieties are the lone homology class of the linear section of that dimension and its rational multiples. Further the only homology classes of the torus "lying on" these subvarieties are those arising from the intersection of the subvarieties with the homology classes of the torus. The following theorem and corollary are demonstrated. Theorem: On the general Abelian variety V^n let $\sigma = \sum a_j \langle J \rangle$ be a basic rational p -cycle. If for each I of the type $(p-1, 1)$, where $i = (p-n)^+, \dots, r-1$, we have the relation $\sum_j a_j [1, J] = 0$ among the minors of the doubled Riemann matrix M , then $\sigma \sim E^{p-r} \cdot \tau$, where τ is a rational cycle. Corollary: The rank of the group of homology classes represented by p -cycles of rank r on the general Abelian variety V^n is $\binom{2n}{p-2r}$.

ON TRANSITIVE TRANSLATION FUNCTIONS, by J. W. Schlesinger. [1958] [4]p. (AF 18(603)91)

Unclassified

Published in Proc. Amer. Math. Soc., v. 9: 507-510, May 1958.

Let p be a continuous map of the space E onto B . According to the definition of W. Hurewicz (Proc. Nat'l. Acad. Sciences, v. 41: 956-961, 1955) the triple (E, B, p) is a fibre space if there exists a continuous lifting function λ which assigns to each pair (e, ω) (consisting of a point $e \in E$ and a path ω in B starting at the point $p(e)$) a path $\lambda(e, \omega)$ in E starting at e such that $\lambda(e, \omega)$ projects onto ω . For any two points $b_0, b_1 \in B$ and any path ω from b_0 to b_1 , one may define a "translation function"

$\tau(\omega): p^{-1}(b_0) \rightarrow p^{-1}(b_1)$ by the formula $[\tau(\omega)](e) = [\lambda(e, \omega)](1)$ for any $e \in p^{-1}(b_0)$. This translation function is said to be transitive if for any three points $b_0, b_1, b_2 \in B$ and paths ω_1 from b_0 to b_1 and ω_2 from b_1 to b_2 , $\tau(\omega_1 \omega_2) = \tau(\omega_2) \circ \tau(\omega_1)$ (where $\omega_1 \omega_2$ is the path obtained by traversing ω_1 and ω_2 in succession). This paper supplies the following answer to the question of when transitive translation functions exist for fiber bundles: If a bundle over a finite polyhedron has a structural group G with no small subgroups, then it has a transitive translation function if and only if it is equivalent in G to an H bundle where H is a totally disconnected subgroup of G . The central result of this paper is that if τ is a transitive translation function and the structural group has no small subgroups, then $\tau(\omega)$ depends only on the homotopy class of ω .

ON HOMOGENEOUS RIEMANNIAN MANIFOLDS, by W. Ambrose and I. M. Singer. [1958] [23]p. (AF 18-(603)91)

Unclassified

Published in Duke Math. Jour., v. 25: 647-669, Dec. 1958.

A homogeneous Riemannian manifold can be characterized in terms of the behavior of the curvature under parallel translation. The manifold M is characterized through the existence of a certain function T which assigns to each x in any tangent space an anti-symmetric linear transformation T_x which satisfies the following relations

$$\Delta_z R_{x,y} = -R_{T_z x, y} + R_{T_z y, x} - [R_{x,y}, T_z]$$
 and

$$\Delta_y T_x = -T_{T_y x} + [T_y, T_x]$$
 where $R_{x,y}$ is the curvature of M and Δ_x is the covariant derivative. Inversely, if M is a complete and simply connected Riemannian manifold and if there exists a transformation T_x satisfying the above conditions, then M is linear and homogeneous. If $T_x = 0$, then M is symmetric. Two separate proofs are given for the above. The first proves that M is homogeneous by constructing a Lie group G such that M is isometric and for which M is a quotient space. The second shows that the curvature parallel translates the same way along singly broken geodesics emanating from any two points of M and shows that there is an isometry carrying any point into any other.

SUBLIMATION MASS TRANSFER THROUGH COMPRESSIBLE BOUNDARY LAYERS ON A FLAT PLATE, by T. K. Sherwood and O. Träss. Final rept. Sept. 1, 1958, 317p. incl. illus. diagrs. tables, refs. (AFOSR-TR-58-131) (AF 48(638)234) AD 203713

Unclassified

Data are obtained on rates of mass transfer from a flat plate to air at speeds up to Mach 3.5. The range of the present knowledge of mass transfer was extended by this data, and a means of checking compressible flow theories was provided. Naphthalene was sublimed from an adiabatic sharp-edged flatplate model exposed to subsonic and supersonic air streams in a continuous-type wind tunnel. Sensitive strain gages equipped with pick-up needles touching the naphthalene surface were used to obtain surface profile traces. One such trace was made before and after each test, their difference giving the thickness decrease of the naphthalene coating and thus the amount sublimed. The resulting profiles of naphthalene thickness decrease gave a continuous sequence of point mass transfer coefficients in the laminar region, through the transition zone, and in the turbulent region. Thus, continuous local friction coefficients over these flow regimes as well as an accurate demarcation of the transition zone were obtained. Experimental results agreed closely with the developed theory.

AN EXPLORATORY INVESTIGATION ON SOME AERO-DYNAMIC HEATING EFFECTS ON FLUTTER, by S. I. Gravitz. Sept. 1958, 83p. incl. illus. diagrs. tables, refs. (Technical note no. 74-1) (AFOSR-TN-58-972) (AF 49-(638)219) AD 205600
Unclassified

An experimental and theoretical investigation is made of the effects of rapid change in Mach number on the flutter characteristics of supersonic wings; and the feasibility of utilizing a heated model in a low stagnation temperature wind tunnel to observe aerodynamic heating effects is studied. Some existing theoretical techniques are briefly reviewed and applied to the simple case of a high aspect ratio solid double wedge wing undergoing rapid deceleration from a high Mach number to a lower one. The wing is flutter unstable both at the lower and higher Mach numbers, but the thermal stresses experienced in the transition are such as to make the wing transiently stable. Estimates of heat transfer coefficients and recovery factors are used to evolve approximate transient temperature and stress distribution which result in changes in the effective stiffness of the wing. Piston flutter theory is adapted to give convenient expressions for quantitative estimates of these changes. A series of experiments conducted in the M.I.T. Supersonic Blowdown Wind Tunnel show that for a model wing heated to a uniform temperature of about 500° and then injected into the airstream, the flutter behavior is appreciably different from that of an identical cold wing. The observed changes, while substantial, are not so large as predicted by the theory used. Some comments are made on factors tending to alleviate aerodynamic heating effects on flutter.

A mathematical analysis was made of propulsion systems necessary to move a desired useful payload to a given destination in as feasible and as efficient a manner as possible. The specific impulse is the most significant factor in the performance of the propulsion system of contemporary chemical rockets. Optimum specific impulse was shown to depend on the particular duty for which the engine was designed. Typical characteristics for various types of reaction engines as they are currently conceived are presented.

AUSTENITIC Cr-Fe-Ni ALLOYS RESISTANT TO STRESS CORROSION CRACKING IN MAGNESIUM CHLORIDE, by H. H. Uhlig, R. A. White, and J. Lincoln, Jr. Jan. 15, 1957, 9p. incl. table. (AFOSR-TN-57-37) (AF 18(600)1221) AD 115075
Unclassified

Also published in Acta Metallurgica, v. 45: 473-475, Aug. 1957.

The results of corrosion studies on Cr-Ni-Fe alloys are given. Austenitic or ferritic Cr-Ni-Fe alloys were produced which resisted cracking for a period of one week or more in a test solution of boiling 42% MgCl₂. The authors suggest that a precipitation process is probably responsible for susceptibility to cracking and the phase transformation from austenitic to ferritic during cold working plays a role, but is not a necessary condition for susceptibility.

STRESS CORROSION CRACKING OF AUSTENITIC STAINLESS STEELS, by H. H. Uhlig, J. Lincoln, Jr., and R. A. White. Apr. 1, 1957 [53]p. incl. diagrs. tables, refs. (AFOSR-TR-57-24) (AF 18(600)1221) AD 120498
Unclassified

Resistance of the Cr-Ni-Fe austenitic alloys to stress corrosion cracking is markedly improved if the alloys are plastically deformed at low temperatures, such as in liquid nitrogen. The alloys of 18-8 composition can be made immune to cracking, whether stressed at high or low temperatures, by reducing nitrogen and carbon contents to about 0.01% or less. For the stable austenitic compositions such as 20% Cr-20% Ni, nitrogen rather than carbon appears to be the responsible interstitial component causing cracking. When nitrogen is reduced to 0.01% or less in this composition alloy, no cracking occurs within the maximum test period of several days. It appears that paths along which stress corrosion cracks form are established by a precipitate in which N or C participate. Nitrogen and carbon, aided by cold work, diffuse to clusters of dislocations induced by plastic deformation, where they are in favorable position and concentration for precipitation as carbide or nitrides should the lattice be deformed further. The diffusion and precipitation processes are inhibited at low temperatures. Alloyed nickel increases resistance to stress corrosion cracking apparently by inhibiting nucleation of carbides or nitrides.

CHEMICAL FACTORS AFFECTING STRESS CORROSION CRACKING OF 18-8 STAINLESS STEELS, by H. H. Uhlig and J. Lincoln, Jr. [1957] [8]p. incl. illus. diagrs. table, refs. (AF 18(600)1221) Unclassified

Published in Jour. Electrochem. Soc., v. 105: 325-332, June 1958.

Transgranular stress corrosion cracking of 18-8 Type 304 specimens in boiling 42% $MgCl_2$ does not depend on rate of stressing (< 1 sec to 10 min) nor on small variations in degree of plastic deformation. Cold worked specimens fail in shorter times than annealed, sheared specimens. Addition of HCl to $MgCl_2$ decreases cracking time whereas addition of NaOH increases the time. Pre-exposure of unstressed specimens to $MgCl_2$ slightly de-

creases cracking times of the same specimens subsequently stressed. Cracks occur along sheared edges of unstressed specimens despite stress relief anneal at 375°C for 2 hr. Cracks propagate along sheared edges of U-bend specimens at 0.5 to 1 cm/hr through that portion of the specimen cross section in tension, the rate being much slower through the remaining cross section. No induction time for cracks to initiate was observed. Sizeable pits are not necessary for cracking in $MgCl_2$, but appear to be essential in media like NaCl

which in absence of pitting is not particularly active in causing cracking. The pitting mechanism produces concentrated low pH metal chlorides (e.g., $FeCl_2$)

within the pit, which like $MgCl_2$ cause immediate cracking. Oxygen is required for pitting of 18-8 by NaCl solutions as shown by Uhlig and Morrill, and hence also for stress corrosion cracking as observed by Williams and Eckel, but oxygen is not necessary in $MgCl_2$ or $FeCl_2$.

Cracking can be prevented by cathodic protection at a C.D. of 0.03 ma/cm² or higher. Anodic C.D. up to 0.01 ma/cm² were found to have no effect on cracking tendency, nor did coupling of 18-8 to Pt.

AUDITORY GENERALIZATION IN THE PIGEON, by H. M. Jenkins and R. H. Harrison. Apr. 1957, 3p. (AFOSR-TN-57-182) (AF 18(603)85) AD 126477

Unclassified

Using a Skinner key-pecking apparatus, generalization gradients are plotted in terms of the rate of response in extinction to tones of different frequencies. The effects of two training procedures are examined. In one,

a discrimination between the presence and absence of a tone is formed using differential reinforcement. The other procedure does not involve discrimination training. Without prior discrimination training, generalization tests revealed no systematic change in response rate over the test stimuli. On the other hand, with prior discrimination training an orderly gradient of response rate along the dimension of tonal frequency was found. (Contractor's abstract)

Massachusetts Inst. of Tech. Dept. of Economics and Social Science, Cambridge.

AUDITORY GENERALIZATION IN THE PIGEON, by H. M. Jenkins and R. H. Harrison. Final rept. Apr. 30, 1958, 29p. incl. diagrs. tables, refs. (AFOSR-TN-58-443) (AF 18(603)85) AD 158248 Unclassified

A test was made of the hypothesis that differential training would produce steeper gradients of auditory generalization on frequency than those produced by non-differential training. The subjects were experimentally naive, 2-yr old, white carneaux pigeons. A Skinner automatic key-pecking apparatus was used to study the auditory generalization along the frequency dimension of pure tones. The generalization gradients were obtained in extinction by observing responses to test stimuli consisting of various frequencies and a no-tone condition. Data from 2 experiments tend to confirm the hypothesis. The effect of differential training in greatly sharpening generalization gradients was attributed to its role in placing auditory stimulus, as a whole, in control of the response. Steep gradients of generalization were obtained following nondifferential training with visual stimuli. Localization of the visual stimulus on the response key was considered to be an important determinant of the difference in the behavior of auditory and visual stimuli.

SUMS OF THREE SQUARES, by N. C. Ankeny. [1957] [4]p. (AF 18(603)90) Unclassified

Published in Proc. Amer. Math. Soc., v. 8: 316-319, Apr. 1957.

The author gives a proof of Legendre's theorem that every positive integer m which is not of the form

$4^a(8n+7)$ is representable as a sum of three integral squares; this proof uses only Minkowski's theorem on the existence of an integer point in a convex body, Dirichlet's theorem on the existence of primes in an arithmetic progression, and simple facts on quadratic reciprocity and on representation by two squares. The details are

given for $m \equiv 3 \pmod{8}$ and square-free, the modifications for other cases being briefly indicated. The essential idea is to represent m as

$$R^2 + 2(qx^2 + bxy + hy^2),$$

where R is a linear form in x, y, z , and q, b, h are suitable integers satisfying $b^2 - 4qh \equiv -m$. The construction of these is such as to permit a proof that $qx^2 + bxy + hy^2$ has no prime factor $\equiv 3 \pmod{4}$ dividing it to an odd power exactly, whence it follows that $2(qx^2 + bxy + hy^2)$ is a sum of two squares. (Math. Rev. abstract)

number $m = m(A, B, C, N, E)$, $0 < m < \infty$, such that (1) possesses a solution $f(x, t)$ valid on the interval $0 \leq t < 1/m$. This solution is continuous, analytic in t for each x , and integrable in x for each t . The proof of this lemma consists in constructing a solution. By direct substitution it can be verified that the series (2) $f(x, t) = \sum_{k=0}^{\infty} a_k(x)t^k$ represents a formal solution of the equation, where

$$a_0(x) = f(x, 0), \quad a_{k+1}(x) = \frac{1}{k+1} \left\{ \sum_{i+j=k} [a_i, a_j] + L a_k \right\}.$$

It is shown that the series (2) is uniformly convergent on the interval $0 \leq t < 1/m$ and satisfies all the conditions of the lemma. This solution is then continued for $t < 1/2m$ and successively to larger values of t ; and the uniqueness of the solution is established by showing that the local existence intervals cover the whole interval $0 \leq t < \infty$. A SCALAR TRANSPORT EQUATION, by Z. A. Melzak. [1957] [14]p. [AF 18(603)90] Unclassified

Published in Trans. Amer. Math. Soc., v. 85: 547-560, July 1957.

This paper is concerned with the existence and uniqueness of the solutions of the following equation

$$(1) \quad \frac{\partial f}{\partial t} = [f(x, t), f(x, t)] + Lf(x, t),$$

where $[f, g]$ and Lf are given by

$$[f, g] = \frac{1}{2} \left\{ \int_0^x f(y)g(x-y)\varphi(y, x-y)dy - f(x) \int_0^x g(y)\varphi(x, y)dy - g(x) \int_0^x f(y)\varphi(x, y)dy \right\},$$

$$Lf = \int_0^x f(y)\psi(y, x)dy - \frac{f(x)}{x} \int_0^x y\psi(x, y)dy.$$

Here the variables x, y, t are non-negative and the functions $f(x, 0)$, $\varphi(x, y)$ and $\psi(x, y)$ are assumed to be known. The functions φ and ψ are assumed to satisfy the following hypotheses: (H_1) $\varphi(x, y)$ is continuous,

$$0 \leq \varphi(x, y) - \varphi(y, x) \leq \sup \varphi(x, y) - A < \infty;$$

(H_2) $\psi(x, y)$ is continuous,

$$0 \leq \psi(x, y) \leq \sup \psi(x, y) = C < \infty,$$

$$\int_0^x y\psi(x, y)dy \leq x, \quad \int_0^x \psi(x, y)dy \leq E - 1 < \infty.$$

The proof of uniqueness depends on the following key lemma: Let $f(x, 0)$ be a continuous, non-negative bounded and integrable function. Let $0 < 0 \sup f(x, 0) = B < \infty$ and $\int_0^x f(x, 0)dx = N < \infty$. Let $\varphi(x, y)$ and $\psi(x, y)$ satisfy hypotheses (H_1) and (H_2) . Then there exists a

AN EXTENSION OF A THEOREM OF MANDELBROJT, by R. A. Kunze. Oct. 30, 1957, 8p. (AFOSR-TN-57-650) (AF 49(638)42) AD 136710 Unclassified

Also published in Proc. Amer. Math. Soc., v. 9: 553-557, Aug. 1958.

Mandelbrojt has given several interesting theorems concerning Fourier transforms and analytic functions. A generalization to n -dimensions has been given of a theorem concerning the analytic continuation into the right half-plane of a function $F \in L_{\infty}$. Let G be an E_n which is to be considered as a vector group. The dual of a cone C in G is a cone C' in the dual group G' consisting of all x such that $(x, t) \geq 0$ for all t in C . Let $T(C')$ be the set of all complex vectors $x + iy$ with $x \in C'$ and $y \in C'$ and $y \in G'$. Let $S(C)$ be the set of the complex vectors $v + iy$, where v is the apex of C and $y \in G'$. This generalization can be accomplished as follows: either $F \in E_{\infty}(G')$ or C , a closed cone, convex with G from the vertex to the origin, and the interior of which is non-empty, or a is an element of C . Suppose each $t \in C$ - a corresponds to a function $K \in L_1(G')$ where $K * F = 0$, with $k(t) \neq 0$, where k is the inverse Fourier transformation of K . There exists then an analytic function F_0 on the interior of $\Gamma(C)$.

FRACTIONAL INTEGRALS ON N -DIMENSIONAL EUCLIDEAN SPACES, by E. M. Stein and G. Weiss.

MIT.19:003, 004; MIT.05:003

Dec. 2, 1957, 21p. (AFOSR-TN-57-689) (AF 49(638)42) AD 136718
 Unclassified

Also published in Jour. Math. and Mech., v. 7: 503-514, July 1958.

Let x denote a general point in Euclidean n -space E^n , let $|x|$ be the absolute value of the vector point x , and let dx be the n -dimensional volume element. Let $T_\lambda f(x) = \int f(y) |x-y|^{-\lambda} dy$. The principal result of the present paper is as follows. Let $0 < \lambda < n$, $1 < p < \infty$, $\alpha < n - n/p$, $\beta < n/q$, $\alpha + \beta \geq 0$, $1/q = 1/p + [(\lambda + \alpha + \beta)/n] - 1$. If $p \leq q < \infty$, then $\|T_\lambda f(x) |x|^\beta\|_q \leq A \|f(x) |x|^\alpha\|_p$, where A depends upon p , α , β , and λ but not upon f . The demonstration splits into two cases $q = p$ and $q > p$, the former being the more difficult. In the course of the demonstration a number of inequalities are generalized from 1 to n dimensions which are of independent interest. For example, it is proved that if $K(u,v) \geq 0$ is defined for $u \geq 0, v \geq 0$, is homogeneous of degree $-n$, and satisfies, for some $p \geq 1$, $\int_0^\infty K(1,t) t^{n-1-n/p} dt < \infty$, and if $Uf(x) = \int K(|x|, |y|) f(y) dy$, then $\|Uf\|_p \leq A \|f\|_p$. ON THE INTERPOLATION OF ANALYTIC FAMILIES OF OPERATORS ACTING ON H^p SPACES, by E. M. Stein and G. Weiss, Dec. 2, 1957, 43p. refs. (AFOSR-TN-57-692) (AF 49(638)42) AD 136719 Unclassified

Also published in Tôkoku Math. Jour., v. 9: 318-339, 1937.

Let \mathcal{P} be the class of polynomials $P(w)$ with complex coefficients and let

$$\|P\|_p = \sup_{0 \leq r < 1} \left\{ (2\pi)^{-1} \int_0^{2\pi} |P(re^{i\theta})|^p d\theta \right\}^{1/p} \quad (p > 0).$$

Let (M, μ) be a measure space and let $L^q(M, \mu)$ denote the space of all complex-valued measurable functions f for which

$$\|f\|_q = \left\{ \int_M |f|^q d\mu \right\}^{1/q} \quad (q > 0)$$

is finite. Let us now assume that $T_z, 0 \leq \operatorname{Re} z \leq 1$, is an analytic family of linear transformations of \mathcal{P} into $L^1(M, \mu)$ which is admissible growth; that is, for every $g \in L^1(M, \mu)$ there exist constants $0 < B, 0 < b < \pi$, such that

$$\left| \int_M (T_z \Omega) g d\mu \right| \leq B \exp \exp b |\operatorname{Im} z| \quad (0 \leq \operatorname{Re} z \leq 1).$$

The principal result of the paper asserts that if T_z is

analytic and of admissible growth; and if p_0, p_1, q_0, q_1 are positive numbers such that for all $y, -\infty < y < \infty$, and all P in \mathcal{P} ,

$$\|T_{iy} P\|_{p_0} \leq A_0(y) \|P\|_{q_0}, \quad \|T_{1+iy} P\|_{p_1} \leq A_1(y) \|P\|_{q_1},$$

where $|A_i(y)| \leq C_i \exp \exp c_i |y|, 0 < C_i, 0 < c_i < \pi$ ($i = 0, 1$); then for each $t, 0 < t < 1, \|T_t P\|_{q_t} \leq A \|P\|_{p_t}$ where $p_t^{-1} = (1-t)p_0^{-1} + tp_1^{-1}, q_t^{-1} = (1-t)q_0^{-1} + tq_1^{-1}$, and where A is independent of P . This generalizes earlier results of Calderón and Zygmund and Salem and Zygmund which dealt with the case in which the transform T_z is a constant function of z . (Math. Rev. abstract)

ON SOME PROBLEMS OF GEL'FAND, by K. Hoffman and I. M. Singer, July 28, 1958, 46p. (AFOSR-TN-58-595) (AF 49(638)42) AD 162119 Unclassified

Also published in Uspehi Mat. Nauk, v. 14(3): 99-114, 1959.

Questions raised on commutative Banach algebras by Gel'fand are answered in the paper. Sup-norm algebras are uniformly closed subalgebras of the algebra $C(Y)$ of all continuous complex-valued functions on a compact Hausdorff space Y , assumed to contain the constant functions. The sup-norm algebra A is used to denote $S(A)$, the space of maximal ideals, i.e., $S(A)$ is the set of all homomorphisms of the algebra A onto the complex numbers with the weakest topology which makes all the elements of A continuous on that set. The questions relate to the possibilities of various operations and mappings upon various sub-algebras and subsets of A .

Torsion of a bar with a sharp longitudinal notch produces plastic yielding at the tip of the notch for any magnitude of the applied torque, however small. It is shown that the shape of the region of incipient plastic yielding can be found for any shape of the cross section provided the solution of the corresponding elastic problem is known. The elastic stress field near the tip of a sharp notch in pure shear similar to the elastic stress field near a similar longitudinal notch in torsion. Since the shape of the plastic region produced at the notch in pure shear is known, the corresponding region in the torsion case can be derived by analogy.

In tests on polycrystalline copper and aluminum, the ratio of the yield stress to modulus of elasticity was found to be strongly dependent on temperature. Also, it was shown that the change of the yield stress with temperature of a material at a given temperature and deformed to a given yield stress, but not necessarily to the same strain, does not depend on previous mechanical thermal history. Likewise, for a material at a given temperature and deformed to a given yield stress, the rate of work hardening is independent of the temperature of prior stressing. (Contractor's abstract)

A solution is presented for supersonic flow of air in a round tube with uniform injection of a foreign gas through the wall. The flow is assumed to be divided into two regions, a boundary layer developing on the tube wall and an isentropic core. Starting from the equations of change derived from kinetic theory, the tensor equations are expanded in cylindrical coordinates and subjected to an order of magnitude analysis to produce boundary layer equations. Introduction of a stream function and power series in a modified length Reynolds number with coefficients which are functions of a wall distance parameter permit separation of the partial differential equations into an infinite series of sets of ordinary differential equations. The viscosity and thermal conductivity of the gas mixture were approximated by products of quadratics in temperature and concentration and the binary diffusion coefficient by a quadratic in temperature only. The quadratics were fitted by least square methods to predictions calculated from kinetic theory. The first three sets of differential equations were integrated numerically using the modified Adams method on the Whirlwind and later the I.B.M. 704 computer of the M.I.T. computation center. The wall boundary conditions for the linear and non-linear two-point boundary-value problems were located by repeating a process of linear

It is postulated that shear fracture occurs in a perfectly plastic material when a critical shear strain is attained throughout a critical volume of material. This postulate is combined with the classical equations of plasticity to predict when cracking will initiate from a notch at nominal shear stresses below the yield stress, when the crack will become unstable on increase of stress, and when unstable cracking will occur if a notch is cut while a constant nominal stress is maintained. Tests on aluminum foil under biaxial tensile stress show results which are qualitatively similar to those predicted by the theory.

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Published in Bull. Amer. Phys. Soc., Series II, v. 2: 21, Jan. 30, 1957.

A description will be given of one of the BNL neutron diffraction spectrometers which has been modified for use as a polarized beam spectrometer. By using a magnetized, ferromagnetic crystal of suitable scattering properties as a monochromator, a beam of high polarization value is available for further study. Crystals of Fe_3O_4 have been used as polarizing monochromators and, when due allowance is made for internal depolarization (arising from incomplete magnetic saturation), the theoretical polarization of 100% is accounted for within experimental error of 1%. The magnetic scattering by crystals of iron and nickel has been studied and the magnetic scattering effects are found to be much enhanced over that found with unpolarized radiation. Other advantages of the polarized beam technique will be outlined.

A polarized-neutron-beam spectrometer has been used

to determine the room-temperature magnetic structure of ordered Fe_3Al . The results show that the aluminum atoms possess no magnetic moment and that the iron moments differ for the two sublattice sites. On one sublattice, where the iron atoms are surrounded by both iron and aluminum nearest neighbors, the average moment/atom is found to be $1.46 \pm 0.1\mu B$. On the other sublattice, where the iron atoms have only iron atoms as nearest neighbors, the average moment/atom is found to be $2.4 \pm 0.1\mu B$. The data taken on higher-order magnetic reflections also permitted a comparison of the magnetic form factors for each of the different sites with that of metallic iron. No difference was observed to within the $\pm 2\%$ accuracy of the measurements on the form factor. (Contractor's abstract)

Presented at meeting of the Amer. Phys. Soc., New York, Jan. 30-Feb. 2, 1957.

Abstract published in Bull. Amer. Phys. Soc., Series II, v. 2: 21-22, Jan. 30, 1957.

The theory of neutron scattering by magnetic crystals as given by Halpern and Johnson predicts changes in the polarization state of the neutron beam upon scattering which depend upon the relative orientation of the neutron polarization vector and the crystal magnetic axis. This effect was investigated experimentally with a polarized beam spectrometer using single crystals of Cr_2O_3 and $\alpha\text{-Fe}_2\text{O}_3$ in which reside unique antiferromagnetic axes. Studies were made on several different reflections in both crystals for a number of different temperatures both below and above the Néel point. Results support the theoretical predictions and indicate directions for the moments in these crystals consistent with previous work. In addition to the above, a more detailed study of the polarization changes in the reflection in $\alpha\text{-Fe}_2\text{O}_3$ at room temperature on application of a magnetic field has also been carried out. The results indicate that the principal source of the parasitic ferromagnetism in hematite is essentially independent of the orientation of the antiferromagnetic domains within the crystal. THEORY OF λ -POINTS AND THE SYMMETRY OF THE SUPERFLUID STATE, by L. Tisza. [1957] [3]p. incl. table. (Sponsored jointly by [Signal Corps, Air Force Office of Scientific Research, Office of Naval Research under DA 36-039-sc-64637] and Air Force Office of Scientific Research under AF 49(638)95) Unclassified

Published in Proc. Fifth Internat'l. Conf. on Low Temperature Phys. and Chem., Madison, Wis. (Aug. 26-31, 1957), Madison, Univ. of Wisconsin Press, 1958, p. 124-126.

The classical Gibb's theory predicts the possible types of phase equilibria from principles of thermodynamic stability. The only major shortcoming is the failure to account for the λ -points in solids and in liquid helium. It is possible to complete the Gibbsian program and subsume λ -points under thermodynamic stability considerations, provided the definition of phase is sharpened to include intrinsic coordinates specifying the symmetry properties of the system. The use of such non-classical parameters in thermodynamics has been tried before, but usually in conjunction with simplifying assumptions leading to a loss of thermodynamic rigor. The present theory is developed rigorously from a set of postulates applicable to experience within well understood limits of validity. This last proviso is inherent even in the

classical theory; it stems from the fact that the concept of homogeneous phase corresponds only within certain limits to the actual distribution of matter. (Contractor's abstract)

GENERALIZED PHASE RULE AND THE SYMMETRY OF THE SUPERFLUID STATE, by L. Tisza. [1958] 6p. incl. refs. (Sponsored jointly by Signal Corps, Air Force Office of Scientific Research, and Office of Naval Research under [DA 36-039-sc-64637] and Air Force Office of Scientific Research under [AF 49(638)95]) AD 152218 Unclassified

Also published in Phys. Rev., v. 110: 587-589, Apr. 15, 1958.

Phases which are otherwise identical may differ by symmetry, crystalline twin phases being a familiar example. The existence of these phases can be taken into account by assigning to a system a "symmetry number" which would ordinarily be 0. An ordered binary mixed crystal is regarded as a 2-phase system, the phases consisting of domains with different type of order; these crystals are assigned a symmetry number equal to unity. Gibb's deduction of the phase rule is reformulated so that the effect of the symmetry is taken into account. Broadly speaking a symmetry number equal to 1 gives rise to an additional degree of freedom. If 2 coexisting phases tend to become identical, the boundary of their coexistence is known as "critical phase." In vapor-liquid equilibrium the critical phase is restricted to a point. In accordance with the author's generalized phase rule the critical phase for an ordered crystal has 1 degree of freedom and is known as the λ -curve. On account of the similarity between the λ -transitions of liquid helium and of mixed crystals, it is concluded that the ground state of liquid helium must be doubly degenerate, contrary to all current views on the nature of superfluids. It is asserted that the phase rule is not a direct consequence of the laws of thermodynamics.

A theoretical method is developed for estimating aerodynamic loads on slender, symmetrical configurations performing small lateral oscillations of limited reduced frequency in a supersonic main stream. This procedure extends an iterative technique originally proposed by Adams and Sears, and applied by Landahl to similar configurations in transonic flow. As a practical example, stability derivatives are calculated for a plane wing centrally mounted in a body of revolution. Under certain limitations on the rapidity of the oscillations, all derivatives prove to be independent of changes in reduced frequency. Many of them, notably the acceleration derivatives, differ appreciably from the results of ordinary slender body theory, being sensitive both to changes in the wing aspect ratio and the diameter of the central body. Especially significant are the effects of these two parameters and the unsteadiness of the flow on the fixed-axis damping in pitch. (Contractor's abstract)

FORCES AND MOMENTS ON OSCILLATING SLENDER WING-BODY COMBINATIONS AT SUPERSONIC SPEED. PART II. APPLICATIONS AND COMPARISON WITH

EXPERIMENT, by H. Kennet, H. Ashley, and R. L. Stapleford. Dec. 1957, 53p. incl. diagrs. tables. (MIT Fluid Dynamics Research Group rept. no. 57-5) (AFOSR-TN-58-114) (AF 18(600)961) AD 152022; PB 147041
Unclassified

Several applications and extensions are described of a theoretical method for estimating aerodynamic loads on slender wing-body configurations performing small oscillations of limited reduced frequency in a supersonic main stream. This procedure involves an iterative technique in ascending orders of aspect ratio and frequency, originally applied to similar shapes in transonic flow. The theory is moderately successful as compared with experimentally determined lift- and moment-curve slopes for a family of delta-wing-body combinations in steady flow. It provides reasonable estimates of the damping in pitch measured on a particular rocket model over a range of supersonic Mach numbers. When applied to a series of possible missile shapes with systematically varied wing planforms, it reveals a strong influence of planform geometry on damping in pitch which cannot be calculated by the conventional slender-body approximation. ON SIMPLE WAVES IN PERFECT AND DISSOCIATING GASES: THEORY AND APPLICATIONS, by H. Kennet. Feb. 1958, 49p. incl. diagrs. refs. (MIT Fluid Dynamics Research Group rept. no. 58-1) (AFOSR-TN-58-302) (AF 18(600)961) AD 154212; PB 143511
Unclassified

A theoretical method is developed for estimating aerodynamic loads on oscillating airfoils in dissociating flow, when the flow is in dissociative equilibrium. This procedure is based on a method of solution originally prepared by Lighthill for the case of a perfect fluid. When the flow is hypersonic, yet real gas effects are negligible, the perfect fluid solution for the prediction of loads on such oscillating airfoils is modified by taking into account the entropy changes at the leading edge. The extension is limited to simple harmonic oscillations with small amplitude-to-airfoil-thickness ratios. It is shown that the changes in the stability derivatives due to the modified theory are small for the thickness ratios and Mach numbers investigated. An extreme case in which real gas effects are not negligible was also investigated.

A series of experiments was performed to define the flow field on the upper surface of high aspect ratio swept wings and narrow delta wings at high angles of attack. It was found that near the root section of either type of wing, the flow is conical. The edge of the vortex sheet which originates at the leading edge is a straight line whose position relative to the leading edge depends only on incidence. On swept wings, the vortex edge turns downstream as soon as the vortex sheet covers the front half of the wing chord, and the flow under the vortex sheet outboard of that turning point is uniform and parallel to the leading edge of the wing. On narrow delta wings the conical symmetry persists almost to the trailing edge.

The influence of a solid object upon the velocity distribution of gas atoms in free molecule flow is studied. A concept of shadow flow makes it possible to consider two distinct velocity categories, and in principle facilitates the calculation of the velocity distribution function at any point in space. Surface adsorption is considered and a cosine dependence of diffuse reflection is found to be useful. (Contractor's abstract, modified)

Experimental and theoretical evidence is assembled which suggests that oscillatory aeroelastic instability (flutter) is very unlikely at the structural-to-fluid mass ratios typical of hydrodynamic operation. Flutter data obtained in high-density fluids are reviewed, and various sources of inaccuracy in its theoretical prediction are analyzed. The need is expressed for more precise means of analytically representing both dynamic-elastic systems and three-dimensional unsteady hydrodynamic loads. For a simple hydrofoil with single degrees of freedom in bending and torsion, the theoretical influence of several significant parameters on high-density flutter is calculated and discussed. Recommendations are made for refinements to existing techniques of analysis to include the presence of channel boundaries, free surfaces, cavitation or separated flow.

A dielectrometer, using the standing-wave method with circular wave guide, has been developed which permits measurements of the complex permittivity and permeability of materials of 50 kmc. The instrument is capable of measuring relative dielectric constants from 1 to 100 and loss tangents as low as 0.0001. Only small samples are required and measurements can be made over a wide temperature range up to 1200°C. Special developmental problems concerning the crystal detector, slotted section, and probe are discussed in detail. Typical dielectric measurements on various samples are appended. The dielectric constant and loss of certain ceramics have been measured up to peak temperatures ranging from 500° to 1200°C with a view of the possible use of some of them as radome materials. Their characteristics are compared with those of certain glasses and crystals. Two main types of loss appear: conduction loss increasing exponentially with temperature, and absorptions centered in the infrared which prove to be nearly temperature-independent at microwave frequency at temperatures below the softening range. Both losses depend on chemical purity, but quantitative interrelation has not been established. A high purity alumina ceramic

A correction term is derived for the van't Hoff equation used for calculating the standard free energy from the dissociation pressure data. This term also allows such calculations in cases in which solid solutions are formed. The standard free energy for the reaction $4\text{Fe}_3\text{O}_4 + \text{O}_2 = 6\text{Fe}_2\text{O}_3$ has been calculated. (Contractor's abstract)

AN X-RAY METHOD FOR DETERMINING CATION DISTRIBUTION IN FERRITES, by P. Skolnick, S. Kondo, and L. R. Lavine. Feb. 1957, 17p. incl. diagrs. tables, refs. (Technical rept. no. 118) (Bound with its Technical rept. no. 117) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under [N5ori-07801]) AD 125503

Also published in Jour. Appl. Phys., v. 29: 198-203, Feb. 1958.

Cation distribution in many ferrites has been difficult to determine by x-ray diffraction since the scattering factors of such cations as Ni, Co, Mn, and Cu are close to that of Fe. By using radiation of a wave length close to the absorption edge of one of the cations (the ferric ion in this case), sufficient difference in x-ray scattering factors can be developed because of anomalous dispersion, thus allowing the cation distribution to be ascertained. This method was employed in the case of nickel ferrite. Ratios of intensities of the diffracted peaks for $\text{FeK}\alpha$ and $\text{FeK}\beta$ radiation from nickel ferrite was used to eliminate certain factors in the intensity equation which are difficult to calculate, e.g. the absorption and temperature factors. A least-squares technique was used to determine the best values of the cation distribution and the oxygen position for the intensity ratios obtained for seven reflections. It was found that the cation distribution coefficient was 0.48 ± 0.02 , in agreement with

MIT.08:076, 077; MIT.27:001, 002

the results obtained by magnetic-moment measurements and neutron diffraction. The oxygen positional parameter was found to be 0.240 ± 0.002 of the lattice parameter with an octahedral position as the origin. The method appears to be of general value in distinguishing between two elements distributed over nonequivalent positions in a crystal lattice when their x-ray scattering factors are almost equal. (Contractor's abstract)

ization, which arises primarily from the interaction between magnetic ions in the octahedral and tetrahedral lattice sites, is greatly affected by the changes in distribution due to quenching. It is hoped that with an understanding of the basic mechanisms involved in the simpler ferrites, such as magnesium ferrite, some idea of what might be occurring in the more complex combinations of technical importance might evolve.

Improvements have been made in the differential pulse transformer bridge which increase its inherent precision by approximately an order of magnitude and extend its range to measurements with electrolytes of twenty times the concentration previously feasible. A circuit is described which permits study of the errors introduced by polarization and self-heating when electrolytic conductivity measurements are carried out with rectangular voltage pulses. Also described is equipment for four-terminal resistance measurements with single-voltage pulses, which allows high-field conductance measurements free from errors caused by contact resistance, self-heating, and space-charge accumulation; it has been applied to semiconductors. Pure TiO is face-centered cubic (fcc) above ca. 950°C. The structure of samples annealed below this temperature is complex, consisting of 2 or possibly 3 phases not in equilibrium. Impurities and excess of O stabilize the fcc form at room temperature. The electrical resistivity of TiO (prepared by melting) is 2.81×10^{-4} ohm cm at room temperature, and increases with temperature between -162° and 362°C. The thermoelectric emf of TiO is of the same order of magnitude as that of metals. The directly measured density is less than that calculated from the lattice constant, indicating that 14.6% of the lattice positions are unoccupied. The properties of the products suggest that the TiO-phase oxides may be considered as solid solutions of O in Ti. X-ray investigations indicate that Ti_3O_4 probably does not exist. The trigonal unit cell of Ti_2O_3 is confirmed between room

MIT.27:003 - MIT.27:005

temperature and 350°C by using an improved technique for developing diffraction photographs; at room temperature $a = 5.428\text{\AA}$; $\alpha = 56^\circ 39'$. The lattice parameters change rapidly between 160° and 200°C, corresponding to the rapid increase in magnetic susceptibility. Ti_2O_3 is antiferromagnetic; $\chi_m = 1.09 \times 10^{-6}$ cgs at 30°C.

The thermal activation energy of electric conduction of Ti_2O_3 in the room-temperature region is 0.08 ev, about half of the observed optical activation energy (0.15 ev). The material is a p-type semiconductor at room temperature, but n-type conduction becomes dominant above 240°C. (Contractor's abstract)

Etching and handling techniques are described for the preparation of single-crystal samples of BaTiO_3 as thin as 1.5 μ , with an area of about 1 x 2 mm. The samples, supported by a Teflon-silicone tape that had cut-out windows, were etched in H_3PO_4 heated at about the BaTiO_3 Curie temperature at a rate of about 1 μ /min at 130°. Crystal thickness during etching was observed with a low-power microscope. Crystals prepared were sufficiently plane-parallel to permit the observation of interference bands in the near infrared.

TRANSITION TO THE FERROELECTRIC STATE IN BARIUM TITANATE, by D. Meyerhofer. Oct. 1957, 66p. incl. illus. diagrs. tables, refs. (Technical rept. no. 121) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-184110) AD 148238 Unclassified

Also published in Phys. Rev., v. 112: 413-423, Oct. 15, 1958.

The phase transition in BaTiO_3 at the Curie point was investigated on single crystals with simultaneous optical and electrical measurements. The direction of light propagation and that of the electric field vectors were

at right angles to each other, the orientation being suited for observations of birefringence, domain walls, and phase boundaries in polarized light. Electric polarization and dielectric constant measurements were made, and properties of the crystal were investigated. The resulting data were fitted to a thermodynamic equation developed by Devonshire (Phil. Mag., v. 40: 1040, 1949; v. 42: 1065, 1951; and Advances in Phys., v. 3: 85, 1954). The single crystals were grown by the Remeika method (Jour. Amer. Chem. Soc., v. 76: 940, 1954) from KF melt in Pt crucibles. The Curie points of the observed crystals varied between 110° and 120° because of impurities. The transitions to and from the cubic phase were divided into 2 categories. (1) In the slow transition, the new phase nucleates after some time at the edges of the crystal and then slowly grows by domain-wall motion; the temperature hysteresis was small but not zero. (2) In the fast change, the crystal was made to switch uniformly in 1 to 2 μ sec, the time being limited only by the mechanical response time of the crystal as determined by the piezoelectric resonances. OXYGEN IMPURITY IN SILICON SINGLE CRYSTALS, by A. Smakula and J. Kalnajs. Nov. 1957, 12p. incl. diagrs. tables, refs. (Technical rept. no. 122) (Sponsored jointly by Office of Naval Research, Signal Corps, and [Air Force Office of Scientific Research] under Nonr-184110) AD 148239 Unclassified

Also published in Jour. Phys. Chem. Solids, v. 6: 46-50, 1958.

Comparison of the lattice constant and density of "pure" silicon crystals and oxygen-contaminated crystals favors the substitutional position of oxygen in the silicon lattice rather than the interstitial. The spectral position and intensities of 15 infrared absorption bands for pure silicon crystals are given. The bands shift slightly toward higher frequency at ca. -130°C but no narrowing was detected. At -130°C the half width of the 1106- cm^{-1} band decreases from 32 to 18 cm^{-1} , the height increases by one third and the maximum shifts to 1120 cm^{-1} . After heat treatment at 1000°C for 48 hr, the intensity of the 1106 cm^{-1} band decreases strongly and three new weak maxima appear at 1065, 1160, and 1230 cm^{-1} . The integrated intensity is lower by only 15 per cent. The above bands coincide with the absorption bands of quartz. This indicates a segregation of SiO and the formation of SiO_2 units. Pure silicon crystals show a higher absorption tail above 1.2 μ , indicating strong strains. (Contractor's abstract)

MIT.27:010 - MIT.27:013

measurements followed the technique of A. Schmidt (Zeit. Physik, v. 117: 754, 1941). Experiments performed on a series of additively colored crystals indicated that, in spite of anomalous effects, useful ac measurements could be made. All samples showed a space-charge layer across which all or part of the applied voltage appeared. At elevated voltages, field emission set in; further increases in applied voltages developed an even greater fraction of the voltage across the bulk while the voltage across the barrier approached an upper limit. The barrier capacitance measured by transients compared well with that computed from the LF ac data. Samples dried for periods of about 1 wk in a P_2O_5 desiccator had about

1/3 the capacitances of samples promptly inserted into the sample holder after fabrication. Samples held in an evacuated sample holder showed no decrease in measured capacitance for similar periods. None of the samples showed pronounced decreases in photocurrent with age and illumination at room temperatures. (ASTIA abstract)

EFFECT OF IRON OXIDE PARTICLE SIZE ON NICKEL FERRITE FORMATION, by G. Economos and T. R. Clevenger, Jr. Nov. 1958, 15p. incl. diags. (Technical rept. no. 130) (Bound with its Technical rept. no. 129, AD 208636) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-184110) AD 208636a Unclassified

Five iron oxides of increasing particle-size distribution, mixed with nickel oxide of a constant-size range, were heated at various temperatures and time intervals. The extent of nickel ferrite formation, as influenced by particle size distribution of the iron oxide constituent, was measured with a compensating-coil magnetometer. Using the Jander relationship for this type of reaction, activation energies ranging from 54 to 70 kcal were computed for increasing particle size. These results are examined and compared with current procedures for the production of ferrite powders. (Contractor's abstract)

UNIVERSITIES IN TRANSITION, by A. von Hippel. Dec. 1958, 9p. (Technical rept. no. 132) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force Office of Scientific Research under Nonr-184110) AD 208637 Unclassified

Interdepartmental research centers are recommended as part of a tripartite system along with the university administration and academic departments. These centers should serve as a meeting ground for the various specialists necessary in the development of modern materials required for defense, technology, and for fundamental research. A "Center for Modern Materials Research" could produce both perfect and imperfect materials used in the studies of the properties of materials in order to engineer new materials as required. The centers should be decentralized in the administrative problems and should be held together by the common interest in the problems under study. Both traditional and modern techniques and disciplines should be required as partners in the centers.

FIELD-STRENGTH EFFECTS IN CADMIUM SULFIDE SINGLE CRYSTALS, by H. Gildea. Dec. 1958, 16p. incl. diags. table. (Technical rept. no. 135) (Sponsored jointly by Office of Naval Research, Signal Corps, and Air Force [Office of Scientific Research] under Nonr-184110, and Atomic Energy Commission under AT(30-1)1937) AD 209817 Unclassified

An extensive series of current-voltage-time characteristics was recorded using cadmium sulfide single crystals with d-c and unidirectional pulse voltages at various temperatures. In addition, transient effects were studied under controlled illumination. While in general the crystals showed a rather high conductivity, which proved essentially independent of temperature in the range from -175° to 100°C , one type exhibited a low conductivity which depended exponentially on temperature. The high-conductivity crystals followed Ohm's law up to a critical point; then a steep current rise and a negative dynamic resistance region were observed. Repeated excitation would generally move this breakover point to a lower voltage. The original conditions could be restored by bulk heating or by a long rest period. The low-conductivity crystals responded similarly to high voltage but space-charge polarization preceded the current rise. The space-charge effect could be neutralized by photoelectric excitation in a relatively short time.

Presented at Conf. on Magnetism and Magnetic Materials, Washington, D. C., Nov. 18-21, 1957.

Also published in Jour. Appl. Phys., v. 29: 376-377, Mar. 1958.

A study has been made of the magnetic properties of the system of quenched magnesium ferrites

magnesium ions in tetrahedral sites, varies from 0.14 to 0.26. Included among the properties examined are: saturation moment, Curie point, initial permeability and coercive force. A limited study of the kinetics of the cation redistribution has also been made. Samples quenched from 1100°C and then tempered at 600° require somewhat less than 16 hr to attain an equilibrium cation distribution at the latter temperature. The approach to equilibrium is consistent with a model in which the rate of approach is proportional to $\exp(-\theta'_0 + \theta'_1 x)/T$, where θ'_0 and θ'_1 are activation constants.

THE STABILITY OF BINARY BOUNDARY LAYERS, by E. E. Covert. June 1957, 30p. incl. illus. (Technical rept. no. 217) (AFOSR-TN-57-200) (AF 18(603)82) AD 126497
Unclassified

The steady properties of a binary-boundary layer, i.e., a boundary layer consisting of a mixture of two component gases, have indicated that there are practical advantages in cooling a surface by introducing a foreign gas into the boundary layer. However, since the calculations are based on laminar flow, it was deemed advisable to consider the stability of the binary laminar-boundary layer. The results indicate that for relatively small injection rates which ensure that the boundary-layer approximation is still valid, the stability can be calculated for the binary boundary layer (and, incidentally, an n-component boundary layer) in the usual way, based upon the steady-state velocity and density profiles without additional complications due to added equations.

The purpose of this test was to determine which of several theories was best able to predict the insulating properties of the boundary layer. The model was a cone. The forward half was cooled uniformly to about 100°F below recovery temperature. The aft half was made of a good thermal insulator and was instrumented so that its temperature distribution could be measured. The cone was tested at a Mach number of 3.5 and at Reynolds numbers of 1.18×10^6 and 4.13×10^6 per ft for the laminar and turbulent layers respectively. Theoretical methods due to Baron, Lighthill, and Libby and Morduchow have been used to predict the temperature decay over the aft part of the cone for the laminar case. Lighthill's theoretical results are in very close agreement with the experimental results. Methods due to Seban, Rubesin, and Hill have been applied to the turbulent case. The experimental results fall about halfway between the predictions of Seban and Rubesin. It is shown that the methods of Lighthill, Seban, Rubesin, and Hill can all be reduced to an integral of the same form and a solution for this integral is given. By changing an appropriate constant in this integral, a semiempirical result is obtained which is in good agreement with the turbulent experimental data. (Contractor's abstract)

Presented at Symposium on Mass-Transfer Cooling for Hypersonic Flight, Santa Monica, Calif., June 24-26, 1957.

Study is made of the general mass transfer situation for which the fluid introduced into the high speed boundary layer differs appreciably in physical properties from those of the external fluid flow. The descriptive system of equations are deduced from Enskog's solution of the Boltzmann equation and include provision for component mass conservation, energy migration resulting from specific enthalpy differences, and thermodynamic coupling between the transport phenomena. A similarity analysis is presented for laminar flows with and without pressure gradients and numerical results are given for helium and carbon-dioxide as foreign gases in a primarily air boundary layer flowing over a flat plate. It is shown that the injection of relatively low density fluid yields considerable alleviation of the thermal levels normally encountered at supersonic Mach numbers. A qualitative argument is offered to explain the effects on the basis of available thermal capacity. The related sublimation problem is considered briefly. (Contractor's abstract)
